| [LogoWidth]    | <p>Defines the width (in pixels) of the logo image that you want displayed in the Web interface instead of the default logo.</p> <p>The valid value is 0 to 199. The default is 145.</p> <p>For more information, see Replacing the Corporate Logo with an Image on page 68.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The optimal setting depends on your screen resolution.</li> <li>▪ If the width of the loaded image is greater than the maximum value, the device automatically resizes the image to the default width size.</li> <li>▪ The height is limited to 24 pixels.</li> <li>▪ The parameter is applicable only when the UseWebLogo parameter is configured to 0.</li> <li>▪ To define the image file, see the LogoFileName parameter.</li> </ul> |
| [LogoFileName] | <p>Defines the name of the image file that you want loaded to the device. This image is displayed as the logo in the Web interface (instead of AudioCodes logo).</p> <p>The file name can be up to 47 characters.</p> <p>For more information, see Replacing the Corporate Logo with an Image on page 68.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The image file type can be one of the following: GIF, PNG, JPG, or JPEG.</li> <li>▪ The size of the image file can be up to 64 Kbytes.</li> <li>▪ The parameter is applicable only when the UseWebLogo parameter is configured to 0.</li> </ul>                                                                                                                                                             |

### 63.1.3 Telnet Parameters

The Telnet parameters are described in the table below.

**Table 63-3: Telnet Parameters**

| Parameter                                                | Description                                                                                                                                                                 |
|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Embedded Telnet Server<br>telnet<br>[TelnetServerEnable] | <p>Enables the device's embedded Telnet server.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable</li> <li>▪ <b>[1]</b> Enable Unsecured (default)</li> </ul> |

| Parameter                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                            | <ul style="list-style-type: none"> <li><b>[2] Enable Secured</b></li> </ul> <p><b>Note:</b> Only management users with Security Administrator level, Administrator level, or Master level can access the device through Telnet (see "Configuring Web User Accounts" on page 76).</p>                                                                                                                                                                                                        |
| Telnet Server TCP Port<br>telnet-port<br>[TelnetServerPort]                | <p>Defines the port number for the embedded Telnet server.</p> <p>The valid range is all valid port numbers. The default port is 23.</p>                                                                                                                                                                                                                                                                                                                                                    |
| Telnet Server Idle Timeout<br>idle-timeout<br>[TelnetServerIdleDisconnect] | <p>Defines the duration of an idle CLI (Telnet or SSH) session after which the session is automatically disconnected.</p> <p>The valid range is any value. The default is 5. When configured to 0, idle sessions are not disconnected.</p> <p><b>Note:</b> If you change the parameter's value when there are current Telnet/SSH sessions, the parameter's previous setting is still applied to these current sessions and the parameter's new setting is applied only to new sessions.</p> |
| Maximum Telnet Sessions<br>telnet-max-sessions<br>[TelnetMaxSessions]      | <p>Defines the maximum number of permitted, concurrent Telnet/SSH sessions.</p> <p>The valid range is 1 to 5 sessions. The default is 2.</p> <p><b>Note:</b> Before changing the value, make sure that not more than this number of sessions are currently active; otherwise, the new setting will not take effect.</p>                                                                                                                                                                     |
| [CLIPrivPass]                                                              | <p>Defines the password to access the Enable configuration mode in the CLI.</p> <p>The valid value is a string of up to 50 characters. The default is "Admin".</p> <p><b>Note:</b> The password is case-sensitive.</p>                                                                                                                                                                                                                                                                      |

### 63.1.4 ini File Parameters

The parameters relating to ini-file management are described in the table below.

**Table 63-4: ini File Parameters**

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [INIPasswordsDisplayType] | <p>Defines how passwords are displayed in the ini file.</p> <ul style="list-style-type: none"> <li><b>[0] Disable (default)</b> = Passwords are obscured ("encoded"). The passwords are displayed in the following syntax: \$1\$&lt;obscured password&gt; (e.g., \$1\$S3p+fno=).</li> <li><b>[1] Enable</b> = All passwords are hidden and replaced by an asterisk (*).</li> </ul> |

### 63.1.5 SNMP Parameters

The SNMP parameters are described in the table below.

Table 63-5: SNMP Parameters

| Parameter                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Disable SNMP<br>disable<br>[DisableSNMP]    | Enables and disables SNMP. <ul style="list-style-type: none"> <li>[0] No = (Default) SNMP is enabled.</li> <li>[1] Yes = SNMP is disabled.</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| port<br>[SNMPPort]                          | Defines the device's local (LAN) UDP port used for SNMP Get/Set commands.<br>The range is 100 to 3999. The default port is 161.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| [ChassisPhysicalAlias]                      | Defines the 'alias' name object for the physical entity as specified by a network manager, and provides a non-volatile 'handle' for the physical entity.<br>The valid range is a string of up to 255 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| [ChassisPhysicalAssetID]                    | Defines the user-assigned asset tracking identifier object for the device's chassis as specified by an EMS, and provides non-volatile storage of this information.<br>The valid range is a string of up to 255 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| [ifAlias]                                   | Defines the textual name of the interface. The value is equal to the ifAlias SNMP MIB object.<br>The valid range is a string of up to 64 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| auto-send-keep-alive<br>[SendKeepAliveTrap] | Enables the device to send NAT keep-alive traps to the port of the SNMP network management station (e.g., AudioCodes EMS). This is used for NAT traversal, and allows SNMP communication with AudioCodes EMS management platform, located in the WAN, when the device is located behind NAT. It is needed to keep the NAT pinhole open for the SNMP messages sent from EMS to the device. The device sends the trap periodically - every 9/10 of the time configured by the NATBindingDefaultTimeout parameter. The trap that is sent is acKeepAlive. For more information on the SNMP trap, refer to the <i>SNMP Reference Guide</i> . <ul style="list-style-type: none"> <li>[0] = (Default) Disable</li> <li>[1] = Enable</li> </ul> For configuring the port number, use the KeepAliveTrapPort parameter.<br><b>Note:</b> For the parameter to take effect, a device reset is required. |
| [KeepAliveTrapPort]                         | Defines the port of the SNMP network management station to which the device sends keep-alive traps.<br>The valid range is 0 - 65534. The default is port 1161.<br>To enable NAT keep-alive traps, use the SendKeepAliveTrap parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| [PM_EnableThresholdAlarms]                  | Enables the sending of the SNMP trap event, acPerformanceMonitoringThresholdCrossing which is sent every time the threshold (high and low) of a Performance Monitored object (e.g., acPMMediaRealmAttributesMediaRealmBytesTxHighThreshold) is crossed. <ul style="list-style-type: none"> <li>[0] = (Default) Disable</li> <li>[1] = Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| sys-oid                                     | Defines the base product system OID.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [SNMPSysOid]                                           | The default is eSNMP_AC_PRODUCT_BASE_OID_D.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| [SNMPTrapEnterpriseOid]                                | Defines the Trap Enterprise OID.<br>The default is eSNMP_AC_ENTERPRISE_OID.<br>The inner shift of the trap in the AcTrap subtree is added to the end of the OID in the parameter.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| [acUserInputAlarmDescription]                          | Defines the description of the input alarm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| [acUserInputAlarmSeverity]                             | Defines the severity of the input alarm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| [AlarmHistoryTableMaxSize]                             | Defines the maximum number of rows in the Alarm History table. The parameter can be controlled by the Config Global Entry Limit MIB (located in the Notification Log MIB).<br>The valid range is 50 to 1000. The default is 500.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| [ActiveAlarmTableMaxSize]                              | Defines the maximum number of currently active alarms that can be displayed in the Active Alarms table. When the table reaches this user-defined maximum capacity (i.e., full), the device sends the SNMP trap event, acActiveAlarmTableOverflow. If the table is full and a new alarm is raised by the <device>, the new alarm is not displayed in the table.<br>The valid range is 50 to 300. The default is 120.<br>For more information on the Active Alarms table, see Viewing Active Alarms on page 863.<br><b>Note:</b> <ul style="list-style-type: none"> <li>For the parameter to take effect, a &lt;device&gt; reset is required.</li> <li>To clear the acActiveAlarmTableOverflow trap, you must reset the device. The reset also deletes all the alarms in the Active Alarms table.</li> </ul> |
| no-alarm-for-disabled-port<br>[NoAlarmForDisabledPort] | Enables the device to not send the SNMP trap acBoardControllerFailureAlarm, which indicates a "disabled" (non-configured) telephony port. A disabled port is one that is not configured at all or that is configured but without a Trunk Group ID (i.e., Trunk Group ID is 0), in the Trunk Group table. <ul style="list-style-type: none"> <li>[0] Disable = (Default) The device sends the SNMP trap for non-configured ports.</li> <li>[1] Enable = The device does not send the SNMP trap for non-configured ports.</li> </ul> <b>Note:</b> <ul style="list-style-type: none"> <li>The parameter is applicable to all telephony (analog and digital) port types.</li> <li>The parameter is applicable only to the Gateway application.</li> </ul>                                                      |
| engine-id<br>[SNMPEngineIDString]                      | Defines the SNMP engine ID for SNMPv2/SNMPv3 agents. This is used for authenticating a user attempting to access the SNMP agent on the device.<br>The ID can be a string of up to 36 characters. The default is 00:00:00:00:00:00:00:00:00:00:00:00 (12 Hex octets characters). The                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Parameter                                                                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                | <p>provided key must be set with 12 Hex values delimited by a colon (":") in the format xx:xx:....:xx. For example, 00:11:22:33:44:55:66:77:88:99:aa:bb</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>Before setting the parameter, all SNMPv3 users must be deleted; otherwise, the parameter setting is ignored.</li> <li>If the supplied key does not pass validation of the 12 Hex values input or it is set with the default value, the engine ID is generated according to RFC 3411.</li> </ul> |
| <b>SNMP Trap Destination Parameters</b> (configure system/snmp trap destination)<br><b>Note:</b> Up to five SNMP trap managers can be defined. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SNMP Manager<br>[SNMPManagerIsUsed_x]                                                                                                          | <p>Determines the validity of the parameters (IP address and port number) of the corresponding SNMP Manager used to receive SNMP traps.</p> <ul style="list-style-type: none"> <li><b>[0]</b> (Check box cleared) = Disabled (default)</li> <li><b>[1]</b> (Check box selected) = Enabled</li> </ul>                                                                                                                                                                                                                                                                                           |
| IP Address<br>ip-address<br>[SNMPManagerTableIP_x]                                                                                             | <p>Defines the IP address of the remote host used as an SNMP Manager. The device sends SNMP traps to this IP address. Enter the IP address in dotted-decimal notation, e.g., 108.10.1.255.</p>                                                                                                                                                                                                                                                                                                                                                                                                 |
| Trap Port<br>port<br>[SNMPManagerTrapPort_x]                                                                                                   | <p>Defines the port number of the remote SNMP Manager. |-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | authNoPriv(2), authentication protocol MD5, authentication text password 'myauthkey', and ReadWriteGroup2.<br>For a description of the table, see "Configuring SNMP V3 Users" on page 106. |

### 63.1.6 Serial Parameters

The serial interface parameters are described in the table below.

**Table 63-6: Serial Parameters**

| Parameter                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>[DisableRS232]</b>      | Enables the device's RS-232 (serial) port. <ul style="list-style-type: none"> <li>[0] = Enabled</li> <li>[1] = (Default) Disabled</li> </ul> The RS-232 serial port can be used to change the networking parameters and view error/notification messages. For how to establish a serial communication with the device, refer to the Installation Manual.<br><b>Note:</b> For the parameter to take effect, a device reset is required. |
| <b>[SerialBaudRate]</b>    | Defines the serial communication baud rate.<br>The valid values include the following: 1200, 2400, 9600, 14400, 19200, 38400, 57600, or 115200 (default).<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                |
| <b>[SerialData]</b>        | Defines the serial communication data bit. <ul style="list-style-type: none"> <li>[7] = 7-bit</li> <li>[8] = (Default) 8-bit</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                     |
| <b>[SerialParity]</b>      | Defines the serial communication polarity. <ul style="list-style-type: none"> <li>[0] = (Default) None</li> <li>[1] = Odd</li> <li>[2] = Even</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                    |
| <b>[SerialStop]</b>        | Defines the serial communication stop bit. <ul style="list-style-type: none"> <li>[1] = (Default) 1-bit (default)</li> <li>[2] = 2-bit</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                           |
| <b>[SerialFlowControl]</b> | Defines the serial communication flow control. <ul style="list-style-type: none"> <li>[0] = (Default) None</li> <li>[1] = Hardware</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                               |

### 63.1.7 Auxiliary and Configuration File Name Parameters

The configuration files (i.e., Auxiliary files) can be loaded to the device using the Web interface. For loading these files using the *ini* file, you need to configure these files in the *ini*

file and configured whether they must be stored in the non-volatile memory. The table below lists the *ini* file parameters associated with these Auxiliary files. For more information on Auxiliary files, see "Loading Auxiliary Files" on page 793.

**Table 63-7: Auxiliary and Configuration File Parameters**

| Parameter                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Parameters</b>                               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| [SetDefaultOnIniFileProcess]                            | <p>Determines if all the device's parameters are set to their defaults before processing the updated <i>ini</i> file.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = Disable - parameters not included in the downloaded <i>ini</i> file are not returned to default settings (i.e., retain their current settings).</li> <li><b>[1]</b> = Enable (default).</li> </ul> <p><b>Note:</b> The parameter is applicable only for automatic HTTP update or Web <i>ini</i> file upload (not applicable if the <i>ini</i> file is loaded using BootP).</p>                                             |
| [SaveConfiguration]                                     | <p>Determines if the device's configuration (parameters and files) is saved to flash (non-volatile memory).</p> <ul style="list-style-type: none"> <li><b>[0]</b> = Configuration isn't saved to flash memory.</li> <li><b>[1]</b> = (Default) Configuration is saved to flash memory.</li> </ul>                                                                                                                                                                                                                                                                                                        |
| <b>Auxiliary and Configuration File Name Parameters</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Call Progress Tones File<br>[CallProgressTonesFilename] | <p>Defines the name of the file containing the Call Progress Tones definitions.</p> <p>For the ini file, the name must be enclosed by single apostrophes, for example, 'cpt_us.dat'.</p> <p>For more information on how to create and load this file, refer to <i>DConvert Utility User's Guide</i>.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                               |
| Prerecorded Tones File<br>[PrerecordedTonesFileName]    | <p>Defines the name of the file containing the Prerecorded Tones.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| CAS File<br>[CASFileName_x]                             | <p>Defines the CAS file name (e.g., 'E_M_WinkTable.dat'), which defines the CAS protocol (where x denotes the CAS file ID 0 to 7). It is possible to define up to eight different CAS files by repeating the parameter. Each CAS file can be associated with one or more of the device's trunks, using the parameter CASTableIndex or it can be associated per B-channel using the parameter CASChannelIndex.</p> <p>For the ini file, the name must be enclosed by single apostrophes, for example, 'cas_us.dat'.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p> |
| Dial Plan<br>[CasTrunkDialPlanName_x]                   | <p>Defines the Dial Plan name (up to 11-character strings) per trunk.</p> <p>For the ini file, the name must be enclosed by single apostrophes, for example, 'dial_plan_2.dat'.</p> <p><b>Note:</b> The x in the ini file parameter name denotes the trunk number, where 0 is Trunk 1.</p>                                                                                                                                                                                                                                                                                                               |
| Dial Plan File<br>[DialPlanFileName]                    | <p>Defines the name of the Dial Plan file. This file should be created using AudioCodes DConvert utility (refer to <i>DConvert Utility User's Guide</i>).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter          | Description                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | For the ini file, the name must be enclosed by single apostrophes, for example, 'dial_plan.dat'.                                                                         |
| [UserInfoFileName] | Defines the name of the file containing the User Information data.<br>For the ini file, the name must be enclosed by single apostrophes, for example, 'userinfo_us.dat'. |

## 63.1.8 Automatic Update Parameters

The automatic update of software and configuration files parameters are described in the table below.

**Table 63-8: Automatic Update of Software and Configuration Files Parameters**

| Parameter                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <pre>configure system &gt; automatic-update &gt; crc-check regular [AUPDCheckIfIniChanged]</pre> | <p>Enables the device to perform cyclic redundancy checks (CRC) on downloaded configuration files (ini) during the Automatic Update process. The CRC checks whether the content (raw data) of the downloaded file is different to the content of the previously downloaded file from the previous Automatic Update process. The device compares the CRC check value (code) result with the check value of the previously downloaded file. If the check values are identical, it indicates that the file has no new configuration settings, and the device discards the file. If the check values are different, the device installs the downloaded file and applies the new configuration settings.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) Disable - the device does not perform CRC and installs the downloaded file regardless.</li> <li><b>[1]</b> = Enable CRC for the entire file, including line order (i.e., same text must be on the same lines). If there are differences between the files, the device installs the downloaded file. If there are no differences, the device discards the newly downloaded file.</li> <li><b>[2]</b> = Enable CRC for individual lines only. Same as option [1], except that the CRC ignores the order of lines (i.e., same text can be on different lines).</li> </ul> |

## 63.2 Networking Parameters

This subsection describes the device's networking parameters.

### 63.2.1 Ethernet Parameters

The Ethernet parameters are described in the table below.

**Table 63-9: Ethernet Parameters**

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 63.2.3 Routing Parameters

The IP network routing parameters are described in the table below.

**Table 63-11: IP Network Routing Parameters**

| Parameter                                                         | Description                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Send ICMP Unreachable Messages<br>[DisableICMPUnreachable]        | Enables sending of ICMP Unreachable messages.<br><ul style="list-style-type: none"> <li>▪ [0] Enable = (Default) Device sends these messages.</li> <li>▪ [1] Disable = Device does not send these messages.</li> </ul>                                              |
| Send and Receive ICMP Redirect Messages<br>[DisableICMPRedirects] | Enables sending and receiving of ICMP Redirect messages.<br><ul style="list-style-type: none"> <li>▪ [0] Enable = (Default) Device sends and accepts these messages.</li> <li>▪ [1] Disable = Device rejects these messages and also does not send them.</li> </ul> |

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Static Route Table</b>                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Static Route Table<br>configure voip ><br>static<br>[StaticRouteTable] | Defines up to 30 static IP routes for the device.<br>The format of the ini file table parameter is as follows:<br>[ StaticRouteTable ]<br>FORMAT StaticRouteTable_Index = StaticRouteTable_DeviceName,<br>StaticRouteTable_Destination, StaticRouteTable_PrefixLength,<br>StaticRouteTable_Gateway, StaticRouteTable_Description;<br>[ \StaticRouteTable ]<br>For a description of the parameter, see "Configuring Static IP Routes" on page 157. |

## 63.2.4 Open Solution Network (OSN) Parameters

The OSN server parameters are described in the table below.

**Table 63-12: OSN Parameters**

| Parameter                                                                                          | Description                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| OSN Native VLAN ID<br>configure system ><br>interface osn ><br>native-vlan <id><br>[OSNAccessVlan] | Defines the OSN Native VLAN ID.<br>The valid value is 0 to 4000. When set to 0 (default), the OSN uses the device's OAMP VLAN ID. When set to any other value, it specifies a VLAN ID configured in the Ethernet Device table and which is assigned to a Media and/or Control application in the Interface table. |
| Block OSN Port<br>configure system ><br>interface osn ><br>shutdown<br>[OSNBlockPort]              | Enables or disables the Ethernet port of the internal switch that interfaces with the OSN. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Enable (default)</li> <li>▪ <b>[1]</b> Disable</li> </ul>                                                                                                          |

## 63.2.5 Quality of Service Parameters

The Quality of Service (QoS) parameters are described in the table below.

**Table 63-13: QoS Parameters**

| Parameter                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                     |

### 63.2.6 NAT and STUN Parameters

The Network Address Translation (NAT) parameters are described in the table below.

**Table 63-14: NAT Parameters**

| Parameter                                      | Description                                                                                        |
|------------------------------------------------|----------------------------------------------------------------------------------------------------|
| <b>NAT Parameters</b>                          |                                                                                                    |
| NAT Mode<br>disable-NAT-traversal<br>[NATMode] | <p>Enables the NAT feature for media when the device communicates with UAs located behind NAT.</p> |

| Parameter                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                | <ul style="list-style-type: none"> <li>▪ [0] Enable NAT Option = NAT traversal is performed only if the UA is located behind NAT: <ul style="list-style-type: none"> <li>✓ UA behind NAT: The device sends the media packets to the IP address:port obtained from the source address of the first media packet received from the UA.</li> <li>✓ UA not behind NAT: The device sends the packets to the IP address:port specified in the SDP 'c=' line (Connection) of the first received SIP message.</li> </ul> </li> </ul> <p>Note: If the SIP session is established (ACK) and the device (not the UA) sends the first packet, it sends it to the address obtained from the SIP message and only after the device receives the first packet from the UA does it determine whether the UA is behind NAT.</p> <ul style="list-style-type: none"> <li>▪ [1] Disable NAT = (Default) The device considers the UA as not located behind NAT and sends media packets to the UA using the IP address:port specified in the SDP 'c=' line (Connection) of the first received SIP message.</li> <li>▪ [2] Force NAT = The device always considers the UA as behind NAT and sends the media packets to the IP address:port obtained from the source address of the first media packet received from the UA. The device only sends packets to the UA after it receives the first packet from the UA (to obtain the IP address).</li> <li>▪ [3] NAT By Signaling = The device identifies whether or not the UA is located behind NAT based on the SIP signaling. The device assumes that if signaling is behind NAT that the media is also behind NAT, and vice versa. If located behind NAT, the device sends media as described in option [2] Force NAT; if not behind NAT, the device sends media as described in option [1] Disable NAT. This option is applicable only to SBC calls. If the parameter is configured to this option, Gateway calls use option [0] Enable NAT Option, by default.</li> </ul> <p>For more information on handling calls from UAs behind NAT, see "First Incoming Packet Mechanism" on page 171.</p> |
| NAT IP Address<br>nat-ip-addr<br>[StaticNatIP] | Defines the global (public) IP address of the device to enable static NAT between the device and the Internet.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| [NATBindingDefaultTimeout]                     | <p>The device sends SNMP keep-alive traps periodically - every 9/10 of the time configured by the parameter (in seconds). Therefore, the parameter is applicable only if the SendKeepAliveTrap parameter is set to 1.</p> <p>The parameter is used to allow SNMP communication with AudioCodes EMS management platform, located in the WAN, when the device is located behind NAT. It is needed to keep the NAT pinhole open for the SNMP messages sent from EMS to the device.</p> <p>The valid range is 0 to 2,592,000. The default is 30.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Incoming SIP messages are processed as received from endpoints that are not located behind NAT and sent according to the SIP standard.</li> <li>▪ <b>[1] Enable (default)</b> = Enables the device's NAT Detection mechanism.</li> </ul> |

## 63.2.7 DNS Parameters

The Domain name System (DNS) parameters are described in the table below.

**Table 63-15: DNS Parameters**

| Parameter                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Internal SRV Table<br>configure voip ><br>voip-network dns<br>Srv2Ip<br>[SRV2IP] | The table defines the internal SRV table for resolving host names into DNS A-Records. Three different A-Records can be assigned to a host name. Each A-Record contains the host name, priority, weight, and port. The format of the ini file table parameter is:<br>[SRV2IP]<br>FORMAT SRV2IP_Index = SRV2IP_InternalDomain,<br>SRV2IP_TransportType, SRV2IP_Dns1, SRV2IP_Priority1,<br>SRV2IP_Weight1, SRV2IP_Port1, SRV2IP_Dns2, SRV2IP_Priority2,<br>SRV2IP_Weight2, SRV2IP_Port2, SRV2IP_Dns3, SRV2IP_Priority3,<br>SRV2IP_Weight3, SRV2IP_Port3;<br>[SRV2IP]<br>For example:<br>SRV2IP 0 =<br>SrvDomain,0,Dnsname1,1,1,500,Dnsname2,2,2,501,\$\$,0,0,0;<br>For a detailed description of the table, see "Configuring the Internal SRV Table" on page 164. |

## 63.2.8 DHCP Parameters

The Dynamic Host Control Protocol (DHCP) parameters are described in the table below.

**Table 63-16: DHCP Parameters**

| Parameter                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable DHCP<br>[DHCPEnable]                                                   | <p>Enables DHCP client functionality.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>For a detailed description of DHCP, see "DHCP-based Provisioning" on page 831.</li> <li>The parameter is a "hidden" parameter. Once defined and saved to flash memory, its value doesn't revert to default even if the parameter doesn't appear in the <i>ini</i> file.</li> </ul>                                                                                                                                                                          |
| [DHCPSpeedFactor]                                                             | <p>Defines the device's DHCP renewal speed for a leased IP address from a DHCP server.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = Disable</li> <li><b>[1]</b> = (Default) Normal</li> <li><b>[2] to [10]</b> = Fast</li> </ul> <p>When set to 0, the DHCP lease renewal is disabled. Otherwise, the renewal time is divided by this factor. Some DHCP-enabled routers perform better when set to 4.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                             |
| DHCP Servers Table                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| DHCP Vendor Class table<br><code>configure voip &gt;</code><br><code>dhcp vendor-class</code><br><code>[DhcpVendorClass]</code>                      | Defines Vendor Class Identifier (VCI) names (DHCP Option 60) for the device's DHCP server. Only if the DHCPDiscover request message, received from the DHCP client, contains this value does the device provide DHCP services.<br><br>The format of the ini file table parameter is as follows:<br><pre>[ DhcpVendorClass ] FORMAT DhcpVendorClass_Index = DhcpVendorClass_DhcpServerIndex, DhcpVendorClass_VendorClassId; [ \DhcpVendorClass ]</pre> For a detailed description of the table, see Configuring the Vendor Class Identifier on page 236. |
| DHCP Option Table                                                                                                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DHCP Option table<br><code>configure voip &gt;</code><br><code>dhcp option</code><br><code>[DhcpOption]</code>                                       | Defines additional DHCP Options that the device's DHCP server can use to service its DHCP clients.<br><br>The format of the ini file table parameter is as follows:<br><pre>[ DhcpOption ] FORMAT DhcpOption_Index = DhcpOption_DhcpServerIndex, DhcpOption_Option, DhcpOption_Type, DhcpOption_Value, DhcpOption_ExpandValue; [ \DhcpOption ]</pre> For a detailed description of the table, see Configuring Additional DHCP Options on page 237.                                                                                                      |
| DHCP Static IP Table                                                                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| DHCP Static IP table<br><code>configure voip &gt;</code><br><code>dhcp static-ip</code><br><code>&lt;index&gt;</code><br><code>[DhcpStaticIP]</code> | Defines static "reserved" IP addresses that the device's DHCP server allocates to specific DHCP clients defined by MAC address.<br><br>The format of the ini file table parameter is as follows:<br><pre>[ DhcpStaticIP ] FORMAT DhcpStaticIP_Index = DhcpStaticIP_DhcpServerIndex, DhcpStaticIP_IPAddress, DhcpStaticIP_MACAddress; [ \DhcpStaticIP ]</pre> For a detailed description of the table, see Configuring Static IP Addresses for DHCP Clients on page 239.                                                                                 |

### 63.2.9 NTP and Daylight Saving Time Parameters

The Network Time Protocol (NTP) and daylight saving time parameters are described in the table below.

**Table 63-17: NTP and Daylight Saving Time Parameters**

| Parameter                                                                                                                                          | Description                                                                                                                          |
|----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>NTP Parameters</b><br><b>Note:</b> For more information on Network Time Protocol (NTP), see "Simple Network Time Protocol Support" on page 133. |                                                                                                                                      |
| NTP Server Address<br><code>primary-server</code>                                                                                                  | Defines the IP address (in dotted-decimal notation or as an FQDN) of the NTP server. The advantage of using an FQDN is that multiple |

| Parameter                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [NTPServerIP]                                                                                  | IP addresses can be resolved from the DNS server, providing NTP server redundancy.<br>The default IP address is 0.0.0.0 (i.e., internal NTP client is disabled).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| NTP Secondary Server Address<br>[NTPSecondaryServerIP]                                         | Defines a second NTP server's address as an FQDN or an IP address (in dotted-decimal notation). This NTP is used for redundancy; if the primary NTP server fails, then this NTP server is used.<br>The default IP address is 0.0.0.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| NTP Update Interval<br>update-interval<br>[NTPUpdateInterval]                                  | Defines the time interval (in seconds) that the NTP client requests for a time update.<br>The default interval is 86400 (i.e., 24 hours). The range is 0 to 214783647.<br><b>Note:</b> It is not recommend to set the parameter to beyond one month (i.e., 2592000 seconds).                                                                                                                                                                                                                                                                                                                                                                                                                        |
| NTP Authentication Key Identifier<br>configure system ><br>ntp > auth-key-id<br>[NtpAuthKeyId] | Defines the NTP authentication key identifier for authenticating NTP messages. The identifier must match the value configured on the NTP server. The NTP server may have several keys configured for different clients; this number identifies which key is used.<br>The valid value is 1 to 65535. The default is 0 (i.e., no authentication is done).                                                                                                                                                                                                                                                                                                                                             |
| NTP Authentication Secret Key<br>configure system ><br>ntp > auth-key-md5<br>[ntpAuthMd5Key]   | Defines the secret authentication key shared between the device (client) and the NTP server, for authenticating NTP messages.<br>The valid value is a string of up to 32 characters. By default, no key is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Regional Clock and Daylight Saving Time Parameters</b>                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| UTC Offset<br>utc-offset<br>[NTPServerUTCOffset]                                               | Defines the Universal Time Coordinate (UTC) offset (in seconds) from the local time.<br>The valid range is -43200 to 43200. The default is 0.<br><b>Note:</b> The offset setting is applied only on the hour. For example, if you configure the parameter at 15:42, the device applies the setting only at 16:00.                                                                                                                                                                                                                                                                                                                                                                                   |
| Daylight Saving Time<br>summer-time<br>[DayLightSavingTimeEnable]                              | Enables daylight saving time (DST). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Start Time / Day of Month<br>Start<br>start<br>[DayLightSavingTimeStart]                       | Defines the date and time when DST begins. This value can be configured using any of the following formats: <ul style="list-style-type: none"> <li>▪ Day of year - <i>mm:dd:hh:mm</i>, where: <ul style="list-style-type: none"> <li>✓ <i>mm</i> denotes month</li> <li>✓ <i>dd</i> denotes date of the month</li> <li>✓ <i>hh</i> denotes hour</li> <li>✓ <i>mm</i> denotes minutes</li> </ul> For example, "05:01:08:00" denotes daylight saving starting from May 1 at 8 A.M. </li> <li>▪ Day of month - <i>mm:day/wk:hh:mm</i>, where: <ul style="list-style-type: none"> <li>✓ <i>mm</i> denotes month (e.g., 04)</li> <li>✓ <i>day</i> denotes day of week (e.g., FRI)</li> </ul> </li> </ul> |

| Parameter                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                  | <ul style="list-style-type: none"> <li>✓ <i>wk</i> denotes week of the month (e.g., 03)</li> <li>✓ <i>hh</i> denotes hour (e.g., 23)</li> <li>✓ <i>mm</i> denotes minutes (e.g., 10)</li> </ul> <p>For example, "04:FRI/03:23:00" denotes Friday, the third week of April, at 11 P.M. The week field can be 1-5, where 5 denotes the last occurrence of the specified day in the specified month. For example, "04:FRI/05:23:00" denotes the last Friday of April, at 11 P.M.</p> |
| End Time / Day of Month<br>End<br>end<br>[DayLightSavingTimeEnd] | Defines the date and time when DST ends. For a description of the format of this value, see the DayLightSavingTimeStart parameter.                                                                                                                                                                                                                                                                                                                                                |
| Offset<br>offset<br>[DayLightSavingTimeOffset]                   | <p>Defines the DST offset (in minutes).<br/>The valid range is 0 to 120. The default is 60.</p> <p><b>Note:</b> The offset setting is applied only on the hour. For example, if you configure the parameter at 15:42, the device applies the setting only at 16:00.</p>                                                                                                                                                                                                           |

## 63.3 Debugging and Diagnostics Parameters

This subsection describes the device's debugging and diagnostic parameters.

### 63.3.1 General Parameters

The general debugging and diagnostic parameters are described in the table below.

**Table 63-18: General Debugging and Diagnostic Parameters**

| Parameter           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [EnableDiagnostics] | <p>Determines the method for verifying correct functioning of the different hardware components on the device. On completion of the check and if the test fails, the device sends information on the test results of each hardware component to the Syslog server.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) Rapid and Enhanced self-test mode.</li> <li>▪ <b>[1]</b> = Detailed self-test mode (full test of DSPs, PCM, Switch, LAN, PHY and Flash).</li> <li>▪ <b>[2]</b> = A quicker version of the Detailed self-test mode (full test of DSPs, PCM, Switch, LAN, PHY, but partial test of Flash).</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p> |
| [LifeLineType]      | <p>Defines the condition (i.e., loss of power to the device) upon which the device activates the Lifeline feature for FXS interfaces. When the analog Lifeline is triggered, the device automatically connects a specific FXS port, which is connected to a "lifeline" POTS phone, to the PSTN (or PBX). Therefore, this allows the FXS endpoint user to continue making and receiving calls with the PSTN despite the loss of power.</p>                                                                                                                                                                                                                                                                                    |

| Parameter                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                             | <ul style="list-style-type: none"> <li>[0] = (Default) Lifeline is activated upon the loss of power to the device, for example, due to a power outage or the unplugging of the device's power cable.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>The parameter is applicable only to the Gateway application and FXS interfaces.</li> <li>If the device is in Lifeline mode and the condition that triggered it (e.g., a power outage) no longer exists (e.g., power returns), the device exits Lifeline mode and performs normal call routing.</li> <li>For information on Lifeline cabling, refer to the <i>Hardware Installation Manual</i>.</li> </ul> |
| Delay After Reset [sec]<br>delay-after-reset<br><b>[GWAppDelayTime]</b>     | <p>Defines the time interval (in seconds) that the device's operation is delayed after a reset.</p> <p>The valid range is 0 to 45. The default is 7 seconds.</p> <p><b>Note:</b> This feature helps overcome connection problems caused by some LAN routers or IP configuration parameters' modifications by a DHCP server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                             |
| [EnableAutoRAITransmitBER]                                                  | <p>Enables the device to send a remote alarm indication (RAI) when the bit error rate (BER) is greater than 0.001.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Ignore BRI LOS Alarm<br>ignore-bri-los-alarm<br><b>[IgnoreBRILOSAAlarm]</b> | <p>Enables the device to ignore LOS alarms received from the BRI user-side trunk and attempts to make a call (relevant for IP-to-Tel calls).</p> <ul style="list-style-type: none"> <li>[0] Disable</li> <li>[1] Enable (default)</li> </ul> <p><b>Note:</b> The parameter is applicable only to BRI interfaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 63.3.2 SIP Test Call Parameters

The SIP Signaling Test Call parameters are described in the table below.

**Table 63-19: SIP Test Call Parameters**

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Test Call DTMF String<br>testcall-dtmf-string<br>[TestCallDtmfString]               | Defines the DTMF tone that is played for answered test calls (incoming and outgoing).<br><br>The DTMF string can be up to 15 strings. The default is "3212333". If no string is defined (empty), DTMF is not played.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Test Call ID<br>testcall-id<br>[TestCallID]                                         | Defines the test call prefix number ( <i>ID</i> ) of the simulated phone on the device. Incoming calls received with this called prefix number are identified as test calls.<br><br>This can be any string of up to 15 characters. By default, no number is defined.<br><br><b>Notes:</b> <ul style="list-style-type: none"> <li>The parameter is only for testing incoming calls destined to this prefix number.</li> <li>This feature is applicable to all applications (Gateway and SBC).</li> </ul>                                                                                                                                                                                 |
| <b>Test Call Table</b>                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Syslog Server IP Address<br>syslog-ip<br>[SyslogServerIP]        | Defines the IP address (in dotted-decimal notation) of the computer on which the Syslog server is running. The Syslog server is an application designed to collect the logs and error messages generated by the device.<br>The default IP address is 0.0.0.0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Syslog Server Port<br>syslog-port<br>[SyslogServerPort]          | Defines the UDP port of the Syslog server.<br>The valid range is 0 to 65,535. The default port is 514.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| CDR Server IP Address<br>cdr-srvr-ip-adrr<br>[CDRSyslogServerIP] | Defines the destination IP address to where CDR logs are sent.<br>The default value is a null string, which causes CDR messages to be sent with all Syslog messages to the Syslog server.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>The CDR messages are sent to UDP port 514 (default Syslog port).</li> <li>This mechanism is active only when Syslog is enabled (i.e., the parameter EnableSyslog is set to 1).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| CDR Report Level<br>cdr-report-level<br>[CDRReportLevel]         | Enables media and signaling-related CDRs to be sent to a Syslog server and determines the call stage at which they are sent. <ul style="list-style-type: none"> <li><b>[0]</b> None = (Default) CDRs are not used.</li> <li><b>[1]</b> End Call = CDR is sent to the Syslog server at the end of each call.</li> <li><b>[2]</b> Start &amp; End Call = CDR report is sent to Syslog at the start and end of each call.</li> <li><b>[3]</b> Connect &amp; End Call = CDR report is sent to Syslog at connection and at the end of each call.</li> <li><b>[4]</b> Start &amp; End &amp; Connect Call = CDR report is sent to Syslog at the start, at connection, and at the end of each call.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>For the SBC application, the parameter enables only signaling-related CDRs. To enable media-related CDRs for SBC calls, use the MediaCDRReportLevel parameter.</li> <li>The CDR Syslog message complies with RFC 3164 and is identified by: Facility = 17 (local1) and Severity = 6 (Informational).</li> <li>This mechanism is active only when Syslog is enabled (i.e., the parameter EnableSyslog is set to 1).</li> </ul> |
| Media CDR Report Level<br>[MediaCDRReportLevel]                  | Enables media-related CDRs of SBC calls to be sent to a Syslog server and determines the call stage at which they are sent. <ul style="list-style-type: none"> <li><b>[0]</b> None = (Default) No media-related CDR is sent.</li> <li><b>[1]</b> End Media = Sends a CDR only at the end of the call.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Parameter                                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                               | <ul style="list-style-type: none"> <li>[2] Start &amp; End Media = Sends a CDR once the media starts. In some calls it may only be after the call is established, but in other calls the media may start at ringback tone. A CDR is also sent upon termination (end) of the media in the call.</li> <li>[3] Update &amp; End Media = Sends a CDR when an update occurs in the media of the call. For example, a call starts and a ringback tone occurs, a re-INVITE is sent for a fax call and as a result, a CDR with the MediaReportType field set to "Update" is sent, as the media was changed from voice to T.38. A CDR is also sent upon termination (end) of the media in the call.</li> <li>[4] Start &amp; End &amp; Update Media = Sends a CDR at the start of the media, upon an update in the media (if occurs), and at the end of the media.</li> </ul> <p><b>Note:</b> To enable CDR generation as well as enable signaling-related CDRs, use the CDRReportLevel parameter.</p> |
| <pre>configure voip &gt; sip- definition settings &gt; time-zone-format</pre> <p>[TimeZoneFormat]</p>                                         | <p>Defines the time zone that is displayed with the timestamp in CDRs. The timestamp appears in the CDR fields "Setup Time", "Connect Time", and "Release Time".</p> <p>The valid value is a string of up to six characters. The default is UTC. For example, if you configure the parameter TimeZoneFormat = GMT+11, the timestamp in CDRs are generated with the following time zone display:</p> <pre>17:47:45.411 GMT+11 Sun Jan 03 2018</pre> <p><b>Note:</b> The time zone is only for display purposes; it does not configure the actual time zone.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <p>Local Storage Max File Size</p> <pre>configure voip &gt; services cdr &gt; cdr- local-max-file-size</pre> <p>[CDRLocalMaxFileSize]</p>     | <p>Defines the size (in kilobytes) of each stored CDR file. Once the file size is reached, the device creates a new file for subsequent CDRs, and so on.</p> <p>The valid value is 100 to 10000. The default is 1024.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <p>Local Storage Max Number Of Files</p> <pre>configure voip &gt; services cdr &gt; cdr- local-max-files</pre> <p>[CDRLocalMaxNomOfFiles]</p> | <p>Defines the maximum number of stored CDR files. If the maximum number is reached, the device replaces (overwrites) the oldest created file with a subsequent new file, and so on.</p> <p>The valid value is 2 to 4096. The default is 5.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <p>Local Storage File Creation Interval</p> <pre>configure voip &gt; services cdr &gt; cdr- local-interval</pre> <p>[CDRLocalInterval]</p>    | <p>Defines how often (in minutes) the device creates a new CDR file. For example, if configured to 60, it creates a new file every hour. This occurs even if the maximum configured file size has not been reached (see the CDRLocalMaxFileSize parameter). However, if the maximum configured file size has been reached and the interval configured by the parameter has not been reached, a new CDR file is created.</p> <p>The valid value is 2 to 1440. The default is 60.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 63.3.4 Resource Allocation Indication Parameters

The Resource Allocation Indication (RAI) parameters are described in the table below.

