

Mediant™ 850 MSBR

Multi-Service Business Router

Session Border Controller

User's Manual

Version 6.6

May 2013

Document # LTRT-10293

Table of Contents

1	Overview	19
	Getting Started with Initial Connectivity.....	21
2	Introduction	23
3	Configuring VoIP-LAN Interface for OAMP	25
3.1	Web Interface	25
3.2	CLI.....	27
4	Configuring Data-Router's LAN and WAN	29
4.1	Configuring Data-Router's LAN Interface.....	29
4.2	Configuring the Device's DHCP Server	30
4.3	Configuring the WAN Interface	30
5	Enabling Remote Management from WAN.....	33
5.1	Remote Web-based (HTTP/S) Management	33
5.2	Remote Telnet-based Management.....	34
	Management Tools	35
6	Introduction	37
7	Web-Based Management.