**Table 63-21: RAI Parameters**

| Parameter                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>[EnableRAI]</b>        | <p>Enables Resource Available Indication (RAI) alarm generation if the device's busy endpoints exceed a user-defined threshold, configured by the RAIHighThreshold parameter. When enabled and the threshold is crossed, the device sends the SNMP trap, acBoardCallResourcesAlarm.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) Disable</li> <li>▪ <b>[1]</b> = Enable</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                             |
| <b>[RAIHighThreshold]</b> | <p>Defines the high threshold percentage of total calls that are active (busy endpoints). When the percentage of the device's busy endpoints exceeds this high threshold, the device sends the SNMP acBoardCallResourcesAlarm alarm trap with a 'major' alarm status.</p> <p>The range is 0 to 100. The default is 90.</p> <p><b>Note:</b> The percentage of busy endpoints is calculated by dividing the number of busy endpoints by the total number of "enabled" endpoints (trunks are physically connected and synchronized with no alarms and endpoints are defined in the Trunk Group table).</p> |
| <b>[RAILowThreshold]</b>  | <p>Defines the low threshold percentage of total calls that are active (busy endpoints).</p> <p>When the percentage of the device's busy endpoints falls below this low threshold, the device sends an SNMP acBoardCallResourcesAlarm alarm trap with a 'cleared' alarm status.</p> <p>The range is 0 to 100%. The default is 90%.</p>                                                                                                                                                                                                                                                                  |
| <b>[RAILoopTime]</b>      | <p>Defines the time interval (in seconds) that the device periodically checks call resource availability.</p> <p>The valid range is 1 to 200. The default is 10.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 63.3.5 PacketSmart Parameters

The PacketSmart parameters are described in the table below. For more information on PacketSmart, see 'Configuring PacketSmart for Network Monitoring' on page 870.

**PacketSmart Parameters**

| Parameter                                                                                                                                                                       | Description                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PacketSmart Agent Mode</b><br><code>configure system &gt;</code><br><code>packetsmart enable</code><br><b>[PacketSmartAgentMode]</b>                                         | Enables the embedded PacketSmart agent. <ul style="list-style-type: none"> <li>▪ [0] Disable (Default)</li> <li>▪ [1] Enable</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                        |
| <b>PacketSmart IP Address</b><br><code>configure system &gt;</code><br><code>packetsmart server</code><br><code>address</code><br><b>[PacketSmartIpAddress]</b>                 | Defines the IP address of the PacketSmart server with which the PacketSmart agent communicates.<br>The default is 0.0.0.0.                                                                                                                |
| <b>PacketSmart IP Address Port</b><br><code>configure system &gt;</code><br><code>packetsmart server</code><br><code>address port</code><br><b>[PacketSmartIpAddressPort]</b>   | Defines the TCP port of the PacketSmart server to which the PacketSmart agent connects.<br>The default is 80.                                                                                                                             |
| <b>Monitoring Interface</b><br><code>configure system &gt;</code><br><code>packetsmart monitor</code><br><code>voip interface-if</code><br><b>[PacketSmartMonitorInterface]</b> | Assigns an IP network interface (configured in the IP Interface table) that handles the voice traffic.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                      |
| <b>Network Interface</b><br><code>configure system &gt;</code><br><code>packetsmart network</code><br><code>voip interface-if</code><br><b>[PacketSmartNetworkInterface]</b>    | Assigns an IP network interface (configured in the IP Interface table) for communicating with the PacketSmart server. This is typically the OAMP interface.<br><b>Note:</b> For the parameter to take effect, a device reset is required. |

### 63.3.6 HA Parameters

The High Availability (HA) parameters are described in the table below.

**Table 63-22: HA Parameters**

| Parameter                                                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>HA Device Name</b><br><code>configure system &gt;</code><br><code>high-availability &gt;</code><br><code>unit-id-name</code><br><b>[HAUnitIdName]</b>         | <p>Defines a name for the device, which is displayed on the Home page to indicate the active device.</p> <p>The valid value is a string of up to 128 characters. The default value is "Device 1" for the active device and "Device 2" for the redundant device.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>HA Remote Address</b><br><code>configure system &gt;</code><br><code>high-availability &gt;</code><br><code>remote-address</code><br><b>[HARemoteAddress]</b> | <p>Defines the Maintenance interface address of the redundant device in the HA system.</p> <p>By default, no value is defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>HA Revertive</b><br><code>configure system &gt;</code><br><code>high-availability &gt;</code><br><code>revertive-mode</code><br><b>[HARevertiveEnabled]</b>   | <p>Enables HA switchover based on HA priority.</p> <ul style="list-style-type: none"> <li>[0] Disable (default) = A switchover over to the redundant device is done only if a failure occurs in the currently active device.</li> <li>[1] Enable = A switchover over to the redundant device is done if a failure occurs in the currently active device. However, a switchover to the device with the highest priority (configured by the HAPriority parameter) occurs whenever the device recovers from a failure. Therefore, whenever possible, the highest priority device is the active one.</li> </ul> <p>For more information on the HA switchover mechanism, see Device Switchover upon Failure on page 766.</p> |
| <b>HA Priority</b><br><code>configure system &gt;</code><br><code>high-availability &gt;</code><br><code>priority</code><br><b>[HAPriority]</b>                  | <p>Defines the priority of the device used in the HA Revertive mechanism. The valid value is 1 (lowest priority) to 10 (highest priority). The default is 5.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only if you configure the 'HA Revertive' parameter to <b>Enable</b>.</li> <li>You must configure each device in the HA system with different parameter values (priorities).</li> </ul>                                                                                                                                                                                                                                                                          |

| <b>HA Network Reachability Destination Address</b><br><b>[HAPingDestination]</b>                                                                                 | <p>Defines the IP address of the destination that the device pings. The default is 0.0.0.0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>HA Network Reachability Source Interface Name</b><br><b>[HAPingSourceInterfaceName]</b>                                                                       | <p>Defines the device's IP network interface from where the ping is sent. The valid value is the name of the IP interface as configured in the 'Interface Name' field of the Interface table. By default, no IP network is defined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                                               | Description                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HA Network Reachability Ping Timeout<br>[HAPingTimeout] | Defines the timeout (in seconds) for which the ping request waits for a reply.<br>The valid value is 1 to 60. The default is 1.                                                                                                                                                                                                                                      |
| HA Network Reachability Ping Retries<br>[HAPingRetries] | Defines the number of ping requests that the device sends after no response is received from the destination, before the destination is declared unavailable. For example, if you specify 2, the destination is declared as down after three consecutive ping requests fail to evoke a response from the destination.<br>The valid value is 0 to 100. The default 2. |

## 63.4 Security Parameters

This subsection describes the device's security parameters.

### 63.4.1 General Security Parameters

The general security parameters are described in the table below.

**Table 63-23: General Security Parameters**

| Parameter                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Firewall Table</b>                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Internal Firewall Parameters<br><code>configure voip &gt;</code><br><code>access-list</code><br><code>[AccessList]</code> | <p>The table defines the device's access list (firewall), which defines network traffic filtering rules.</p> <p>The format of the ini file table parameter is:<br/> <code>[AccessList]</code><br/>           FORMAT AccessList_Index = AccessList_Source_IP, AccessList_Source_Port, AccessList_PrefixLen, AccessList_Source_Port, AccessList_Start_Port, AccessList_End_Port, AccessList_Protocol, AccessList_Use_Specific_Interface, AccessList_Interface_ID, AccessList_Packet_Size, AccessList_Byte_Rate, AccessList_Byte_Burst, AccessList_Allow_Type;<br/> <code>[AccessList]</code></p> <p>For example:<br/>           AccessList 10 = mgmt.customer.com, , , 32, 0, 80, tcp, 1, OAMP, 0, 0, 0, allow;<br/>           AccessList 22 = 10.4.0.0, , , 16, 4000, 9000, any, 0, , 0, 0, 0, block;</p> <p>In the example above, Rule #10 allows traffic from the host 'mgmt.customer.com' destined to TCP ports 0 to 80 on interface OAMP (OAMP). Rule #22 blocks traffic from the subnet 10.4.xxx.yyy destined to ports 4000 to 9000.</p> <p>For a detailed description of the table, see "Configuring Firewall Settings" on page 177.</p> |
| <b>Media Latching</b>                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Inbound Media Latch Mode<br><code>inbound-media-latch-mode</code><br><code>[InboundMediaLatchMode]</code>                 | <p>Enables the Media Latching feature.</p> <ul style="list-style-type: none"> <li>[0] Strict = Device latches onto the first original stream (IP address:port). It does not latch onto any other stream during the session.</li> <li>[1] Dynamic = (Default) Device latches onto the first stream. If it receives at least a minimum number of consecutive packets (configured by New&lt;media type&gt;StreamPackets) from a different source(s) and the device has not received packets from the current stream for a user-defined period (TimeoutToRelatch&lt;media type&gt;Msec), it latches onto the next packet received from any other stream. If other packets of a different media type are received from the new stream, based on IP address and SSRC for RTCP/RTP and based on IP address only for T.38, the packet is accepted immediately. Note: If a packet from the original (first latched onto) IP address:port is received at any time, the device latches onto this stream.</li> </ul>                                                                                                                                      |

The default is 200.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Timeout To Relatch SRTP<br>[TimeoutToRelatchSRTPMsec]       | <p>Defines a period (msec) during which if no packets are received from the current SRTP session, the channel can re-latch onto another stream.</p> <p>The valid range is any value from 0. The default is 200.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Timeout To Relatch Silence<br>[TimeoutToRelatchSilenceMsec] | <p>Defines a period (msec) during which if no packets are received from the current RTP/SRTP session and the channel is in silence mode, the channel can re-latch onto another stream.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                                             | Description                                                                                                                                                                                                           |
|-------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                       | The valid range is any value from 0. The default is 200.                                                                                                                                                              |
| Timeout To Relatch RTCP<br>[TimeoutToRelatchRTCPMsec] | Defines a period (msec) during which if no packets are received from the current RTCP session, the channel can re-latch onto another RTCP stream.<br>The valid range is any value from 0. The default is 10,000.      |
| Fax Relay Rx/Tx Timeout<br>[FaxRelayTimeoutSec]       | Defines a period (sec) during which if no T.38 packets are received or sent from the current T.38 fax relay session, the channel can re-latch onto another stream.<br>The valid range is 0 to 255. The default is 10. |

## 63.4.2 HTTPS Parameters

The Secure Hypertext Transport Protocol (HTTPS) parameters are described in the table below.

**Table 63-24: HTTPS Parameters**

| Parameter                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Secured Web Connection (HTTPS)<br>secured-connection<br>[HTTPSOnly]                                     | Determines the protocol used to access the Web interface. <ul style="list-style-type: none"> <li><b>[0]</b> HTTP and HTTPS (default).</li> <li><b>[1]</b> HTTPS Only = Unencrypted HTTP packets are blocked.</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| https-port<br>[HTTPSPort]                                                                               | Defines the local Secured HTTPS port of the device. The parameter allows secure remote device Web management from the LAN. To enable secure Web management from the LAN, configure the desired port.<br>The valid range is 1 to 65535 (other restrictions may apply within this range). The default port is 443.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| HTTPS Cipher String<br>https-cipher-string<br>[HTTPSCipherString]                                       | Defines the Cipher string for HTTPS (in OpenSSL cipher list format). For the valid range values, refer to URL <a href="http://www.openssl.org/docs/apps/ciphers.html">http://www.openssl.org/docs/apps/ciphers.html</a> .<br>The default is 'RC4:EXP' (Export encryption algorithms). For example, use 'ALL' for all ciphers suites (e.g., for ARIA encryption for TLS). The only ciphers available are RC4 and DES, and the cipher bit strength is limited to 56 bits.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>If the installed Software License Key includes the Strong Encryption feature, the default of the parameter is changed to 'RC4:EXP', enabling RC-128bit encryption.</li> <li>The value 'ALL' can be configured only if the installed Software License Key includes the Strong Encryption feature.</li> </ul> |
| Requires Client Certificates for HTTPS connection<br>req-client-cert<br>[HTTPSRequireClientCertificate] | Enables the requirement of client certificates for HTTPS connection. <ul style="list-style-type: none"> <li><b>[0]</b> Disable = (Default) Client certificates are not required.</li> <li><b>[1]</b> Enable = Client certificates are required. The client certificate must be preloaded to the device and its matching</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <p>private key must be installed on the managing PC. Time and date must be correctly set on the device for the client certificate to be verified.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>For a description on implementing client certificates, see "TLS for Remote Device Management" on page 129.</li> </ul> |

### 63.4.3 SRTP Parameters

The Secure Real-Time Transport Protocol (SRTP) parameters are described in the table below.

**Table 63-25: SRTP Parameters**

| Parameter                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Media Security<br><code>media-security-enable</code><br>[EnableMediaSecurity]                     | <p>Enables Secure Real-Time Transport Protocol (SRTP).</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                  |
| Media Security Behavior<br><code>media-sec-bhavior</code><br>[MediaSecurityBehaviour]             | <p>Global parameter that defines the handling of SRTP (when the EnableMediaSecurity parameter is set to 1). You can also configure this functionality per specific calls, using IP Profiles (IpProfile_MediaSecurityBehaviour). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see Configuring IP Profiles on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p> |
| Master Key Identifier (MKI) Size<br><code>SRTP-tx-packet-MKI-size</code><br>[SRTPTxPacketMKISize] | <p>Global parameter that defines the size (in bytes) of the Master Key Identifier (MKI) in SRTP Tx packets. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_MKISize). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                                                                               |

| Parameter                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Symmetric MKI Negotiation<br><code>symmetric-mki</code><br>[EnableSymmetricMKI]        | <p>Global parameter that enables symmetric MKI negotiation. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_EnableSymmetricMKI). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Offered SRTP Cipher Suites<br><code>offer-srtp-cipher</code><br>[SRTPofferedSuites]    | <p>Defines the offered crypto suites (cipher encryption algorithms) for SRTP.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> All = (Default) All available crypto suites.</li> <li>▪ <b>[1]</b> AES-CM-128-HMAC-SHA1-80 = device uses AES-CM encryption with a 128-bit key and HMAC-SHA1 message authentication with a 80-bit tag.</li> <li>▪ <b>[2]</b> AES-CM-128-HMAC-SHA1-32 = device uses AES-CM encryption with a 128-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> <li>▪ <b>[4]</b> ARIA-CM-128-HMAC-SHA1-80 = device uses ARIA encryption algorithm with a 128-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> <li>▪ <b>[8]</b> ARIA-CM-192-HMAC-SHA1-80 = device uses ARIA encryption algorithm with a 192-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For enabling ARIA encryption, use the AriaProtocolSupport parameter.</li> <li>▪ The parameter also affects the selection of the crypto in the device's answer. For example, if the device receives an offer with two crypto lines containing HMAC_SHA1_80 and HMAC_SHA_32, it uses the HMAC_SHA_32 key in its SIP 200 OK response if the parameter is set to 2.</li> </ul> |
| <code>configure voip &gt; sbc general-setting &gt; sbc-dtls-mtu</code><br>[SbcDtlsMtu] | <p>Defines the maximum transmission unit (MTU) size for the DTLS handshake. The device does not attempt to send handshake packets that are larger than the configured value. Adjusting the MTU is useful when there are network constraints on the size of packets that can be sent.</p> <p>The valid value range is 228 to 1500. The default is 1500.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Aria Protocol Support<br>ARIA-protocol-support<br>[AriaProtocolSupport]                                                                          | Enables ARIA algorithm cipher encryption for SRTP. This is an alternative option to the existing support for the AES algorithm. ARIA is a symmetric key block cipher algorithm standard developed by the Korean National Security Research Institute. <ul style="list-style-type: none"> <li>[0] Disable (default)</li> <li>[1] Enable</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>To configure the ARIA bit-key encryption size (128 or 192 bit) with HMAC SHA-1 cryptographic hash function, use the SRTPofferedSuites parameter.</li> <li>The ARIA feature is available only if the device is installed with a Software License Key that includes this feature. For installing a Software License Key, see Software License Key on page 819.</li> </ul> |
| Authentication On Transmitted RTP Packets<br>RTP-authentication-disable-tx<br>[RTPAuthenticationDisableTx]                                       | Enables authentication on transmitted RTP packets in a secured RTP session. <ul style="list-style-type: none"> <li>[0] Enable (default)</li> <li>[1] Disable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Encryption On Transmitted RTP Packets<br>RTP-encryption-disable-tx<br>[RTPEncryptionDisableTx]                                                   | Enables encryption on transmitted RTP packets in a secured RTP session. <ul style="list-style-type: none"> <li>[0] Enable (default)</li> <li>[1] Disable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| srtplib-state-behavior-mode<br>[ResetSRTPStateUponRekey] | <p>Global parameter that enables synchronization of the SRTP state between the device and a server when a new SRTP key is generated upon a SIP session expire. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_ResetSRTPStateUponRekey). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p> |

## 63.4.4 TLS Parameters

The Transport Layer Security (TLS) parameters are described in the table below.

**Table 63-26: TLS Parameters**

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TLS Contexts Table</b>                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| TLS Contexts Table<br>configure system > tls #<br>[TLSContexts] | <p>Defines SSL/TLS certificates.</p> <p>The format of the ini file table parameter is as follows:</p> <pre>[ TLSContexts ] FORMAT TLSContexts_Index = TLSContexts_Name, TLSContexts_TLSVersion, TLSContexts_ServerCipherString, TLSContexts_ClientCipherString, TLSContexts_OcspEnable, TLSContexts_OcspServerPrimary, TLSContexts_OcspServerSecondary, TLSContexts_OcspServerPort, TLSContexts_OcspDefaultResponse; [ \TLSContexts ]</pre> <p>For a detailed description of the table, see "Configuring TLS Certificate Contexts" on page 117.</p> |
| TLS Client Re-Handshake Interval                                | <p>Defines the time interval (in minutes) between TLS Re-Handshakes initiated by the device.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| tls-re-hndshk-int<br>[TLSReHandshakeInterval]                      | The interval range is 0 to 1,500 minutes. The default is 0 (i.e., no TLS Re-Handshake).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| TLS Mutual Authentication<br>[SIPSRequireClientCertificate]        | <p>Defines the device's mode of operation regarding mutual authentication and certificate verification for TLS connections.</p> <ul style="list-style-type: none"> <li>▪ <b>[0] Disable = (Default)</b> <ul style="list-style-type: none"> <li>✓ Device acts as a client: Verification of the server's certificate depends on the VerifyServerCertificate parameter.</li> <li>✓ Device acts as a server: The device does not request the client certificate.</li> </ul> </li> <li>▪ <b>[1] Enable =</b> <ul style="list-style-type: none"> <li>✓ Device acts as a client: Verification of the server certificate is required to establish the TLS connection.</li> <li>✓ Device acts as a server: The device requires the receipt and verification of the client certificate to establish the TLS connection.</li> </ul> </li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ This feature can be configured per SIP Interface (see "Configuring SIP Interfaces" on page 360).</li> <li>▪ The SIPS certificate files can be changed using the parameters HTTPSCertFileName and HTTPSRootFileName.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                    |
| Peer Host Name Verification Mode<br>[PeerHostNameVerificationMode] | <p>Determines whether the device verifies the Subject Name of a remote certificate when establishing TLS connections.</p> <ul style="list-style-type: none"> <li>▪ <b>[0] Disable (default).</b></li> <li>▪ <b>[1] Server Only =</b> Verify Subject Name only when acting as a client for the TLS connection.</li> <li>▪ <b>[2] Server &amp; Client =</b> Verify Subject Name when acting as a server or client for the TLS connection.</li> </ul> <p>When the device receives a remote certificate and the parameter is not disabled, the IP address from which the certificate is received is compared with the addresses defined for the Proxy Sets. If no Proxy Set with the source address is found, the connection is refused. Otherwise, the value of SubjectAltName field in the certificate is compared with the addresses\ DNS Names of the classified Proxy Set. If a match is found for any of the configured Proxies, the TLS connection is established.</p> <p>The comparison is performed if the SubjectAltName is either a DNS name (DNSName) or an IP address. If no match is found and the SubjectAltName is marked as 'critical', the TLS connection is not established. If DNSName is used, the certificate can also use wildcards ('*') to replace parts of the domain name.</p> <p>If the SubjectAltName is not marked as 'critical' and there is no match, the CN value of the SubjectName field is compared with the parameter TLSRemoteSubjectName. If a match is found, the connection is established; otherwise, the connection is terminated.</p> |

| Parameter                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                         | <p><b>Note:</b> If you set the parameter to [2] (Server &amp; Client), for this functionality to operate you also need to set the SIPRequireClientCertificate parameter to [1] (Enable).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TLS Client Verify Server Certificate<br>tls-vrfy-srvr-cert<br>[VerifyServerCertificate] | <p>Determines whether the device, when acting as a client for TLS connections, verifies the Server certificate. The certificate is verified with the Root CA information.</p> <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul> <p><b>Note:</b> If Subject Name verification is necessary, the parameter PeerHostNameVerificationMode must be used as well.</p>                                                                                                                                                                                                                                                                                                              |
| Strict Certificate Extension Validation<br>require-strict-cert<br>[RequireStrictCert]   | <p>Enables the validation of the extensions (keyUsage and extendedKeyUsage) of peer certificates. This validation ensures that the signing CA is authorized to sign certificates and that the end-entity certificate is authorized to negotiate a secure TLS connection.</p> <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                               |
| TLS Remote Subject Name<br>tls-rmt-subs-name<br>[TLSRemoteSubjectName]                  | <p>Defines the Subject Name that is compared with the name defined in the remote side certificate when establishing TLS connections.</p> <p>If the SubjectAltName of the received certificate is not equal to any of the defined Proxies Host names/IP addresses and is not marked as 'critical', the Common Name (CN) of the Subject field is compared with this value. If not equal, the TLS connection is not established. If the CN uses a domain name, the certificate can also use wildcards ("*") to replace parts of the domain name. The valid range is a string of up to 49 characters.</p> <p><b>Note:</b> The parameter is applicable only if the parameter PeerHostNameVerificationMode is set to 1 or 2.</p> |
| TLS Expiry Check Start<br>expiry-check-start<br>[TLSExpiryCheckStart]                   | <p>Defines the number of days before the installed TLS server certificate is to expire at which the device must send a trap (acCertificateExpiryNotification) to notify of this.</p> <p>The valid value is 0 to 3650. The default is 60.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TLS Expiry Check Period<br>expiry-check-period<br>[TLSExpiryCheckPeriod]                | <p>Defines the periodical interval (in days) for checking the TLS server certificate expiry date.</p> <p>The valid value is 1 to 3650. The default is 7.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TLS FIPS 140 Mode<br>[TLS_Fips140_Mode]                                                 | <p>Enables FIPS 140-2 conformance mode for TLS.</p> <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 63.4.5 SSH Parameters

Secure Shell (SSH) parameters are described in the table below.

**Table 63-27: SSH Parameters**

| Parameter         | Description                               |
|-------------------|-------------------------------------------|
| Enable SSH Server | Enables the device's embedded SSH server. |

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ssh<br>[SSHServerEnable]                                                           | <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul>                                                                                                                                                                                                                                                                                              |
| Server Port<br>ssh-port<br>[SSHServerPort]                                         | Defines the port number for the embedded SSH server.<br>Range is any valid port number. The default port is 22.                                                                                                                                                                                                                                                                                        |
| SSH Admin Key<br>ssh-admin-key<br>[SSHAdminKey]                                    | Defines the RSA public key for strong authentication for logging in to the SSH interface (if enabled).<br>The value should be a base64-encoded string. The value can be a maximum length of 511 characters.                                                                                                                                                                                            |
| Require Public Key<br>ssh-require-public-key<br>[SSHRequirePublicKey]              | <p>Enables RSA public keys for SSH.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) RSA public keys are optional if a value is configured for the parameter SSHAdminKey.</li> <li><b>[1]</b> = RSA public keys are mandatory.</li> </ul> <p><b>Note:</b> To define the key size, use the TLSPkeySize parameter.</p>                                                                  |
| Max Payload Size<br>ssh-max-payload-size<br>[SSHMaxPayloadSize]                    | Defines the maximum uncompressed payload size (in bytes) for SSH packets.<br>The valid value is 550 to 32768. The default is 32768.                                                                                                                                                                                                                                                                    |
| Max Binary Packet Size<br>ssh-max-binary-packet-size<br>[SSHMaxBinaryPacketSize]   | Defines the maximum packet size (in bytes) for SSH packets.<br>The valid value is 582 to 35000. The default is 35000.                                                                                                                                                                                                                                                                                  |
| Maximum SSH Sessions<br>ssh-max-sessions<br>[SSHMaxSessions]                       | Defines the maximum number of simultaneous SSH sessions.<br>The valid range is 1 to 5. The default is 5 sessions.                                                                                                                                                                                                                                                                                      |
| Enable Last Login Message<br>ssh-last-login-message<br>[SSHEnableLastLoginMessage] | <p>Enables message display in SSH sessions of the time and date of the last SSH login. The SSH login message displays the number of unsuccessful login attempts since the last successful login.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable</li> <li><b>[1]</b> Enable (default)</li> </ul> <p><b>Note:</b> The last SSH login information is cleared when the device is reset.</p> |
| Max Login Attempts<br>ssh-max-login-attempts<br>[SSHMaxLoginAttempts]              | <p>Defines the maximum SSH login attempts allowed for entering an incorrect password by an administrator before the SSH session is rejected.</p> <p>The valid range is 1 to 5. the default is 3.</p> <p><b>Note:</b> The new setting takes effect only for new subsequent SSH connections.</p>                                                                                                         |

### 63.4.6 IDS Parameters

The Intrusion Detection System (IDS) parameters are described in the table below.

**Table 63-28: IDS Parameters**

| Parameter                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Intrusion Detection System (IDS)<br>enable-ids<br>[EnableIDS] | Enables the IDS feature. <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                     |
| ids-clear-period<br>[IDSArmClearPeriod]                       | Defines the interval (in seconds) after which an IDS alarm is cleared from the Active Alarms table if no thresholds are crossed during this time. However, this "quiet" period must be at least twice the Threshold Window value. For example, if IDSArmClearPeriod is set to 20 sec and the Threshold Window is set to 15 sec, the IDSArmClearPeriod parameter is ignored and the alarm is cleared only after 30 seconds (2 x 15 sec).<br><br>The valid value is 0 to 86400. The default is 300. |
| <b>IDS Policy Table</b>                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IDS Policy Table<br>[IDSPolicy]                               | Defines IDS Policies.<br>The format of the ini file parameter is:<br>[ IDSPolicy ]<br>FORMAT IDSPolicy_Index = IDSPolicy_Name, IDSPolicy_Description;<br>[ \IDSPolicy ]<br><br>For a detailed description of the table, see "Configuring IDS Policies" on page 184.                                                                                                                                                                                                                               |
| <b>IDS Rule Table</b>                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IDS Rule Table<br>[IDSRule]                                   | Defines rules for IDS Policies.<br>The format of the ini file parameter is:<br>[ IDSRule ]<br>FORMAT IDSRule_Index = IDSRule_Policy, IDSRule_RuleID, IDSRule_Reason, IDSRule_ThresholdScope, IDSRule_ThresholdWindow, IDSRule_MinorAlarmThreshold, IDSRule_MajorAlarmThreshold, IDSRule_CriticalAlarmThreshold, IDSRule_DenyThreshold, IDSRule_DenyPeriod;<br>[ \IDSRule ]<br><br>For a detailed description of the table, see "Configuring IDS Policies" on page 184.                            |
| <b>IDS Match Table</b>                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| IDS Match Table<br>[IDSMatch]                                 | Defines target rules per IDS Policy.<br>The format of the ini file parameter is:<br>[ IDSMatch ]<br>FORMAT IDSMatch_Index = IDSMatch_SIPInterface, IDSMatch_ProxySet, IDSMatch_Subnet, IDSMatch_Policy;<br>[ \IDSMatch ]<br><br>For a detailed description of the table, see "Assigning IDS Policies" on page 188.                                                                                                                                                                                |

## 63.4.7 OCSP Parameters

The Online Certificate Status Protocol (OCSP) parameters are described in the table below.

**Table 63-29: OCSP Parameters**

| Parameter                                                                             | Description                                                                                                                                                                                                                                           |
|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable OCSP Server<br>enable<br>[OCSPEnable]                                          | Enables or disables certificate checking using OCSP. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> For a description of OCSP, see Configuring Certificate Revocation Checking (OCSP). |
| Primary Server IP<br>server-ip<br>[OCSPServerIP]                                      | Defines the IP address of the OCSP server.<br>The default IP address is 0.0.0.0.                                                                                                                                                                      |
| Secondary Server IP<br>secondary-server-ip<br>[OCSPSecondaryServerIP]                 | Defines the IP address (in dotted-decimal notation) of the secondary OCSP server (optional).<br>The default IP address is 0.0.0.0.                                                                                                                    |
| Server Port<br>server-port<br>[OCSPServerPort]                                        | Defines the OCSP server's TCP port number.<br>The default port number is 2560.                                                                                                                                                                        |
| Default Response When Server Unreachable<br>default-response<br>[OCSPDefaultResponse] | Determines whether the device allows or rejects peer certificates when the OCSP server cannot be contacted. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Reject (default)</li> <li>▪ <b>[1]</b> Allow</li> </ul>                               |

## 63.5 Quality of Experience Parameters

The Quality of Experience (QoE) parameters are described in the table below.

**Table 63-30: Quality of Experience Parameters**

| Parameter                                                                                                           | Description                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SEM Parameters</b>                                                                                               |                                                                                                                                                                                                                                                                      |
| Server IP<br>configure voip/qoe<br>configuration/server-ip<br>[QOEServerIP]                                         | Defines the IP address of the primary Session Experience Manager (SEM) server to where the quality experience reports are sent.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                        |
| Redundant Server IP<br>configure voip > qoe<br>configuration > set<br>secondary-server-ip<br>[QOESecondaryServerIp] | Defines the IP address of the secondary SEM server to where the quality experience reports are sent. This is applicable when the SEM/EMS server is in Geographical Redundancy HA mode.<br><b>Note:</b> For the parameter to take effect, a device reset is required. |
| Interface Name<br>configure voip/qoe<br>configuration/interface-<br>name<br>[QOEInterfaceName]                      | Defines the IP network interface on which the quality experience reports are sent.<br>The default is the OAMP interface.<br><b>Note:</b> For the parameter to take effect, a device reset is required.                                                               |

## 63.6 Control Network Parameters

### 63.6.1 IP Group, Proxy, Registration and Authentication Parameters

The proxy server, registration and authentication SIP parameters are described in the table below.

**Table 63-31: Proxy, Registration and Authentication SIP Parameters**

| Parameter                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                   | <ul style="list-style-type: none"> <li>If a specific Transport Type is configured, a NAPTR query is not performed.</li> <li>To enable NAPTR/SRV queries for Proxy servers only, use the global parameter ProxyDNSQueryType, or use the proxy Set table.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Proxy DNS Query Type<br>proxy-dns-query<br>[ProxyDNSQueryType]                    | <p>Global parameter that defines the DNS query record type for resolving the Proxy server's configured domain name (FQDN) into an IP address.</p> <ul style="list-style-type: none"> <li><b>[0]</b> A-Record (default) = A-record DNS query.</li> <li><b>[1]</b> SRV = If the Proxy IP address parameter contains a domain name without port definition (e.g., ProxyIP = domain.com), an SRV query is performed. The SRV query returns up to four Proxy host names and their weights. The device then performs DNS A-record queries for each Proxy host name (according to the received weights) to locate up to four Proxy IP addresses. Thus, if the first SRV query returns two domain names and the A-record queries return two IP addresses each, no additional searches are performed.</li> <li><b>[2]</b> NAPTR = NAPTR query is done. If successful, an SRV query is sent according to the information received in the NAPTR response. If the NAPTR query fails, an SRV query is done according to the configured transport type. If the Proxy IP address parameter contains a domain name with port definition (e.g., ProxyIP = domain.com:5080), the device performs a regular DNS A-record query. If a specific Transport Type is defined, a NAPTR query is not performed.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>This functionality can be configured per Proxy Set in the Proxy Set table (see "Configuring Proxy Sets" on page 381).</li> <li>When enabled, NAPTR/SRV queries are used to discover Proxy servers even if the parameter DNSQueryType is disabled.</li> </ul> |
| Use Gateway Name for OPTIONS<br>use-gw-name-for-opt<br>[UseGatewayNameForOptions] | <p>Determines whether the device uses its IP address or string name ("gateway name") in keep-alive SIP OPTIONS messages (host part of the Request-URI). To configure the "gateway name", use the SIPGatewayName parameter. The device uses the OPTIONS request as a keep-alive message with its primary and redundant SIP proxy servers (i.e., the EnableProxyKeepAlive parameter is set to 1).</p> <ul style="list-style-type: none"> <li><b>[0]</b> No = (Default) Device's IP address is used in keep-alive OPTIONS messages.</li> <li><b>[1]</b> Yes = Device's "gateway name" is used in keep-alive OPTIONS messages.</li> <li><b>[2]</b> Server = Device's IP address is used in the From and To headers in keep-alive OPTIONS messages.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Challenge Caching Mode</b><br>challenge-caching<br>[SIPChallengeCachingMode]          | <p>Enables local caching of SIP message authorization challenges from Proxy servers.</p> <p>The device sends the first request to the Proxy without authorization. The Proxy sends a 401/407 response with a challenge for credentials. The device saves (caches) the response for further uses. The device sends a new request with the appropriate credentials. Subsequent requests to the Proxy are automatically sent with credentials (calculated from the saved challenge). If the Proxy doesn't accept the new request and sends another challenge, the old challenge is replaced with the new one. One of the benefits of the feature is that it may reduce the number of SIP messages transmitted through the network.</p> <ul style="list-style-type: none"> <li><b>[0]</b> None = (Default) Challenges are not cached. Every new request is sent without preliminary authorization. If the request is challenged, a new request with authorization data is sent.</li> <li><b>[1]</b> INVITE Only = Challenges issued for INVITE requests are cached. This prevents a mixture of REGISTER and INVITE authorizations.</li> <li><b>[2]</b> Full = Caches all challenges from the proxies.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Challenge caching is used with all proxies and not only with the active one.</li> <li>For the Gateway application: The challenge can be cached per endpoint or per Account.</li> <li>For the SBC application: The challenge can be cached per Account or per user whose credentials are known through the User Info table.</li> </ul> |

| Registrar IP Address<br><code>ip-addr-rgstr</code><br>[RegistrarIP]                            | <p>Defines the IP address (or FQDN) and port number (optional) of the Registrar server. The IP address is in dotted-decimal notation, e.g., 201.10.8.1:&lt;5080&gt;.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to the Gateway application.</li> <li>▪ If not specified, the REGISTER request is sent to the primary Proxy server.</li> <li>▪ When a port number is specified, DNS NAPTR/SRV queries aren't performed, even if the parameter DNSQueryType is set to 1 or 2.</li> <li>▪ If the parameter RegistrarIP is set to an FQDN and is resolved to multiple addresses, the device also provides real-time switching (hotswap mode) between different Registrar IP addresses (the parameter IsProxyHotSwap is set to 1). If the first Registrar doesn't respond to the REGISTER message, the same REGISTER message is sent immediately to the next Proxy. To allow this mechanism, the parameter EnableProxyKeepAlive must be set to 0.</li> <li>▪ When a specific transport type is defined using the parameter RegistrarTransportType, a DNS NAPTR query is not performed even if the parameter DNSQueryType is set to 2.</li> </ul> |
| Registrar Transport Type<br><code>registrar-transport</code><br>[RegistrarTransportType]       | <p>Determines the transport layer used for outgoing SIP dialogs initiated by the device to the Registrar.</p> <ul style="list-style-type: none"> <li>▪ [-1] Not Configured (default)</li> <li>▪ [0] UDP</li> <li>▪ [1] TCP</li> <li>▪ [2] TLS</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to the Gateway application.</li> <li>▪ When set to 'Not Configured', the value of the parameter SIPTransportType is used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Registration Time<br><code>registration-time</code><br>[RegistrationTime]                      | <p>Defines the time interval (in seconds) for registering to a Proxy server. The value is used in the SIP Expires header. The parameter also defines the time interval between Keep-Alive messages when the parameter EnableProxyKeepAlive is set to 2 (REGISTER).</p> <p>Typically, the device registers every 3,600 sec (i.e., one hour). The device resumes registration according to the parameter RegistrationTimeDivider.</p> <p>The valid range is 10 to 2,000,000. The default is 180.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Re-registration Timing [%]<br><code>re-registration-timing</code><br>[RegistrationTimeDivider] | <p>Defines the re-registration timing (in percentage). The timing is a percentage of the re-register timing set by the Registrar server.</p> <p>The valid range is 50 to 100. The default is 50.</p> <p>For example: If the parameter is set to 70% and the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                                                                                                              | <p>Protocol (SIP)" for reliable, connection-orientated transport types such as TCP.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p>The SIP user agent/client (i.e., device) uses a simple periodic message as a keep-alive mechanism to keep their flow to the proxy or registrar alive (used for example, to keep NAT bindings open). For connection-oriented transports such as TCP/TLS this is based on CRLF. This mechanism uses a client-to-server "ping" keep-alive and a corresponding server-to-client "pong" message. This ping-pong sequence allows the client, and optionally the server, to tell if its flow is still active and useful for SIP traffic. If the client does not receive a pong in response to its ping, it declares the flow "dead" and opens a new flow in its place. In the CRLF Keep-Alive mechanism the client periodically (defined by the PingPongKeepAliveTime parameter) sends a double-CRLF (the "ping") then waits to receive a single CRLF (the "pong"). If the client does not receive a "pong" within an appropriate amount of time, it considers the flow failed.</p> <p><b>Note:</b> The device sends a CRLF message to the Proxy Set only if the Proxy Keep-Alive feature (EnableProxyKeepAlive parameter) is enabled and its transport type is set to TCP or TLS. The device first sends a SIP OPTION message to establish the TCP/TLS connection and if it receives any SIP response, it continues sending the CRLF keep-alive sequences.</p> |
| [PingPongKeepAliveTime]                                                                                                      | <p>Defines the periodic interval (in seconds) after which a "ping" (double-CRLF) keep-alive is sent to a proxy/registrar, using the CRLF Keep-Alive mechanism.</p> <p>The default range is 5 to 2,000,000. The default is 120.</p> <p>The device uses the range of 80-100% of this user-defined value as the actual interval. For example, if the parameter value is set to 200 sec, the interval used is any random time between 160 to 200 seconds. This prevents an "avalanche" of keep-alive by multiple SIP UAs to a specific server.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Max Generated Register Rate<br>configure voip > sip-definition<br>settings > max-gen-reg-rate<br>[MaxGeneratedRegistersRate] | <p>Defines the maximum number of user register requests (REGISTER messages) that the device sends (to a proxy or registrar server) at a user-defined rate configured by the GeneratedRegistersInterval parameter. The parameter is useful in that it may be used to prevent an overload on the device's CPU caused by sending many registration requests at a given time.</p> <p>The valid value is 30 to 300 register requests per second. The default is 150.</p> <p>For configuration examples, see the description of the GeneratedRegistersInterval parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Generated Registers interval<br>gen-reg-int<br>[GeneratedRegistersInterval]                                                  | <p>Defines the rate (in seconds) at which the device sends user register requests (REGISTER messages). The parameter is based on the maximum number of REGISTER messages that can be sent at this rate, configured by the MaxGeneratedRegistersRate parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Parameter | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## 63.6.2 Network Application Parameters

The SIP network application parameters are described in the table below.

**Table 63-32: SIP Network Application Parameters**

| Parameter                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 63.7 General SIP Parameters

The general SIP parameters are described in the table below.

**Table 63-33: General SIP Parameters**

| Parameter                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max Call Duration (min)<br>mx-call-duration<br>[MaxCallDuration]                                                     | Defines the maximum duration (in minutes) of a call. If this duration is reached, the device terminates the call. This feature is useful for ensuring available resources for new calls, by ensuring calls are properly terminated.<br><br>The valid range is 0 to 35,791. The default is 0 (i.e., no limitation).                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Send reject on overload<br>configure voip/sip-definition advanced-settings/reject-on-ovrld<br>[SendRejectOnOverload] | Disables the sending of SIP 503 (Service Unavailable) responses upon receipt of new SIP dialog-initiating requests when the device's CPU is overloaded and thus, unable to accept and process new SIP messages. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = No SIP 503 response is sent when CPU overloaded.</li> <li>▪ <b>[1]</b> Enable (default) = SIP 503 response is sent when CPU overloaded.</li> <li>▪ <b>Note:</b> Even if the parameter is disabled (i.e., 503 is not sent), the device still discards the new SIP dialog-initiating requests when the CPU is overloaded.</li> </ul>                                                                                                                                        |
| SIP 408 Response upon non-INVITE<br>enbl-non-inv-408<br>[EnableNonInvite408Reply]                                    | Enables the device to send SIP 408 responses (Request Timeout) upon receipt of non-INVITE transactions. Disabling this response complies with RFC 4320/4321. By default, and in certain circumstances such as a timeout expiry, the device sends a SIP 408 Request Timeout in response to non-INVITE requests (e.g., REGISTER). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = SIP 408 response is not sent upon receipt of non-INVITE messages (to comply with RFC 4320).</li> <li>▪ <b>[1]</b> Enable = (Default) SIP 408 response is sent upon receipt of non-INVITE messages, if necessary.</li> </ul>                                                                                                                               |
| SIP Remote Reset<br>sip-remote-reset<br>[EnableSIPRemoteReset]                                                       | Enables a specific device action upon the receipt of a SIP NOTIFY request, where the action depends on the value received in the Event header. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> The action depends on the Event header value: <ul style="list-style-type: none"> <li>▪ 'check-sync;reboot=false': triggers the regular Automatic Update feature (if Automatic Update has been enabled on the device)</li> <li>▪ 'check-sync;reboot=true': triggers a device reset</li> </ul> <b>Note:</b> <ul style="list-style-type: none"> <li>▪ The Event header value is proprietary to AudioCodes.</li> <li>▪ The parameter is applicable only to the Gateway application.</li> </ul> |
| Max SIP Message Length [KB]<br>[MaxSIPMessageLength]                                                                 | Defines the maximum size (in Kbytes) for each SIP message that can be sent over the network. The device rejects messages exceeding this user-defined size.<br><br>The valid value range is 1 to 100. The default is 100.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Parameter                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [SIPForceRport]                                                                          | <p>Determines whether the device sends SIP responses to the UDP port from where SIP requests are received even if the 'rport' parameter is not present in the SIP Via header.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) Disabled. The device sends the SIP response to the UDP port defined in the Via header. If the Via header contains the 'rport' parameter, the response is sent to the UDP port from where the SIP request is received.</li> <li>▪ <b>[1]</b> = Enabled. SIP responses are sent to the UDP port from where SIP requests are received even if the 'rport' parameter is not present in the Via header.</li> </ul>                                                                                                                        |
| Reject Cancel after Connect<br>reject-cancel-after-connect<br>[RejectCancelAfterConnect] | <p>Enables or disables the device to accept or reject SIP CANCEL requests received after the receipt of a 200 OK in response to an INVITE (i.e., call established). According to the SIP standard, a CANCEL can be sent only during the INVITE transaction (before 200 OK), and once a 200 OK response is received the call can be rejected only by a BYE request.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) Accepts a CANCEL request received during the INVITE transaction by sending a 200 OK response and terminates the call session.</li> <li>▪ <b>[1]</b> Enable = Rejects a CANCEL request received during the INVITE transaction by sending a SIP 481 (Call/Transaction Does Not Exist) response and maintains the call session.</li> </ul> |
| Verify Received RequestURI<br>verify-rcvd-requri<br>[VerifyReceeedRequestUri]            | <p>Enables the device to reject SIP requests (such as ACK, BYE, or re-INVITE) whose user part in the Request-URI is different from the user part received in the Contact header of the last sent SIP request.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) Even if the user is different, the device accepts the SIP request.</li> <li>▪ <b>[1]</b> Enable = If the user is different, the device rejects the SIP request (BYE is responded with 481; re-INVITE is responded with 404; ACK is ignored).</li> </ul>                                                                                                                                                                                                                                      |
| Max Number of Active Calls<br>max-nb-of--act-calls<br>[MaxActiveCalls]                   | <p>Defines the maximum number of simultaneous active calls supported by the device. If the maximum number of calls is reached, new calls are not established.</p> <p>The valid range is 1 to the maximum number of supported channels. The default value is the maximum available channels (i.e., no restriction on the maximum number of calls).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Number of Calls Limit<br>[IpProfile_CallLimit,]                                          | <p>Defines the maximum number of concurrent calls per IP Profile (see "Configuring IP Profiles" on page 419).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| QoS statistics in SIP Release Call<br>[QoSStatistics]                                    | <p>Enables the device to include call quality of service (QoS) statistics in SIP BYE and SIP 200 OK response to BYE, using the proprietary SIP header X-RTP-Stat.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = Disable (default)</li> <li>▪ <b>[1]</b> = Enable</li> </ul> <p>The X-RTP-Stat header provides the following statistics:</p> <ul style="list-style-type: none"> <li>▪ Number of received and sent voice packets</li> <li>▪ Number of received and sent voice octets</li> <li>▪ Received packet loss, jitter (in ms), and latency (in ms)</li> </ul> <p>The X-RTP-Stat header contains the following fields:</p> <ul style="list-style-type: none"> <li>▪ PS=&lt;voice packets sent&gt;</li> <li>▪ OS=&lt;voice octets sent&gt;</li> </ul>                   |

| Enable Early 183<br>early-183<br>[EnableEarly183]             | <p>Global parameter that enables the device to send SIP 183 responses with SDP to the IP upon receipt of INVITE messages. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_EnableEarly183). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see Configuring IP Profiles on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| [IgnoreAlertAfterEarlyMedia]                                  | <p>Defines the device's interworking of Alerting messages for IP-to-Tel calls (ISDN). It determines whether the device sends a 180 Ringing response to the caller after the device sends a 183 Session Progress response to the caller. The 180 Ringing response indicates that the INVITE has been received by the ISDN side and that alerting is taking place (i.e., ISDN Progress message), indicating to the IP PBX to play a ringback tone. The 183 Session Progress response allows an early media session to be established prior to the call being answered, for example, to hear a ring tone, busy tone or recorded announcement.</p> <ul style="list-style-type: none"> <li>[0] = (Default) Disable. If the device sends a 183 response with SDP (due to a received ISDN Progress or Proceeding with PI messages, i.e., a ring tone, busy tone or recorded announcement played to the ISDN side) and an Alerting message is then received from the ISDN side (with or without Progress Indicator), the device also sends a 180 Ringing response to the caller. Therefore, in this case, early media is played to the ISDN side and then the ringback tone is played by the IP PBX.</li> <li>[1] = Enable. If the device sends a 183 response with SDP (due to a received ISDN Progress or Proceeding with PI messages) and an Alerting message is then received from the ISDN side (with or without Progress Indicator), the device does not send a 180 Ringing response to the caller and the voice channel remains open. Therefore, in this case, early media is played to the ISDN side and a ringback tone is not played by the IP PBX.</li> </ul> <p><b>Note:</b> The parameter is applicable only if the EnableEarlyMedia parameter is set to 1 (i.e., enabled).</p> |
| 183 Message Behavior<br>183-msg-behavior<br>[SIP183Behaviour] | <p>Digital: Defines the ISDN message that is sent when the 183 Session Progress message is received for IP-to-Tel calls. Analog: Defines the response of the device upon receipt of a SIP 183 response.</p> <ul style="list-style-type: none"> <li>[0] Progress = (Default) Digital: The device sends a Progress message. Analog: A 183 response (without SDP) does not cause the device to play a ringback tone.</li> <li>[1] Alert = Digital: The device sends an Alerting message (upon receipt of a 183 response) instead of an ISDN Progress message. Analog: 183 response is handled by the device as if a 180 Ringing response is received, and the device plays a ringback tone.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| [ReleaseIP2ISDNCallOnProgressWithCause]                       | <p>Typically, if an Q.931 Progress message with a Cause is received from the PSTN for an outgoing IP-to-ISDN call and the EnableEarlyMedia parameter is set to 1 (i.e., the Early Media feature is enabled), the device interworks the Progress to 183 + SDP to enable the originating party to hear the PSTN announcement about the call failure. Conversely, if EnableEarlyMedia is set to 0, the device disconnects the call by sending a SIP 4xx response to the originating</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Session-Expires Time<br>session-expires-time<br>[SIPSessionExpires]                              | <p>Defines the numerical value sent in the Session-Expires header in the first INVITE request or response (if the call is answered).</p> <p>The valid range is 1 to 86,400 sec. The default is 0 (i.e., the Session-Expires header is disabled).</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Minimum Session-Expires<br>min-session-expires<br>[MinSE]                                        | <p>Defines the time (in seconds) that is used in the Min-SE header. This header defines the minimum time that the user agent refreshes the session.</p> <p>The valid range is 10 to 100,000. The default is 90.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Session Expires Disconnect Time<br>session-exp-disconnect-time<br>[SessionExpiresDisconnectTime] | <p>Defines a session expiry timeout.</p> <p>The new session expiry timeout is calculated by subtracting the configured value from the original timeout as specified in the Session-Expires header. However, the new timeout must be greater than or equal to one-third (1/3) of the Session-Expires value. If the refresher does not send a refresh request within the new timeout, the device disconnects the session (i.e., sends a SIP BYE).</p> <p>For example, if you configure the parameter to 32 seconds and the Session-Expires value is 180 seconds, the session timeout occurs 148 seconds (i.e., 180 minus 32) after the last session refresh. If the Session-Expires header value is 90 seconds, the timeout occurs 60 seconds after the last refresh. This is because 90 minus 32 is 58 seconds, which is less than one third of the Session-Expires value (i.e., 60/3 is 30, and 90 minus 30 is 60).</p> <p>The valid range is 0 to 32 (in seconds). The default is 32.</p> |
| Session Expires Method<br>session-exp-method<br>[SessionExpiresMethod]                           | <p>Determines the SIP method used for session-timer updates.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Re-INVITE = (Default) Uses re-INVITE messages for session-timer updates.</li> <li>▪ <b>[1]</b> UPDATE = Uses UPDATE messages.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to the Gateway application.</li> <li>▪ The device can receive session-timer refreshes using both methods.</li> <li>▪ The UPDATE message used for session-timer is excluded from the SDP body.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                      |
| [RemoveToTagInFailureResponse]                                                                   | <p>Determines whether the device removes the 'to' header tag from final SIP failure responses to INVITE transactions.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Use Tgrp Information<br><code>use-tgrp-inf</code><br><code>[UseSIPtgrp]</code> | <p>Determines whether the SIP 'tgrp' parameter is used. This SIP parameter specifies the Trunk Group to which the call belongs (according to RFC 4904). For example, the SIP message below indicates that the call belongs to Trunk Group ID 1:</p> <pre>INVITE sip::+16305550100;tgrp=1;trunk-context=example.com@10.1.0.3;user=phone SIP/2.0</pre> <ul style="list-style-type: none"> <li>[0] Disable = (Default) The 'tgrp' parameter isn't used.</li> <li>[1] Send Only = The Trunk Group number or name (configured in the Trunk Group Settings table) is added to the 'tgrp' parameter value in the Contact header of outgoing SIP messages. If a Trunk Group number / name is not associated with the call, the 'tgrp' parameter isn't included. If a 'tgrp' value is specified in incoming messages, it is ignored.</li> <li>[2] Send and Receive = The functionality of outgoing SIP messages is identical to the functionality described for option [1]. In addition, for incoming SIP INVITES, if the Request-URI includes a 'tgrp' parameter, the device routes the call according to that value (if possible). The Contact header in the outgoing SIP INVITE (Tel-to-IP call) contains "tgrp=&lt;source trunk group ID&gt;;trunk-context=&lt;gateway IP address&gt;". The &lt;source trunk group ID&gt; is the Trunk Group ID where incoming calls from Tel is received. For IP-Tel calls, the SIP 200 OK device's response contains "tgrp=&lt;destination trunk group ID&gt;;trunk-context=&lt;gateway IP address&gt;". The &lt;destination trunk group ID&gt; is the Trunk Group ID used for outgoing Tel calls. The &lt;gateway IP address&gt; in "trunk-context" can be configured using the SIPGatewayName parameter.</li> <li>[3] Hotline = Interworks the hotline "Off Hook Indicator" parameter between SIP and ISDN:               <ul style="list-style-type: none"> <li>✓ For IP-to-ISDN calls:                   <ul style="list-style-type: none"> <li>The device interworks the SIP tgrp=hotline parameter (received in INVITE) to ISDN Setup with the Off Hook Indicator IE of "Voice", and "Speech" Bearer Capability IE. Note that the Off Hook Indicator IE is described in UCR 2008 specifications.</li> <li>The device interworks the SIP tgrp=hotline-ccdata parameter (received in INVITE) to ISDN Setup with an Off Hook Indicator IE of "Data", and with "Unrestricted 64k" Bearer Capability IE. The following is an example of the INVITE with tgrp=hotline-ccdata:                       <pre>INVITE sip:1234567;tgrp=hotline-ccdata;trunk-context=dsn.mil@example.com</pre> </li> </ul> </li> <li>✓ For ISDN-to-IP calls:                   <ul style="list-style-type: none"> <li>The device interworks ISDN Setup with an Off Hook Indicator of "Voice" to SIP INVITE with "tgrp=hotline;trunk-context=dsn.mil" in the Contact header.</li> <li>The device interworks ISDN Setup with an Off Hook indicator of "Data" to SIP INVITE with "tgrp=hotline-</li> </ul> </li> </ul> </li> </ul> |

The 'dtg' parameter appears in the INVITE Request-URI (and in the To header).</p> <p>For example, the received SIP message below routes the call to Trunk Group ID 56:</p> <pre>INVITE sip:123456@192.168.1.2;dtg=56;user=phone SIP/2.0</pre> <p><b>Note:</b> If the Trunk Group is not found based on the 'dtg' parameter, the IP to Trunk Group Routing table is used instead for routing the call to the appropriate Trunk Group.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <p>Enable GRUU<br/>enable-gruu<br/>[EnableGRUU]</p> | <p>Determines whether the Globally Routable User Agent URIs (GRUU) mechanism is used, according to RFC 5627. This is used for obtaining a GRUU from a registrar and for communicating a GRUU to a peer within a dialog.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p>A GRUU is a SIP URI that routes to an instance-specific UA and can be reachable from anywhere. There are a number of contexts in which it is desirable to have an identifier that addresses a single UA (using GRUU) rather than the group of UA's indicated by an Address of Record (AOR). For example, in call transfer where user A is talking to user B, and user A wants to transfer the call to user C. User A sends a REFER to user C:</p> <pre>REFER sip:C@domain.com SIP/2.0 From: sip:A@domain.com;tag=99asd To: sip:C@domain.com Refer-To: (URI that identifies B's UA)</pre> <p>The Refer-To header needs to contain a URI that user C can use to place a call to user B. This call needs to route to the specific UA instance that user B is using to talk to user A. User B should provide user A with a URI that has to be usable by anyone. It needs to be a GRUU.</p> <ul style="list-style-type: none"> <li>▪ Obtaining a GRUU: The mechanism for obtaining a GRUU is through registrations. A UA can obtain a GRUU by generating a REGISTER request containing a Supported header field with the value "gruu". The UA includes a "+sip.instance" Contact header parameter of each contact for which the GRUU is desired. This Contact parameter contains a globally unique ID that identifies the UA instance. The global unique ID is created from one of the following: <ul style="list-style-type: none"> <li>✓ If the REGISTER is per the device's client (endpoint), it is the MAC address concatenated with the phone number of the client.</li> <li>✓ If the REGISTER is per device, it is the MAC address only.</li> <li>✓ When using TP, "User Info" can be used for registering per endpoint. Thus, each endpoint can get a unique id – its phone number. The globally unique ID in TP is the MAC address concatenated with the phone number of the endpoint.</li> </ul> </li> </ul> <p>If the remote server doesn't support GRUU, it ignores the parameters of the GRUU. Otherwise, if the remote side also supports GRUU, the REGISTER responses contain the "gruu" parameter in each Contact header. The parameter contains a SIP or SIPS URI that represents a GRUU corresponding to the UA instance that registered the contact.</p> |

| Parameter                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                     | <p>The server provides the same GRUU for the same AOR and instance-id when sending REGISTER again after registration expiration. RFC 5627 specifies that the remote target is a GRUU target if its' Contact URL has the "gr" parameter with or without a value.</p> <ul style="list-style-type: none"> <li>Using GRUU: The UA can place the GRUU in any header field that can contain a URI. It must use the GRUU in the following messages: INVITE request, its 2xx response, SUBSCRIBE request, its 2xx response, NOTIFY request, REFER request and its 2xx response.</li> </ul>                                                                                                                                                                                                                                                                   |
| [IsCiscoSCEMode]                                                    | <p>Determines whether a Cisco gateway exists at the remote side.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) No Cisco gateway exists at the remote side.</li> <li><b>[1]</b> = A Cisco gateway exists at the remote side.</li> </ul> <p>When a Cisco gateway exists at the remote side, the device must set the value of the 'annexb' parameter of the fmtp attribute in the SDP to 'no'. This logic is used if Silence Suppression for the used coder is configured to 2 (enable without adaptation). In this case, Silence Suppression is used on the channel but not declared in the SDP.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to the Gateway application.</li> <li>The IsCiscoSCEMode parameter is applicable only when the selected coder is G.729.</li> </ul> |
| User-Agent Information<br>user-agent-info<br>[UserAgentDisplayInfo] | <p>Defines the string that is used in the SIP User-Agent and Server response headers. When configured, the string &lt;UserAgentDisplayInfo value&gt;/software version' is used, for example:</p> <pre>User-Agent: myproduct/v.6.80A.227.005</pre> <p>If not configured, the default string, &lt;AudioCodes product-name&gt;/software version' is used, for example:</p> <pre>User-Agent: Audiocodes-Sip-Gateway-Mediant 800B Gateway and E-SBC/v.6.80A.227.005</pre> <p>The maximum string length is 50 characters.</p> <p><b>Note:</b> The software version number and preceding forward slash (/) cannot be modified. Therefore, it is recommended not to include a forward slash in the parameter's value (to avoid two forward slashes in the SIP header, which may cause problems).</p>                                                         |
| SDP Session Owner<br>sdp-session-owner<br>[SIPSDPSessionOwner]      | <p>Defines the value of the Owner line ('o' field) in outgoing SDP messages.</p> <p>The valid range is a string of up to 39 characters. The default is "AudiocodesGW".</p> <p>For example:</p> <pre>o=AudiocodesGW 1145023829 1145023705 IN IP4 10.33.4.126</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| sdp-ver-nego<br>[EnableSDPVersionNegotiation]                       | <p>Enables the device to ignore new SDP re-offers (from the media negotiation perspective) in certain scenarios (such as session expires). According to RFC 3264, once an SDP session is established, a new SDP offer is considered a new offer only when the SDP origin value is incremented. In scenarios such as session expires, SDP negotiation is irrelevant and thus, the origin field is not changed.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Parameter                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| anonymous-mode<br>[AnonymousMode]                                               | <p>Determines whether the device's IP address is used as the URI host part instead of "anonymous.invalid" in the INVITE's From header for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) If the device receives a call from the Tel with blocked caller ID, it sends an INVITE with From: "anonymous"&lt;anonymous@anonymous.invalid&gt;</li> <li><b>[1]</b> = The device's IP address is used as the URI host part instead of "anonymous.invalid".</li> </ul> <p>The parameter may be useful, for example, for service providers who identify their SIP Trunking customers by their source phone number or IP address, reflected in the From header of the SIP INVITE. Therefore, even customers blocking their Caller ID can be identified by the service provider. Typically, if the device receives a call with blocked Caller ID from the PSTN side (e.g., Trunk connected to a PBX), it sends an INVITE to the IP with a From header as follows: From: "anonymous" &lt;anonymous@anonymous.invalid&gt;. This is in accordance with RFC 3325. However, when the parameter is set to 1, the device replaces the "anonymous.invalid" with its IP address.</p> |

|                                                                     | <ul style="list-style-type: none"> <li>The default release cause is described in the Q.931 notation and is translated to corresponding SIP 40x or 50x values (e.g., 3 to SIP 404, and 34 to SIP 503).</li> <li>Analog: For more information on mapping PSTN release causes to SIP responses, see Mapping PSTN Release Cause to SIP Response on page 521.</li> <li>When the Trunk is disconnected or is not synchronized, the internal cause is 27. This cause is mapped, by default, to SIP 502.</li> <li>For mapping SIP-to-Q.931 and Q.931-to-SIP release causes, see Configuring Release Cause Mapping on page 511.</li> <li>For a list of SIP responses-Q.931 release cause mapping, see Alternative Routing to Trunk upon Q.931 Call Release Cause Code on page 550.</li> </ul>                                                                                                                                                                                                                                                                                                                                          |
| Enable Microsoft Extension<br>microsoft-ext<br>[EnableMicrosoftExt] | <p>Enables the modification of the called and calling number for numbers received with Microsoft's proprietary "ext=xxx" parameter in the SIP INVITE URI user part. Microsoft Office Communications Server sometimes uses this proprietary parameter to indicate the extension number of the called or calling party.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p>For example, if a calling party makes a call to telephone number 622125519100 Ext. 104, the device receives the SIP INVITE (from Microsoft's application) with the URI user part as INVITE sip:622125519100;ext=104@10.1.1.10 (or INVITE tel:622125519100;ext=104). If the parameter EnableMicrosoftExt is enabled, the device modifies the called number by adding an "e" as the prefix, removing the "ext=" parameter, and adding the extension number as the suffix (e.g., e622125519100<b>104</b>). Once modified, the device can then manipulate the number further, using the Number Manipulation tables to leave only the last 3 digits (for example) for sending to a PBX.</p> |
| [UseSIPURIForDiversionHeader]                                       | <p>Defines the URI format in the SIP Diversion header.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = 'tel:' (default)</li> <li><b>[1]</b> = 'sip:'</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| [TimeoutBetween100And18x]                                           | <p>Defines the timeout (in msec) between receiving a 100 Trying response and a subsequent 18x response. If a 18x response is not received within this timeout period, the call is disconnected. The valid range is 0 to 180,000 (i.e., 3 minutes). The default is 32000 (i.e., 32 sec).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Comfort Noise Generation Negotiation<br>com-noise-gen-nego<br>[ComfortNoiseNegotiation] | <p>Enables negotiation and usage of Comfort Noise (CN) for Gateway calls.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable</li> <li>▪ <b>[1]</b> Enable (default)</li> </ul> <p>The use of CN is indicated by including a payload type for CN on the media description line of the SDP. The device can use CN with a codec whose RTP time stamp clock rate is 8,000 Hz (G.711/G.726). The static payload type 13 is used. The use of CN is negotiated between sides. Therefore, if the remote side doesn't support CN, it is not used. Regardless of the device's settings, it always attempts to adapt to the remote SIP UA's request for CNG, as described below.</p> <p>To determine CNG support, the device uses the ComfortNoiseNegotiation parameter and the codec's SCE (silence suppression setting) using the CodersGroup parameter.</p> <p>If the ComfortNoiseNegotiation parameter is enabled, then the following occurs:</p> <ul style="list-style-type: none"> <li>▪ If the device is the initiator, it sends a "CN" in the SDP only if the SCE of the codec is enabled. If the remote UA responds with a "CN" in the SDP, then CNG occurs; otherwise, CNG does not occur.</li> <li>▪ If the device is the receiver and the remote SIP UA does not send a "CN" in the SDP, then no CNG occurs. If the remote side sends a "CN", the device attempts to be compatible with the remote side and even if the codec's SCE is disabled, CNG occurs.</li> </ul> <p>If the ComfortNoiseNegotiation parameter is disabled, then the device does not send "CN" in the SDP. However, if the codec's SCE is enabled, then CNG occurs.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p> |

The 'ecan' attribute is used in the SDP to indicate the use of echo cancellation.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) The 'ecan' attribute appears on the 'a=gpmr' line.</li> <li>▪ <b>[1]</b> = The 'ecan' attribute appears as a separate attribute.</li> <li>▪ <b>[2]</b> = The 'ecan' attribute is not included in the SDP.</li> <li>▪ <b>[3]</b> = The 'ecan' attribute and the 'vbd' parameter are not included in the SDP.</li> </ul> <p><b>Note:</b> The parameter is applicable only when the IsFaxUsed parameter is set to 2, and for re-INVITE messages generated by the device as result of modem or fax tone detection.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| First Call Ringback Tone ID<br>1st-call-rbt-id<br>[FirstCallRBTId]                      | <p>Defines the index of the first ringback tone in the CPT file. This option enables an Application server to request the device to play a distinctive ringback tone to the calling party according to the destination of the call. The tone is played according to the Alert-Info header received in the 180 Ringing SIP response (the value of the Alert-Info header is added to the value of the parameter).</p> <p>The valid range is -1 to 1,000. The default is -1 (i.e., play standard ringback tone).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Reanswer Time<br><code>reanswer-time</code><br>[RegretTime]                        | <p>Analog: Defines the time interval from when the user hangs up the phone until the call is disconnected (FXS). This allows the user to hang up and then pick up the phone (before this timeout) to continue the call conversation. Thus, it's also referred to as regret time.</p> <p>Digital: Defines the time period the device waits for an MFC R2 Resume (Reanswer) signal once a Suspend (Clear back) signal is received from the PBX. If this timer expires, the call is released. Note that this is applicable only to the MFC-R2 CAS Brazil variant.</p> <p>The valid range is 0 to 255 (in seconds). The default is 0.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Enable Reanswering Info<br><code>reans-info-enbl</code><br>[EnableReansweringINFO] | <p>Enables the device to send a SIP INFO message with the On-Hook/Off-Hook parameter when the FXS phone goes on-hook during an ongoing call and then off-hook again, within the user-defined regret timeout (configured by the parameter RegretTime). Therefore, the device notifies the far-end that the call has been re-answered.</p> <ul style="list-style-type: none"> <li>[0] Disable (default)</li> <li>[1] Enable</li> </ul> <p>The parameter is typically implemented for incoming IP-to-Tel collect calls to the FXS port. If the FXS user does not wish to accept the collect call, the user disconnects the call by on-hooking the phone. The device notifies the softswitch (or Application server) of the unanswered collect call (on-hook) by sending a SIP INFO message. As a result, the softswitch disconnects the call (sends a BYE message to the device). If the call is a regular incoming call and the FXS user on-hooks the phone without intending to disconnect the call, the softswitch does not disconnect the call (during the regret time).</p> <p>The INFO message format is as follows:</p> <pre>INFO sip:12345@10.50.228.164:5082 SIP/2.0 Via: SIP/2.0/UDP 127.0.0.1;branch=z9hG4bK_05_905924040-90579 From: &lt;sip:+551137077803@ims.acme.com.br:5080;user=phone&gt;;tag=008277765 To: &lt;sip:notavailable@unknown.invalid&gt;;tag=svw-0-1229428367 Call-ID: ConorCCR-0-LU-1229417827103300@dtas-stdn.fs5000group0-000.l CSeq: 1 INFO Contact: sip:10.20.7.70:5060 Content-Type: application/On-Hook (application/Off-Hook) Content-Length: 0</pre> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only if the parameter RegretTime is configured.</li> <li>The parameter is applicable only to FXS interfaces.</li> </ul> |

| Parameter                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PSTN Alert Timeout<br>pstn-alert-timeout<br>[PSTNAlertTimeout]                 | <p>Digital: Defines the Alert Timeout (in seconds) for calls sent to the PSTN. This timer is used between the time a Setup message is sent to the Tel side (IP-to-Tel call establishment) and a Connect message is received. If an Alerting message is received, the timer is restarted. If the timer expires before the call is answered, the device disconnects the call and sends a SIP 408 request timeout response to the SIP party that initiated the call.</p> <p>Analog: Defines the Alert Timeout (in seconds) for calls to the Tel side. This timer is used between the time a ring is generated (FXS) or a line is seized (FXO), until the call is connected. For example: If the FXS device receives an INVITE, it generates a ring to the phone and sends a SIP 180 Ringing response to the IP. If the phone is not answered within the time interval set by the parameter, the device cancels the call by sending a SIP 408 response.</p> <p>The valid value range is 1 to 600 (in seconds). The default is 180.</p> <p><b>Note:</b> If per trunk configuration (using TrunkPSTNAlertTimeout) is set to other than default, the PSTNAlertTimeout parameter value is overridden.</p>                                                                                                                                                                  |
| RTP Only Mode<br>rtp-only-mode<br>[RTPOnlyMode]                                | <p>Enables the device to send and receive RTP packets to and from remote endpoints without the need to establish a SIP session. The remote IP address is determined according to the Tel-to-IP Routing table (Prefix parameter). The port is the same port as the local RTP port (configured by the BaseUDPPort parameter and the channel on which the call is received).</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Transmit &amp; Receive = Send and receive RTP packets.</li> <li>▪ <b>[2]</b> Transmit Only= Send RTP packets only.</li> <li>▪ <b>[3]</b> Receive Only= Receive RTP packets only.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ To activate the RTP Only feature without using ISDN / CAS signaling, you must do the following:               <ul style="list-style-type: none"> <li>✓ Configure E1/T1 Transparent protocol type (set the ProtocolType parameter to 5 or 6).</li> <li>✓ Enable the TDM-over-IP feature (set the EnableTDMoverIP parameter to 1).</li> </ul> </li> <li>▪ To configure the RTP Only mode per trunk, use the RTPOnlyModeForTrunk_x parameter.</li> <li>▪ If per trunk configuration (using the RTPOnlyModeForTrunk_ID parameter) is set to a value other than the default, the RTPOnlyMode parameter value is ignored.</li> </ul> |
| [RTPOnlyModeForTrunk_x]                                                        | <p>Enables the RTP Only feature per trunk. The x in the parameter name denotes the trunk number, where 0 is Trunk 1. For a description of the parameter, see the RTPOnlyMode parameter.</p> <p><b>Note:</b> For using the global parameter (i.e., setting the RTP Only feature for all trunks), set the parameter to -1 (default).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Media IP Version Preference<br>media-ip-ver-pref<br>[MediaIPVersionPreference] | <p>Global parameter that defines the preferred RTP media IP addressing version (IPv4 or IPv6) for outgoing SIP calls. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_MediaIPVersionPreference). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see Configuring IP Profiles on page 419.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIT Q850 Cause<br>[SITQ850Cause]             | <p>Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when a Special Information Tone (SIT) is detected on an IP-to-Tel call.</p> <p>The valid range is 0 to 127. The default is 34.</p> <p><b>Note:</b> For mapping specific SIT tones, you can use the SITQ850CauseForNC, SITQ850CauseForIC, SITQ850CauseForVC, and SITQ850CauseForRO parameters.</p>                                                                                  |
| SIT Q850 Cause For NC<br>[SITQ850CauseForNC] | <p>Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-NC (No Circuit Found Special Information Tone) is detected from the Tel side for IP-to-Tel calls.</p> <p>The valid range is 0 to 127. The default is 34.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>When not configured (i.e., default), the SITQ850Cause parameter is used.</li> <li>The parameter is applicable only to FXO interfaces.</li> </ul> |
| SIT Q850 Cause For IC<br>[SITQ850CauseForIC] | <p>Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-IC (Operator Intercept Special Information Tone) is detected from the Tel for IP-to-Tel calls.</p> <p>The valid range is 0 to 127. The default is -1 (not configured).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>When not configured (i.e., default), the SITQ850Cause parameter is used.</li> <li></li> </ul>                                      |
| SIT Q850 Cause For VC<br>[SITQ850CauseForVC] | <p>Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-VC (Vacant Circuit - non-registered number Special Information Tone) is detected from the Tel for IP-to-Tel calls.</p> <p>The valid range is 0 to 127. The default is -1 (not configured).</p> <p><b>Note:</b> When not configured (i.e., default), the SITQ850Cause parameter is used.</p>                                                                               |
| SIT Q850 Cause For RO<br>[SITQ850CauseForRO] | <p>Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-RO (Reorder - System Busy Special Information Tone) is detected from the Tel for IP-to-Tel calls.</p> <p>The valid range is 0 to 127. The default is -1 (not configured).</p> <p><b>Note:</b> When not configured (i.e., default), the SITQ850Cause parameter is used.</p>                                                                                                |
| [GWInboundManipulationSet]                   | <p>Selects the Manipulation Set ID for manipulating all inbound INVITE messages. The Manipulation Set is defined using the MessageManipulations parameter. By default, no manipulation is done (i.e. Manipulation Set ID is set to -1).</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>                                                                                                                                                              |
| [GWOutboundManipulationSet]                  | <p>Selects the Manipulation Set ID for manipulating all outbound INVITE messages. The Manipulation Set is defined using the MessageManipulations parameter. By default, no manipulation is done (i.e. Manipulation Set ID is set to -1).</p>                                                                                                                                                                                                                                              |

| Parameter                                                                                                                                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <p>Tel Profile Settings</p> <pre>configure voip &gt; coders-and-profiles tel-profile [TelProfile]</pre> | <p>Defines the Tel Profile table. Each Tel Profile ID includes a set of parameters (which are typically configured separately using their individual, "global" parameters). You can later assign these Tel Profile IDs to other elements such as in the Trunk Group table (TrunkGroup parameter). Therefore, Tel Profiles allow you to apply the same settings of a group of parameters to multiple channels, or apply specific settings to different channels.</p> <p>The format of the ini file table parameter is as follows:</p> <pre>[TelProfile] FORMAT TelProfile_Index = TelProfile_ProfileName, TelProfile_TelPreference, TelProfile_CodersGroupID, TelProfile_IsFaxUsed, TelProfile_JitterBufMinDelay, TelProfile_JitterBufOptFactor, TelProfile_IPDiffServ, TelProfile_SigIPDiffServ, TelProfile_DtmfVolume, TelProfile_InputGain, TelProfile_VoiceVolume, TelProfile_EnableReversePolarity, TelProfile_EnableCurrentDisconnect, TelProfile_EnableDigitDelivery, TelProfile_EnableEC, TelProfile_MWIAAnalog, TelProfile_MWIDisplay, TelProfile_FlashHookPeriod, TelProfile_EnableEarlyMedia, TelProfile_ProgressIndicator2IP, TelProfile_TimeForReorderTone, TelProfile_EnableDIDWink, TelProfile_IsTwoStageDial, TelProfile_DisconnectOnBusyTone, TelProfile_EnableVoiceMailDelay, TelProfile_DialPlanIndex, TelProfile_Enable911PSAP, TelProfile_SwapTelToIpPhoneNumbers, TelProfile_EnableAGC, TelProfile_ECNIPMode, TelProfile_DigitalCutThrough, TelProfile_EnableFXODoubleAnswer, TelProfile_CallPriorityMode; [\\TelProfile]</pre> <p>For a description of the parameter, see Configuring Tel Profiles on page 415.</p> |

## 63.9 Channel Parameters

This subsection describes the device's channel parameters.

### 63.9.1 Voice Parameters

The voice parameters are described in the table below.

**Table 63-35: Voice Parameters**

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input Gain<br>input-gain<br>[InputGain]                     | Global parameter that defines the pulse-code modulation (PCM) input (received) gain control level (in decibels). You can also configure this functionality per specific calls, using IP Profiles (IpProfile_InputGain) or Tel Profiles. For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419 or in the Tel Profile table, see Configuring Tel Profiles on page 415.<br><b>Note:</b> If this functionality is configured for a specific profile, the settings of this global parameter is ignored for calls associated with the profile.                    |
| Voice Volume<br>voice-volume<br>[VoiceVolume]               | Global parameter that defines the voice gain control (in decibels). This defines the level of the transmitted (IP-to-Tel) signal. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_VoiceVolume) or Tel Profiles. For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419 or in the Tel Profile table, see Configuring Tel Profiles on page 415.<br><b>Note:</b> If this functionality is configured for a specific profile, the settings of this global parameter is ignored for calls associated with the profile. |
| G726-voice-payload-format<br>[VoicePayloadFormat]           | Determines the bit ordering of the G.726 voice payload format.<br><ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) Little Endian</li> <li>▪ <b>[1]</b> = Big Endian</li> </ul> <b>Note:</b> To ensure high voice quality when using G.726, both communicating ends should use the same endianness format. Therefore, when the device communicates with a third-party entity that uses the G.726 voice coder and voice quality is poor, change the settings of the parameter (between Big Endian and Little Endian).                                                                                                                          |
| MF Transport Type<br>MF-transport-type<br>[MFTransportType] | Currently, not supported.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Echo Canceler<br>echo-canceller-enable                      | Global parameter that enables echo cancellation (i.e., echo from voice calls is removed). You can also configure this functionality per specific calls, using IP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [EnableEchoCanceller]                                                                                              | Profiles (IpProfile_EnableEchoCanceller) or Tel Profiles. For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419 or Tel Profile table, see Configuring Tel Profiles on page 415.<br><b>Note:</b> If this functionality is configured for a specific profile, the settings of this global parameter is ignored for calls associated with the profile. |
| Network Echo Suppressor Enable<br>acoustic-echo-suppressor-enable<br>[AcousticEchoSuppressorSupport]               | Enables the network Acoustic Echo Suppressor feature on SBC calls. This feature removes echoes and sends only the near-end's desired speech signal to the network (i.e., to the far-end party). <ul style="list-style-type: none"><li>▪ [0] Disable (default)</li><li>▪ [1] Enable</li></ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                             |
| Echo Canceller Type<br>echo-canceller-type<br>[EchoCancellerType]                                                  | Defines the echo canceller type. <ul style="list-style-type: none"><li>▪ [0] Line echo canceller = (Default) Echo canceller for Tel side.</li><li>▪ [1] Acoustic Echo suppressor - netw = Echo canceller for IP side.</li></ul>                                                                                                                                                                                                                     |
| Attenuation Intensity<br>acoustic-echo-suppressor-attenuation-intensity<br>[AcousticEchoSuppAttenuationIntensity]  | Defines the acoustic echo suppressor signals identified as echo attenuation intensity.<br>The valid range is 0 to 3. The default is 0.                                                                                                                                                                                                                                                                                                              |
| Max ERL Threshold - DB<br>acoustic-echo-suppressor-max-ERL<br>[AcousticEchoSuppMaxERLThreshold]                    | Defines the acoustic echo suppressor maximum ratio between signal level and returned echo from the phone (in decibels).<br>The valid range is 0 to 60. The default is 10.                                                                                                                                                                                                                                                                           |
| Min Reference Delay x10 msec<br>acoustic-echo-suppressor-min-reference-delay<br>[AcousticEchoSuppMinRefDelayx10ms] | Defines the acoustic echo suppressor minimum reference delay (in 10-ms units).<br>The valid range is 0 to 40. The default is 0.                                                                                                                                                                                                                                                                                                                     |
| Max Reference Delay x10 msec<br>acoustic-echo-suppressor-max-reference-delay<br>[AcousticEchoSuppMaxRefDelayx10ms] | Defines the acoustic echo suppressor maximum reference delay (in 10-ms units).<br>The valid range is 0 to 40. The default is 40 (i.e., 40 x 10 = 400 ms).                                                                                                                                                                                                                                                                                           |
| echo-canceller-hybrid-loss<br>[ECHybridLoss]                                                                       | Defines the four-wire to two-wire worst-case Hybrid loss, the ratio between the signal level sent to the hybrid and the echo level returning from the hybrid. <ul style="list-style-type: none"><li>▪ [0] = (Default) 6 dB</li><li>▪ [1] = N/A</li><li>▪ [2] = 0 dB</li><li>▪ [3] = 3 dB</li></ul>                                                                                                                                                  |
| echo-canceller-NLP-mode<br>[ECNLPMode]                                                                             | Enables Non-Linear Processing (NLP) mode for echo cancellation. <ul style="list-style-type: none"><li>▪ [0] = (Default) NLP adapts according to echo changes</li></ul>                                                                                                                                                                                                                                                                              |

| Parameter                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                   |

| Answer Detector Redirection<br>[AnswerDetectorRedirection]                                            | Currently, not supported.                                                                                                                                                                                                                                                                                                                                     |
| Answer Detector Sensitivity<br>answer-detector-sensitivity<br>[AnswerDetectorSensitivity]             | <p>Defines the Answer Detector sensitivity.</p> <p>The range is 0 (most sensitive) to 2 (least sensitive). The default is 0.</p>                                                                                                                                                                                                                              |

## 63.9.2 Coder Parameters

The coder parameters are described in the table below.

**Table 63-36: Coder Parameters**

| Parameter                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Silk Tx Inband FEC<br>silk-tx-inband-fec<br>[SilkTxInbandFEC]                    | Enables forward error correction (FEC) for the SILK coder. <ul style="list-style-type: none"> <li>[0] Disable (default)</li> <li>[1] Enable</li> </ul>                                                                                                                                                                                                                                                                                                                           |
| Silk Max Average Bit Rate<br>silk-max-average-bitrate<br>[SilkMaxAverageBitRate] | Defines the maximum average bit rate for the SILK coder. The valid value range is 5000 to 30000. The default is 16000. The SILK coder is Skype's default audio codec used for Skype-to-Skype calls.                                                                                                                                                                                                                                                                              |
| vbr-coder-header-format<br>[VBRCoderHeaderFormat]                                | Determines the format of the RTP header for VBR coders. <ul style="list-style-type: none"> <li>[0] = (Default) Payload only (no header, TOC, or m-factor) - similar to RFC 3558 Header Free format.</li> <li>[1] = Supports RFC 2658 - 1 byte for interleaving header (always 0), TOC, no m-factor.</li> <li>[2] = Payload including TOC only, allow m-factor.</li> <li>[3] = RFC 3558 Interleave/Bundled format.</li> </ul>                                                     |
| vbr-coder-hangover<br>[VBRCoderHangover]                                         | Defines the required number of silence frames at the beginning of each silence period when using the VBR coder silence suppression. The range is 0 to 255. The default is 1.                                                                                                                                                                                                                                                                                                     |
| AMR Payload Format<br>[AmrOctetAlignedEnable]                                    | Defines the AMR payload format type. <ul style="list-style-type: none"> <li>[0] Bandwidth Efficient</li> <li>[1] Octet Aligned (default)</li> </ul> <b>Note:</b> The AMR payload type can also be configured per Coder Group (see Configuring Coder Groups on page 413). The Coder Group configuration overrides the parameter.                                                                                                                                                  |
| [AMRCoderHeaderFormat]                                                           | Determines the payload format of the AMR header. <ul style="list-style-type: none"> <li>[0] = Non-standard multiple frames packing in a single RTP frame. Each frame has a CMR and TOC header.</li> <li>[1] = AMR frame according to RFC 3267 bundling.</li> <li>[2] = AMR frame according to RFC 3267 interleaving.</li> <li>[3] = AMR is passed using the AMR IF2 format.</li> </ul> <b>Note:</b> Bandwidth Efficient mode is not supported; the mode is always Octet-aligned. |

### 63.9.3 DTMF Parameters

The dual-tone multi-frequency (DTMF) parameters are described in the table below.

**Table 63-37: DTMF Parameters**

| Parameter                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| DTMF Transport Type<br>DTMF-transport-type<br>[DTMFTransportType]       | <p>Determines the DTMF transport type.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Mute DTMF = DTMF digits are removed from the voice stream and are not relayed to remote side.</li> <li>▪ <b>[2]</b> Transparent DTMF = DTMF digits remain in the voice stream.</li> <li>▪ <b>[3]</b> RFC 2833 Relay DTMF = (Default) DTMF digits are removed from the voice stream and are relayed to remote side according to RFC 2833.</li> <li>▪ <b>[7]</b> RFC 2833 Relay Decoder Mute = DTMF digits are sent according to RFC 2833 and muted when received.</li> </ul> <p><b>Note:</b> The parameter is automatically updated if the parameters FirstTxDTMFOption or RxDTMFOption are configured.</p> |
| DTMF Volume (-31 to 0 dB)<br>DTMF-volume<br>[DTMFVolume]                | <p>Defines the DTMF gain control value (in decibels) to the Tel side. The valid range is -31 to 0 dB. The default is -11 dB.</p> <p><b>Note:</b> The parameter can also be configured in a Tel Profile.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| DTMF Generation Twist<br>DTMF-generation-twist<br>[DTMFGenerationTwist] | <p>Defines the range (in decibels) between the high and low frequency components in the DTMF signal. Positive decibel values cause the higher frequency component to be stronger than the lower one. Negative values cause the opposite effect. For any parameter value, both components change so that their average is constant.</p> <p>The valid range is -10 to 10 dB. The default is 0 dB.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                     |
| inter-digit-interval<br>[DTMFInterDigitInterval]                        | <p>Defines the time (in msec) between generated DTMF digits to the Tel side (if FirstTxDTMFOption = 1, 2 or 3).</p> <p>The valid range is 0 to 32767. The default is 100.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| [DTMFDigitLength]                                                       | <p>Defines the time (in msec) for generating DTMF tones to the Tel side (if FirstTxDTMFOption = 1, 2 or 3). It also configures the duration that is sent in INFO (Cisco) messages.</p> <p>The valid range is 0 to 32767. The default is 100.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| default-dtmf-signal-duration<br>[RxDTMFHangOverTime]                    | <p>Defines the Voice Silence time (in msec) after playing DTMF or MF digits to the Tel side that arrive as Relay from the IP side.</p> <p>Valid range is 0 to 2,000 msec. The default is 1,000 msec.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| digit-hangover-time-tx<br>[TxDTMFHangOverTime]                          | <p>Defines the Voice Silence time (in msec) after detecting the end of DTMF or MF digits at the Tel side when the DTMF Transport Type is either Relay or Mute.</p> <p>Valid range is 0 to 2,000 msec. The default is 1,000 msec.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| NTE Max Duration<br>telephony-events-max-duration<br>[NTEMaxDuration]   | <p>Defines the maximum time for sending Named Telephony Events / NTEs (RFC 4733/2833 DTMF relay) to the IP side, regardless of the DTMF signal duration on the TDM side.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Parameter | Description                                                                                                   |
|-----------|---------------------------------------------------------------------------------------------------------------|
|           | The range is -1 to 200,000,000 msec. The default is -1 (i.e., NTE stops only upon detection of an End event). |

## 63.9.4 RTP, RTCP and T.38 Parameters

The RTP, RTCP and T.38 parameters are described in the table below.

**Table 63-38: RTP/RTCP and T.38 Parameters**

| Parameter                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dynamic Jitter Buffer Minimum Delay<br><code>jitter-buffer-minimum-delay</code><br>[DJBufMinDelay]              | Global parameter that defines the minimum delay (in msec) of the device's dynamic Jitter Buffer.<br><br>You can also configure this functionality per specific calls, using IP Profiles (IpProfile_JitterBufMinDelay) or Tel Profiles. For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see Configuring IP Profiles on page 419, or in the Tel Profile table, see Configuring Tel Profiles on page 415.<br><br><b>Note:</b> If this functionality is configured for a specific profile, the settings of this global parameter is ignored for calls associated with the profile. |
| Dynamic Jitter Buffer Optimization Factor<br><code>jitter-buffer-optimization-factor</code><br>[DJBufOptFactor] | Global parameter that defines the Dynamic Jitter Buffer frame error/delay optimization factor.<br><br>You can also configure this functionality per specific calls, using IP Profiles or Tel Profiles. For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see Configuring IP Profiles on page 419, or in the Tel Profile table, see Configuring Tel Profiles on page 415.<br><br><b>Note:</b> If this functionality is configured for a specific profile, the settings of this global parameter is ignored for calls associated with the profile.                                 |
| Analog Signal Transport Type<br>[AnalogSignalTransportType]                                                     | Determines the analog signal transport type.<br><ul style="list-style-type: none"><li>▪ [0] Ignore Analog Signals = (Default) Ignore.</li><li>▪ [1] RFC 2833 Analog Signal Relay = Transfer hookflash using RFC 2833.</li></ul><br><b>Note:</b> The parameter is applicable only to FXS and FXO interfaces.                                                                                                                                                                                                                                                                                                                                |
| RTP Redundancy Depth<br><code>RTP-redundancy-depth</code><br>[RTPRedundancyDepth]                               | Global parameter that enables the device to generate RFC 2198 redundant packets. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_RTPRedundancyDepth). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.<br><br><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.                                                                                                      |
| Enable RTP Redundancy Negotiation                                                                               | Enables the device to include the RTP redundancy dynamic payload type in the SDP (according to RFC 2198).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>rtp-rdcy-nego-enbl</code><br>[EnableRTPRedundancyNegotiation]                                 | <ul style="list-style-type: none"> <li>[0] Disable (default)</li> <li>[1] Enable = The device includes in the SDP message the RTP payload type "RED" and the payload type configured by the parameter RFC2198PayloadType.</li> </ul> <pre>a=rtpmap:&lt;PT&gt; RED/8000</pre> <p>Where &lt;PT&gt; is the payload type as defined by RFC2198PayloadType. The device sends the INVITE message with "a=rtpmap:&lt;PT&gt; RED/8000" and responds with a 18x/200 OK and "a=rtpmap:&lt;PT&gt; RED/8000" in the SDP.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to the Gateway application.</li> <li>For this feature to be functional, you must also set the parameter RTPRedundancyDepth to 1 (i.e., enabled).</li> <li>Currently, the negotiation of "RED" payload type is not supported and therefore, it should be configured to the same PT value for both parties.</li> </ul> |
| RFC 2198 Payload Type<br><code>RTP-redundancy-payload-type</code><br>[RFC2198PayloadType]           | <p>Defines the RTP redundancy packet payload type (according to RFC 2198).</p> <p>The valid value is 96 to 127. The default is 104.</p> <p><b>Note:</b> The parameter is applicable only if the RTPRedundancyDepth parameter is set to 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Packing Factor<br>[RTPPackingFactor]                                                                | <p>N/A. Controlled internally by the device according to the selected coder.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| RFC 2833 TX Payload Type<br><code>telephony-events-payload-type-tx</code><br>[RFC2833TxPayloadType] | <p>Defines the Tx RFC 2833 DTMF relay dynamic payload type for outbound calls.</p> <p>The valid range is 96 to 127. The default is 96.</p> <p><b>Note:</b> When RFC 2833 payload type negotiation is used (i.e., the parameter FirstTxDTMFOption is set to 4), this payload type is used for the received DTMF packets. If negotiation isn't used, this payload type is used for receive and for transmit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| RFC 2833 RX Payload Type<br><code>telephony-events-payload-type-rx</code><br>[RFC2833RxPayloadType] | <p>Defines the Rx RFC 2833 DTMF relay dynamic payload type for inbound calls.</p> <p>The valid range is 96 to 127. The default is 96.</p> <p><b>Note:</b> When RFC 2833 payload type negotiation is used (i.e., the parameter FirstTxDTMFOption is set to 4), this payload type is used for the received DTMF packets. If negotiation isn't used, this payload type is used for receive and for transmit.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Gateway RTCP XR Report Mode<br>rtcp-xr-rep-mode<br>[RTCPXRReportMode]      | <p>Enables the device to send RTCP XR in SIP PUBLISH messages and defines the interval at which they are sent.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) RTCP XR is not sent.</li> <li>▪ <b>[1]</b> End Call = RTCP XR is sent at the end of the call.</li> <li>▪ <b>[2]</b> End Call &amp; Periodic = RTCP XR is sent at the end of the call and periodically according to the RTCPInterval parameter.</li> <li>▪ <b>[3]</b> End Call &amp; End Segment = RTCP XR is sent at the end of the call and at the end of each media segment of the call. A media segment is a change in media, for example, when the coder is changed or when the caller toggles between two called parties (using call hold/retrieve). The RTCP XR sent at the end of a media segment contains information only of that segment. If the segment does not contain RTP/RTCP content, the RTCP XR is not sent. For call hold, the device sends an RTCP XR each time the call is placed on hold and each time it is retrieved. In addition, the Start timestamp in the RTCP XR indicates the start of the media segment; the End timestamp indicates the time of the last sent periodic RTCP XR (typically, up to 5 seconds before reported segment ends).</li> </ul> <p>▪</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p> |
| SBC RTCP XR Report Mode<br>sbc-rtcpxr-report-mode<br>[SBCRtcpXrReportMode] | <p>Enables the sending of RTCP XR reports of QoE metrics at the end of each call session (i.e., after a SIP BYE). The RTCP XR is sent in the SIP PUBLISH message.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> End of Call</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 63.10 Gateway Application Parameters

### 63.10.1 Fax and Modem Parameters

The fax and modem parameters are described in the table below.

**Table 63-39: Fax and Modem Parameters**

| Parameter                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fax Transport Mode<br>fax-transport-mode<br>[FaxTransportMode]                   | Determines the fax transport mode used by the device. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = transparent mode</li> <li>▪ <b>[1]</b> T.38 Relay (default)</li> <li>▪ <b>[2]</b> Bypass</li> <li>▪ <b>[3]</b> Events Only</li> </ul> <b>Note:</b> The parameter is overridden by the parameter IsFaxUsed. If the parameter IsFaxUsed is set to 1 (T.38 Relay) or 3 (Fax Fallback), then FaxTransportMode is always set to 1 (T.38 relay). |
| V34-fax-transport-type<br>[V34FaxTransportType]                                  | Determines the V.34 fax transport method (whether V34 fax falls back to T.30 or pass over Bypass). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = Transparent</li> <li>▪ <b>[1]</b> = (Default) Relay</li> <li>▪ <b>[2]</b> = Bypass</li> <li>▪ <b>[3]</b> = Transparent with Events</li> </ul> <b>Note:</b> To configure V34FaxTransportType to 1 (i.e., fax relay), you also need to configure FaxTransportMode to 1 (fax relay).                     |
| V.21 Modem Transport Type<br>V21-modem-transport-type<br>[V21ModemTransportType] | Determines the V.21 modem transport type. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) Transparent.</li> <li>▪ <b>[2]</b> Enable Bypass</li> <li>▪ <b>[3]</b> Events Only = Transparent with Events.</li> </ul> <b>Note:</b> You can also configure this functionality per specific calls, using IP Profiles (IpProfile_VxxTransportType). For more information, see "Configuring IP Profiles" on page 419.                         |
| V.22 Modem Transport Type<br>V22-modem-transport-type<br>[V22ModemTransportType] | Determines the V.22 modem transport type. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = Transparent.</li> <li>▪ <b>[2]</b> Enable Bypass (default)</li> <li>▪ <b>[3]</b> Events Only = Transparent with Events.</li> </ul> <b>Note:</b> You can also configure this functionality per specific calls, using IP Profiles (IpProfile_VxxTransportType). For more information, see "Configuring IP Profiles" on page 419.                         |
| V.23 Modem Transport Type                                                        | Determines the V.23 modem transport type.                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| V23-modem-transport-type<br>[V23ModemTransportType]                              | <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = Transparent.</li> <li>▪ <b>[2]</b> Enable Bypass (default)</li> <li>▪ <b>[3]</b> Events Only = Transparent with Events.</li> </ul> <p><b>Note:</b> You can also configure this functionality per specific calls, using IP Profiles (IpProfile_VxxTransportType). For more information, see "Configuring IP Profiles" on page 419.</p>                                                                                                                                                                                                                                                                            |
| V.32 Modem Transport Type<br>V32-modem-transport-type<br>[V32ModemTransportType] | <p>Determines the V.32 modem transport type.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = Transparent.</li> <li>▪ <b>[2]</b> Enable Bypass (default)</li> <li>▪ <b>[3]</b> Events Only = Transparent with Events.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter applies only to V.32 and V.32bis modems.</li> <li>▪ You can also configure this functionality per specific calls, using IP Profiles (IpProfile_VxxTransportType). For more information, see "Configuring IP Profiles" on page 419.</li> </ul>                                                                                                    |
| V.34 Modem Transport Type<br>V34-modem-transport-type<br>[V34ModemTransportType] | <p>Determines the V.90/V.34 modem transport type.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = Transparent.</li> <li>▪ <b>[2]</b> Enable Bypass (default)</li> <li>▪ <b>[3]</b> Events Only = Transparent with Events.</li> </ul> <p><b>Note:</b> You can also configure this functionality per specific calls, using IP Profiles (IpProfile_VxxTransportType). For more information, see "Configuring IP Profiles" on page 419.</p>                                                                                                                                                                                                                      |
| bell-modem-transport-type<br>[BellModemTransportType]                            | <p>Determines the Bell modem transport method.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = Transparent (default)</li> <li>▪ <b>[2]</b> = Bypass</li> <li>▪ <b>[3]</b> = Transparent with events</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Fax CNG Mode<br>fax_cng_mode<br>[FaxCNGMode]                                     | <p>Determines the device's handling of fax relay upon detection of a fax CNG tone or a V.34/Super G3 V8-CM (Call Menu) signal from originating faxes.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Doesn't send T.38 Re-INVITE = (Default) SIP re-INVITE is not sent.</li> <li>▪ <b>[1]</b> Sends on CNG tone = Sends a SIP re-INVITE with T.38 parameters in SDP to the terminating fax upon detection of a fax CNG tone, if the CNGDetectorMode parameter is set to 1.</li> <li>▪ <b>[2]</b> Sends on CNG or v8-cn = Sends a SIP re-INVITE with T.38 parameters in SDP to the terminating fax upon detection of a fax CNG tone (if the CNGDetectorMode</li> </ul> |

| Parameter                                                                                                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                                                                                                             | <p>parameter is set to 1) or upon detection of a V8-CM signal.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ If the parameter is set to [2] and the CNGDetectorMode parameter is set to [0], the device sends a re-INVITE only if it detects a V8-CM signal from the originating fax.</li> <li>▪ This feature is applicable only if the IsFaxUsed parameter is set to [1] or [3].</li> <li>▪ The device also sends T.38 re-INVITE if the CNGDetectorMode parameter is set to [2], regardless of the FaxCNGMode parameter settings.</li> </ul>                                  |
| <b>CNG Detector Mode</b><br><code>coder</code><br><b>[CNGDetectorMode]</b>                                                                                                                                                  | <p>Global parameter that enables the detection of the fax calling tone (CNG) and defines the detection method. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_CNGmode). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                       |
| <b>Fax Detect Timeout Since Connect</b><br><code>configure voip &gt; sip-definition</code><br><code>general-settings &gt; fax-detect-</code><br><code>timeout-since-connect</code><br><b>[FaxDetectTimeoutSinceConnect]</b> | <p>Defines a timeout (in msec) for detecting fax from the Tel side during an established voice call. The interval starts from when the voice call is established. If the device detects a fax tone within the interval, it ends the voice session and sends a T.38 or VBD re-INVITE message to the IP side and processes the fax. If the interval expires without any received fax event, the device ignores all subsequent fax events during the voice session.</p> <p>The valid value is 0 to 120000. The default is 0. If set to 0, the device can detect fax during the entire voice call.</p> |
| <b>SIP T.38 Version</b><br><code>sip-t38-ver</code><br><b>[SIPT38Version]</b>                                                                                                                                               | <p>Determines the T.38 fax relay version.</p> <ul style="list-style-type: none"> <li>▪ [-1] Not Configured = (Default) No T.38</li> <li>▪ [0] Version 0</li> <li>▪ [3] Version 3 = T.38 Version 3 (V.34 over T.38)</li> </ul> <p><b>Note:</b> For a description on V.34 over T.38 fax relay, see V.34 Fax Support on page 205.</p>                                                                                                                                                                                                                                                                 |

| Fax Relay Redundancy Depth<br>redundancy-depth<br>[FaxRelayRedundancyDepth] | Defines the number of times that each fax relay payload is retransmitted to the network. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) No redundancy</li> <li>▪ <b>[1]</b> = One packet redundancy</li> <li>▪ <b>[2]</b> = Two packet redundancy</li> </ul> <b>Note:</b> The parameter is applicable only to non-V.21 packets.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Fax Relay Max Rate (bps)<br>max-rate<br>[FaxRelayMaxRate]                   | Defines the maximum rate (in bps) at which fax relay messages are transmitted (outgoing calls). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> 2400 = 2.4 kbps</li> <li>▪ <b>[1]</b> 4800 = 4.8 kbps</li> <li>▪ <b>[2]</b> 7200 = 7.2 kbps</li> <li>▪ <b>[3]</b> 9600 = 9.6 kbps</li> <li>▪ <b>[4]</b> 12000 = 12.0 kbps</li> <li>▪ <b>[5]</b> 14400 = 14.4 kbps (default)</li> <li>▪ [6] 16800bps = 16.8 kbps</li> <li>▪ [7] 19200bps = 19.2 kbps</li> <li>▪ [8] 21600bps = 21.6 kbps</li> <li>▪ [9] 24000bps = 24 kbps</li> <li>▪ [10] 26400bps = 26.4 kbps</li> <li>▪ [11] 28800bps = 28.8 kbps</li> <li>▪ [12] 31200bps = 31.2 kbps</li> <li>▪ [13] 33600bps = 33.6 kbps</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The rate is negotiated between both sides (i.e., the device adapts to the capabilities of the remote side). Negotiation of the T.38 maximum supported fax data rate is provided in SIP's SDP T38MaxBitRate parameter. The negotiated T38MaxBitRate is the minimum rate supported between the local and remote endpoints.</li> <li>▪ Fax relay rates greater than 14.4 kbps are applicable only to V.34 / T.38 fax relay. For non-T.38 V.34 supporting devices, configuration greater than 14.4 kbps is truncated to 14.4 kbps.</li> </ul> |
| Fax Relay ECM Enable<br>ecm-mode<br>[FaxRelayECMEnable]                     | Enables Error Correction Mode (ECM) mode during fax relay. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable</li> <li>▪ <b>[1]</b> Enable (default)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Fax/Modem Bypass Coder Type<br>[FaxModemBypassCoderType]                    | Determines the coder used by the device when performing fax/modem bypass. Typically, high-bit-rate coders such as G.711 should be used. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> G.711Alaw= (Default) G.711 A-law 64</li> <li>▪ <b>[1]</b> G.711Mulaw = G.711 <math>\mu</math>-law</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fax/Modem Bypass Packing Factor<br>packing-factor<br>[FaxModemBypassM]              | Defines the number (20 msec) of coder payloads used to generate a fax/modem bypass packet.<br>The valid range is 1, 2, or 3 coder payloads.<br>The default is 1 coder payload.                                                                                                                                                                                                           |
| fax-modem-telephony-events-mode<br>[FaxModemNTEMode]                                | Determines whether the device sends RFC 2833 ANS/ANSam events upon detection of fax and/or modem Answer tones (i.e., CED tone). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = Disabled (default)</li> <li>▪ <b>[1]</b> = Enabled</li> </ul> <b>Note:</b> The parameter is applicable only when the fax or modem transport type is set to bypass or Transparent-with-Events.      |
| Fax Bypass Payload Type<br>fax-bypass-payload-type<br>[FaxBypassPayloadType]        | Defines the fax bypass RTP dynamic payload type.<br>The valid range is 0 to 127. The default is 102.                                                                                                                                                                                                                                                                                     |
| modem-bypass-payload-type<br>[ModemBypassPayloadType]                               | Defines the modem bypass dynamic payload type.<br>The range is 0 to 127. The default is 103.                                                                                                                                                                                                                                                                                             |
| volume<br>[FaxModemRelayVolume]                                                     | Defines the fax gain control.<br>The range is -18 to -3, corresponding to -18 dBm to -3 dBm in 1-dB steps. The default is -6 dBm fax gain control.                                                                                                                                                                                                                                       |
| Fax Bypass Output Gain<br>fax-bypass-output-gain<br>[FaxBypassOutputGain]           | Defines the fax bypass output gain control.<br>The range is -31 to +31 dB, in 1-dB steps. The default is 0 (i.e., no gain).                                                                                                                                                                                                                                                              |
| Modem Bypass Output Gain<br>[ModemBypassOutputGain]                                 | Defines the modem bypass output gain control.<br>The range is -31 dB to +31 dB, in 1-dB steps. The default is 0 (i.e., no gain).                                                                                                                                                                                                                                                         |
| modem-bypass-output-gain<br>[FaxModemBypassBasicRTTPacketInterval]                  | Defines the basic frame size used during fax/modem bypass sessions. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) Determined internally</li> <li>▪ <b>[1]</b> = 5 msec (not recommended)</li> <li>▪ <b>[2]</b> = 10 msec</li> <li>▪ <b>[3]</b> = 20 msec</li> </ul> <b>Note:</b> When set to 5 msec (1), the maximum number of simultaneous channels supported is 120. |
| jitter-buffer-minimum-delay<br>[FaxModemBypassDJBufMinDelay]                        | Defines the Jitter Buffer delay (in milliseconds) during fax and modem bypass session.<br>The range is 0 to 150 msec. The default is 40.                                                                                                                                                                                                                                                 |
| enable-fax-modem-inband-network-detection<br>[EnableFaxModemInbandNetworkDetection] | Enables in-band network detection related to fax/modem. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> = (Default) Disable.</li> </ul>                                                                                                                                                                                                                                              |

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                      | <ul style="list-style-type: none"> <li><b>[1]</b> = Enable. When the parameter is enabled on Bypass and transparent with events mode (VxxTransportType is set to 2 or 3), a detection of an Answer Tone from the network triggers a switch to bypass mode in addition to the local Fax/Modem tone detections. However, only a high bit-rate coder voice session effectively detects the Answer Tone sent by a remote endpoint. This can be useful when, for example, the payload of voice and bypass is the same, allowing the originator to switch to bypass mode as well.</li> </ul>                                                                         |
| NSE-mode<br>[NSEMode]                                                | <p>Global parameter that enables Cisco's compatible fax and modem bypass mode, Named Signaling Event (NSE) packets. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_NSEMode). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                                                                              |
| NSE-payload-type<br>[NSEPayloadType]                                 | <p>Defines the NSE payload type for Cisco Bypass compatible mode.</p> <p>The valid range is 96-127. The default is 105.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to the Gateway application.</li> <li>Cisco gateways usually use NSE payload type of 100.</li> </ul>                                                                                                                                                                                                                                                                                                                                   |
| [T38UseRTPPort]                                                      | <p>Defines the port (with relation to RTP port) for sending and receiving T.38 packets.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) Use the RTP port +2 to send/receive T.38 packets.</li> <li><b>[1]</b> = Use the same port as the RTP port to send/receive T.38 packets.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, you must reset the device.</li> <li>When the device is configured to use V.152 to negotiate audio and T.38 coders, the UDP port published in SDP for RTP and for T38 must be different. Therefore, set the T38UseRTPPort parameter to 0.</li> </ul> |
| T.38 Max Datagram Size<br>t38-mx-datagram-sz<br>[T38MaxDatagramSize] | <p>Defines the maximum size of a T.38 datagram that the device can receive. This value is included in the outgoing SDP when T.38 is used.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|--------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                                | <ul style="list-style-type: none"> <li><b>[1]</b> Immediate Start on Fax = Device activates T.38 fax relay upon receipt of a re-INVITE with T.38 only in the SDP.</li> <li><b>[2]</b> Immediate Start on Fax &amp; Voice = Device activates T.38 fax relay upon receipt of a re-INVITE with T.38 and audio media in the SDP.</li> </ul> <p>The parameter is used for transmission from fax machines connected to the device and located inside a NAT. Generally, the firewall blocks T.38 (and other) packets received from the WAN, unless the device behind NAT sends at least one IP packet from the LAN to the WAN through the firewall. If the firewall blocks T.38 packets sent from the termination IP fax, the fax fails.</p> <p>To overcome this, the device sends No-Op (“no-signal”) packets to open a pinhole in the NAT for the answering fax machine. The originating fax does not wait for an answer, but immediately starts sending T.38 packets to the terminating fax machine.</p> <p><b>Note:</b> To enable No-Op packet transmission, use the NoOpEnable and NoOpInterval parameters.</p> |
| V.150.1 Modem over IP<br><b>Note:</b> These parameters are applicable only to the Gateway application.                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 63.10.3 Digit Collection and Dial Plan Parameters

The digit collection and dial plan parameters are described in the table below.

**Table 63-41: Digit Collection and Dial Plan Parameters**

| Parameter                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Dial Plan Index<br>dial-plan-index<br>[DialPlanIndex] | <p>Defines the Dial Plan index to use in the external Dial Plan file. The Dial Plan file is loaded to the device as a .dat file (converted using the DConvert utility). The Dial Plan index can be defined globally or per Tel Profile.</p> <p>The valid value range is 0 to 7, where 0 denotes PLAN1, 1 denotes PLAN2, and so on. The default is -1, indicating that no Dial Plan file is used.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ If the parameter is configured to select a Dial Plan index, the settings of the parameter DigitMapping are ignored.</li> <li>▪ If the parameter is configured to select a Dial Plan index from an external Dial Plan file, the device first attempts to locate a matching digit pattern in the Dial Plan file, and if not found, then attempts to locate a matching digit pattern in the Digit Map rules configured by the DigitMapping parameter.</li> <li>▪ The parameter is applicable also to ISDN with overlap dialing.</li> <li>▪ For E1 CAS MFC-R2 variants (which don't support terminating digit for the called party number, usually I-15), the parameter and the DigitMapping parameter are ignored. Instead, you can</li> </ul> |

| Digit Mapping Rules<br>default-dm<br>[DigitMapping]                          | <p>Defines the digit map pattern (used to reduce the dialing period when ISDN overlap dialing for digital interfaces). If the digit string (i.e., dialed number) matches one of the patterns in the digit map, the device stops collecting digits and establishes a call with the collected number.</p> <p>The digit map pattern can contain up to 52 options (rules), each separated by a vertical bar ( ). The maximum length of the entire digit pattern is 152 characters. The available notations include the following:</p> <ul style="list-style-type: none"> <li><b>[n-m]</b>: Range of numbers (not letters).</li> <li><b>.</b> (single dot): Repeat digits until next notation (e.g., T).</li> <li><b>x</b>: Any single digit.</li> <li><b>T</b>: Dial timeout (configured by the TimeBetweenDigits parameter).</li> <li><b>S</b>: Short timer (configured by the TimeBetweenDigits parameter; default is two seconds) that can be used when a specific rule is defined after a more general rule. For example, if the digit map is 99 998, then the digit collection is terminated after the first two 9 digits are received. Therefore, the second rule of 998 can never be matched. But when the digit map is 99s 998, then after dialing the first two 9 digits, the device waits another two seconds within which the caller can enter the digit 8.</li> </ul> <p>An example of a digit map is shown below:<br/> 11xS 00T [(1-7)xxx 8xxxxxxx #xxxxxxx]*xx 91xxxxxxxxxx 9011x.T<br/> In the example above, the last rule can apply to International numbers: 9 for dialing tone, 011 Country Code, and then any number of digits for the local number ('x').</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For ISDN interfaces, the digit map mechanism is applicable only when ISDN overlap dialing is used (ISDNRxOverlap is set to 1).</li> <li>If the DialPlanIndex parameter is configured (to select a Dial Plan index), then the device first attempts to locate a matching digit pattern in the Dial Plan file, and if not found, then attempts to locate a matching digit pattern in the Digit Map rules configured by the DigitMapping parameter.</li> <li>For more information on digit mapping, see "Digit Mapping" on page 556.</li> </ul> |
| Max Digits in Phone Num                                                      | <p>Defines the maximum number of collected destination number digits that can be received (i.e., dialed) from the Tel side (analog)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 63.10.4 Voice Mail Parameters

The voice mail parameters are described in the table below. For more information on the Voice Mail application, refer to the *CPE Configuration Guide for Voice Mail*.

**Table 63-42: Voice Mail Parameters**

| Parameter                                                    | Description                                                                                                                                                                                                                                                                           |
|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Voice Mail Interface<br>vm-interface<br>[VoiceMailInterface] | <p>Enables the device's Voice Mail application and determines the communication method between the device and PBX.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> None (default)</li> <li>▪ <b>[1]</b> DTMF</li> <li>▪ <b>[2]</b> SMDI</li> <li>▪ <b>[3]</b> QSIG</li> </ul> |

| Parameter                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                    |    |                   |         |    |     |           |    |     |          |    |     |            |    |         |               |    |     |        |    |     |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|----|-------------------|---------|----|-----|-----------|----|-----|----------|----|-----|------------|----|---------|---------------|----|-----|--------|----|-----|
|                                                                | <ul style="list-style-type: none"><li>▪ [4] SETUP Only = Applicable only to ISDN.</li><li>▪ [5] MATRA/AASTRA QSIG</li><li>▪ [6] QSIG SIEMENS = QSIG MWI activate and deactivate messages include Siemens Manufacturer Specific Information (MSI)</li><li>▪ [8] ETSI = Euro ISDN, according to ETS 300 745-1 V1.2.4, section 9.5.1.1. Enables MWI interworking from IP to Tel, typically used for BRI phones.</li><li>▪ [9] NI2= ISDN PRI trunks set to NI-2. This is used for interworking the SIP Message Waiting Indication (MWI) NOTIFY message to ISDN PRI NI-2 Message Waiting Notification (MWN) that is sent in the ISDN Facility IE message. This option is applicable when the device is connected to a PBX through an ISDN PRI trunk configured to NI-2.</li></ul> <p><b>Note:</b> To disable voice mail per Trunk Group, you can use a Tel Profile with the EnableVoiceMailDelay parameter set to disabled (0). This eliminates the phenomenon of call delay on Trunks not implementing voice mail when voice mail is enabled using this global parameter.</p>                                                  |                    |    |                   |         |    |     |           |    |     |          |    |     |            |    |         |               |    |     |        |    |     |

| MWI Suffix Pattern<br>mwi-suffix-pattern<br>[MWISuffixCode]                                                                                                                                                                                 | Defines the digit code used by the device as a suffix for 'MWI On Digit Pattern' and 'MWI Off Digit Pattern'. This suffix is added to the generated DTMF string after the extension number.<br>The valid range is a 25-character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| MWI Source Number<br>mwi-source-number<br>[MWISourceNumber]                                                                                                                                                                                 | Defines the calling party's phone number used in the Q.931 MWI Setup message to PSTN. If not configured, the channel's phone number is used as the calling number.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| mwi-subs-ipgrpid<br>[MWISubscribeIPGroupID]                                                                                                                                                                                                 | Defines the IP Group ID used when subscribing to an MWI server. The 'The SIP Group Name' field value of the IP Group table is used as the Request-URI host name in the outgoing MWI SIP SUBSCRIBE message. The request is sent to the IP address defined for the Proxy Set that is associated with the IP Group. The Proxy Set's capabilities such as proxy redundancy and load balancing are also applied to the message.<br><br>For example, if the 'SIP Group Name' field of the IP Group is set to "company.com", the device sends the following SUBSCRIBE message:<br><br><pre>SUBSCRIBE sip:company.com...</pre><br>Instead of:<br><pre>SUBSCRIBE sip:10.33.10.10...</pre><br><b>Note:</b> If the parameter is not configured, the MWI SUBSCRIBE message is sent to the MWI server as defined by the MWIServerIP parameter. |
| [NotificationIPGroupID]                                                                                                                                                                                                                     | Defines the IP Group ID to which the device sends SIP NOTIFY MWI messages.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>This is used for MWI Interrogation. For more information on the interworking of QSIG MWI to IP, see Message Waiting Indication on page 573.</li> <li>To determine the handling method of MWI Interrogation messages, use the TrunkGroupSettings_MWIInterrogationType, parameter (in the Trunk Group Settings table).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                |
| [MWIQsigMsgCentredIDPartyNumber]                                                                                                                                                                                                            | Defines the Message Centred ID party number used for QSIG MWI messages. If not configured (default), the parameter is not included in MWI (activate and deactivate) QSIG messages.<br>The valid value is a string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Digit Patterns</b> The following digit pattern parameters apply only to voice mail applications that use the DTMF communication method. For the available pattern syntaxes, refer to the <i>CPE Configuration Guide for Voice Mail</i> . |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Forward on Busy Digit Pattern (Internal)<br>fwd-busy-dig-ptn-int<br>[DigitPatternForwardOnBusy]                                                                                                                                             | Defines the digit pattern used by the PBX to indicate 'call forward on busy' when the original call is received from an internal extension.<br>The valid range is a 120-character string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                                                                                                     | Description                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Forward on No Answer Digit Pattern (Internal)<br>fwd-no-ans-dig-pat-int<br>[DigitPatternForwardOnNoAnswer]    | Defines the digit pattern used by the PBX to indicate 'call forward on no answer' when the original call is received from an internal extension.<br>The valid range is a 120-character string.                             |
| Forward on Do Not Disturb Digit Pattern (Internal)<br>fwd-dnd-dig-ptrn-int<br>[DigitPatternForwardOnDND]      | Defines the digit pattern used by the PBX to indicate 'call forward on do not disturb' when the original call is received from an internal extension.<br>The valid range is a 120-character string.                        |
| Forward on No Reason Digit Pattern (Internal)<br>fwd-no-rsn-dig-ptrn-int<br>[DigitPatternForwardNoReason]     | Defines the digit pattern used by the PBX to indicate 'call forward with no reason' when the original call is received from an internal extension.<br>The valid range is a 120-character string.                           |
| Forward on Busy Digit Pattern (External)<br>fwd-bsy-dig-ptrn-ext<br>[DigitPatternForwardOnBusyExt]            | Defines the digit pattern used by the PBX to indicate 'call forward on busy' when the original call is received from an external line (not an internal extension).<br>The valid range is a 120-character string.           |
| Forward on No Answer Digit Pattern (External)<br>fwd-no-ans-dig-pat-ext<br>[DigitPatternForwardOnNoAnswerExt] | Defines the digit pattern used by the PBX to indicate 'call forward on no answer' when the original call is received from an external line (not an internal extension).<br>The valid range is a 120-character string.      |
| Forward on Do Not Disturb Digit Pattern (External)<br>fwd-dnd-dig-ptrn-ext<br>[DigitPatternForwardOnDNDExt]   | Defines the digit pattern used by the PBX to indicate 'call forward on do not disturb' when the original call is received from an external line (not an internal extension).<br>The valid range is a 120-character string. |
| Forward on No Reason Digit Pattern (External)<br>fwd-no-rsn-dig-ptrn-ext<br>[DigitPatternForwardNoReasonExt]  | Defines the digit pattern used by the PBX to indicate 'call forward with no reason' when the original call is received from an external line (not an internal extension).<br>The valid range is a 120-character string.    |
| Internal Call Digit Pattern<br>int-call-dig-ptrn<br>[DigitPatternInternalCall]                                | Defines the digit pattern used by the PBX to indicate an internal call.<br>The valid range is a 120-character string.                                                                                                      |
| External Call Digit Pattern<br>ext-call-dig-ptrn<br>[DigitPatternExternalCall]                                | Defines the digit pattern used by the PBX to indicate an external call.<br>The valid range is a 120-character string.                                                                                                      |
| Disconnect Call Digit Pattern<br>disc-call-dig-ptrn<br>[TelDisconnectCode]                                    | Defines a digit pattern that when received from the Tel side, indicates the device to disconnect the call.<br>The valid range is a 25-character string.                                                                    |
| Digit To Ignore Digit Pattern<br>dig-to-ignore-dig-pattern<br>[DigitPatternDigitToIgnore]                     | Defines a digit pattern that if received as Src (S) or Redirect (R) numbers is ignored and not added to that number.<br>The valid range is a 25-character string.                                                          |

## 63.10.5 Supplementary Services Parameters

This subsection describes the device's supplementary telephony services parameters.

### 63.10.5.1 Caller ID Parameters

The caller ID parameters are described in the table below.

**Table 63-43: Caller ID Parameters**

| Parameter                                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Caller ID Permissions Table</b>                                                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Caller ID Permissions Table<br><code>configure voip &gt; gw</code><br><code>analoggw enable-caller-id</code><br><code>[EnableCallerID]</code>            | <p>This table parameter enables (per port) Caller ID generation (for FXS interfaces) and detection (for FXO interfaces). The format of the ini file table parameter is as follows:</p> <pre>[EnableCallerID] FORMAT EnableCallerID_Index = EnableCallerID_IsEnabled, EnableCallerID_Module, EnableCallerID_Port; [\\EnableCallerID]</pre> <p>Where,</p> <ul style="list-style-type: none"> <li>Module = Module number, where 1 denotes the module in Slot 1.</li> <li>Port = Port number, where 1 denotes Port 1 of a module.</li> </ul> <p>For example:<br/> <code>EnableCallerID 0 = 1,3,1;</code> (caller ID enabled on Port 1 of Module 3)<br/> <code>EnableCallerID 1 = 0,3,2;</code> (caller ID disabled on Port 2 of Module 3)</p> <p>For a detailed description of the table, see Configuring Caller ID Permissions on page 614.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The indexing of the parameter starts at 0.</li> <li>The parameter is applicable only to FXS and FXO interfaces.</li> </ul> |
| <b>Caller Display Information Table</b>                                                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Caller Display Information Table<br><code>configure voip &gt; gw</code><br><code>analoggw caller-display-info</code><br><code>[CallerDisplayInfo]</code> | <p>This table parameter enables the device to send Caller ID information to the IP side when a call is made. The called party can use this information for caller identification. The information configured in this table is sent in the SIP INVITE message's From header.</p> <p>The format of the ini file table parameter is as follows:</p> <pre>[CallerDisplayInfo] FORMAT CallerDisplayInfo_Index = CallerDisplayInfo_DisplayString, CallerDisplayInfo_IsCidRestricted, CallerDisplayInfo_Module, CallerDisplayInfo_Port; [\\CallerDisplayInfo]</pre> <p>Where,</p> <ul style="list-style-type: none"> <li>Module = Module number, where 1 denotes the module in Slot 1.</li> <li>Port = Port number, where 1 denotes Port 1 of a module.</li> </ul>                                                                                                                                                                                                                                                                         |

| Parameter                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <p>Enable FXS Caller ID Category Digit For Brazil Telecom</p> <p>fxs-callid-cat-brazil</p> <p>[AddCPCPrefix2BrazilCallerID]</p> | <p>Enables the interworking of Calling Party Category (cpc) code from SIP INVITE messages to FXS Caller ID first digit.</p> <ul style="list-style-type: none"><li>[0] Disable (default)</li><li>[1] Enable</li></ul> <p>When the parameter is enabled, the device sends the Caller ID number (calling number) with the cpc code (received in the SIP INVITE message) to the device's FXS port. The cpc code is added as a prefix to the caller ID (after IP-to-Tel calling number manipulation). For example, assuming that the incoming INVITE contains the following From (or P-Asserted-Id) header:</p> <div>From:&lt;sip:+551137077801;cpc=payphone@10.20.7.35&gt;;tag=53700</div> <p>The calling number manipulation removes "+55" (leaving 10 digits), and then adds the prefix 7, the cpc code for payphone user. Therefore, the Caller ID number that is sent to the FXS port, in this example is 71137077801.</p> <p>If the incoming INVITE message doesn't contain the 'cpc' parameter, nothing is added to the Caller ID number.</p> <table><tr><th>CPC Value in Received INVITE</th><th>CPC Code Prefixed to Caller ID (Sent to FXS Endpoint)</th><th>Description</th></tr><tr><td>cpc=unknown</td><td>1</td><td>Unknown user</td></tr><tr><td>cpc=subscribe</td><td>1</td><td>-</td></tr><tr><td>cpc=ordinary</td><td>1</td><td>Ordinary user</td></tr><tr><td>cpc=priority</td><td>2</td><td>Pre-paid user</td></tr><tr><td>cpc=test</td><td>3</td><td>Test user</td></tr><tr><td>cpc=operator</td><td>5</td><td>Operator</td></tr><tr><td>cpc=data</td><td>6</td><td>Data call</td></tr><tr><td>cpc=payphone</td><td>7</td><td>Payphone user</td></tr></table> <p><b>Notes:</b></p> <ul style="list-style-type: none"><li>The parameter is applicable only to FXS interfaces.</li><li>For the parameter to be enabled, you must also set the parameter EnableCallingPartyCategory to 1.</li></ul> | CPC Value in Received INVITE | CPC Code Prefixed to Caller ID (Sent to FXS Endpoint) | Description | cpc=unknown | 1 | Unknown user | cpc=subscribe | 1 | - | cpc=ordinary | 1 | Ordinary user | cpc=priority | 2 | Pre-paid user | cpc=test | 3 | Test user | cpc=operator | 5 | Operator | cpc=data | 6 | Data call | cpc=payphone | 7 | Payphone user |

The default is 120.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Call Forward Ring Tone ID<br><code>cfe-ring-tone-id</code><br><code>[CallForwardRingToneID]</code>                                                                                                                                                       | Defines the ringing tone type played when call forward notification is accepted.<br>The valid value range is 1 to 5. The default is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 63.10.5.4 Message Waiting Indication Parameters

The message waiting indication (MWI) parameters are described in the table below.

**Table 63-46: MWI Parameters**

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable MWI<br>enable-mwi<br>[EnableMWI]                         | Enables Message Waiting Indication (MWI). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default).</li> <li>▪ <b>[1]</b> Enable</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to FXS interfaces.</li> <li>▪ The device supports only the receipt of SIP MWI NOTIFY messages (the device doesn't generate these messages).</li> <li>▪ For more information on MWI, see "Message Waiting Indication" on page 573.</li> </ul>                                |
| MWI Analog Lamp<br>mwi-analog-lamp<br>[MWIAnalogLamp]           | Enables the visual display of MWI. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default).</li> <li>▪ <b>[1]</b> Enable = Enables visual MWI by supplying line voltage of approximately 100 VDC to activate the phone's lamp.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only for FXS interfaces.</li> <li>▪ The parameter can also be configured in a Tel Profile.</li> </ul>                                                                             |
| MWI Display<br>enable-mwi<br>[MWIDisplay]                       | Enables sending MWI information to the phone display. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) MWI information isn't sent to display.</li> <li>▪ <b>[1]</b> Enable = The device generates an MWI message (determined by the parameter CallerIDType), which is displayed on the MWI display.</li> </ul> <b>Note:</b> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to FXS interfaces.</li> <li>▪ The parameter can also be configured in a Tel Profile.</li> </ul> |
| Subscribe to MWI<br>subscribe-to-mwi<br>[EnableMWISubscription] | Enables subscription to an MWI server. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No (default)</li> <li>▪ <b>[1]</b> Yes</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ To configure the MWI server address, use the MWIServerIP parameter.</li> <li>▪ To configure whether the device subscribes per endpoint or per the entire device, use the parameter SubscriptionMode.</li> </ul>                                                                                                          |
| MWI Server IP Address<br>mwi-srvr-ip-addr<br>[MWIServerIP]      | Defines the MWI server's IP address. If provided, the device subscribes to this IP address. The MWI server address can be configured as a numerical IP address or as a domain name. If not configured, the Proxy IP address is used instead.                                                                                                                                                                                                                                                                                 |

| Parameter                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MWI Server Transport Type<br>mwi-srvr-transp-type<br>[MWIServerTransportType] | <p>Determines the transport layer used for outgoing SIP dialogs initiated by the device to the MWI server.</p> <ul style="list-style-type: none"> <li>▪ [-1] Not Configured (default)</li> <li>▪ [0] UDP</li> <li>▪ [1] TCP</li> <li>▪ [2] TLS</li> </ul> <p><b>Note:</b> When set to 'Not Configured', the value of the parameter SIPTransportType is used.</p>                                                                                                                                                                                                          |
| MWI Subscribe Expiration Time<br>mwi-subs-expr-time<br>[MWIExpirationTime]    | <p>Defines the MWI subscription expiration time in seconds. The default is 7200 seconds. The range is 10 to 2,000,000.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MWI Subscribe Retry Time<br>mwi-subs-rtry-time<br>[SubscribeRetryTime]        | <p>Defines the subscription retry time (in seconds) after last subscription failure. The default is 120 seconds. The range is 10 to 2,000,000.</p>                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Subscription Mode<br>subscription-mode<br>[SubscriptionMode]                  | <p>Determines the method the device uses to subscribe to an MWI server.</p> <ul style="list-style-type: none"> <li>▪ [0] Per Endpoint = (Default) Each endpoint subscribes separately - typically used for FXS interfaces.</li> <li>▪ [1] Per Gateway = Single subscription for the entire device - typically used for FXO interfaces.</li> </ul>                                                                                                                                                                                                                         |
| etsi-vmwi-type-one-standard<br>[ETSIVMWITypeOneStandard]                      | <p>Determines the ETSI Visual Message Waiting Indication (VMWI) Type 1 sub-standard.</p> <ul style="list-style-type: none"> <li>▪ [0] = (Default) ETSI VMWI between rings</li> <li>▪ [1] = ETSI VMWI before ring DT_AS</li> <li>▪ [2] = ETSI VMWI before ring RP_AS</li> <li>▪ [3] = ETSI VMWI before ring LR_DT_AS</li> <li>▪ [4] = ETSI VMWI not ring related DT_AS</li> <li>▪ [5] = ETSI VMWI not ring related RP_AS</li> <li>▪ [6] = ETSI VMWI not ring related LR_DT_AS</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p> |
| bellcore-vmwi-type-one-standard<br>[BellcoreVMWITypeOneStandard]              | <p>Determines the Bellcore VMWI sub-standard.</p> <ul style="list-style-type: none"> <li>▪ [0] = (Default) Between rings.</li> <li>▪ [1] = Not ring related.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                 |

### 63.10.5.5 Call Hold Parameters

The call hold parameters are described in the table below.

**Table 63-47: Call Hold Parameters**

| Parameter                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable Hold<br>hold<br>[EnableHold]                                     | <p>Global parameter that enables the Call Hold feature (analog interfaces) and interworking of the Hold/Retrieve supplementary service from ISDN PRI to SIP. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_EnableHold). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                                                                                                     |
| Hold Format<br>hold-format<br>[HoldFormat]                              | <p>Defines the format of the SDP in the sent re-INVITE hold request.</p> <ul style="list-style-type: none"> <li><b>[0]</b> 0.0.0.0 = (Default) The SDP "c=" field contains the IP address "0.0.0.0" and the "a=inactive" attribute.</li> <li><b>[1]</b> Send Only = The SDP "c=" field contains the device's IP address and the "a=sendonly" attribute.</li> <li><b>[2]</b> x.y.z.t = The SDP "c=" field contains the device's IP address and the "a=inactive" attribute.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The device does not send any RTP packets when it is in hold state.</li> <li>For digital interfaces: The parameter is applicable only to QSIG and Euro ISDN protocols.</li> </ul> |
| Held Timeout<br>held-timeout<br>[HeldTimeout]                           | <p>Defines the time interval that the device allows for a call to remain on hold. If a Resume (un-hold Re-INVITE) message is received before the timer expires, the call is renewed. If this timer expires, the call is released (terminated).</p> <ul style="list-style-type: none"> <li><b>[-1]</b> = (Default) The call is placed on hold indefinitely until the initiator of the on hold retrieves the call again.</li> <li><b>[0 - 2400]</b> = Time to wait (in seconds) after which the call is released.</li> </ul>                                                                                                                                                                                                        |
| Call Hold Reminder Ring Timeout<br>call-hold-remnd-rng<br>[CHRRTimeout] | <p>Defines the duration (in seconds) that the Call Hold Reminder Ring is played. If a user hangs up while a call is still on hold or there is a call waiting, then the FXS interface immediately rings the extension for the duration specified by the parameter. If the user off-hooks the phone, the call becomes active.</p> <p>The valid range is 0 to 600. The default is 30.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXS interfaces.</li> <li>This Reminder Ring feature can be disabled using the DisableReminderRing parameter.</li> </ul>                                                                                                                    |
| dis-reminder-ring<br>[DisableReminderRing]                              | <p>Disables the reminder ring, which notifies the FXS user of a call on hold or a waiting call when the phone is returned to on-hook position.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) The reminder ring feature is active. In other words, if a call is on hold or there is a call waiting and the phone is changed from offhook to onhook, the phone rings (for a duration defined by the CHRRTimeout parameter) to "remind" you of the call hold or call waiting.</li> </ul>                                                                                                                                                                                                                         |

| Parameter                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                          | <ul style="list-style-type: none"> <li>[1] = Disables the reminder ring. If a call is on hold or there is a call waiting and the phone is changed from offhook to onhook, the call is released (and the device sends a SIP BYE to the IP).</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXS interfaces.</li> <li>The parameter is typically used for MLPP, allowing preemption to clear held calls.</li> </ul>                                                                                                                                                       |
| dtmf-during-hold<br>[PlayDTMFduringHold] | <p>Determines whether the device sends DTMF signals (or DTMF SIP INFO message) when a call is on hold.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) Disable.</li> <li><b>[1]</b> = Enable - If the call is on hold, the device stops playing the Held tone (if it is played) and sends DTMF: <ul style="list-style-type: none"> <li>✓ To Tel side: plays DTMF digits according to the received SIP INFO message(s). (The stopped held tone is not played again.)</li> <li>✓ To IP side: sends DTMF SIP INFO messages to an IP destination if it detects DTMF digits from the Tel side.</li> </ul> </li> </ul> |

### 63.10.5.6 Call Transfer Parameters

The call transfer parameters are described in the table below.

**Table 63-48: Call Transfer Parameters**

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable Transfer<br>enable-transfer<br>[EnableTransfer] | <p>Enables the Call Transfer feature.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable</li> <li><b>[1]</b> Enable = (Default) The device responds to a REFER message with the Referred-To header to initiate a call transfer. For analog interfaces: If the transfer service is enabled, the user can activate Transfer using hook-flash signaling. If this service is enabled, the remote party performs the call transfer.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>To use call transfer, the devices at both ends must support this option.</li> <li>To use call transfer, set the parameter EnableHold to 1.</li> </ul> |
| Transfer Prefix<br>transfer-prefix<br>[xferPrefix]     | <p>Defines the string that is added as a prefix to the transferred/forwarded called number when the REFER/3xx message is received.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The number manipulation rules apply to the user part of the Refer-To and/or Contact URI before it is sent in the INVITE message.</li> <li>The parameter can be used to apply different manipulation rules to differentiate transferred/forwarded number from the originally dialed number.</li> </ul>                                                                                                                                                               |
| Transfer Prefix IP 2 Tel<br>xfer-prefix-ip2tel         | <p>Defines the prefix that is added to the destination number received in the SIP Refer-To header (for IP-to-Tel calls). The parameter is applicable to FXO/CAS blind transfer modes,</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [XferPrefixIP2Tel]                                                                 | <p>i.e., LineTransferMode = 1, 2 or 3, and TrunkTransferMode = 1 or 3 (for CAS).</p> <p>The valid range is a string of up to 9 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter is also applicable to ISDN Blind Transfer, according to AT&amp;T Toll Free Transfer Connect Service (TR 50075) "Courtesy Transfer-Human-No Data". To support this transfer mode, you need to configure the parameter XferPrefixIP2Tel to "*8" and the parameter TrunkTransferMode to 5.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Enable Semi-Attended Transfer<br>semi-att-transfer<br>[EnableSemiAttendedTransfer] | <p>Determines the device behavior when Transfer is initiated while in Alerting state.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable = (Default) Send REFER with the Replaces header.</li> <li><b>[1]</b> Enable = Send CANCEL, and after a 487 response is received, send REFER without the Replaces header.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Blind<br>blind-transfer<br>[KeyBlindTransfer]                                      | <p>Defines the keypad sequence to activate blind transfer for established Tel-to-IP calls. The Tel user can perform blind transfer by dialing the KeyBlindTransfer digits, followed by a transferee destination number.</p> <p>After the KeyBlindTransfer DTMF digits sequence is dialed, the current call is put on hold (using a Re-INVITE message), a dial tone is played to the channel, and then the phone number collection starts.</p> <p>After the destination phone number is collected, it is sent to the transferee in a SIP REFER request in a Refer-To header. The call is then terminated and a confirmation tone is played to the channel. If the phone number collection fails due to a mismatch, a reorder tone is played to the channel.</p> <p><b>Note:</b> For FXS/FXO interfaces, it is possible to configure whether the KeyBlindTransfer code is added as a prefix to the dialed destination number, by using the parameter KeyBlindTransferAddPrefix.</p> |
| blind-xfer-add-prefix<br>[KeyBlindTransferAddPrefix]                               | <p>Determines whether the device adds the Blind Transfer code (defined by the KeyBlindTransfer parameter) to the dialed destination number.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXO and FXS interfaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [UseDifferentRTPportAfterHold] | <p>device sends a re-INVITE to the held call to retrieve it and to change the RTP port to a different port number.</p> <p>For example: A first calls B on port 6000 and places B on hold. A then calls C, also on port 6000. The device sends a re-INVITE to the held call to retrieve it and changes the port to 6010.</p> <ul style="list-style-type: none"> <li>▪ <b>[1] Enable</b> = The FXS endpoint makes the first and second calls on different RTP ports in the initial outgoing INVITE request. If a three-way conference is then made, the device sends a re-INVITE to the held call to retrieve it, without changing the port of the held call.</li> </ul> <p>For example: A first calls B on port 6000 and places B on hold. A then calls C on port 6010. The device sends a re-INVITE to the held call to retrieve it (without changing the port, i.e., remains 6010).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ When this feature is enabled and only one RTP port is available, only one call can be made by the FXS endpoint, as there is no free RTP port for a second call.</li> <li>▪ When this feature is enabled and you are using the Call Forking feature, every forked call is sent with a different RTP port. As the device can fork a call to up to 10 destinations, the device requires at least 10 free RTP ports.</li> <li>▪ The parameter is applicable only to FXS interfaces.</li> </ul> |

### 63.10.5.9 MLPP and Emergency Call Parameters

The Multilevel Precedence and Preemption (MLPP) and emergency E911 call parameters are described in the table below.

**Table 63-51: MLPP and Emergency E911 Call Parameters**

| Parameter                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Call Priority Mode<br>call-prio-mode<br>[CallPriorityMode] | <p>Defines priority call handling, for all calls.</p> <ul style="list-style-type: none"> <li>▪ <b>[0] Disable</b> (default).</li> <li>▪ <b>[1] MLPP</b> = MLPP Priority Call handling is enabled. MLPP prioritizes call handling whereby the relative importance of various kinds of communications is strictly defined, allowing higher precedence communication at the expense of lower precedence communications. Higher priority calls override less priority calls when, for example, congestion occurs in a network.</li> <li>▪ <b>[2] Emergency</b> = Preemption of IP-to-Tel E911 emergency calls. If the device receives an E911 call and there are unavailable channels to receive the call, the device terminates one of the channel calls and sends the E911 call to that channel. The preemption is done only on a channel pertaining to the same Trunk Group for which the E911 call was initially destined and if the channel select mode (configured by the ChannelSelectMode parameter) is set to other than By Dest Phone Number (0). The preemption is done only if the incoming IP-to-Tel call is identified as an</li> </ul> |

| Parameter                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                        | <p>emergency call. The device identifies emergency calls by one of the following:</p> <ul style="list-style-type: none"> <li>✓ The destination number of the IP call matches one of the numbers defined by the EmergencyNumbers parameter. (For E911, you must define the parameter with the value "911".)</li> <li>✓ The incoming SIP INVITE message contains the "emergency" value in the Priority header.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable to FXS/FXO, CAS, and ISDN.</li> <li>▪ For FXO interfaces, the preemption is done only on existing IP-to-Tel calls. In other words, if all the current FXO channels are busy with calls that were initiated by the FXO (i.e., Tel-to-IP calls), new incoming emergency IP-to-Tel calls are dropped.</li> <li>▪ MLPP and Emergency services can also be configured in a Tel Profile.</li> <li>▪ For more information, see "Pre-empting Existing Call for E911 IP-to-Tel Call" on page 586.</li> </ul> |

| Emergency Numbers<br>emerg-nbs<br>[EmergencyNumbers]                                  | <p>Defines a list of “emergency” numbers.</p> <p>For FXS: When one of these numbers is dialed, the outgoing INVITE message includes the SIP Priority and Resource-Priority headers. If the user places the phone on-hook, the call is not disconnected. Instead, a Hold Re-INVITE request is sent to the remote party. Only if the remote party disconnects the call (i.e., a BYE is received) or a timer expires (set by the EmergencyRegretTimeout parameter) is the call terminated.</p> <p>For FXO, CAS, and ISDN: These emergency numbers are used for the preemption of E911 IP-to-Tel calls when there are unavailable or busy channels. In this scenario, the device terminates one of the busy channels and sends the emergency call to this channel. This feature is enabled by setting the CallPriorityMode parameter to 2 (“Emergency”). For a description of this feature, see “Pre-empting Existing Call for E911 IP-to-Tel Call” on page 586.</p> <p>The list can include up to four different numbers, where each number can be up to four digits long.<br/> Example: EmergencyNumbers = ‘100’, ‘911’, ‘112’</p> |
| Emergency Calls Regret Timeout<br>emerg-calls-regrt-t-out<br>[EmergencyRegretTimeout] | <p>Defines the time (in minutes) that the device waits before tearing-down an emergency call (defined by the parameter EmergencyNumbers). Until this time expires, an emergency call can only be disconnected by the remote party, typically, by a Public Safety Answering Point (PSAP).</p> <p>The valid range is 1 to 30. The default is 10.</p> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| MLPP DiffServ<br>mlpp-diffserv<br>[MLPPDiffserv]                                     | <p>Defines the DiffServ value (differentiated services code point/DSCP) used in IP packets containing SIP messages that are related to MLPP calls. The parameter defines DiffServ for incoming and outgoing MLPP calls with the Resource-Priority header.</p> <p>The valid range is 0 to 63. The default is 50.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Preemption Tone Duration<br>preemp-tone-dur<br>[PreemptionToneDuration]              | <p>Defines the duration (in seconds) in which the device plays a preemption tone to the Tel and IP sides if a call is preempted.</p> <p>The valid range is 0 to 60. The default is 3.</p> <p><b>Note:</b> If set to 0, no preemption tone is played.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| MLPP Normalized Service Domain<br>mlpp-norm-ser-dmn<br>[MLPPNormalizedServiceDomain] | <p>Defines the MLPP normalized service domain string. If the device receives an MLPP ISDN incoming call, it uses the parameter (if different from 'FFFFFF') as a Service domain in the SIP Resource-Priority header in outgoing INVITE messages. If the parameter is configured to 'FFFFFF', the Resource-Priority header is set to the MLPP Service Domain obtained from the Precedence IE.</p> <p>The valid value is 6 hexadecimal digits. The default is '000000'.</p> <p><b>Note:</b> The parameter is applicable only to the MLPP NI-2 ISDN variant with CallPriorityMode set to 1.</p>                                                                                                                                                                                                                                                            |
| mlpp-nwrk-id<br>[MLPPNetworkIdentifier]                                              | <p>Defines the MLPP network identifier (i.e., International prefix or Telephone Country Code/TCC) for IP-to-ISDN calls, according to the UCR 2008 and ITU Q.955 specifications.</p> <p>The valid range is 1 to 999. The default is 1 (i.e., USA).</p> <p>The MLPP network identifier is sent in the Facility IE of the ISDN Setup message. For example:</p> <ul style="list-style-type: none"> <li>MLPPNetworkIdentifier set to default (i.e., USA, 1):<br/>PlaceCall- MLPPNetworkID:0100<br/>MlppServiceDomain:123abc, MlppPrecLevel:5<br/>Fac(1c): 91 a1 15 02 01 05 02 01 19 30 0d 0a 01 05 0a 01 01 04 05 01 00 12 3a bc</li> <li>MLPPNetworkIdentifier set to 490:<br/>PlaceCall- MLPPNetworkID:9004<br/>MlppServiceDomain:123abc, MlppPrecLevel:5<br/>Fac(1c): 91 a1 15 02 01 0a 02 01 19 30 0d 0a 01 05 0a 01 01 04 05 90 04 12 3a bc</li> </ul> |
| MLPP Default Service Domain<br>mlpp-dflt-srv-domain<br>[MLPPDefaultServiceDomain]    | <p>Defines the MLPP default service domain string. If the device receives a non-MLPP ISDN incoming call (without a Precedence IE), it uses the parameter (if different than "FFFFFF") as a Service domain in the SIP Resource-Priority header in outgoing (Tel-to-IP calls) INVITE messages. The parameter is used in conjunction with the parameter SIPDefaultCallPriority.</p> <p>If MLPPDefaultServiceDomain is set to 'FFFFFF', the device interworks the non-MLPP ISDN call to non-MLPP SIP call, and</p>                                                                                                                                                                                                                                                                                                                                          |

| Parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                       |                                                  |            |         |   |          |   |           |   |       |   |                |             |                         |

| Parameter                                                                                         | Description                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| RTP DSCP for MLPP Routine<br>dscp-4-mlpp-rtn<br>[MLPPRoutineRTPDSCP]                              | Defines the RTP DSCP for MLPP Routine precedence call level.<br>The valid range is -1 to 63. The default is -1.<br><b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.                 |
| RTP DSCP for MLPP Priority<br>dscp-4-mlpp-prio<br>[MLPPPriorityRTPDSCP]                           | Defines the RTP DSCP for MLPP Priority precedence call level.<br>The valid range is -1 to 63. The default is -1.<br><b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.                |
| RTP DSCP for MLPP Immediate<br>dscp-4-mlpp-immed<br>[MLPPImmediateRTPDSCP]                        | Defines the RTP DSCP for MLPP Immediate precedence call level.<br>The valid range is -1 to 63. The default is -1.<br><b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.               |
| RTP DSCP for MLPP Flash<br>dscp-4-mlpp-flsh<br>[MLPPFlashRTPDSCP]                                 | Defines the RTP DSCP for MLPP Flash precedence call level.<br>The valid range is -1 to 63. The default is -1.<br><b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.                   |
| RTP DSCP for MLPP Flash Override<br>dscp-4-mlpp-flsh-ov<br>[MLPPFlashOverRTPDSCP]                 | Defines the RTP DSCP for MLPP Flash-Override precedence call level.<br>The valid range is -1 to 63. The default is -1.<br><b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.          |
| RTP DSCP for MLPP Flash-Override-Override<br>dscp-4-mlpp-flsh-ov-ov<br>[MLPPFlashOverOverRTPDSCP] | Defines the RTP DSCP for MLPP Flash-Override-Override precedence call level.<br>The valid range is -1 to 63. The default is -1.<br><b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call. |

### 63.10.5.10 Call Cut-Through Parameters

The call cut-through parameters are described in the table below.

**Table 63-52: Call Cut-Through Parameters**

| Parameter                                                     | Description                                                                                                                                                                             |
|---------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable Calls Cut Through<br>calls-cut-through<br>[CutThrough] | Enables FXS endpoints to receive incoming IP calls while the port is in off-hook state. <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul> |

| Parameter                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| [TargetOfChannel] | <p>TargetOfChannel_Type, TargetOfChannel_Module, TargetOfChannel_Port, TargetOfChannel_HotLineToneDuration; [TargetOfChannel]</p> <p>For example, the below configuration defines automatic dialing of phone number 911 when the phone connected to Port 1 of Module 1 is off-hooked for over 10 seconds:<br/>TargetOfChannel 0 = 911, 1, 1, 1, 10;</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The first index of this table ini file parameter is 0.</li> <li>▪ TargetOfChannel_Module is the module number, where 1 denotes the module in Slot 1.</li> <li>▪ TargetOfChannel_Port is the port number, where 1 denotes Port 1 on the module.</li> <li>▪ This parameter is applicable only to FXS and FXO interfaces.</li> <li>▪ For a detailed description of the table, see "Configuring Automatic Dialing" on page 608.</li> </ul> |

### 63.10.5.12 Direct Inward Dialing Parameters

The Direct Inward Dialing (DID) parameters are described in the table below.

**Table 63-54: DID Parameters**

| Parameter                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>DID Wink<br/>did-wink-enbl<br/>[EnabledDIDWink]</p> | <p>Enables Direct Inward Dialing (DID) using Wink-Start signaling, typically used for signaling between an E-911 switch and the PSAP.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Single = The device can be used for connection to EIA/TIA-464B DID Loop Start lines. Both FXO (detection) and FXS (generation) are supported: <ul style="list-style-type: none"> <li>✓ The FXO interface dials DTMF (or MF) digits upon detection of a Wink signal, instead of a dial tone.</li> <li>✓ The FXS interface generates a Wink signal upon detection of an off-hook state, instead of playing a dial tone.</li> </ul> <p>For example: (Wink) KP I(I) xxx-xxxx ST (Off Hook)</p> <p>Where:</p> <ul style="list-style-type: none"> <li>✓ I = one or two information digits</li> <li>✓ x = ANI</li> </ul> <p><b>Note:</b> The FXO interface generates such MF digits when the Enable911PSAP parameter is set to 1.</p> </li> <li>▪ <b>[2]</b> Double Wink = Double-wink signaling. This is applicable to FXS interfaces only. The FXS interface generates the first Wink upon detection of an off-hook state in the line. The second Wink is generated after a user-defined interval (configured by the TimeBetweenDIDWinks parameter) after which the DTMF/MF digits are collected by the device. Digits that arrive between the first and second Wink are ignored as they contain the same number. For example:<br/>(Wink) KP 911 ST (Wink) KP I(I) xxx-xxxx ST (Off Hook)</li> <li>▪ <b>[3]</b> Wink &amp; Polarity= <ul style="list-style-type: none"> <li>✓ <b>FXS:</b> The FXS interface generates the first Wink after it detects an off-hook state. A polarity change from normal to reversed is</li> </ul> </li> </ul> |

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                    | <p>generated after a user-defined time (configured by the TimeBetweenDIDWinks parameter). DTMF/MF digits are collected by the device only after this polarity change. Digits that arrive between the first Wink and the polarity change are ignored as they always contain the same number. In this mode, the FXS interface does not generate a polarity change to normal if the Tel-to-IP call is answered by an IP party. Polarity reverts to normal when the call is released. For example:<br/> (Wink) KP 911 ST (Polarity) KP I(l) xxx-xxxx ST (Off Hook)</p> <p>✓ <b>FXO:</b> For IP-to-Tel calls:</p> <ol style="list-style-type: none"> <li>1) Upon incoming INVITE message, the FXO interface goes off-hook (seizes the line).</li> <li>2) Upon detection of a Wink signal from the Tel side (instead of a dial tone), the FXO interface dials the digits, "KP911ST" (denotes *911#).</li> <li>3) The FXO interface waits for polarity reversal change from normal to reverse for an interval of 2,000 msec.</li> <li>4) Upon detection of a polarity reversal change, the FXO interface dials the DTMF (or MF) digits of the calling party (number that dialed 911) in the format "KP&lt;ANI&gt;ST" (*ANI#), where ANI is the calling number from the INVITE. If no polarity reversal, the FXO goes idle.</li> </ol> <p>For example: (Wink) KP911ST (Polarity Change) KP02963700ST<br/> Note: The Enable911PSAP parameter must be set to 1.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The EnableReversalPolarity and PolarityReversalType parameters must be set to 1 for FXS interfaces.</li> <li>▪ The parameter can also be configured in a Tel Profile.</li> </ul> |
| [TimeBetweenDIDWinks]                                              | <p>Defines the interval (in msec) for wink signaling:</p> <ul style="list-style-type: none"> <li>▪ Double-wink signaling [2]: interval between the first and second wink</li> <li>▪ Wink and Polarity signaling [3]: interval between wink and polarity change</li> </ul> <p>The valid range is 100 to 2000. The format of the ini file table parameter is as follows:<br>[CharConversion]<br>FORMAT CharConversion_Index = CharConversion_CharName,<br>CharConversion_FirstByte, CharConversion_SecondByte,<br>CharConversion_ConvertedOutput;<br>[CharConversion]<br>For a detailed description of the table, see "Converting Accented Characters from IP to Tel" on page 601. |

### 63.10.6 PSTN Parameters

This subsection describes the device's PSTN parameters.

### 63.10.6.1 General Parameters

The general PSTN parameters are described in the table below.

**Table 63-57: General PSTN Parameters**

| Parameter                                                                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Trunk Name</b><br><code>name (config-voip &gt;</code><br><code>interface &lt;e1 t1 bri&gt;</code><br><code>name</code><br><code>[DigitalPortInfo_x]</code> | <p>Defines an arbitrary name for a trunk (where x denotes the trunk number for the ini file parameter). This can be used to help you easily identify the trunk.</p> <p>The valid value is a string of up to 40 characters. The following special characters can be used (without the quotes):</p> <ul style="list-style-type: none"> <li>▪ " " (space)</li> <li>▪ "." (period)</li> <li>▪ "=" (equal sign)</li> <li>▪ "-" (hyphen)</li> <li>▪ "_" (underscore)</li> <li>▪ "#" (pound sign)</li> </ul> <p>By default, the value is undefined.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Protocol Type</b><br><code>protocol</code><br><code>[ProtocolType]</code>                                                                                  | <p>Defines the PSTN protocol for all the Trunks. To configure the protocol type for a specific Trunk, use the <i>ini</i> file parameter <code>ProtocolType_x</code>:</p> <ul style="list-style-type: none"> <li>▪ <b>[0] NONE</b></li> <li>▪ <b>[1] E1 EURO ISDN</b> = ISDN PRI Pan-European (CTR4) protocol</li> <li>▪ <b>[2] T1 CAS</b> = Common T1 robbed bits protocols including E&amp;M wink start, E&amp;M immediate start, E&amp;M delay dial/start and loop-start and ground start.</li> <li>▪ <b>[3] T1 RAW CAS</b></li> <li>▪ <b>[4] T1 TRANSPARENT</b> = Transparent protocol, where no signaling is provided by the device. Timeslots 1 to 24 of all trunks are mapped to DSP channels.</li> <li>▪ <b>[5] E1 TRANSPARENT 31</b> = Transparent protocol, where no signaling is provided by the device. Timeslots 1 to 31 of each trunk are mapped to DSP channels.</li> <li>▪ <b>[6] E1 TRANSPARENT 30</b> = Transparent protocol, where no signaling is provided by the device. Timeslots 1 to 31, excluding time slot 16 of all trunks are mapped to DSP channels.</li> <li>▪ <b>[7] E1 MFCR2</b> = Common E1 MFC/R2 CAS protocols (including line signaling and compelled register signaling).</li> <li>▪ <b>[8] E1 CAS</b> = Common E1 CAS protocols (including line signaling and MF/DTMF address transfer).</li> <li>▪ <b>[9] E1 RAW CAS</b></li> <li>▪ <b>[10] T1 NI2 ISDN</b> = National ISDN 2 PRI protocol</li> <li>▪ <b>[11] T1 4ESS ISDN</b> = ISDN PRI protocol for the Lucent™/AT&amp;T™ 4ESS switch.</li> <li>▪ <b>[12] T1 5ESS 9 ISDN</b> = ISDN PRI protocol for the Lucent™/AT&amp;T™ 5ESS-9 switch.</li> <li>▪ <b>[13] T1 5ESS 10 ISDN</b> = ISDN PRI protocol for the Lucent™/AT&amp;T™ 5ESS-10 switch.</li> <li>▪ <b>[14] T1 DMS100 ISDN</b> = ISDN PRI protocol for the Nortel™ DMS switch.</li> </ul> |

| Parameter        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

The device can support different variants of CAS and PRI protocols on different E1/T1 spans (no more than four simultaneous PRI variants).</li> <li>BRI trunks can operate together with E1 or T1 trunks.</li> <li>The ISDN BRI North American variants (NI-2, DMS-100, and 5ESS) are partially supported by the device. Please contact your AudioCodes sales representative before implementing this protocol.</li> </ul> |
| [ProtocolType_x] | Defines the protocol type for a specific trunk ID (where x denotes the Trunk ID and 0 is the first trunk). For more information, see the ProtocolType parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| [ISDNTimerT310]  | Defines the T310 override timer for DMS, Euro ISDN, and ISDN NI-2 variants. An ISDN timer is started when a Q.931 Call Proceeding message is received. The timer is stopped when a Q.931 Alerting, Connect, or Disconnect message is received from the other end. If no ISDN Alerting, Progress, or Connect message is received within the duration of T310 timer, the call clears.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|                                              | <p>The valid value range is 0 to 600 seconds. The default is 0 (i.e., use the default timer value according to the protocol's specifications).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>When both the parameters ISDNDmsTimerT310 and ISDNTimerT310 are configured, the value of the parameter ISDNTimerT310 prevails.</li> </ul>                                                                                                                                                                                                                                                                                          |
| [ISDNDMSTimerT310]                           | <p>Defines the override T310 timer for the DMS-100 ISDN variant. T310 defines the timeout between the receipt of a Proceeding message and the receipt of an Alerting/Connect message. The valid range is 10 to 30. The default is 10 (seconds).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>Instead of configuring the parameter, it is recommended to use the parameter ISDNTimerT310.</li> <li>The parameter is applicable only to Nortel DMS and Nortel MERIDIAN PRI variants (ProtocolType = 14 and 35).</li> </ul>                                                                                                                                                                              |
| [ISDNTimerT301]                              | <p>Defines the override T301 timer (in seconds). The T301 timer is started when a Q.931 Alert message is received. The timer is stopped when a Q.931 Connect/Disconnect message is received from the other side. If no Connect or Disconnect message is received within the duration of T301, the call is cleared.</p> <p>The valid range is 0 to 2400. The default is 0 (i.e., the default T301 timer value - 180 seconds - is used). If set to any value other than 0, it overrides the timer with this value.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>The parameter is applicable only to the QSIG variant.</li> </ul> |
| [ISDNJapanNTTTimerT3JA]                      | <p>Defines the T3_JA timer (in seconds). The parameter overrides the internal PSTN T301 timeout on the Users Side (TE side). If an outgoing call from the device to ISDN is not answered during this timeout, the call is released.</p> <p>The valid value is -1 to 300. The default is 0 (meaning 50 sec). The value -1 means that no timer is activated.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>This timer is also affected by the parameter PSTNAlertTimeout.</li> <li>The parameter is applicable only to the Japan NTT PRI variant (ProtocolType = 16).</li> </ul>                                                                                                                         |
| Trace Level<br>[TraceLevel]                  | <p>Defines the trace level:</p> <ul style="list-style-type: none"> <li><b>[0]</b> No Trace (default)</li> <li><b>[1]</b> Full ISDN Trace</li> <li><b>[2]</b> Layer 3 ISDN Trace</li> <li><b>[3]</b> Only ISDN Q.931 Messages Trace</li> <li><b>[4]</b> Layer 3 ISDN No Duplication Trace</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Framing Method<br>framing<br>[FramingMethod] | <p>Determines the physical framing method for the trunk.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Extended Super Frame = (Default) Depends on protocol type:</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Parameter                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 63.10.6.2 TDM Bus and Clock Timing Parameters

The TDM Bus parameters are described in the table below.

Table 63-58: TDM Bus and Clock Timing Parameters

| Parameter                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>TDM Bus Parameters</b>                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| PCM Law Select<br>[PCMLawSelect]                         | <p>Determines the type of pulse-code modulation (PCM) companding algorithm law in input and output TDM bus.</p> <ul style="list-style-type: none"> <li>▪ <b>[1]</b> Alaw</li> <li>▪ <b>[3]</b> MuLaw</li> </ul> <p>The default value is automatically selected according to the Protocol Type of the selected trunk. E1 defaults to ALaw; T1 defaults to MuLaw. If the Protocol Type is set to NONE, the default is MuLaw.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ Typically, A-Law is used for E1 spans, Mu-Law for T1/J1 spans, and BRI is A-Law is used for most BRI variants.</li> </ul> |
| Idle PCM Pattern<br>idle-pcm-pattern<br>[IdlePCMPattern] | <p>Defines the PCM Pattern that is applied to the E1/T1 timeslot (B-channel) when the channel is idle.</p> <p>The range is 0 to 255. The default is set internally according to the Law select 1 (0xFF for Mu-Law; 0x55 for A-law).</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| Idle ABCD Pattern<br>[IdleABCDPattern]                   | <p>Defines the ABCD (CAS) Pattern that is applied to the CAS signaling bus when the channel is idle.</p> <p>The valid range is 0x0 to 0xF. The default is -1 (i.e., default pattern is 0000).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ The parameter is applicable only when using PSTN interface with the RAW_CAS protocol.</li> </ul>                                                                                                                                                                                                                                                       |
| TDM Bus Clock Source<br>[TDMBusClockSource]              | <p>Defines the clock source to which the device synchronizes.</p> <ul style="list-style-type: none"> <li>▪ <b>[1]</b> Internal = (Default) Generate clock from local source.</li> <li>▪ <b>[4]</b> Network = Recover clock from PSTN line.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> </ul>                                                                                                                                                                                                                                                                                                     |
| TDM Bus Local Reference<br>[TDMBusLocalReference]        | <p>Defines the physical Trunk ID from which the device recovers (receives) its clock synchronization.</p> <p>The range is 0 to the maximum number of Trunks. The default is 0.</p> <p><b>Note:</b> The parameter is applicable only if the parameter TDMBusClockSource is set to 4 and the parameter TDMBusPSTNAutoClockEnable is set to 0.</p>                                                                                                                                                                                                                                                                                                                                                 |
| TDM Bus Enable Fallback<br>[TDMBusEnableFallback]        | <p>Defines the automatic fallback of the clock.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Manual (default)</li> <li>▪ <b>[1]</b> Auto Non-Revertive</li> <li>▪ <b>[2]</b> Auto Revertive</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| TDM Bus Net Reference Speed<br>[TDMBusNetrefSpeed]       | <p>Defines the NetRef frequency (for both generation and synchronization).</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> 8 kHz (default)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| TDM Bus PSTN Auto FallBack Clock<br>[TDMBusPSTNAutoClockEnable]           | <p>Enables the PSTN trunk Auto-Fallback Clock feature.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) Recovers the clock from the E1/T1 line defined by the parameter TDMBusLocalReference.</li> <li>▪ <b>[1]</b> Enable = Recovers the clock from any connected synchronized slave E1/T1 line. If this trunk loses its synchronization, the device attempts to recover the clock from the next trunk. Note that initially, the device attempts to recover the clock from the trunk defined by the parameter TDMBusLocalReference.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ The parameter is applicable only if the TDMBusClockSource parameter is set to 4.</li> </ul> |
| TDM Bus PSTN Auto Clock Reverting<br>[TDMBusPSTNAutoClockRevertingEnable] | <p>Enables the PSTN trunk Auto-Fallback Reverting feature. If enabled and a trunk returning to service has an AutoClockTrunkPriority parameter value that is higher than the priority of the local reference trunk (set in the TDMBusLocalReference parameter), the local reference reverts to the trunk with the higher priority that has returned to service for the device's clock source.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ The parameter is applicable only when the TDMBusPSTNAutoClockEnable parameter is set to 1.</li> </ul>                                                  |
| Auto Clock Trunk Priority<br>clock-priority<br>[AutoClockTrunkPriority]   | <p>Defines the trunk priority for auto-clock fallback (per trunk parameter).</p> <p>The valid range is 0 to 100, where 0 (default) is the highest priority and 100 indicates that the device does not perform a fallback to the trunk (typically, used to mark untrusted source of clock).</p> <p><b>Note:</b> Fallback is enabled when the TDMBusPSTNAutoClockEnable parameter is set to 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                              |

### 63.10.6.3 CAS Parameters

The Common Channel Associated (CAS) parameters are described in the table below. Note that CAS is not applicable to BRI interfaces.

**Table 63-59: CAS Parameters**

| Parameter                                                      | Description                                                                                                                                                                |
|----------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CAS Transport Type<br>cas-transport-type<br>[CASTransportType] | <p>Determines the ABCD signaling transport type over IP.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> CAS Events Only = (Default) Disable CAS relay.</li> </ul> |

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                             | <ul style="list-style-type: none"> <li><b>[1]</b> CAS RFC2833 Relay = Enable CAS relay mode using RFC 2833.</li> </ul> <p>The CAS relay mode can be used with the TDM tunneling feature to enable tunneling over IP for both voice and CAS signaling bearers.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| [CASAddressingDelimiters]                                   | <p>Enables the addition of delimiters to the received address or received ANI digits string.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (default) Disable. The address and ANI strings remain without delimiters.</li> <li><b>[1]</b> = Enable. Delimiters such as '*', '#', and 'ST' are added to the received address or received ANI digits string.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                          |
| cas-delimiters-types<br>[CASDelimitersPaddingUsage]         | <p>Defines the digits string delimiter padding usage per trunk.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) Default address string padding: '*XXX#' (where XXX is the digit string that begins with '*' and ends with '#', when using padding).</li> <li><b>[1]</b> = Special use of asterisks delimiters: '*XXX*YYY*' (where XXX is the address, YYY is the source phone number, and '*' is the only delimiter padding).</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                            |
| CAS Table per Trunk<br>cas-table-index<br>[CASTableIndex_x] | <p>Defines the CAS protocol per trunk from a list of CAS protocols defined by the parameter CASFileName_x.</p> <p>For example, the below configuration specifies Trunks 0 and 1 to use the E&amp;M Winkstart CAS (E_M_WinkTable.dat) protocol, and Trunks 2 and 3 to use the E&amp;M Immediate Start CAS (E_M_ImmediateTable.dat) protocol:</p> <pre>CASFileName_0 = 'E_M_WinkTable.dat' CASFileName_1 = 'E_M_ImmediateTable.dat' CASTableIndex_0 = 0 CASTableIndex_1 = 0 CASTableIndex_2 = 1 CASTableIndex_3 = 1</pre> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>You can define CAS tables per B-channel using the parameter CASChannelIndex.</li> <li>The x in the ini file parameter name denotes the trunk number, where 0 is Trunk 1.</li> </ul> |
| Dial Plan<br>cas-dial-plan-name<br>[CASTrunkDialPlanName_x] | <p>Defines the CAS Dial Plan name per trunk.</p> <p>The range is up to 11 characters.</p> <p>For example, the below configures E1_MFCR2 trunk with a single protocol (Trunk 5):</p> <pre>ProtocolType_5 = 7 CASFileName_0='R2_Korea_CP_ANI.dat' CASTableIndex_5 = 0 DialPlanFileName = 'DialPlan_USA.dat' CASTrunkDialPlanName_5 = 'AT_T'</pre> <p><b>Note:</b> The x in the ini file parameter name denotes the trunk number, where 0 is Trunk 1.</p>                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [CASFileName_x]                                                 | <p>Defines the CAS file name (e.g., 'E_M_WinkTable.dat') that defines the CAS protocol, where x denotes the CAS file ID (0-7). It is possible to define up to eight different CAS files by repeating the parameter. Each CAS file can be associated with one or more of the device's trunks, using the parameter CASTableIndex_x.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CAS Table per Channel<br>cas-channel-index<br>[CASChannelIndex] | <p>Defines the loaded CAS protocol table index per B-channel pertaining to a CAS trunk. The parameter is assigned a string value and can be set in one of the following two formats:</p> <ul style="list-style-type: none"> <li> <b>CAS table per channel:</b> Each channel is separated by a comma and the value entered denotes the CAS table index used for that channel. The syntax is &lt;CAS index&gt;,&lt;CAS index&gt; (e.g., "1,2,1,2..."). For this format, 31 indices must be defined for E1 trunks (including dummy for B-channel 16), or 24 indices for T1 trunks. Below is an example for configuring a T1 CAS trunk (Trunk 5) with several CAS variants:               <pre>ProtocolType_5 = 7 CASFILENAME_0='E_M_FGBWinkTable.dat' CASFILENAME_1='E_M_FGDWinkTable.dat' CASFILENAME_2='E_M_WinkTable.txt' CasChannelIndex_5 = '0,0,0,1,1,1,2,2,2,0,0,0,1,1,1,0,1,2,0,2,1,2,2,2' CASDelimitersPaddingUsage_5 = 1</pre> </li> <li> <b>CAS table per channel group:</b> Each channel group is separated by a colon and each channel is separated by a comma. The syntax is &lt;x-y channel range&gt;:&lt;CAS table index&gt;, (e.g., "1-10:1,11-31:3"). Every B-channel (including 16 for E1) must belong to a channel group. Below is an example for configuring an E1 CAS trunk (Trunk 5) with several CAS variants:               <pre>ProtocolType_5 = 8 CASFILENAME_2='E1_R2D' CASFILENAME_7= E_M_ImmediateTable_A-Bit.txt' CasChannelIndex_5 = '1-10:2,11-20:7,21-31:2'</pre> </li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>To configure the parameter, the trunk must first be stopped.</li> <li>Only one of these formats can be implemented; not both.</li> <li>When the parameter is not configured, a single CAS table for the entire trunk is used, configured by the parameter CASTableIndex.</li> </ul> |
| [CASTablesNum]                                                  | <p>Defines how many CAS protocol configurations files are loaded.</p> <p>The valid range is 1 to 8.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>CAS State Machines Parameters</b>                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Note:</b> For configuring the CAS State Machine table using the Web interface, see "Configuring CAS State Machines" on page 466. The CAS state machine can be configured only through the Web-based management tool. |                                                                                                                                                                                                                                                                                                                                          |
| Generate Digit On Time<br>[CASStateMachineGenerateDigitOnTime]                                                                                                                                                          | Generates digit on-time (in msec).<br>The value must be a positive value. The default is -1.                                                                                                                                                                                                                                             |
| Generate Inter Digit Time<br>[CASStateMachineGenerateInterDigitTime]                                                                                                                                                    | Generates digit off-time (in msec).<br>The value must be a positive value. The default is -1.                                                                                                                                                                                                                                            |
| DTMF Max Detection Time<br>[CASStateMachineDTMFMaxOnDetectionTime]                                                                                                                                                      | Detects digit maximum on time (according to DSP detection information event) in msec units.<br>The value must be a positive value. The default is -1.                                                                                                                                                                                    |
| DTMF Min Detection Time<br>[CASStateMachineDTMFMinOnDetectionTime]                                                                                                                                                      | Detects digit minimum on time (according to DSP detection information event) in msec units. The digit time length must be longer than this value to receive a detection. Any number may be used, but the value must be less than CasStateMachineDTMFMaxOnDetectionTime.<br>The value must be a positive value. The default is -1.        |
| MAX Incoming Address Digits<br>[CASStateMachineMaxNumOfIncomingAddressDigits]                                                                                                                                           | Defines the limitation for the maximum address digits that need to be collected. After reaching this number of digits, the collection of address digits is stopped.<br>The value must be an integer. The default is -1.                                                                                                                  |
| MAX Incoming ANI Digits<br>[CASStateMachineMaxNumOfIncomingANIDigits]                                                                                                                                                   | Defines the limitation for the maximum ANI digits that need to be collected. After reaching this number of digits, the collection of ANI digits is stopped.<br>The value must be an integer. The default is -1.                                                                                                                          |
| Collect ANI<br>[CASStateMachineCollectANI]                                                                                                                                                                              | In some cases, when the state machine handles the ANI collection (not related to MFCR2), you can enable the state machine to collect ANI or discard ANI. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No = Don't collect ANI.</li> <li>▪ <b>[1]</b> Yes = Collect ANI.</li> <li>▪ <b>[-1]</b> Default = Default value.</li> </ul> |
| Digit Signaling System<br>[CASStateMachineDigitSignalingSystem]                                                                                                                                                         | Defines which Signaling System to use in both directions (detection\generation). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> DTMF = DTMF signaling.</li> <li>▪ <b>[1]</b> MF = (Default) MF signaling.</li> <li>▪ <b>[-1]</b> Default = Default value.</li> </ul>                                                                |

#### 63.10.6.4 ISDN Parameters

The ISDN parameters are described in the table below.

**Table 63-60: ISDN Parameters**

| Parameter                                      | Description                           |
|------------------------------------------------|---------------------------------------|
| ISDN Termination Side<br>isdn-termination-side | Determines the ISDN termination side. |

| Parameter                                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [TerminationSide]                                                                                                                 | <ul style="list-style-type: none"> <li>[0] User side = (Default) ISDN User Termination Equipment (TE) side.</li> <li>[1] Network side = ISDN Network Termination (NT) side.</li> </ul> <p><b>Note:</b> Select 'User side' when the PSTN or PBX side is configured as 'Network side' and vice versa. If you don't know the device's ISDN termination side, choose 'User side'. If the D-channel alarm is indicated, choose 'Network Side'.</p> <p>The BRI module supports the ITU-T I.430 standard, which defines the ISDN-BRI layer 1 specification. The BRI and PRI ports are configured similarly, using the parameter. When an NT port is active, it drives a 38-V line and sends an INFO1 signal (as defined in ITU-T I.430 Table 4) on the data line to synchronize to a TE port that might be connected to it. To stop the voltage and the INFO1 signal on the line, stop the trunk using the Stop Trunk button.</p> |
| [TerminationSide_x]                                                                                                               | Same as the description for parameter TerminationSide, but for a specific trunk ID (where x denotes the Trunk ID and 0 is the first Trunk).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

For example, to support both [16] and [32] features, set ISDNGeneralCCBehavior = 48 (i.e., 16 + 32).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Outgoing Calls Behavior<br>isdn-bits-outgoing-calls-behavior<br>[ISDNOutCallsBehavior] | <p>Determines several behaviour options (bit fields) that influence the behaviour of the ISDN Stack outgoing calls. To select options, click the arrow button, and then for each required option, select 1 to enable. The default is 0 (i.e., disable).</p> <ul style="list-style-type: none"> <li>▪ <b>[2] USER SENDING COMPLETE</b> = The default behavior of the device (when this bit is not set) is to automatically generate the Sending-Complete IE in the Setup message. This behavior is used when overlap dialing is not needed. When overlap dialing is needed, set this bit and the behavior is changed to suit the scenario, i.e., Sending-Complete IE is added when required in the Setup message for Enblock mode or in the last Digit with Overlap mode.</li> <li>▪ <b>[16] USE MU LAW</b> = The device sends G.711-m-Law in outgoing voice calls. When disabled, the device sends G.711-A-Law in outgoing voice calls.<br/> <b>Note:</b> This option is applicable only to the Korean variant.</li> <li>▪ <b>[128] DIAL WITH KEYPAD</b> = The device uses the Keypad IE to store the called number digits instead of the CALLED_NB IE.<br/> <b>Note:</b> This option is applicable only to the Korean variant (Korean network). This is useful for Korean switches that don't accept the CALLED_NB IE.</li> <li>▪ <b>[256] STORE CHAN ID IN SETUP</b> = The device forces the sending of a Channel-Id IE in an outgoing Setup message even if it's not required by the standard (i.e., optional) and no Channel-Id has been specified in the establishment request. This is useful for improving required compatibility with switches. On BRI lines, the Channel-Id IE indicates 'any channel'. On PRI lines it indicates an unused channel ID, preferred only.</li> <li>▪ <b>[512] USE A LAW</b> = The device sends G.711 A-Law in outgoing voice calls. When disabled, the device sends the default G.711-Law in outgoing voice calls.<br/> <b>Note:</b> This option is applicable only to the E10 variant.</li> <li>▪ <b>[1024]</b> = Numbering plan/type for T1 IP-to-Tel calling numbers are defined according to the manipulation tables or according to the RPID header (default). Otherwise, the plan/type for T1 calls are set according to the length of the calling number.</li> <li>▪ <b>[2048]</b> = The device accepts any IA5 character in the called_nb and calling_nb strings and sends any IA5 character in the called_nb, and is not restricted to extended digits only (i.e., 0-9,*,#).</li> <li>▪ <b>[16384] DLCI REVERSED OPTION</b> = Behavior bit used in the IUA interface groups to indicate that the reversed format of the DLCI field must be used.</li> </ul> |

### 63.10.7 ISDN and CAS Interworking Parameters

The ISDN and CAS interworking parameters are described in the table below.

**Table 63-61: ISDN and CAS Interworking Parameters**

| Parameter              | Description |
|------------------------|-------------|
| <b>ISDN Parameters</b> |             |

| Parameter                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Send Local Time To ISDN Connect<br>[SendLocalTimeToISDNConnect]                 | <p>Determines the device's handling of the date and time sent in the ISDN Connect message (Date / Time IE) upon receipt of SIP 200 OK messages.</p> <ul style="list-style-type: none"> <li>▪ <b>[0] Disable = (Default)</b> If the SIP 200 OK includes the Date header, the device sends its value in the ISDN Connect Date / Time IE. If the 200 OK does not include this header, it does not add the Date / Time IE to the sent ISDN Connect message.</li> <li>▪ <b>[1] Enable =</b> If the SIP 200 OK includes the Date header, the device sends its value (i.e. date and time) in the ISDN Connect Date / Time IE. If the 200 OK does not include this header, the device uses its internal, local date and time for the Date / Time IE, which it adds to the sent ISDN Connect message.</li> <li>▪ <b>[2] Always Send Local Date and Time =</b> The device always sends its local date and time (obtained from its internal clock) to PBXs in ISDN Q.931 Connect messages (Date / Time IE). It does this regardless of whether or not the incoming SIP 200 OK includes the Date header. If the SIP 200 OK includes the Date header, the device ignores its value.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ This feature is applicable only to Tel-to-IP calls.</li> <li>▪ For IP-to-Tel calls, the parameter is not applicable. Only if the incoming ISDN Connect message contains the Date / Time IE does the device add the Date header to the sent SIP 200 OK message.</li> </ul> |
| Min Routing Overlap Digits<br>min-dg-b4-routing<br>[MinOverlapDigitsForRouting] | <p>Defines the minimum number of overlap digits to collect (for ISDN overlap dialing) before sending the first SIP message for routing Tel-to-IP calls.</p> <p>The valid value range is 0 to 49. The default is 1.</p> <p><b>Note:</b> The parameter is applicable when the ISDNRxOverlap parameter is set to [2] or [3].</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| ISDN Overlap IP to Tel Dialing<br>isdn-tx-overlap<br>[ISDNTxOverlap]            | <p>Enables ISDN overlap dialing for IP-to-Tel calls. This feature is part of ISDN-to-SIP overlap dialing according to RFC 3578.</p> <ul style="list-style-type: none"> <li>▪ <b>[1] Through SIP =</b> The device sends the first received digits from the initial INVITE to the Tel side in an ISDN Setup message. For each subsequently received re-INVITE message of the same dialog session, the device sends the collected digits to the Tel side in ISDN Info Q.931 messages. For each received re-INVITE, the device sends a SIP 484 Address Incomplete response to maintain the current dialog session and to receive additional digits from subsequent re-INVITEs.</li> <li>▪ <b>[2] Through SIP INFO =</b> The device sends the first received digits from the initial INVITE to the Tel side in an ISDN Setup message and then responds to the IP side with a SIP 183. For each subsequently received SIP INFO message with additional digits of the same dialog session, the device sends the collected digits to the Tel side in ISDN Info Q.931 messages. For each received SIP INFO, the device sends a SIP 200 OK response to maintain the current dialog session and to receive additional digits from subsequent INFOS.</li> </ul> <p><b>Note:</b> When IP-to-Tel overlap dialing is enabled, to send ISDN Setup messages without the Sending Complete IE, the</p>                                                                                                                                       |

| Parameter                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Enable Receiving of Overlap Dialing<br>ovrlp-rcving-type<br>[ISDNRxOverlap_x] | <p>Determines the receiving (Rx) type of ISDN overlap dialing for Tel-to-IP calls, per trunk.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> None = (Default) Disabled.</li> <li>▪ <b>[1]</b> Local receiving = ISDN Overlap Dialing - the complete number is sent in the INVITE Request-URI user part. The device receives ISDN called number that is sent in the 'Overlap' mode. The ISDN Setup message is sent to IP only after the number (including the Sending Complete IE) is fully received (via Setup and/or subsequent Info Q.931 messages). In other words, the device waits until it has received all the ISDN signaling messages containing parts of the called number, and only then it sends a SIP INVITE with the entire called number in the Request-URI.</li> <li>▪ <b>[2]</b> Through SIP = Interworking of ISDN Overlap Dialing to SIP according to RFC 3578. The device sends the first received digits from the ISDN Setup message to the IP side in the initial INVITE message. For each subsequently received ISDN Info Q.931 message, the device sends the collected digits to the IP side in re-INVITE messages.</li> <li>▪ <b>[3]</b> Through SIP INFO = Interworking of ISDN Overlap Dialing to SIP according to RFC 3578. The device sends the first received digits from the ISDN Setup message to the IP side in the initial INVITE message. For each subsequently received ISDN Info Q.931 message, the device sends the collected digits to the IP side in INFO messages.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ When option [2] or [3] is configured, you can define the minimum number of overlap digits to collect before sending the first SIP message for routing the call, using the MinOverlapDigitsForRouting parameter.</li> <li>▪ When option [2] or [3] is configured, even if SIP 4xx responses are received during this ISDN overlap receiving, the device does not release the call.</li> <li>▪ The MaxDigits parameter can be used to limit the length of the collected number for ISDN overlap dialing (if Sending Complete is not received).</li> <li>▪ If a digit map pattern is defined (using the DigitMapping or DialPlanIndex parameters), the device collects digits until a match is found (e.g., for closed numbering schemes) or until a timer expires (e.g., for open numbering schemes). If a match is found (or the timer expires), the digit collection process is terminated even if Sending Complete is not received.</li> <li>▪ For enabling ISDN overlap dialing for IP-to-Tel calls, use the ISDNTxOverlap parameter.</li> <li>▪ The x in the ini file parameter name denotes the trunk number, where 0 is Trunk 1.</li> <li>▪ For more information on ISDN overlap dialing, see "ISDN Overlap Dialing" on page 478.</li> </ul> |

|           | <ul style="list-style-type: none"> <li>✓ For RLT ISDN transfer, the parameter SendISDNTransferOnConnect must be set to 1.</li> <li>✓ The parameter SendISDNTransferOnConnect can be used to define if the TBCT/ECT transfer is performed after receipt of Alerting or Connect messages. For RLT, the transfer is always done after receipt of Connect (SendISDNTransferOnConnect is set to 1).</li> <li>✓ This transfer can be performed between B-channels from different trunks or Trunk Groups, by using the parameter EnableTransferAcrossTrunkGroups.</li> <li>✓ The device initiates the ECT process after receiving a SIP REFER message only for trunks that are configured to User side.</li> </ul> <ul style="list-style-type: none"> <li>▪ <b>[3]</b> = Supports CAS Normal transfer. When a SIP REFER message is received, the device performs a Blind Transfer by executing a CAS Wink, dialing the Refer-to number to the switch, and then releasing the call.</li> <li>▪ <b>[4]</b> = Supports QSIG Single Step transfer (PRI/BRI):<br/> IP-to-Tel: When a SIP REFER message is received, the device performs a transfer by sending a Facility message to the PBX, initiating Single Step transfer. Once a success return result is received, the transfer is completed.<br/> Tel-to-IP: When a Facility message initiating Single Step transfer is received from the PBX, a SIP REFER message is sent to the IP side.</li> <li>▪ <b>[5]</b> = IP-to-Tel Blind Transfer mode supported for ISDN (PRI/BRI) protocols and implemented according to AT&amp;T Toll Free Transfer Connect Service (TR 50075) "Courtesy Transfer-Human-No Data". When the device receives a SIP REFER message, it performs a blind transfer by first dialing the DTMF digits (transfer prefix) defined by the parameter XferPrefixIP2Tel (configured to "*8" for AT&amp;T service), and then (after 500 msec) the device dials the DTMF of the number (referred) from the Refer-To header sip:URI userpart.<br/> If the hostpart of the Refer-To sip:URI contains the device's IP address, and if the Trunk Group selected according to the IP to Tel Routing table is the same Trunk Group as the original call, then the device performs the in-band DTMF transfer; otherwise, the device sends the INVITE according to regular transfer rules. After completing the in-band transfer, the device waits for the ISDN Disconnect message. If the Disconnect message is received during the first 5 seconds, the device sends a SIP NOTIFY with 200 OK message; otherwise, the device sends a NOTIFY with 4xx message.</li> <li>▪ <b>[6]</b> = Supports AT&amp;T toll free out-of-band blind transfer for trunks configured with the 4ESS ISDN protocol. AT&amp;T courtesy transfer is a supplementary service which enables a user (e.g., user "A") to transform an established call between it and user "B" into a new call between users "B" and "C", whereby user "A" does not have a call established with user "C" prior to call transfer. The device handles this feature as follows: <ul style="list-style-type: none"> <li>✓ IP-to-Tel (user side): When a SIP REFER message is received, the device initiates a transfer by sending a Facility message to the PBX.</li> </ul> </li> </ul> |

### 63.10.8 Answer and Disconnect Supervision Parameters

The answer and disconnect supervision parameters are described in the table below.

Table 63-62: Answer and Disconnect Parameters

| Parameter                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wait before PSTN Release-Ack<br>wait-befor-pstn-rel-ack<br>[TimeToWaitForPstnReleaseAck]       | <p>Defines a timeout (in milliseconds) that the device waits for the receipt of an ISDN Q.931 Release message from the PSTN side before releasing the channel. The Release ACK is typically sent by the PSTN in response to the device's Disconnect message to end the call. If the timeout expires and a Release message has not yet been received, the device releases the call channel.</p> <p>The valid value is 1 to 360,000. The default is 6,000.</p> <p><b>Note:</b> The parameter is applicable only to Digital interfaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| configure voip > interface<br>e1-t1 > isdn-japan-ntt-<br>timer-t305<br>[ISDNJapanNttTimerT305] | <p>Defines a timeout (in seconds) that the device waits before sending an ISDN Release message after it has sent a Disconnect message, if no SIP message (e.g., 4xx response) is received within the timeout. The parameter is applicable when the device's trunk is configured for the Japanese NTT ISDN PRI (T1) variant (i.e., [ProtocolType] is [16], as described in Configuring Trunk Settings).</p> <p>The valid value is 0 to 480. The default is 0 (i.e., timeout is 30 seconds).</p> <p>For more information on this feature, see SIP-to-ISDN Disconnect Release Cause Code Mapping on page 513.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>The parameter is applicable only to digital interfaces (T1 NTT).</li> </ul>                                                                                                                                                        |
| Answer Supervision<br>answer-supervision<br>[EnableVoiceDetection]                             | <p>Enables the sending of SIP 200 OK upon detection of speech, fax, or modem.</p> <ul style="list-style-type: none"> <li><b>[1] Yes</b> = The device sends a SIP 200 OK (in response to an INVITE message) when speech, fax, or modem is detected (from the Tel side, for analog interfaces).</li> <li><b>[0] No</b> = (Default) The device sends a SIP 200 OK only after it completes dialing (to the Tel side, for analog interfaces).</li> </ul> <p>Typically, this feature is used only when early media (enabled using the EnableEarlyMedia parameter) is used to establish the voice path before the call is answered.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>FXO interfaces: This feature is applicable only to one-stage dialing (FXO).</li> <li>Digital interfaces: To activate this feature, set the EnableDSIPMDetectors parameter to 1.</li> <li>Digital interfaces: This feature is applicable only when the protocol type is CAS.</li> </ul> |
| configure voip > sip<br>advanced-settings > set mn-<br>call-duration<br>[MinCallDuration]      | <p>Defines the minimum call duration (in seconds) for the Tel side. If an established call is terminated by the IP side before this duration expires, the device terminates the call with the IP side, but delays the termination toward the Tel side until this timeout expires.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                | <p>The valid value range is 0 to 10 seconds, where 0 (default) disables this feature.</p> <p>For example: assume the minimum call duration is set to 10 seconds and an IP phone hangs up a call established with a BRI phone after 2 seconds. As the call duration is less than the minimum call duration, the device does not disconnect the call on the Tel side. However, it sends a SIP 200 OK immediately upon receipt of the BYE to disconnect from the IP phone. The call is disconnected from the Tel side only when the call duration is greater than or equal to the minimum call duration.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable to IP-to-Tel and Tel-to-IP calls.</li> <li>▪ The parameter is applicable only to ISDN and CAS protocols.</li> </ul> |
| Disconnect on Dial Tone<br>disc-on-dial-tone<br>[DisconnectOnDialTone]                         | <p>Determines whether the device disconnects a call when a dial tone is detected from the PBX.</p> <ul style="list-style-type: none"> <li>▪ [0] Disable = (Default) Call is not released.</li> <li>▪ [1] Enable = Call is released if a dial tone is detected on the device's FXO port.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to FXO interfaces.</li> <li>▪ This option is in addition to the mechanism that disconnects a call when either busy or reorder tones are detected.</li> </ul>                                                                                                                                                                                                                                                          |
| Send Digit Pattern on Connect<br>digit-pttrn-on-conn<br>[TelConnectCode]                       | <p>Defines a digit pattern to send to the Tel side after a SIP 200 OK is received from the IP side. The digit pattern is a user-defined DTMF sequence that is used to indicate an answer signal (e.g., for billing).</p> <p>The valid range is 1 to 8 characters.</p> <p><b>Note:</b> The parameter is applicable only to FXO/CAS.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Disconnect on Broken Connection<br>disc-broken-conn<br>[DisconnectOnBrokenConnection]          | <p>Global parameter that defines the device's handling of calls if RTP packets are not received within a user-defined timeout (configured by the BrokenConnectionEventTimeout parameter). You can also configure this functionality per specific calls, using IP Profiles (IpProfile_DisconnectOnBrokenConnection). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.</p> <p><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.</p>                                                                                                                                                            |
| Broken Connection Timeout<br>broken-connection-event-timeout<br>[BrokenConnectionEventTimeout] | <p>Defines the time period (in 100-msec units) after which a call is disconnected if an RTP packet is not received.</p> <p>The valid range is from 3 (i.e., 300 msec) to an unlimited value (e.g., 20 hours). The default is 100 (i.e., 10000 msec or 10 seconds).</p> <p><b>Notes:</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Parameter                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Trunk Alarm Call Disconnect Timeout<br>trk-alm-call-disc-to<br>[TrunkAlarmCallDisconnectTimeout]   | Defines the duration (in seconds) to wait after a E1/T1/BRI trunk "Red" alarm (LOS / LOF) is raised, before the device disconnects the SIP call. If this timeout expires and the alarm is still raised, the device sends a SIP BYE message to terminate the call. If the alarm is cleared before this timeout expires, the call is not terminated, but continues as normal. The range is 1 to 3600. The default is 0 (20 for BRI, 20 for E1 and 40 for T1).                                                                                                                                                                                                                                                                                                                                        |
| Disconnect Call on Busy Tone Detection (ISDN)<br>disc-on-busy-tone-i<br>[ISDNDisconnectOnBusyTone] | Determines whether a call is disconnected upon detection of a busy tone (for ISDN). <ul style="list-style-type: none"> <li>[0] Disable = (Default) Do not disconnect call upon detection of busy tone.</li> <li>[1] Enable = Disconnect call upon detection of busy tone.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>The parameter is applicable only to ISDN protocols.</li> <li>IP-to-ISDN calls are disconnected on detection of SIT tones only in call alert state. If the call is in connected state, the SIT does not disconnect the calls. Detection of busy or reorder tones disconnects the IP-to-ISDN calls also in call connected state.</li> <li>For IP-to-CAS calls, detection of busy, reorder, or SIT tones disconnect the calls in any call state.</li> </ul> |
| Disconnect Call on Busy Tone Detection<br>disc-on-busy-tone-c<br>[DisconnectOnBusyTone]            | Determines whether a call is disconnected upon detection of a busy tone. <ul style="list-style-type: none"> <li><b>[0]</b> Disable = Call is not disconnected upon detection of a busy tone.</li> <li><b>[1]</b> Enable = (Default) Call is released upon detection of busy or reorder (fast busy) tone.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXO and CAS.</li> <li>The parameter can also be configured in a Tel Profile.</li> </ul>                                                                                                                                                                                                                                                                                               |
| Polarity (Current) Reversal for Call Release (Analog Interfaces) Parameters                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| fxs-fxo > default-linepolarity-state<br>[SetDefaultLinePolarityState]                              | Defines the FXO line polarity, required for DID signaling. <ul style="list-style-type: none"> <li>[0] = Positive line polarity</li> <li>[1] = Negative line polarity</li> <li>[2] = (Default) Auto - The device detects the polarity upon power-up or upon insertion of the RJ-11 cable, and uses it as a reference polarity.</li> </ul> Typically, if the RJ-11 cabling is connected correctly (without crossing, Tip to Tip, Ring to Ring), the Tip line is positive compared to the Ring line. In this case, set the parameter to 0. With this configuration, the device assumes that the idle line polarity is Tip line positive.                                                                                                                                                              |

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

The default is 4 Volts.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXO interfaces.</li> <li>For the parameter to take effect, a device reset is required.</li> </ul>                                                                                                                                                                                             |
| time-to-sample-analog-line-voltage<br>[TimeToSampleAnalogLineVoltage] | <p>Defines the frequency at which the analog line voltage is sampled (after offhook), for detection of the current disconnect threshold.</p> <p>The valid range is 100 to 2500 msec. The default is 1000 msec.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXO interfaces.</li> <li>For the parameter to take effect, a device reset is required.</li> </ul>                                                                                                                                            |

## 63.10.9 Tone Parameters

This subsection describes the device's tone parameters.

### 63.10.9.1 Telephony Tone Parameters

The telephony tone parameters are described in the table below.

**Table 63-63: Tone Parameters**

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIP Hold Behavior<br>sip-hold-behavior<br>[SIPHoldBehavior] | <p>Enables the device to handle incoming re-INVITE messages with the "a=sendonly" attribute in the SDP, in the same way as if an "a=inactive" is received in the SDP. When enabled, the device plays a held tone to the Tel phone and responds with a SIP 200 OK containing the "a=recvnly" attribute in the SDP.</p> |

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                    | <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Dial Tone Duration<br>dt-duration<br>[TimeForDialTone]                             | <p>Defines the duration (in seconds) that the dial tone is played (for digital interfaces, to an ISDN terminal).</p> <p>For digital interfaces: The parameter is applicable for overlap dialing when ISDNInCallsBehavior is set to 65536. The dial tone is played if the ISDN Setup message doesn't include the called number.</p> <p>The valid range is 0 to 60. The default is 5.</p> <p>For analog interfaces: FXS interfaces play the dial tone after the phone is picked up (off-hook). FXO interfaces play the dial tone after the port is seized in response to ringing (from PBX/PSTN).</p> <p>The valid range is 0 to 60. The default time is 16.</p> <p>Notes for analog interfaces:</p> <ul style="list-style-type: none"> <li>▪ During play of dial tone, the device waits for DTMF digits.</li> <li>▪ The parameter is not applicable when Automatic Dialing is enabled.</li> </ul>                                                        |
| Stutter Tone Duration<br>sttr-tone-duration<br>[StutterToneDuration]               | <p>Defines the duration (in msec) of the confirmation tone. A stutter tone is played (instead of a regular dial tone) when a Message Waiting Indication (MWI) is received. The stutter tone is composed of a confirmation tone (Tone Type #8), which is played for the defined duration (StutterToneDuration) followed by a stutter dial tone (Tone Type #15). Both these tones are defined in the CPT file.</p> <p>The range is 1,000 to 60,000. The default is 2,000 (i.e., 2 seconds).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter is applicable only to FXS interfaces.</li> <li>▪ If you want to configure the duration of the confirmation tone to longer than 16 seconds, you must increase the value of the parameter TimeForDialTone accordingly.</li> <li>▪ The MWI tone overrides the call forwarding reminder tone. For more information on MWI, see Message Waiting Indication on page 573.</li> </ul> |
| FXO AutoDial Play BusyTone<br>fxo-autodial-play-bsytn<br>[FXOAutoDialPlayBusyTone] | <p>Determines whether the device plays a busy / reorder tone to the PSTN side if a Tel-to-IP call is rejected by a SIP error response (4xx, 5xx or 6xx). If a SIP error response is received, the device seizes the line (off-hook), and then plays a busy / reorder tone to the PSTN side (for the duration defined by the parameter TimeForReorderTone). After playing the tone, the line is released (on-hook).</p> <ul style="list-style-type: none"> <li>▪ [0] = Disable (default)</li> <li>▪ [1] = Enable</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXO interfaces.</p>                                                                                                                                                                                                                                                                                                                                                      |
| Hotline Dial Tone Duration<br>hotline-dt-dur<br>[HotLineToneDuration]              | <p>Defines the duration (in seconds) of the hotline dial tone. If no digits are received during this duration, the device initiates a call to a user-defined number (configured in the Automatic Dialing table - TargetOfChannel - see Configuring Automatic Dialing on page 608).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Play Busy Tone to Tel<br><code>play-busy-tone-2tel</code><br>[PlayBusyTone2ISDN]                                                                                                             | <p>Enables the device to play a busy or reorder tone to the PSTN after a Tel-to-IP call is released.</p> <ul style="list-style-type: none"> <li>[0] Don't Play = (Default) Immediately sends an ISDN Disconnect message.</li> <li>[1] Play when Disconnecting = Sends an ISDN Disconnect message with PI = 8 and plays a busy or reorder tone to the PSTN (depending on the release cause).</li> <li>[2] Play before Disconnect = Delays the sending of an ISDN Disconnect message for a user-defined time (configured by the TimeForReorderTone parameter) and plays a busy or reorder tone to the PSTN. This is applicable only if the call is released from the IP [Busy Here (486) or Not Found (404)] before it reaches the Connect state; otherwise, the Disconnect message is sent immediately and no tones are played.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital PSTN interfaces.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <code>configure voip &gt; gw</code><br><code>digitalgw digital-gw-</code><br><code>parameters &gt; q850-reason-</code><br><code>code-2play-user-tone</code><br>[Q850ReasonCode2PlayUserTone] | <p>Defines an ISDN Q.8931 release cause code(s), which if mapped to the SIP release reason received from the IP side, causes the device to play a user-defined tone from the installed PRT file to the Tel side. For example, if the received SIP release cause is 480 Temporarily Unavailable and you configure the parameter with Q.931 release code 18 (No User Responding), the device plays the user-defined tone to the Tel side.</p> <p>The user-defined tone is configured when creating the PRT file, using AudioCodes DConvert utility. The tone must be assigned to the "acSpecialConditionTone" (Tone Type 21) option in DConvert.</p> <p>The parameter can be configured with up to 10 release codes. When configuring multiple codes, separate the codes by commas (without spaces). For example:</p> <p><code>Q850ReasonCode2PlayUserTone = 1,18,24</code></p> <p>If the SIP release reason received from the IP side is mapped to the Q.931 release code specified by the parameter, the device plays the user-defined tone. Otherwise, if not specified and the release code is 17 (User Busy), the device plays the busy tone and for all other release codes, the device plays the reorder tone.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to digital PSTN interfaces.</li> <li>To enable the feature, the 'Play Busy Tone to Tel' (PlayBusyTone2ISDN) parameter must be enabled (set to 1 or 2).</li> </ul> |

| Parameter                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|-----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|           | <ul style="list-style-type: none"> <li>✓ If the device receives a SIP 180 Ringing response (with or without SDP) and the LocalISDNRBSource parameter is set to 1, it plays a ringback tone and sends an ISDN Alert with PI = 8 (unless the ProgressIndicator2ISDN_x parameter is configured differently).</li> <li>✓ If the LocalISDNRBSource parameter is set to 0, the device doesn't play a ringback tone and an Alert message without PI is sent to the ISDN. In this case, the PBX / PSTN plays the ringback tone to the originating terminal. Note that the receipt of a 183 response does not cause the device to play a ringback tone; the device sends a Progress message (unless SIP183Behaviour is set to 1). If the SIP183Behaviour parameter is set to 1, the 183 response is handled the same way as a 180 Ringing response.</li> <li>▪ [2] Prefer IP = Plays according to 'Early Media'. If a SIP 180 response is received and the voice channel is already open (due to a previous 183 early media response or due to an SDP in the current 180 response), the device configured for ISDN / CAS doesn't play the ringback tone; PI = 8 is sent in an ISDN Alert message (unless the ProgressIndicator2ISDN_x parameter is configured differently).<br/>If a 180 response is received, but the 'early media' voice channel is not opened, the device configured for CAS plays a ringback tone to the PSTN. The device configured for ISDN operates according to the LocalISDNRBSource parameter: <ul style="list-style-type: none"> <li>✓ If LocalISDNRBSource is set to 1, the device plays a ringback tone and sends an ISDN Alert with PI = 8 to the ISDN (unless the ProgressIndicator2ISDN_x parameter is configured differently).</li> <li>✓ If LocalISDNRBSource is set to 0, the device doesn't play a ringback tone. No PI is sent in the ISDN Alert message (unless the ProgressIndicator2ISDN_x parameter is configured differently). In this case, the PBX / PSTN plays a ringback tone to the originating terminal. Note that the receipt of a 183 response results in an ISDN Progress message (unless SIP183Behaviour is set to 1). If SIP183Behaviour is set to 1 (183 is handled the same way as a 180 with SDP), the device sends an Alert message with PI = 8 without playing a ringback tone.</li> </ul> </li> <li>▪ [3] Play Local Until Remote Media Arrive = Plays tone according to received media. The behaviour is similar to option [2]. If a SIP 180 response is received and the voice channel is already open (due to a previous 183 early media response or due to an SDP in the current 180 response), the device plays a local ringback tone if there are no prior received RTP packets. The device stops playing the local ringback tone as soon as it starts receiving RTP packets. At this stage, if the device receives additional 18x responses, it does not resume playing the local ringback tone. Note that for ISDN trunks, this option is applicable only if LocalISDNRBSource is set to 1.</li> </ul> |

| Parameter                                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|                                                                     | <ul style="list-style-type: none"> <li>SITDetectorEnable = 1</li> <li>UserDefinedToneDetectorEnable = 1</li> <li>DisconnectOnBusyTone = 1 (applicable for busy, reorder, and SIT tones)</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>The IP-to-ISDN call is disconnected on detection of a SIT tone only in call alert state. If the call is in connected state, the SIT does not disconnect the call. Detection of busy or reorder tones disconnect these calls also in call connected state.</li> <li>For IP-to-CAS calls, detection of busy, reorder, or SIT tones disconnect the call in any call state.</li> </ul> |
| udt-detector-frequency-deviation<br>[UDTDetectorFrequencyDeviation] | Defines the deviation (in Hz) allowed for the detection of each signal frequency.<br>The valid range is 1 to 50. The default is 50.<br><p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| cpt-detector-frequency-deviation<br>[CPTDetectorFrequencyDeviation] | Defines the deviation (in Hz) allowed for the detection of each CPT signal frequency.<br>The valid range is 1 to 30. The default is 10.<br><p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 63.10.9.3 Metering Tone Parameters

The metering tone parameters are described in the table below.

**Table 63-65: Metering Tone Parameters**

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate Metering Tones<br>gen-mtr-tones<br>[PayPhoneMeteringMode] | Defines the method for configuring metering tones that are generated to the Tel side. <ul style="list-style-type: none"> <li><b>[0]</b> Disable = (Default) Metering tones are not generated.</li> <li><b>[1]</b> Internal Table = Metering tones are generated by the device according to the Charge Code table (see Configuring Charge Codes on page 598) and sent to the Tel side.</li> <li><b>[2]</b> SIP Interval Provided = (Proprietary method of TELES Communications Corporation) Advice-of-Charge service toward the PSTN. Periodic generation of AOC-D and AOC-E toward the PSTN. Calculation is based on seconds. The time interval is calculated according to the scale and tariff provided in the proprietary formatted file included in SIP INFO messages, which is always sent before 200 OK. The device ignores tariffs sent after the call is established.</li> <li><b>[3]</b> SIP RAW Data Provided = (Proprietary method of Cirpack) Advice-of-Charge service toward the PSTN. The received AOC-D messages contain a subtotal. When receiving AOC-D in raw format, provided in the header of SIP INFO messages, the device parses AOC-D raw data to obtain the number of units. This number is sent</li> </ul> |

| Parameter                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                  | <p>in the Facility message with AOC-D. In addition, the device stores the latest number of units in order to send them in AOC-E IE when the call is disconnected.</p> <ul style="list-style-type: none"> <li>[4] SIP RAW Data Incremental Provided = (Proprietary method of Cirpack) Advice-of-Charge service toward the PSTN. The AOC-D message in the payload is an increment. When receiving AOC-D in raw format, provided in the header of SIP INFO messages, the device parses AOC-D raw data to obtain the number of units. This number is sent in the Facility message with AOC-D. The device generates the AOC-E. Parsing every AOC-D received and summing the values is required to obtain the total sum (that is placed in the AOC-E).</li> <li>[5] SIP 2 TEL INTERWORKING = Enables IP-to-Tel AOC, using AudioCodes' proprietary SIP header, AOC.</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXS interfaces and ISDN Euro trunks for sending AOC Facility messages (see Advice of Charge Services for Euro ISDN on page 596).</p> |
| Analog Metering Type<br>metering-type<br>[MeteringType]                          | <p>Determines the metering method for generating pulses (sinusoidal metering burst frequency) by the FXS port.</p> <ul style="list-style-type: none"> <li>[0] 12 KHz = (Default) 12 kHz sinusoidal bursts.</li> <li>[1] 16 KHz = 16 kHz sinusoidal bursts.</li> <li>[2] = Polarity Reversal pulses.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the parameter to take effect, a device reset is required.</li> <li>The parameter is applicable only to FXS interfaces.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 63.10.10 Telephone Keypad Sequence Parameters

The telephony keypad sequence parameters are described in the table below.

**Table 63-66: Telephone Keypad Sequence Parameters**

| Parameter                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Call Pickup Key<br><code>sip-definition advanced-settings &gt; call-pickup-key</code><br><code>[KeyCallPickup]</code> | Defines the keying sequence for performing a call pick-up. Call pick-up allows the FXS endpoint to answer another telephone's incoming call by pressing this user-defined sequence of digits. When the user dials these digits (e.g., #77), the incoming call from another phone is forwarded to the user's phone.<br>The valid value is a string of up to 15 characters (0-9, #, and *). By default, no value is defined.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>Call pick-up is configured only for FXS endpoints pertaining to the same Trunk Group.</li> <li>The parameter is applicable only to FXS interfaces.</li> </ul>                                                                                                                     |
| <b>Prefix for External Line</b>                                                                                       |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <code>[Prefix2ExtLine]</code>                                                                                         | Defines a string prefix (e.g., '9' dialed for an external line) that when dialed, the device plays a secondary dial tone (i.e., stutter tone) to the FXS line and then starts collecting the subsequently dialed digits from the FXS line.<br>The valid range is a one-character string. By default, no value is defined.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>You can enable the device to add this string as the prefix to the collected (and sent) digits, using the parameter <code>AddPrefix2ExtLine</code>.</li> <li>The parameter is applicable only to FXS interfaces.</li> </ul>                                                                                                                                                         |
| <code>prefix-2-ext-line</code><br><code>[AddPrefix2ExtLine]</code>                                                    | Determines whether the prefix string for accessing an external line (defined by the parameter <code>Prefix2ExtLine</code> ) is added to the dialed number as the prefix and together sent to the IP destination (Tel-to-IP calls). <ul style="list-style-type: none"> <li><b>[0]</b> = Disable (default)</li> <li><b>[1]</b> = Enable</li> </ul> For example, if the parameter is enabled and the prefix string for the external line is defined as "9" (using the parameter <code>Prefix2ExtLine</code> ) and the FXS user wants to make a call to destination "123", the device collects and sends all the dialed digits, including the prefix string, as "9123" to the IP destination number.<br><b>Note:</b> The parameter is applicable only to FXS interfaces. |
| <b>Hook Flash Parameters</b>                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Keypad Feature - Call Waiting Parameters</b>                                                                                                                                                                                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                         | Description                                                                                                                                                                                 |
|-------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Call Waiting Activate<br>cw-act<br>[KeyCallWaiting]               | Defines the keypad sequence to activate the Call Waiting option. After the sequence is pressed, a confirmation tone is heard.                                                               |
| Call Waiting Deactivate<br>cw-deact<br>[KeyCallWaitingDeact]      | Defines the keypad sequence to deactivate the Call Waiting option. After the sequence is pressed, a confirmation tone is heard.                                                             |
| <b>Keypad Feature - Reject Anonymous Call Parameters</b>          |                                                                                                                                                                                             |
| Reject Anonymous Call Activate<br>[KeyRejectAnonymousCall]        | Defines the keypad sequence to activate the reject anonymous call option, whereby the device rejects incoming anonymous calls. After the sequence is pressed, a confirmation tone is heard. |
| Reject Anonymous Call Deactivate<br>[KeyRejectAnonymousCallDeact] | Defines the keypad sequence that de-activates the reject anonymous call option. After the sequence is pressed, a confirmation tone is heard.                                                |

### 63.10.11 FXO and FXS Parameters

The general FXO and FXS parameters are described in the table below.

**Table 63-67: General FXO and FXS Parameters**

| Parameter                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Update Port Info<br>[AnalogPortInfo_x ]                                      | <p>Defines an arbitrary name for an analog (FXS or FXO) port. This can be used to easily identify the port.</p> <p>The valid value is a string of up to 40 characters. By default, the value is undefined.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For the ini file parameter, the x denotes the port number.</li> <li>For configuring a port name through the Web interface, see "Assigning a Port Name" on page 74.</li> </ul> |
| <b>FXS Parameters</b>                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FXS Coefficient Type<br>fxs-country-coefficients<br>[FXSCountryCoefficients] | <p>Determines the FXS line characteristics (AC and DC) according to USA or Europe (TBR21) standards.</p> <ul style="list-style-type: none"> <li><b>[66]</b> Europe = TBR21</li> <li><b>[70]</b> USA = (Default) United States</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                               |
| <b>FXO Parameters</b>                                                        |                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| FXO Coefficient Type<br>fxo-country-coefficients<br>[CountryCoefficients]    | <p>Determines the FXO line characteristics (AC and DC) according to USA or TBR21 standard.</p> <ul style="list-style-type: none"> <li><b>[66]</b> Europe = TBR21</li> <li><b>[70]</b> USA = (Default) United States</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                         |
| fxo-dc-termination                                                           | Defines the FXO line DC termination (i.e., resistance).                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

If the dial tone is not detected within 6 seconds, the device releases the call and sends a SIP 500 "Server Internal Error" response.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Time to Wait before Dialing<br>time-wait-b4-dialing<br>[WaitForDialTime]           | <p>For digital interfaces: Defines the delay after hook-flash is generated and until dialing begins. Applies to call transfer (i.e., the parameter TrunkTransferMode is set to 3) on CAS protocols.</p> <p>For analog interfaces: Defines the delay before the device starts dialing on the FXO line in the following scenarios:</p> <ul style="list-style-type: none"> <li>The delay between the time the line is seized and dialing begins during the establishment of an IP-to-Tel call.<br/><b>Note:</b> Applicable only for one-stage dialing when the parameter IsWaitForDialTone is disabled.</li> <li>The delay between detection of a Wink and the start of dialing during the establishment of an IP-to-Tel call (for DID lines, see the EnableDIDWink parameter).</li> <li>For call transfer - the delay after hook-flash is generated and dialing begins.</li> </ul> <p>The valid range (in milliseconds) is 0 to 20,000 (i.e., 20 seconds). The default is 1,000 (i.e., 1 second).</p>                                                                                                                                                                                                                                                    |
| Ring Detection Timeout<br>ring-detection-tout<br>[FXOBetweenRingTime]              | <p>Defines the timeout (in seconds) for detecting the second ring after the first detected ring.</p> <p>If automatic dialing is not used and Caller ID is enabled, the device seizes the line after detection of the second ring signal (allowing detection of caller ID sent between the first and the second rings). If the second ring signal is not received within this timeout, the device doesn't initiate a call to IP.</p> <p>If automatic dialing is used, the device initiates a call to IP when the ringing signal is detected. The FXO line is seized only if the remote IP party answers the call. If the remote party doesn't answer the call and the second ring signal is not received within this timeout, the device releases the IP call.</p> <p>The parameter is typically set to between 5 and 8. The default is 8.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only for Tel-to-IP calls.</li> <li>This timeout is calculated from the end of the ring until the start of the next ring. For example, if the ring cycle is two seconds on and four seconds off, the timeout value should be configured to five seconds (i.e., greater than the off time, e.g., four).</li> </ul> |
| Rings before Detecting Caller ID<br>rings-b4-det-callerid<br>[RingsBeforeCallerID] | <p>Determines the number of rings before the device starts detecting Caller ID.</p> <ul style="list-style-type: none"> <li><b>[0]</b> 0 = Before first ring.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Parameter                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Guard Time Between Calls<br>guard-time-btwn-calls<br>[GuardTimeBetweenCalls] | <p>Defines the time interval (in seconds) after a call has ended and a new call can be accepted for IP-to-Tel (FXO) calls. The valid range is 0 to 10. The default is 1.</p> <p><b>Note:</b> Occasionally, after a call ends and on-hook is applied, a delay is required before placing a new call (and performing off-hook). This is necessary to prevent incorrect hook-flash detection or other glare phenomena.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| FXO Double Answer<br>fxo-dbl-ans<br>[EnableFXODoubleAnswer]                  | <p>Enables the FXO Double Answer feature, which rejects (disconnects) incoming Tel (FXO)-to-IP collect calls and signals (informs) this call denial to the PSTN.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p><b>Note:</b> The parameter can be configured for a Tel Profile.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| FXO Ring Timeout<br>fxo-ring-timeout<br>[FXORingTimeout]                     | <p>Defines the delay (in msec) before the device generates a SIP INVITE (call) to the IP side upon detection of a RING_START event from the Tel (FXO) side. This occurs instead of waiting for a RING_END event.</p> <p>This feature is useful for telephony services that employ constant ringing (i.e., no RING_END is sent). For example, Ringdown circuit is a service that sends a constant ringing current over the line, instead of cadence-based 2 second on, 4 second off. For example, when a telephone goes off-hook, a phone at the other end instantly rings.</p> <p>If a RING_END event is received before the timeout expires, the device does not initiate a call and ignores the detected ring. The device ignores RING_END events detected after the timeout expires.</p> <p>The valid value range is 0 to 50 (msec), in steps of 100-msec. For example, a value of 50 represents 5 sec. The default value is 0 (i.e., standard ring operation - the FXO interface sends an INVITE upon receipt of the RING_END event).</p> <p><b>Note:</b> The parameter can be configured for a Tel Profile.</p> |

### 63.10.12 Trunk Groups and Routing Parameters

The routing parameters are described in the table below.

**Table 63-68: Routing Parameters**

| Parameter                                                                                   | Description                                                                                                                                                |
|---------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Trunk Group Table                                                                           |                                                                                                                                                            |

The parameter applies to the following:</p> <ul style="list-style-type: none"> <li>All Trunk Groups configured without a channel select mode in the Trunk Group Settings table (see "Configuring Trunk Group Settings" on page 485).</li> <li>All channels and trunks configured without a Trunk Group ID.</li> </ul> <p>for all Trunk Groups channels that are configured without a Trunk Group ID,.</p> <ul style="list-style-type: none"> <li><b>[0]</b> By Dest Phone Number</li> <li><b>[1]</b> Cyclic Ascending (default)</li> <li><b>[2]</b> Ascending</li> <li><b>[3]</b> Cyclic Descending</li> <li><b>[4]</b> Descending</li> <li><b>[5]</b> Dest Number + Cyclic Ascending.</li> <li><b>[6]</b> By Source Phone Number</li> <li><b>[7]</b> Trunk Cyclic Ascending</li> <li><b>[8]</b> Trunk &amp; Channel Cyclic Ascending</li> <li><b>[9]</b> Ring to Hunt Group</li> <li><b>[10]</b> Select Trunk By Supplementary Service Table</li> <li><b>[11]</b> Dest Number + Ascending</li> </ul> <p>For a detailed description of the parameter's options, see "Configuring Trunk Group Settings" on page 485.</p> |

| Parameter                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Destination Number<br>dflt-dest-nb<br>[DefaultNumber]                              | Defines the default destination phone number, which is used if the received message doesn't contain a called party number and no phone number is configured in the Trunk Group table (see Configuring the Trunk Groups on page 483). The parameter is used as a starting number for the list of channels comprising all the device's Trunk Groups. The default is 1000.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Source IP Address Input<br>src-ip-addr-input<br>[SourceIPAddressInput]                     | Determines which IP address the device uses to determine the source of incoming INVITE messages for IP-to-Tel routing. <ul style="list-style-type: none"> <li>▪ <b>[-1]</b> = (Default) Auto Decision - the parameter is automatically set to SIP Contact Header (1).</li> <li>▪ <b>[0]</b> SIP Contact Header = The IP address in the Contact header of the incoming INVITE message is used.</li> <li>▪ <b>[1]</b> Layer 3 Source IP = The actual IP address (Layer 3) from where the SIP packet was received is used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Use Source Number As Display Name<br>src-nb-as-disp-name<br>[UseSourceNumberAsDisplayName] | Determines the use of Tel Source Number and Display Name for Tel-to-IP calls. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No = (Default) If a Tel Display Name is received, the Tel Source Number is used as the IP Source Number and the Tel Display Name is used as the IP Display Name. If no Display Name is received from the Tel side, the IP Display Name remains empty.</li> <li>▪ <b>[1]</b> Yes = If a Tel Display Name is received, the Tel Source Number is used as the IP Source Number and the Tel Display Name is used as the IP Display Name. If no Display Name is received from the Tel side, the Tel Source Number is used as the IP Source Number and also as the IP Display Name.</li> <li>▪ <b>[2]</b> Overwrite = The Tel Source Number is used as the IP Source Number and also as the IP Display Name (even if the received Tel Display Name is not empty).</li> <li>▪ <b>[3]</b> Original = Similar to option [2], except that the operation is done before regular calling number manipulation.</li> </ul> |
| Use Display Name as Source Number<br>disp-name-as-src-nb<br>[UseDisplayNameAsSourceNumber] | Defines how the display name (caller ID) received from the IP side (in the SIP From header) effects the source number sent to the Tel side, for IP-to-Tel calls. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No = (Default) If a display name is received from the IP side, the source number of the IP side is used as the Tel source number.</li> <li>▪ <b>[1]</b> Yes = If a display name is received from the IP side, the display name of the IP side is used as the Tel source number and Presentation is set to Allowed (0). If no display name is received from the IP side, the source number of the IP side is used as the Tel source number and Presentation is set to Restricted (1). For example:               <ul style="list-style-type: none"> <li>✓ If 'From: 100 &lt;sip:200@201.202.203.204&gt;' is received from the IP side, the outgoing source number (and display name) are set to "100" and Presentation is set to Allowed (0).</li> </ul> </li> </ul>                                                      |

| Parameter                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                             | <ul style="list-style-type: none"> <li>✓ If 'From: &lt;sip:400@101.102.103.104&gt;' is received from the IP side, the outgoing source number is set to "400" and Presentation is set to Restricted (1).</li> <li>▪ [2] Preferred = If a display name is received from the IP side, the display name of the IP side is used as the Tel source number. If no display name is received from the IP side, this setting does not affect the Tel source number.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                      |
| ENUM Resolution<br>enum-service-domain<br>[EnumService]                                                     | Defines the ENUM service for translating telephone numbers to IP addresses or domain names (FQDN), for example, e164.arpa, e164.customer.net, or NRENum.net.<br>The valid value is a string of up to 50 characters. The default is "e164.arpa".<br><b>Note:</b> ENUM-based routing is configured in the Tel-to-IP Routing table using the "ENUM" string value as the destination address to denote the parameter's value.                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Use Routing Table for Host Names and Profiles<br>rte-tbl-4-host-names<br>[AlwaysUseRouteTable]              | Determines whether to use the device's routing table to obtain the URI host name and optionally, an IP profile (per call) even if a Proxy server is used.<br><ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) Don't use the Tel-to-IP Routing table.</li> <li>▪ <b>[1]</b> Enable = Use the Tel-to-IP Routing table.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The parameter appears only if the 'Use Default Proxy' parameter is enabled.</li> <li>▪ The domain name is used instead of a Proxy name or IP address in the INVITE SIP URI.</li> </ul>                                                                                                                                                                                                                                                                      |
| Tel to IP Routing Mode<br>onfigure voip > gw routing general-setting > tel2ip-rte-mode<br>[RouteModeTel2IP] | Determines whether to route Tel calls to an IP destination before or after manipulation of the destination number. This applies to Tel-to-IP routing rules configured in the Tel-to-IP Routing table.<br><ul style="list-style-type: none"> <li>▪ <b>[0]</b> Route calls before manipulation = Calls are routed before the number manipulation rules are applied (default).</li> <li>▪ <b>[1]</b> Route calls after manipulation = Calls are routed after the number manipulation rules are applied.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The parameter is not applicable if outbound proxy routing is used.</li> <li>▪ For number manipulation, see "Configuring Source/Destination Number Manipulation" on page 493.</li> <li>▪ For configuring Tel-to-IP routing rules, see "Configuring Tel-to-IP Routing Rules" on page 524.</li> </ul> |
| <b>Tel-to-IP Routing table</b>                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <p>IP Security</p> <pre>ip-security</pre> <p>[SecureCallsFromIP]</p>                                          | <p>Determines the device's policy on accepting or blocking SIP calls (IP-to-Tel calls). This is useful in preventing unwanted SIP calls, SIP messages, and/or VoIP spam.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = (Default) The device accepts all SIP calls.</li> <li>▪ <b>[1]</b> Secure Incoming calls = The device accepts SIP calls (i.e., calls from the IP side) only from IP addresses that are configured in the Tel-to-IP Routing table or Proxy Set table, or IP addresses resolved from DNS servers from FQDN values configured in the Proxy Set table. All other incoming calls are rejected.</li> <li>▪ <b>[2]</b> Secure All calls = The device accepts SIP calls only from IP addresses (in dotted-decimal notation format) that are defined in the Tel-to-IP Routing table or Proxy Set table, and rejects all other incoming calls. In addition, if an FQDN is defined in the routing table or Proxy Set table, the call is allowed to be sent only if the resolved DNS IP address appears in one of these tables; otherwise, the call is rejected. Therefore, the difference between this option and option [1] is that this option is concerned only about numerical IP addresses that are defined in the tables.</li> </ul> |

| Parameter                                                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | <p>the ISDN. The 'cic' parameter is a three- or four-digit code used in routing tables to identify the network that serves the remote user when a call is routed over many different networks. The 'cic' parameter is carried in the SIP INVITE and maps to the ISDN Transit Network Selection Information Element (TNS IE) in the outgoing ISDN Setup message (if the EnableCIC parameter is set to 1). The TNS IE identifies the requested transportation networks and allows different providers equal access support, based on customer choice. For example, as a result of receiving the below INVITE, the destination number after number manipulation is cic+167895550001:</p> <p>INVITE<br/>sip:5550001;cic=+16789@172.18.202.60:5060;user=phone SIP/2.0</p> <p><b>Note:</b> After the cic prefix is added, the IP to Trunk Group Routing table can be used to route this call to a specific Trunk Group. The Destination Number IP to Tel Manipulation table must be used to remove this prefix before placing the call to the ISDN.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| [FaxReroutingMode] | <p>Enables the re-routing of incoming Tel-to-IP calls that are identified as fax calls. If a CNG tone is detected on the Tel side of a Tel-to-IP call, the device adds the string, "FAX" as a prefix to the destination number before routing and manipulation. A routing rule in the Tel-to-IP Routing table having the value "FAX" (case-sensitive) as the destination number is then used to re-route the call to a fax destination and the destination number manipulation mechanism is used to remove the "FAX" prefix before sending the fax, if required. If the initial INVITE used to establish the voice call (not fax) was already sent, a CANCEL (if not connected yet) or a BYE (if already connected) is sent to release the voice call.</p> <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Rerouting without Delay = Upon detection of a CNG tone, the device immediately releases the call of the initial INVITE and then sends a new INVITE to a specific IP Group or fax server according to the Tel-to-IP Routing table. To enable this feature, set the CNGDetectorMode parameter to 2 and the IsFaxUsed parameter to 1, 2, or 3.</li> <li>▪ [2] Progress and Delay = (Applicable only to ISDN). Incoming ISDN calls are delayed until a CNG tone detection or timeout, set by the FaxReroutingDelay parameter. If the EnableComfortTone parameter is set to 1, a Q.931 Progress message with Protocol Discriminator set to 1 is sent to the PSTN and a comfort tone is played accordingly to the PSTN. When the timeout expires, the device sends an INVITE to a specific IP Group or to a fax server, according to the Tel-to-IP Routing table rules.</li> <li>▪ [3] Connect and Delay = (Applicable only to ISDN). Incoming ISDN calls are delayed until a CNG tone detection or timeout, set by the FaxReroutingDelay</li> </ul> |

| Parameter                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                    | <p>parameter. A Q.931 Connect message is sent to the PSTN. If the EnableComfortTone parameter is set to 1, a comfort tone is played to the PSTN. When the timeout expires, the device sends an INVITE to a specific IP Group or to a fax server according to the Tel-to-IP Routing table rules.</p> <p><b>Note:</b> The parameter has replaced the EnableFaxRerouting parameter. For backward compatibility, the EnableFaxRerouting parameter set to 1 is equivalent to the FaxReroutingMode parameter set to 1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| [FaxReroutingDelay]                                                | <p>Defines the maximum time interval (in seconds) that the device waits for CNG detection before re-routing calls identified as fax calls to fax destinations (terminating fax machine).</p> <p>The valid value range is 1-10. The default is 5.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Call Forking Parameters</b>                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Forking Handling Mode<br>forking-handling<br>[ForkingHandlingMode] | <p>Determines how the device handles the receipt of multiple SIP 18x forking responses for Tel-to-IP calls. The forking 18x response is the response with a different SIP to-tag than the previous 18x response. These responses are typically generated (initiated) by Proxy / Application servers that perform call forking, sending the device's originating INVITE (received from SIP clients) to several destinations, using the same Call ID.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Parallel handling = (Default) If SIP 18x with SDP is received, the device opens a voice stream according to the received SDP and disregards any subsequently received 18x forking responses (with or without SDP). If the first response is 180 without SDP, the device responds according to the PlayRBTone2TEL parameter and disregards the subsequent forking 18x responses.</li> <li>▪ <b>[1]</b> Sequential handling = If 18x with SDP is received, the device opens a voice stream according to the received SDP. The device re-opens the stream according to subsequently received 18x responses with SDP, or plays a ringback tone if 180 response without SDP is received. If the first received response is 180 without SDP, the device responds according to the PlayRBTone2TEL parameter and processes the subsequent 18x forking responses.</li> </ul> <p><b>Note:</b> Regardless of the parameter setting, once a SIP 200 OK response is received, the device uses the RTP information and re-opens the voice stream, if necessary.</p> |
| Forking Timeout<br>forking-timeout<br>[ForkingTimeOut]             | <p>Defines the timeout (in seconds) that is started after the first SIP 2xx response has been received for a User Agent when a Proxy server performs call forking (Proxy server forwards the INVITE to multiple SIP User Agents). The device sends a SIP ACK and BYE in response to any additional SIP 2xx received from the Proxy within this timeout. Once this timeout elapses, the device ignores any subsequent SIP 2xx.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Parameter                                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 63.10.13 IP Connectivity Parameters

The IP connectivity parameters are described in the table below.

**Table 63-69: IP Connectivity Parameters**

| Parameter                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable Alt Routing Tel to IP<br>alt-routing-tel2ip<br>[AltRoutingTel2IPEnable]                        | Enables the Alternative Routing feature for Tel-to-IP calls. <ul style="list-style-type: none"> <li><b>[0]</b> Disable = (Default) Disables the Alternative Routing feature.</li> <li><b>[1]</b> Enable = Enables the Alternative Routing feature.</li> <li><b>[2]</b> Status Only = The Alternative Routing feature is disabled, but read-only information on the QoS of the destination IP addresses is provided.</li> </ul> <p><b>Note:</b> If the parameter is enabled, the Busy Out feature (see EnableBusyOut parameter) does not function with the Proxy Set keep-alive mechanism. To use the Busy Out feature with the Proxy Set keep-alive mechanism (for IP Groups), disable the parameter.</p>                                                                                                                                                                                                                                                                                                                                                                                                           |
| Alt Routing Tel to IP Mode<br>alt-rte-tel2ip-mode<br>[AltRoutingTel2IPMode]                           | Determines the IP Connectivity event(s) reason for triggering Alternative Routing. <ul style="list-style-type: none"> <li><b>[0]</b> None = Alternative routing is not used.</li> <li><b>[1]</b> Connectivity = Alternative routing is performed if SIP OPTIONS message to the initial destination fails (determined according to the AltRoutingTel2IPConnMethod parameter).</li> <li><b>[2]</b> QoS = Alternative routing is performed if poor QoS is detected.</li> <li><b>[3]</b> Both = (Default) Alternative routing is performed if either SIP OPTIONS to initial destination fails, poor QoS is detected, or the DNS host name is not resolved.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>QoS is quantified according to delay and packet loss calculated according to previous calls. QoS statistics are reset if no new data is received within two minutes.</li> <li>To receive quality information (displayed in the 'Quality Status' and 'Quality Info.' fields in "Viewing IP Connectivity" on page 886) per destination, the parameter must be set to 2 or 3.</li> </ul> |
| Alt Routing Tel to IP Connectivity Method<br>alt-rte-tel2ip-method<br>[AltRoutingTel2IPConnMethod]    | Determines the method used by the device for periodically querying the connectivity status of a destination IP address. <ul style="list-style-type: none"> <li><b>[0]</b> ICMP Ping = (Default) Internet Control Message Protocol (ICMP) ping messages.</li> <li><b>[1]</b> SIP OPTIONS = The remote destination is considered offline if the latest OPTIONS transaction timed out. Any response to an OPTIONS request, even if indicating an error, brings the connectivity status to online.</li> </ul> <p><b>Note:</b> ICMP Ping is currently not supported for the IP Connectivity feature.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Alt Routing Tel to IP Keep Alive Time<br>alt-rte-tel2ip-keep-alive<br>[AltRoutingTel2IPKeepAliveTime] | Defines the time interval (in seconds) between SIP OPTIONS Keep-Alive messages used for the IP Connectivity application. The valid range is 5 to 2,000,000. The default is 60.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                                                       | Description                                                                                                                                                                                        |
|-------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Max Allowed Packet Loss for Alt Routing [%]<br>mx-pkt-loss-4-alt-rte<br>[IPConnQoSMaxAllowedPL] | Defines the packet loss (in percentage) at which the IP connection is considered a failure and Alternative Routing mechanism is activated.<br>The default is 20%.                                  |
| Max Allowed Delay for Alt Routing<br>mx-all-dly-4-alt-rte<br>[IPConnQoSMaxAllowedDelay]         | Defines the transmission delay (in msec) at which the IP connection is considered a failure and the Alternative Routing mechanism is activated.<br>The range is 100 to 10,000. The default is 250. |

### 63.10.14 Alternative Routing Parameters

The alternative routing parameters are described in the table below.

**Table 63-70: Alternative Routing Parameters**

| Parameter                                                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3xx Use Alt Route Reasons<br>configure voip/sip-<br>definition advanced-<br>settings/3xx-use-alt-<br>route<br>[UseAltRouteReasonsFor3xx] | Defines the handling of received SIP 3xx responses regarding call redirection to listed contacts in the Contact header. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No = (Default) Upon receipt of a 3xx response, the device tries each contact, one by one, listed in the Contact headers, until a successful destination is found. However, if a contact responds with a 486 or 600, the device does not try to redirect the call to next contact, and drops the call.</li> <li>▪ <b>[1]</b> No if 6xx = Upon receipt of a 3xx response, the device tries each contact, one by one, listed in the Contact headers. However, if a 6xx Global Failure response is received during this process (e.g., 600 Busy Everywhere) the device does not try to redirect the call to the next contact, and drops the call.</li> <li>▪ <b>[2]</b> Yes = Upon receipt of a 3xx response, the device redirects the call to the first contact listed in the Contact header. If the contact responds with a SIP response that is defined in the Reasons for Tel-to-IP Alternative Routing table, the device tries to redirect the call to the next contact, and so on. If a contact responds with a response that is not configured in the table, the device does not try to redirect the call to the next contact, and drops the call.</li> </ul> |
| Redundant Routing Mode<br>redundant-routing-m<br>[RedundantRoutingMode]                                                                  | Determines the type of redundant routing mechanism when a call can't be completed using the main route. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = No redundant routing is used. If the call can't be completed using the main route (using the active Proxy or the first matching rule in the Routing table), the call is disconnected.</li> <li>▪ <b>[1]</b> Routing Table = (Default) Internal routing table is used to locate a redundant route.</li> <li>▪ <b>[2]</b> Proxy = Proxy list is used to locate a redundant route.</li> </ul> <p><b>Note:</b> To implement the Redundant Routing Mode mechanism, you first need to configure the parameter AltRouteCauseTEL2IP (Reasons for Alternative Routing table).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                                                                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [DisconnectCallwithPlifAlt]                                                                                                                    | <p>Defines when the device sends the IP-to-Tel call to an alternative route (if configured) when it receives an ISDN Q.931 Disconnect message from the Tel side.</p> <ul style="list-style-type: none"> <li>[0] (Default) = The device forwards early media to the IP side if Disconnect includes PI, and disconnects the call when a Release message is received. Only after the call is disconnected does the device send the call to an alternative route.</li> <li>[1] = The device immediately sends the call to the alternative route.</li> </ul> <p>For more information, see Alternative Routing upon ISDN Disconnect on page 553.</p>                                                                           |
| [EnableAltMapTel2IP]                                                                                                                           | <p>Enables different Tel-to-IP destination number manipulation rules per routing rule when several (up to three) Tel-to-IP routing rules are defined and if alternative routing using release causes is used. For example, if an INVITE message for a Tel-to-IP call is returned with a SIP 404 Not Found response, the call can be re-sent to a different destination number (as defined using the parameter NumberMapTel2IP).</p> <ul style="list-style-type: none"> <li>[0] = Disable (default)</li> <li>[1] = Enable</li> </ul>                                                                                                                                                                                      |
| [TR104FXOSwitchover]                                                                                                                           | <p>Enables the device to automatically switch the destination of an FXS call from the FXO (PSTN) to the IP (SIP Trunk) when the PSTN disconnects the FXS subscriber.</p> <ul style="list-style-type: none"> <li>[0] = (Default) Disable</li> <li>[1] = Enable</li> </ul> <p>For more information, see Alternative Routing from FXO to IP on page 553.</p>                                                                                                                                                                                                                                                                                                                                                                |
| Alternative Routing Tone Duration<br>alt-rte-tone-duration<br>[AltRoutingToneDuration]                                                         | <p>Defines the duration (in milliseconds) for which the device plays a tone to the endpoint on each attempt for Tel-to-IP alternative routing. When the device finishes playing the tone, a new SIP INVITE message is sent to the new IP destination. The tone played is the call forward tone (Tone Type #25 in the CPT file).</p> <p>The valid range is 0 to 20,000. The default is 0 (i.e., no tone is played).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXS or FXO interfaces.</li> <li>The parameter is applicable only to Tel-to-IP alternative routing based on SIP responses (see Alternative Routing Based on SIP Responses on page 545).</li> </ul> |
| <b>Reasons for Alternative Tel-to-IP Routing Table</b>                                                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Reasons for Alternative Routing<br>configure voip > gw<br>manipulations<br>general-setting alt-<br>route-cause-tel2ip<br>[AltRouteCauseTel2IP] | <p>Defines SIP call failure reason values received from the IP side. If an IP call is released as a result of one of these reasons, the device attempts to locate an alternative IP route for the call in the Tel-to-IP Routing table (if a Proxy is not used) or used as a redundant Proxy (you need to set the parameter RedundantRoutingMode to 2). The release reason for Tel-to-IP calls is provided in SIP 4xx, 5xx, and 6xx response codes.</p> <p>The format of the ini file table parameter is as follows:</p> <p>[AltRouteCauseTel2IP]<br/> FORMAT AltRouteCauseTel2IP_Index =</p>                                                                                                                             |

| Parameter                                                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| [SwapTel2IPCalled&CallingNumbers]                                                | Determines whether the device swaps the calling and called numbers received from the Tel side (for Tel-to-IP calls). The SIP INVITE message contains the swapped numbers. <ul style="list-style-type: none"> <li>[0] = (Default) Disabled</li> <li>[1] = Swap calling and called numbers</li> </ul> <b>Note:</b> The parameter can also be configured for a Tel Profile (in the Tel Profile table).                                                                                                                                                                                                                             |
| Add Prefix to Redirect Number<br>add-pref-to-redir-nb<br>[Prefix2RedirectNumber] | Defines a string prefix that is added to the Redirect number received from the Tel side. This prefix is added to the Redirect Number in the SIP Diversion header.<br><br>The valid range is an 8-character string. By default, no value is defined.                                                                                                                                                                                                                                                                                                                                                                             |
| Add Number Plan and Type to RPI Header<br>np-n-type-to-rpi-hdr<br>[AddTON2RPI]   | Determines whether the TON/PLAN parameters are included in the Remote-Party-ID (RPID) header. <ul style="list-style-type: none"> <li>[0] No</li> <li>[1] Yes (default)</li> </ul> If the Remote-Party-ID header is enabled (EnableRPIHeader = 1) and AddTON2RPI = 1, it's possible to configure the calling and called number type and number plan using the Number Manipulation tables for Tel-to-IP calls.                                                                                                                                                                                                                    |
| Source Manipulation Mode<br>src-manipulation<br>[SourceManipulationMode]         | Determines the SIP headers containing the source number after manipulation: <ul style="list-style-type: none"> <li>[0] = (Default) The SIP From and P-Asserted-Identity headers contain the source number after manipulation.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                        |

The additional manipulation is done on the initially manipulated source number, and this additional rule is also configured in the manipulation table (SourceNumberMapIP2Tel parameter). This enables you to configure only a few manipulation rules for complex number manipulation requirements (that generally require many rules). <ul style="list-style-type: none"> <li>▪ [0] = Disable (default)</li> <li>▪ [1] = Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                       |

| Phone Context Table<br>configure voip > gw<br>manipulations phone-<br>context-table<br>[PhoneContext]                            | Defines the Phone Context table. The parameter maps NPI and TON to the SIP 'phone-context' parameter, and vice versa.<br>The format for the parameter is as follows:<br>[PhoneContext]<br>FORMAT PhoneContext_Index = PhoneContext_Npi,<br>PhoneContext_Ton, PhoneContext_Context;<br>[\PhoneContext]<br>For example:<br>PhoneContext 0 = 0,0,unknown.com<br>PhoneContext 1 = 1,1,host.com<br>PhoneContext 2 = 9,1,na.e164.host.com<br>For a detailed description of the table, see "Configuring NPI/TON-SIP Phone-Context Mapping Rules" on page 509.                                                                                                                                                                                                                                                                                                                       |
| Add Phone Context As Prefix<br>add-ph-cntxt-as-pref<br>[AddPhoneContextAsPrefix]                                                 | Determines whether the received Phone-Context parameter is added as a prefix to the outgoing ISDN Setup message with (for digital interfaces) Called and Calling numbers. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## 63.11 SBC Parameters

The SBC and CRP parameters are described in the table below.

**Table 63-72: SBC and CRP Parameters**

| Parameter                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| sbc-max-fwd-limit<br>[SBCMaxForwardsLimit]                                                    | <p>Defines the Max-Forwards SIP header value. The Max-Forwards header is used to limit the number of servers (such as proxies) that can forward the SIP request. The Max-Forwards value indicates the remaining number of times this request message is allowed to be forwarded. This count is decremented by each server that forwards the request.</p> <p>The parameter affects the Max-Forwards header in the received message as follows:</p> <ul style="list-style-type: none"> <li>▪ If the received header's original value is 0, the message is not passed on and is rejected.</li> <li>▪ If the received header's original value is less than the parameter's value, the header's value is decremented before being sent on.</li> <li>▪ If the received header's original value is greater than the parameter's value, the header's value is replaced by the user-defined parameter's value.</li> </ul> <p>The valid value range is 1-70. The default is 10.</p>                                                                                                                                                     |
| SBC Session-Expires<br>sbc-sess-exp-time<br>[SBCSessionExpires]                               | <p>Defines the SBC session refresh timer (in seconds) in the Session-Expires header of outgoing INVITE messages.</p> <p>The valid value range is 90 (according to RFC 4028) to 86400. The default is 180.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Minimum Session-Expires<br>min-session-expires<br>[SBCMinSE]                                  | <p>Defines the minimum amount of time (in seconds) between session refresh requests in a dialog before the session is considered timed out. This value is conveyed in the SIP Min-SE header.</p> <p>The valid range is 0 (default) to 1,000,000, where 0 means that the device does not limit Session-Expires.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| configure voip/sbc general-setting/sbc-session-refresh-policy<br>[SBCSessionRefreshingPolicy] | <p>Defines the SIP user agent responsible for periodically sending refresh requests for established sessions (active calls). The session refresh allows SIP UAs or proxies to determine the status of the SIP session. When a session expires, the session is considered terminated by the UAs, regardless of whether a SIP BYE was sent by one of the UAs.</p> <p>The SIP Session-Expires header conveys the lifetime of the session, which is sent in re-INVITE or UPDATE requests (session refresh requests). The 'refresher=' parameter in the Session-Expires header (sent in the initial INVITE or subsequent 2xx response) indicates who sends the session refresh requests. If the parameter contains the value 'uac', the device performs the refreshes; if the parameter contains the value 'uas', the remote proxy performs the refreshes. An example of the Session-Expires header is shown below:</p> <pre>Session-Expires: 4000;refresher=uac</pre> <p>Thus, the parameter is useful when a UA does not support session refresh requests or does not support the indication of who performs session refresh</p> |

| Parameter                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                                                                   | 'SIP Group Name' parameter (configured in the IP Groups table).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| SBC Remote Refer Behavior<br>sbc-refer-bhvr<br>[SBCReferBehavior] | Global parameter that defines the handling of SIP REFER requests. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_SBCRemoteReferBehavior). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.<br><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.                                                                                                                                                                                 |
| sbc-xfer-prefix<br>[SBCXferPrefix]                                | When the SBCReferBehavior is set to 1, the device, while interworking the SIP REFER message, adds the prefix "T~&R-" to the user part of the URI in the Refer-To header. After this, the device can receive an INVITE with such a prefix (the INVITE is sent by the UA that receives the REFER message or 302 response). If the device receives an INVITE with such a prefix, it replaces the prefix with the value defined for the SBCXferPrefix parameter.<br>By default, no value is defined.<br><b>Note:</b> This feature is also applicable to 3xx redirect responses. The device adds the prefix "T~&R-" to the URI user part in the Contact header if the SBC3xxBehavior parameter is set to 1. |
| sbc-3xx-bhvt<br>[SBC3xxBehavior]                                  | Global parameter that defines the handling of SIP 3xx redirect responses. You can also configure this functionality per specific calls, using IP Profiles (IpProfile_SBCRemote3xxBehavior). For a detailed description of the parameter and for configuring this functionality in the IP Profile table, see "Configuring IP Profiles" on page 419.<br><b>Note:</b> If this functionality is configured for a specific IP Profile, the settings of this global parameter is ignored for calls associated with the IP Profile.                                                                                                                                                                           |
| [SBCEnforceMediaOrder]                                            | Enables the device to include all previously negotiated media lines within the current session ('m=' line) in the SDP offer-answer exchange (RFC 3264).<br><ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> For example, assume a call (audio) has been established between two endpoints and one endpoint wants to subsequently send an image in the same call session. If the parameter is enabled, the endpoint includes the previously negotiated media type (i.e., audio) with the new negotiated media type (i.e., image) in its SDP offer:                                                                                         |

| Parameter                                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| [SBCRandomizeExpires]                                                                            | <p>of SIP 200 OK responses for user registration and subscription requests from users.</p> <p>The expiry time value appears in the Expires header in REGISTER and SUBSCRIBE SIP messages. When the device receives such a request from a user, it forwards it to the proxy or registrar server. Upon a successful registration or subscription, the server sends a SIP 200 OK response. If the expiry time was unchanged by the server, the device applies this feature and changes the expiry time in the SIP 200 OK response before forwarding it to the user; otherwise, the device does not change the expiry time.</p> <p>This feature is useful in scenarios where multiple users may refresh their registration or subscription simultaneously, thereby causing the device to handle many such sessions at a given time. This may result in an overload of the device (reaching maximum session capacity), thereby preventing the establishment of new calls or preventing the handling of some user registration or subscription requests. When this feature is enabled, the device assigns a random expiry time to each user registration or subscription and thus, ensuring future user registration and subscription requests are more distributed over time (i.e., do not all occur simultaneously).</p> <p>The device takes any random number between 0 and the value configured by the parameter, and then subtracts this random number from the original expiry time value. For example, assume that the original expiry time is 120 and the parameter is set to 10. If the device randomly chooses the number 5 (i.e., between 0 and 10), the resultant expiry time will be 115 (120 minus 5).</p> <p>The valid value is 0 to 20. The default is 10. If set to 0, the device does not change the expiry time.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The lowest expiry time that the device sends in the 200 OK, regardless of the resultant calculation, is 10 seconds. For example, if the original expiry time is 12 seconds and the parameter is set to 5, theoretically, the new expiry time can be less than 10 (e.g., <math>12 - 4 = 8</math>). However, the expiry time will be set to 10.</li> <li>▪ The expiry time received from the user can be changed by the device before forwarding it to the proxy. This is configured by the SBCUserRegistrationTime parameter.</li> </ul> |
| SBC Survivability Registration Time<br>sbc-surv-rgstr-time<br>[SBCSurvivabilityRegistrationTime] | <p>Defines the duration of the periodic registrations between the user and the device, when the device is in survivability state (i.e., when REGISTER requests cannot be forwarded to the proxy and are terminated by the device). When set to 0, the device uses the</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 63.11.1 Supplementary Services

The SBC and CRP supplementary services parameters are described in the table below.

**Table 63-73: SBC and CRP Supplementary Services Parameters**

| Parameter                                                                                                                                                                | Description                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Emergency Call Preemption Parameters</b><br>For more information on SBC emergency call preemption, "Configuring Call Preemption for SBC Emergency Calls" on page 733. |                                                                                                                                                                                                                                        |
| <b>SBC Preemption Mode</b><br>configure voip > sbc<br>general-setting > sbc-<br>preemption-mode<br>[SBCPreemptionMode]                                                   | Enables SBC emergency call preemption. <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul>                                                                                                 |
| <b>SBC Emergency Message Condition</b><br>configure voip > sbc<br>general-setting > sbc-<br>emerg-condition<br>[SBCEmergencyCondition]                                   | Defines the index of the Message Condition rule in the Message Condition table that is used to identify emergency calls.<br><b>Note:</b> The device applies the rule only after call classification (but before inbound manipulation). |
| <b>SBC Emergency RTP DiffServ</b><br>configure voip > sbc<br>general-setting > sbc-<br>emerg-rtp-diffserv<br>[SBCEmergencyRTPDiffserv]                                   | Defines DiffServ bits sent in the RTP for SBC emergency calls. The valid value is 0 to 63. The default is 46.                                                                                                                          |
| <b>SBC Emergency Signaling DiffServ</b><br>configure voip > sbc<br>general-setting > sbc-<br>emerg-sig-diffserv<br>[SBCEmergencySignalingDiffserv]                       | Defines DiffServ bits sent in SIP signaling messages for SBC emergency calls. This is included in the SIP Resource-Priority header.<br>The valid value is 0 to 63. The default is 40.                                                  |

## 63.12 Standalone Survivability Parameters

The Stand-alone Survivability (SAS) parameters are described in the table below. For a detailed description of SAS, refer to the *SAS Configuration Guide*.

**Table 63-74: SAS Parameters**

| Parameter                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Enable SAS<br>enable-sas<br>[EnableSAS]                                 | <p>Enables the Stand-Alone Survivability (SAS) feature.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p>When enabled, the device receives the registration requests from different SIP entities in the local network and then forwards them to the defined proxy. If the connection to the proxy fails ('Emergency Mode'), the device serves as a proxy by allowing calls internal to the local network or outgoing to PSTN.</p> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                     |
| SAS Default Gateway IP<br>sas-default-gw-ip<br>[SASDefaultGatewayIP]    | <p>Defines the Default Gateway used in SAS 'Emergency Mode'. When an incoming SIP INVITE is received and the destination Address-Of-Record is not included in the SAS database, the request is immediately sent to this default gateway.</p> <p>The address can be configured as an IP address (dotted-decimal notation) or as a domain name (up to 49 characters). You can also configure the IP address with a destination port, e.g., "10.1.2.3:5060". The default is a null string, i.e., the local IP address of the gateway.</p>                                                                                                                                                                  |
| SAS Registration Time<br>sas-registration-time<br>[SASRegistrationTime] | <p>Defines the value of the SIP Expires header that is sent in a 200 OK response to an incoming REGISTER message when in SAS 'Emergency Mode'.</p> <p>The valid range is 0 (Analog) or 10 (Digital) to 2,000,000. The default is 20.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| SAS Connection Reuse<br>sas-connection-reuse<br>[SASConnectionReuse]    | <p>Enables the re-use of the same TCP connection for sessions with the same user in the SAS application.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable</li> <li><b>[1]</b> Enable (default)</li> </ul> <p>The device can use the same TCP connection for multiple SIP requests / responses for a specific SIP UA. For example, assume the following:</p> <ul style="list-style-type: none"> <li>User A sends a REGISTER message to SAS with transport=TCP.</li> <li>User B sends an INVITE message to A using SAS.</li> </ul> <p>In this scenario, the SAS application forwards the INVITE request using the TCP connection that User A initially opened with the REGISTER message.</p> |
| Enable Record-Route<br>record-route<br>[SASEnableRecordRoute]           | <p>Determines whether the device's SAS application adds the SIP Record-Route header to SIP requests. This ensures that SIP messages traverse the device's SAS agent by including the SAS IP address in the Record-Route header.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p>The Record-Route header is inserted in a request by a SAS proxy to force future requests in the dialog session to be routed through the SAS agent. Each traversed proxy in the path can insert this header, causing all future dialogs in the session to pass through it as well.</p>                                                                  |

| Parameter                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                            | <p>When this feature is enabled, the SIP Record-Route header includes the URI "lr" parameter, indicating loose routing, for example:</p> <pre>Record-Route: &lt;sip:server10.biloxi.com;lr&gt;</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SAS Proxy Set<br><code>sas-proxy-set</code><br>[SASProxySet]                               | <p>Defines the Proxy Set (index number) used in SAS Normal mode to forward REGISTER and INVITE requests from users that are served by the SAS application.</p> <p>The valid range is 0 to 5. The default is 0 (i.e., default Proxy Set).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Redundant SAS Proxy Set<br><code>rdcy-sas-proxy-set</code><br>[RedundantSASProxySet]       | <p>Defines the Proxy Set (index number) used in SAS Emergency mode for fallback when the user is not found in the Registered Users database. Each time a new SIP request arrives, the SAS application checks whether the user is listed in the registration database. If the user is located in the database, the request is sent to the user. If the user is not found, the request is forwarded to the next redundant SAS defined in the Redundant SAS Proxy Set. If that SAS Proxy IP appears in the Via header of the request, it is not forwarded (thereby, preventing loops in the request's course). If no such redundant SAS exists, the SAS sends the request to its default gateway (configured by the parameter SASDefaultGatewayIP).</p> <p>The valid range is -1 to 5. The default is -1 (i.e., no redundant Proxy Set).</p>                                                                                                                                        |
| SAS Block Unregistered Users<br><code>sas-block-unreg-usrs</code><br>[SASBlockUnRegUse rs] | <p>Determines whether the device rejects SIP INVITE requests received from unregistered SAS users. This applies to SAS Normal and Emergency modes.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Un-Block = (Default) Allow INVITE from unregistered SAS users.</li> <li>▪ <b>[1]</b> Block = Reject dialog-establishment requests from un-registered SAS users.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <code>sas-contact-replace</code><br>[SASEnableContactRe place]                             | <p>Enables the device to change the SIP Contact header so that it points to the SAS host and therefore, the top-most SIP Via header and the Contact header point to the same host.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> (default) = Disable - when relaying requests, the SAS agent adds a new Via header (with the SAS IP address) as the top-most Via header and retains the original Contact header. Thus, the top-most Via header and the Contact header point to different hosts.</li> <li>▪ <b>[1]</b> = Enable - the device changes the Contact header so that it points to the SAS host and therefore, the top-most Via header and the Contact header point to the same host.</li> </ul> <p><b>Note:</b> Operating in this mode causes all incoming dialog requests to traverse the SAS, which may cause load problems.</p>                                                                                                                           |
| SAS Survivability Mode<br><code>sas-survivability</code><br>[SASSurvivabilityMode]         | <p>Determines the Survivability mode used by the SAS application.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Standard = (Default) Incoming INVITE and REGISTER requests are forwarded to the defined Proxy list of SASProxySet in Normal mode and handled by the SAS application in Emergency mode.</li> <li>▪ <b>[1]</b> Always Emergency = The SAS application does not use Keep-Alive messages towards the SASProxySet, instead it always operates in Emergency mode (as if no Proxy in the SASProxySet is available).</li> <li>▪ <b>[2]</b> Ignore Register = Use regular SAS Normal/Emergency logic (same as option [0]), but when in Normal mode incoming REGISTER requests are ignored.</li> <li>▪ <b>[3]</b> Auto-answer REGISTER = When in Normal mode, the device responds to received REGISTER requests by sending a SIP 200 OK (instead of relaying the registration requests to a Proxy), and enters the registrations in its SAS database.</li> </ul> |

| Parameter                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|                                                                                 | <ul style="list-style-type: none"> <li><b>[4]</b> Use Routing Table only in Normal mode = The device uses the IP-to-IP Routing table to route IP-to-IP SAS calls only when in SAS Normal mode (and is unavailable when SAS is in Emergency mode). This allows routing of SAS IP-to-IP calls to different destinations (and not only to the SAS Proxy Set).</li> </ul>                                                                                                                                                                                                                                                                                                                          |
| SAS Subscribe Response<br>sas-subscribe-resp<br>[SASSubscribeResponse]          | <p>Defines the SIP response upon receipt of a SUBSCRIBE message when SAS is in Emergency mode. For example, if the parameter is set to "200", then SAS sends a SIP 200 OK in response to a SUBSCRIBE message, when in Emergency mode.</p> <p>The valid value is 200 to 699. The default is 489.</p>                                                                                                                                                                                                                                                                                                                                                                                            |
| Enable ENUM<br>enable-enum<br>[SASEnableENUM]                                   | <p>Enables SAS to perform ENUM (E.164 number to URI mapping) queries when receiving INVITE messages in SAS emergency mode.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| SAS Binding Mode<br>sasbindingmode<br>[SASBindingMode]                          | <p>Determines the SAS application database binding mode.</p> <ul style="list-style-type: none"> <li><b>[0]</b> URI = (Default) If the incoming AoR in the INVITE requests is using a 'tel:' URI or 'user=phone' is defined, the binding is performed according to the user part of the URI only. Otherwise, the binding is according to the entire URI, i.e., User@Host.</li> <li><b>[1]</b> User Part only = The binding is always performed according to the User Part only.</li> </ul>                                                                                                                                                                                                      |
| SAS Emergency Numbers<br>sas-emerg-nb<br>[SASEmergencyNumbers]                  | <p>Defines emergency numbers for the device's SAS application. When the device's SAS agent receives a SIP INVITE (from an IP phone) that includes one of the emergency numbers (in the SIP user part), it forwards the INVITE to the default gateway (configured by the parameter SASDefaultGatewayIP), i.e., the device itself, which sends the call directly to the PSTN. This is important for routing emergency numbers such as 911 (in North America) directly to the PSTN. This is applicable to SAS operating in Normal and Emergency modes.</p> <p>Up to four emergency numbers can be defined, where each number can be up to four digits.</p>                                        |
| sas-emerg-prefix<br>[SASEmergencyPrefix]                                        | <p>Defines a prefix that is added to the Request-URI user part of the INVITE message that is sent by the device's SAS agent when in Emergency mode to the default gateway or to any other destination (using the IP-to-IP Routing table). The parameter is required to differentiate between normal SAS calls routed to the default gateway and emergency SAS calls. Therefore, this allows you to define different manipulation rules for normal and emergency calls.</p> <p>This valid value is a character string. By default, no value is defined.</p>                                                                                                                                     |
| SAS Entering Emergency Mode<br>sas-enter-emg-mode<br>[SASEnteringEmergencyMode] | <p>Determines for which sent SIP message types the device enters SAS Emergency mode if no response is received for them from the proxy server.</p> <ul style="list-style-type: none"> <li><b>[0]</b> = (Default) SAS enters Emergency mode only if no response is received from sent SIP OPTIONS messages.</li> <li><b>[1]</b> = SAS enters Emergency mode if no response is received from sent SIP OPTIONS, INVITE, or REGISTER messages.</li> </ul> <p><b>Note:</b> If the keep-alive mechanism is disabled for the Proxy Set (in the Proxy Set table) and the parameter is set to [1], SAS enters Emergency mode only if no response is received from sent INVITE or REGISTER messages.</p> |

| Parameter                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| SAS Inbound Manipulation Mode<br>sas-inb-manipulation-mode<br>[SASInboundManipulationMode]                            | Enables destination number manipulation of incoming INVITE messages when SAS is in Emergency mode. The manipulation rule is done in the IP to IP Inbound Manipulation table. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> None (default)</li> <li>▪ <b>[1]</b> Emergency Only</li> </ul> <b>Note:</b> Inbound manipulation applies only to INVITE requests.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>SAS Registration Manipulation Table</b>                                                                            |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| SAS Registration Manipulation<br>configure voip > sas<br>sasregistrationmanipulation<br>[SASRegistrationManipulation] | Defines the SAS Registration Manipulation table. This table is used by the SAS application to manipulate the SIP Request-URI user part of incoming INVITE messages and of incoming REGISTER request AoR (To header), before saving it to the registered users database. The format of The table is as follows:<br>[SASRegistrationManipulation]<br>FORMAT SASRegistrationManipulation_Index = SASRegistrationManipulation_RemoveFromRight, SASRegistrationManipulation_LeaveFromRight;<br>[SASRegistrationManipulation]<br>For example, the manipulation rule below routes an INVITE with Request-URI header "sip:7184002@10.33.4.226" to user "4002@10.33.4.226" (i.e., keep only four digits from right of user part):<br>SASRegistrationManipulation 0 = 0, 4; |
| <b>SAS IP-to-IP Routing Table</b>                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| [IP2IPRouting]                                                                                                        | Defines the IP-to-IP Routing table for SAS routing rules. The format of the ini file table parameter is as follows:<br>[IP2IPRouting]<br>FORMAT IP2IPRouting_Index = IP2IPRouting_SrcIPGroupName, IP2IPRouting_SrcUsernamePrefix, IP2IPRouting_SrcHost, IP2IPRouting_DestUsernamePrefix, IP2IPRouting_DestHost, IP2IPRouting_DestType, IP2IPRouting_DestIPGroupName, IP2IPRouting_DestSRDID, IP2IPRouting_DestAddress, IP2IPRouting_DestPort, IP2IPRouting_DestTransportType, IP2IPRouting_AltRouteOptions;<br>[IP2IPRouting]<br>For example:<br>IP2IPRouting 1 = -1, *, *, *, *, 0, -1, -1, , 0, -1, 0;                                                                                                                                                          |

## 63.13 IP Media Parameters

The IP media parameters are described in the table below.

Table 63-75: IP Media Parameters

| Parameter                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| IPMedia Detectors<br>IPM-detectors-enable<br>[EnableDSPIPMDetectors] | <p>Enables the device's DSP detectors for detection features such as AMD.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ The DSP Detectors feature is available only if the device is installed with a Software License Key that includes this feature. For installing a Software License Key, see "Software License Key" on page 819.</li> <li>▪ When enabled (1), the number of available channels is reduced.</li> </ul> |
| Number of Media Channels<br>media-channels<br>[MediaChannels]        | <p>Defines the maximum number of DSP channels allocated for various functionalities such as transcoding, IP conferencing. The default is 0.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ The SBC application does not require DSP channels. The SBC application uses DSP channels only if media transcoding is needed, where two DSP channels are used per transcoding session.</li> <li>▪ Other DSP channels can be used for PSTN interfaces.</li> </ul>                                                                               |
| Conferencing Parameters                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Conference ID<br>[ConferenceID]                                      | <p>Defines the Conference Identification string.</p> <p>The valid value is a string of up to 16 characters. The default is "conf".</p> <p><b>Note:</b> To join a conference, the INVITE URI must include the Conference ID string preceded by the number of the participants in the conference and terminated by a unique number. For example:</p> <pre>INVITE sip:4conf1234@10.1.10.10</pre> <p>INVITE messages with the same URI join the same conference.</p>                                                                                                                                                                      |
| Automatic Gain Control (AGC) Parameters                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Enable AGC<br>AGC-enable<br>[EnableAGC]                              | <p>Enables the AGC mechanism. The AGC mechanism adjusts the level of the received signal to maintain a steady (configurable) volume level.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ The parameter can also be configured for a Tel Profile (in the Tel Profile table).</li> <li>▪ For a description of AGC, see Automatic Gain Control (AGC) on page 225.</li> </ul>                                                                                                                           |
| AGC Slope                                                            | Determines the AGC convergence rate:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|-----------|----------------------------------------------------------------------------|
|           | <b>Note:</b> For the parameter to take effect, a device reset is required. |

## 63.14 Services

### 63.14.1 SIP-based Media Recording Parameters

The SIP-based media recording parameters are described in the table below.

**Table 63-76: SIP-based Media Recording Parameters**

| Parameter                                                                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SIP Recording Application<br>configure<br>voip/services sip-<br>recording general-<br>setting/enable-sip-rec<br>[EnableSIPRec]                                                   | Enables the SIP-based Media Recording feature: <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                |
| Recording Server (SRS)<br>Destination Username<br>configure<br>voip/services sip-<br>recording general-<br>setting/siprec-server-<br>dest-username<br>[SIPRecServerDestUsername] | Defines the SIP user part for the recording server. This user part is added in the SIP To header of the INVITE message that the device sends to the recording server.<br><br>The valid value is a string of up to 50 characters. By default, no user part is defined.                                                                                                                                                                                                                                                                                                                                  |
| SIP Recording Time Stamp<br>Format<br>configure<br>voip/services sip-<br>recording general-<br>setting/siprec-time-<br>stamp<br>[SIPRecTimeStamp]                                | Defines the format of the device's time (timestamp) in SIP messages that are sent to the SIP Recording Server (SRS). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Local Time = (Default) The device's local time (without the UTC time zone) is used for the timestamp.</li> <li>▪ <b>[1]</b> UTC = The device's UTC time is used for the timestamp.</li> </ul> <b>Note:</b> The timestamp is contained in the XML body of the SIP message. If the timestamp uses the UTC time, the time is suffixed with the letter "Z", for example:<br><associate-time>2017-09-07T06:33:38Z</associate-time> |

| Parameter                                                                                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## 63.14.2 RADIUS and LDAP Parameters

### 63.14.2.1 General Parameters

The general RADIUS and LDAP parameters are described in the table below.

**Table 63-77: General RADIUS and LDAP Parameters**

| Parameter                                                                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use Local Users Database<br><code>configure system &gt;</code><br><code>mgmt-auth &gt; use-local-users-db</code><br><b>[MgmtUseLocalUsersDatabase]</b>              | Defines when the device uses its local management-users database (Web Users table) or an LDAP/RADIUS server for authenticating the login credentials (username-password) of users when logging into the device's management interface (e.g., Web or CLI). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> When No Auth Server Defined = (Default) The device authenticates the users using the Web Users table in the following scenarios:               <ul style="list-style-type: none"> <li>✓ If no LDAP/RADIUS server is configured.</li> <li>✓ If an LDAP/RADIUS server is configured, but connectivity with the server is down. If there is connectivity with the server, the device uses the server to authenticate the user.</li> </ul> </li> <li>▪ <b>[1]</b> Always = The device first attempts to authenticate the user using the Web Users table. If no user is found (based on the username-password combination), it attempts to authenticate the user using the LDAP/RADIUS server.</li> </ul> |
| Behavior upon Authentication Server Timeout<br><code>configure system &gt;</code><br><code>mgmt-auth &gt; timeout-behavior</code><br><b>[MgmtBehaviorOnTimeout]</b> | Defines the device's response when a connection timeout occurs with the LDAP/RADIUS server. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Deny Access = User is denied access to the management platform.</li> <li>▪ <b>[1]</b> Verify Access Locally = (Default) Device verifies the user's credentials in its Web Users table (local database).</li> </ul> <p><b>Note:</b> The parameter is applicable to LDAP- and RADIUS-based management-user login authentication.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Default Access Level<br><code>default-access-level</code><br><b>[DefaultAccessLevel]</b>                                                                            | Defines the default access level for the device when the LDAP/RADIUS response doesn't include an access level attribute for determining the user's management access level.<br>The valid range is 0 to 255. The default is 200 (i.e., Security Administrator).<br><p><b>Note:</b> The parameter is applicable to LDAP- or RADIUS-based management-user login authentication and authorization.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 63.14.2.2 RADIUS Parameters

The RADIUS parameters are described in the table below.

**Table 63-78: RADIUS Parameters**

| Parameter                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                      |
|---------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General RADIUS Parameters</b>                                                            |                                                                                                                                                                                                                                                                                                                                                                                  |
| Enable RADIUS Access Control<br>enable<br>[EnableRADIUS]                                    | Enables the RADIUS application. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (Default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                         |
| [RadiusTrafficType]                                                                         | Defines the device's network interface for communicating (RADIUS traffic) with the RADIUS server(s). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> OAMP (default)</li> <li>▪ <b>[1]</b> Control</li> </ul> <b>Note:</b> If set to Control, only one Control interface must be configured in the Interface table; otherwise, RADIUS communication will fail.                |
| RADIUS VSA Vendor ID<br>configure system ><br>radius > vsa-vendor-id<br>[RadiusVSAVendorID] | Defines the vendor ID that the device accepts when parsing a RADIUS response packet.<br>The valid range is 0 to 0xFFFFFFFF. The default is 5003.                                                                                                                                                                                                                                 |
| [MaxRADIUSSessions]                                                                         | Defines the number of concurrent calls that can communicate with the RADIUS server (optional).<br>The valid range is 0 to 240. The default is 240.                                                                                                                                                                                                                               |
| RADIUS Packets Retransmission<br>[RADIUSRetransmission]                                     | Defines the number of RADIUS retransmission retries when no response is received from the RADIUS server. See also the RadiusTo parameter.<br>The valid range is 1 to 10. The default is 1.                                                                                                                                                                                       |
| RADIUS Response Time Out<br>[RadiusTO]                                                      | Defines the time interval (in seconds) that the device waits for a response before it performs a RADIUS retransmission. See also the RADIUSRetransmission parameter.<br>The valid range is 1 to 30. The default is 2.                                                                                                                                                            |
| <b>RADIUS Accounting Parameters</b>                                                         |                                                                                                                                                                                                                                                                                                                                                                                  |
| RADIUS Accounting Type<br>radius-accounting<br>[RADIUSAccountingType]                       | Determines when the RADIUS accounting messages are sent to the RADIUS accounting server. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> At Call Release = (Default) Sent at call release only.</li> <li>▪ <b>[1]</b> At Connect &amp; Release = Sent at call connect and release.</li> <li>▪ <b>[2]</b> At Setup &amp; Release = Sent at call setup and release.</li> </ul> |
| AAA Indications<br>aaa-indications<br>[AAAIndications]                                      | Determines the Authentication, Authorization and Accounting (AAA) indications. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> None = (Default) No indications.</li> <li>▪ <b>[3]</b> Accounting Only = Only accounting indications are used.</li> </ul>                                                                                                                     |
| <b>RADIUS User Authentication Parameters</b>                                                |                                                                                                                                                                                                                                                                                                                                                                                  |
| Use RADIUS for Web/Telnet Login                                                             | Enables RADIUS queries for Web and Telnet login authentication. When enabled, logging into the device's Web and Telnet embedded servers is done through a RADIUS server. The device communicates                                                                                                                                                                                 |

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| enable-mgmt-login<br>[WebRADIUSLogin]                                               | <p>with a user-defined RADIUS server and verifies the given username and password against a remote database, in a secure manner.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ For RADIUS login authentication to function, you must also configure the EnableRADIUS parameter to 1 (Enable).</li> <li>▪ RADIUS authentication requires HTTP basic authentication, where the username and password are transmitted in clear text over the network. Therefore, it's recommended to set the HTTPSONly parameter to 1 to force the use of HTTPS, since the transport is encrypted.</li> </ul> |
| Password Local Cache Mode<br>local-cache-mode<br>[RadiusLocalCacheMode]             | <p>Defines the device's mode of operation regarding the timer (configured by the parameter RadiusLocalCacheTimeout) that determines the validity of the username and password (verified by the RADIUS server).</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Absolute Expiry Timer = When you access a Web page, the timeout doesn't reset, instead it continues decreasing.</li> <li>▪ <b>[1]</b> Reset Timer Upon Access = (Default) Upon each access to a Web page, the timeout always resets (reverts to the initial value configured by RadiusLocalCacheTimeout).</li> </ul>                                                                                                                                  |
| Password Local Cache Timeout<br>local-cache-timeout<br>[RadiusLocalCacheTimeout]    | <p>Defines the time (in seconds) the locally stored username and password (verified by the RADIUS server) are valid. When this time expires, the username and password become invalid and a must be re-verified with the RADIUS server.</p> <p>The valid range is 1 to 0xFFFFFFFF. The default is 300 (5 minutes).</p> <ul style="list-style-type: none"> <li>▪ <b>[-1]</b> = Never expires.</li> <li>▪ <b>[0]</b> = Each request requires RADIUS authentication.</li> </ul>                                                                                                                                                                                                                                                 |
| RADIUS VSA Access Level Attribute<br>vsa-access-level<br>[RadiusVSAAccessAttribute] | <p>Defines the code that indicates the access level attribute in the Vendor Specific Attributes (VSA) section of the received RADIUS packet.</p> <p>The valid range is 0 to 255. The default is 35.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

### 63.14.2.3 LDAP Parameters

The Lightweight Directory Access Protocol (LDAP) parameters are described in the table below.

**Table 63-79: LDAP Parameters**

| Parameter                                                                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LDAP Service</b><br><code>configure voip/ldap/enable</code><br><b>[LDAPServiceEnable]</b>                                                                | <p>Enables the LDAP feature.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                                                                    |
| <b>LDAP Authentication Filter</b><br><code>configure voip &gt; ldap &gt; auth-filter</code><br><b>[LDAPAuthFilter]</b>                                      | <p>Defines the LDAP search filter attribute for searching the login username in the directory's subtree for LDAP-based user authentication and authorization.</p> <p>You can use the dollar (\$) sign to represent the username. For example, if the parameter is set to "(sAMAccountName=*)" and the user logs in with the username "SueM", the LDAP query is run for sAMAccountName=SueM.</p> |
| <b>Use LDAP for Web/Telnet Login</b><br><code>configure voip &gt; ldap &gt; enable-mgmt-login</code><br><b>[MgmtLDAPLogin]</b>                              | <p>Enables LDAP-based management-user login authentication and authorization.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable (default)</li> <li><b>[1]</b> Enable</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device reset is required.</p>                                                                                                                   |
| <b>[LDAPDebugMode]</b>                                                                                                                                      | <p>Determines whether to enable the LDAP task debug messages. This is used for providing debug information regarding LDAP tasks.</p> <p>The valid value range is 0 to 3. The default is 0.</p>                                                                                                                                                                                                  |
| <b>LDAP Numeric Attribute</b><br><code>configure voip &gt; sip-definition advanced-settings &gt; ldap-numeric-attr</code><br><b>[LDAPNumericAttributes]</b> | <p>Defines up to five LDAP Attributes (separated by commas) for which the device employs LDAP query searches in the AD for numbers that may have characters between the digits.</p> <p>For more information, see Enabling LDAP Searches for Numbers with Characters on page 279.</p>                                                                                                            |
| <b>MS LDAP OCS Number attribute name</b><br><code>ldap-ocs-nm-attr</code><br><b>[MSLDAPOCSNumAttributeName]</b>                                             | <p>Defines the name of the attribute that represents the user's Lync number in the Microsoft AD database.</p> <p>The valid value is a string of up to 49 characters. The default is "msRTCSIP-Line".</p>                                                                                                                                                                                        |
| <b>MS LDAP PBX Number attribute name</b><br><code>ldap-pbx-nm-attr</code><br><b>[MSLDAPPBXNumAttributeName]</b>                                             | <p>Defines the name of the attribute that represents the user PBX number in the Microsoft AD database.</p> <p>The valid value is a string of up to 49 characters. The default is "telephoneNumber".</p>                                                                                                                                                                                         |
| <b>MS LDAP MOBILE Number attribute name</b><br><code>ldap-mobile-nm-attr</code><br><b>[MSLDAPMobileNumAttributeName]</b>                                    | <p>Defines the name of the attribute that represents the user Mobile number in the Microsoft AD database.</p> <p>The valid value is a string of up to 49 characters. The default is "mobile".</p>                                                                                                                                                                                               |

| Parameter                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ldap-private-nm-attr<br>[MSLDAPPrivateNumAttributeName]                                          | Defines the name of the attribute that represents the user's private number in the AD. If this value equals the value of the MSLDAPPrimaryKey or MSLDAPSecondaryKey parameter, then the device queries the AD for the destination number in this private attribute name; otherwise, the parameter is not used as a search key. The default is "msRTCSIP-PrivateLine".                                                                                                                                                                                                                                                                                                                            |
| MS LDAP DISPLAY Name Attribute Name<br>ldap-display-nm-attr<br>[MSLDAPDisplayNameAttributeName]  | Defines the attribute name that represents the Calling Name in the AD for LDAP queries based on calling number.<br><br>The valid value is a string of up to 49 characters. The default is "displayName".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| ldap-primary-key<br>[MSLDAPPrimaryKey]                                                           | Defines the name of the attribute used as a query search key for the destination number in the AD. This is used instead of the "PBX" attribute name (configured by the MSLDAPPBXNumAttributeName parameter).<br><br>The default is not configured.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| ldap-secondary-key<br>[MSLDAPSecondaryKey]                                                       | Defines the name of the attribute used as the second query search key for the destination number in the AD, if the primary search key or PBX search is not found.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| LDAP Cache Service<br>cache<br>[LDAPCacheEnable]                                                 | Enables the LDAP cache service. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ For the parameter to take effect, a device reset is required.</li> <li>▪ For more information on LDAP caching, see "Configuring the Device's LDAP Cache" on page 270.</li> </ul>                                                                                                                                                                                                                                                                                                            |
| <b>LDAP Configuration Table</b>                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 63.14.6 HTTP Proxy Parameters

The HTTP Proxy service parameters are described in the table below.

**Table 63-83: HTTP Proxy Service Parameters**

| Parameter                                                                                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| HTTP Proxy Application<br><code>configure system &gt;</code><br><code>http-proxy &gt; http-</code><br><code>proxy-app</code><br><code>[HTTPProxyApplication]</code> | Enables the HTTP Proxy application. <ul style="list-style-type: none"> <li>▪ [0] Disable (default)</li> <li>▪ [1] Enable</li> </ul> <b>Note:</b> For the parameter to take effect, a device reset is required.                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| HTTP Interfaces Table<br><code>configure system &gt;</code><br><code>http-proxy &gt; http-</code><br><code>interface</code><br><code>[HTTPInterface]</code>         | Defines local listening interfaces for receiving HTTP/S requests from Web clients for HTTP/S-based services.<br>The format of the ini file table parameter is as follows:<br><pre>[ HTTPInterface ] FORMAT HTTPInterface_Index = HTTPInterface_InterfaceName, HTTPInterface_NetworkInterface, HTTPInterface_Protocol, HTTPInterface_Port, HTTPInterface_TLSTContext, HTTPInterface_VerifyCert; [ \HTTPInterface ]</pre> For a description of the table, see 'Configuring HTTP Interfaces' on page 302.                                                                                                                                         |
| HTTP Proxy Services Table<br><code>configure system &gt;</code><br><code>http-proxy &gt; http-</code><br><code>proxy-serv</code><br><code>[HTTPProxyService]</code> | Defines HTTP Proxy based services.<br>The format of the ini file table parameter is as follows:<br><pre>[ HTTPProxyService ] FORMAT HTTPProxyService_Index = HTTPProxyService_ServiceName, HTTPProxyService_ListeningInterface, HTTPProxyService_URLPrefix, HTTPProxyService_KeepAliveMode; [ \HTTPProxyService ]</pre> For a description of the table, see 'Configuring HTTP Proxy Services' on page 304.                                                                                                                                                                                                                                     |
| HTTP Proxy Hosts Table<br><code>configure system &gt;</code><br><code>http-proxy &gt; http-</code><br><code>proxy-host</code><br><code>[HTTPProxyHost]</code>       | Defines HTTP Proxy hosts. The table is a "child" of the HTTP Proxy Services table (HTTPProxyService). An HTTP Proxy Host represents the HTTP-based managed equipment (e.g., IP Phone).<br>The format of the ini file table parameter is as follows:<br><pre>[ HTTPProxyHost ] FORMAT HTTPProxyHost_Index = HTTPProxyHost_HTTPProxyServiceId, HTTPProxyHost_HTTPProxyHostId, HTTPProxyHost_NetworkInterface, HTTPProxyHost_IpAddress, HTTPProxyHost_Protocol, HTTPProxyHost_Port, HTTPProxyHost_TLSTContext, HTTPProxyHost_VerifyCert; [ \HTTPProxyHost ]</pre> For a description of the table, see 'Configuring HTTP Proxy Hosts' on page 305. |

| Parameter                                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|----------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>EMS Services Table</p> <pre>configure system &gt; http-proxy &gt; ems- serv</pre> <p>[EMSService]</p> | <p>Defines an HTTP-based EMS Service so that the device can act as an HTTP Proxy that enables AudioCodes EMS to manage AudioCodes equipment (such as IP Phones) over HTTP when the equipment is located behind NAT (e.g., in the LAN) and EMS is located in a public domain (e.g., in the WAN).</p> <p>The format of the ini file table parameter is as follows:</p> <pre>[ EMSService ] FORMAT EMSService_Index = EMSService_ServiceName, EMSService_PrimaryServer, EMSService_SecondaryServer, EMSService_DeviceLoginInterface, EMSService_EMSServiceInterface; [ \EMSService ]</pre> <p>For a description of the table, see 'Configuring an HTTP-based EMS Service' on page 307.</p> |

## 64 SBC and DSP Channel Capacity

This chapter lists the supported DSP firmware templates and channel capacity.

### Notes:

- Installation and use of voice coders is subject to obtaining the appropriate license and royalty payments.
- The number of channels refers to the maximum channel capacity of the device.
- For additional DSP templates, contact your AudioCodes sales representative.

### 64.1 Signaling-Media Sessions & User Registrations

The table below lists the maximum capacity figures for SIP signaling, media sessions, and registered users.

**Table 64-1: Maximum Signaling, Media Sessions and Registered Users**

| Product                      | Signaling Sessions | Media Sessions |                      |                   | Registered Users |
|------------------------------|--------------------|----------------|----------------------|-------------------|------------------|
|                              |                    | RTP-to-RTP     | SRTP-RTP or SRTP-TDM | Codec Transcoding |                  |
| Mediant 800 Gateway & E-SBC  | 60                 | 60             | 60                   | See               | 200              |
| Mediant 800B Gateway & E-SBC | 250                | 250            | 180                  | See               | 0                |
|                              | 250                | 100            | 60                   | See               | 800              |

**Notes:**

- The figures listed in the table are accurate at the time of publication of this document. However, these figures may change due to a later software update. For the latest figures, please contact your AudioCodes sales representative.
- The RTP-to-RTP column represents maximum media sessions when all media sessions are RTP-to-RTP only. The same applies to the SRTP-RTP or SRTP-TDM column.
- *Registered Users* is the maximum number of users that can be registered with the device. This applies to the supported application (SBC or CRP).
- Regarding signaling, media, and transcoding session resources:
  - ✓ A signaling session is a SIP dialog session between two SIP entities, traversing the SBC and using one signaling session resource.
  - ✓ A media session is an audio (RTP or SRTP), fax (T.38), or video session between two SIP entities, traversing the SBC and using one media session resource.
  - ✓ A gateway session (i.e. TDM-RTP or TDM-SRTP) is also considered as a media session for the calculation of media sessions. In other words, the maximum Media Sessions specified in the table refer to the sum of Gateway and SBC sessions.
  - ✓ In case of direct media (i.e., anti-tromboning / Non-Media Anchoring), where only SIP signaling traverses the SBC and media flows directly between the SIP entities, only a signaling session resource is used. Thus, for products with a greater signaling session capacity than media, even when media session resources have been exhausted, additional signaling sessions can still be handled for direct-media calls.
  - ✓ For call sessions requiring transcoding, one transcoding session resource is also used. For example, for a non-direct media call in which one leg uses G.711 and the other leg G.729, one signaling resource, one media session resource, and one transcoding session resource is used.

## 64.2 Channel Capacity and Capabilities

The device's channel capacity and DSP capabilities are listed in the table below.

**Table 64-2: Session Capacity per Capabilities (SBC Only)**

| H/W Configuration | DSP Channels for PSTN | SBC Transcoding Sessions                                 |         |                |        |                |         |              |              | Max. SBC Sessions |              |
|-------------------|-----------------------|----------------------------------------------------------|---------|----------------|--------|----------------|---------|--------------|--------------|-------------------|--------------|
|                   |                       | From Profile 2 with Additional Advanced DSP Capabilities |         |                |        |                |         | To Profile 1 | To Profile 2 | Mediant 800       | Mediant 800B |
|                   |                       | Opus-NB                                                  | Opus-WB | AMR-NB / G.722 | AMR-WB | SILK-NB / iLBC | SILK-WB |              |              |                   |              |
| SBC               | N/A                   | -                                                        | -       | -              | -      | -              | -       | 57           | 48           | 60                | 250          |
|                   | N/A                   | -                                                        | -       | ✓              | -      | -              | -       | 51           | 42           | 60                | 250          |

| H/W Configuration | DSP Channels for PSTN | SBC Transcoding Sessions                                    |         |                |        |                |         |              |              | Max. SBC Sessions |              |

**Notes:**

- Profile 1: G.711 at 20ms only, with in-band signaling (in voice channel) and Silence Suppression (no fax detection or T.38 support).
- Profile 2: G.711, G.726, G.729, and G.723.1, T.38 with fax detection, in-band signaling (in voice channel), and Silence Compression.
- All hardware assemblies also support the following DSP channel capabilities: echo cancellation (EC), CID (caller ID), RTCP-XR reporting, and SRTP.
- SBC enhancements (e.g. Acoustic Echo Suppressor, Noise Reduction) are also available for these configurations. For more information, please contact your AudioCodes sales representative.
- Automatic Gain Control (AGC) and Answer Detector / Answer Machine Detector (AD/AMD) are also available for these configurations. For more information, please contact your AudioCodes sales representative.
- V.150.1 is supported only for the US Department of Defense (DoD).
- Transcoding Sessions represents part of the total SBC sessions.
- Conference Participants represents the number of concurrent analog ports in a three-way conference call.
- For availability of the telephony assemblies listed in the table, please contact your AudioCodes sales representative.

## 65 Technical Specifications

The device's technical specifications are listed in the table below.

### Notes:

- All specifications in this document are subject to change without prior notice.
- The compliance and regulatory information can be downloaded from AudioCodes website at <http://www.audiocodes.com/library>.

**Table 65-1: Technical Specifications**

| Function                              | Specification                                                                                                                                                                                                                                                                                                                                                                 |

The maximum cable length for a point-to-point BRI service (BRI port to BRI endpoint) is 1,000 m (3,280 ft).</li> <li>▪ ISDN PRI: Up to 2 E1/T1 spans (RJ-48c ports) with an option for PSTN Fallback.</li> </ul> |
| <b>Clock Source</b>                   | 5 ppm High Precision                                                                                                                                                                                                                                                                                                                                                          |
| <b>Networking Interfaces</b>          |                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Ethernet</b>                       | 4 GE / 4 GE + 8 FE interfaces, configured in 1+1 redundancy or as individual ports.                                                                                                                                                                                                                                                                                           |
| <b>High Availability (HA)</b>         |                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Full HA</b>                        | Two deployed devices for 1+1 high availability, communicating through a Maintenance network interface. Upon failure of the active device, all functionality is switched over to the redundant device                                                                                                                                                                          |
| <b>OSN Server Platform (Optional)</b> |                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Single Chassis Integration</b>     | Embedded, open Network Solution Platform for third-party services                                                                                                                                                                                                                                                                                                             |
| <b>Memory</b>                         | Up to 16 GB RAM                                                                                                                                                                                                                                                                                                                                                               |
| <b>Storage</b>                        | HDD or SSD                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Security</b>                       |                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Encryption and Authentication</b>  | TLS, DTLS, SRTP, HTTPS, SSH, client/server SIP Digest authentication, RADIUS Digest                                                                                                                                                                                                                                                                                           |
| <b>Access Control</b>                 | DoS/DDoS line rate protection, bandwidth throttling, dynamic blacklisting                                                                                                                                                                                                                                                                                                     |
| <b>VoIP Firewall</b>                  | RTP pinhole management, rogue RTP detection and prevention, SIP message policy, advanced RTP latching                                                                                                                                                                                                                                                                         |
| <b>Privacy</b>                        | Topology hiding, user privacy                                                                                                                                                                                                                                                                                                                                                 |

| Function                                 | Specification                                                                                                                                                                                         |
|------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Traffic Separation</b>                | VLAN/physical interface separation for multiple media, control and OAMP interfaces                                                                                                                    |
| <b>Intrusion Detection System</b>        | Detection and prevention of VoIP attacks, theft of service and unauthorized access                                                                                                                    |
| <b>Interoperability</b>                  |                                                                                                                                                                                                       |
| <b>SIP B2BUA</b>                         | Full SIP transparency, mature & broadly deployed SIP stack                                                                                                                                            |
| <b>SIP Interworking</b>                  | 3xx redirect, REFER, PRACK, session timer, early media, call hold, delayed offer                                                                                                                      |
| <b>Registration and Authentication</b>   | User registration restriction control, registration and authentication on behalf of users, SIP authentication server for SBC users                                                                    |
| <b>Transport Mediation</b>               | SIP over UDP/TCP/TLS/WebSocket, IPv4 to IPv6, RTP to SRTP (SDS/DTLS)                                                                                                                                  |
| <b>Message Manipulation</b>              | Ability to add/modify/delete SIP headers and message body using advanced regular expressions (regex)                                                                                                  |
| <b>URI and Number Manipulations</b>      | URI user and host name manipulations, ingress and egress digit manipulation                                                                                                                           |
| <b>Transcoding and Vocoders</b>          | Coder normalization including transcoding, coder enforcement and re-prioritization, extensive vocoder support: G.711, G.723.1, G.726, G.729, GSM-FR, AMR-NB, AMR-WB (G.722.2), SILK-NB/WB, Opus-NB/WB |
| <b>NAT</b>                               | Local and far-end NAT traversal for support of remote workers                                                                                                                                         |
| <b>Signal Conversion</b>                 | DTMF/RFC 2833/SIP, T.38 fax, T.38 V3, V.34, packet-time conversion, V.150.1                                                                                                                           |
| <b>WebRTC Controller</b>                 | Interworking between WebRTC devices and SIP networks<br>Supports WebSocket, Opus, VP8 video coder, lite ICE, DTLS, RTP multiplexing, secure RTCP with feedback                                        |
| <b>Voice Quality and SLA</b>             |                                                                                                                                                                                                       |
| <b>Call Admission Control</b>            | Based on bandwidth, session establishment rate, number of connections/registrations                                                                                                                   |
| <b>Packet Marking</b>                    | 802.1p/Q VLAN tagging, DiffServ, TOS                                                                                                                                                                  |
| <b>Standalone Survivability</b>          | Maintain local calls in the event of WAN failure, Outbound calls can use PSTN fallback for external connectivity (including E911).                                                                    |
| <b>Impairment Mitigation</b>             | Packet Loss Concealment, Dynamic Programmable Jitter Buffer, Silence Suppression/Comfort Noise Generation, RTP redundancy, broken connection detection                                                |
| <b>Voice Enhancement</b>                 | Transrating, RTCP-XR, acoustic echo cancellation, replacing voice profile due to impairment detection, fixed & dynamic voice gain control                                                             |
| <b>Direct Media (No Media Anchoring)</b> | Hair-pinning of local calls to avoid unnecessary media delays and bandwidth consumption                                                                                                               |
| <b>Voice Quality Monitoring</b>          | RTCP-XR, AudioCodes Session Experience Manager (SEM)                                                                                                                                                  |

| Function                              | Specification                                                                                                                                                                   |
|---------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>High Availability (Redundancy)</b> | SBC high availability with two-box redundancy, active calls preserved                                                                                                           |
| <b>Quality of Experience</b>          | Access control and media quality enhancements based on QoE and bandwidth utilization                                                                                            |
| <b>Test Agent</b>                     | Ability to remotely verify connectivity, voice quality and SIP message flow between SIP UAs                                                                                     |
| <b>SIP Routing</b>                    |                                                                                                                                                                                 |
| <b>Routing Methods</b>                | Request URL, IP Address, FQDN, ENUM, advanced LDAP, third-party routing control through REST API                                                                                |
| <b>Advanced Routing Criteria</b>      | QoE, bandwidth, SIP message (SIP request, coder type, etc.), Layer-3 parameters                                                                                                 |
| <b>Redundancy</b>                     | Detection of proxy failures and subsequent routing to alternative proxies                                                                                                       |
| <b>Routing Features</b>               | Least-cost routing, call forking, load balancing, E911 gateway support, emergency call detection and prioritization                                                             |
| <b>SIPRec</b>                         | IETF standard SIP recording interface                                                                                                                                           |
| <b>Management</b>                     |                                                                                                                                                                                 |
| <b>OAM&amp;P</b>                      | Browser-based GUI, CLI, SNMP, EMS, INI Configuration file, REST API                                                                                                             |
| <b>Physical / Environmental</b>       |                                                                                                                                                                                 |
| <b>Dimensions (HxWxD)</b>             | 1U x 320 mm (12.6") x 345 mm (13.6")                                                                                                                                            |
| <b>Weight</b>                         | Approx. 5.95lb (2.7kg) installed with OSN                                                                                                                                       |
| <b>Mounting</b>                       | Desktop or 19" rack mount                                                                                                                                                       |
| <b>Power</b>                          | 100-240 VAC, 50-60 Hz, 4 A                                                                                                                                                      |
| <b>Environmental</b>                  | <ul style="list-style-type: none"> <li>Operational: 5 to 40°C (41 to 104°F)</li> <li>Storage: -25 to 85°C (-13 to 185°F)</li> <li>Humidity: 10 to 90% non-condensing</li> </ul> |
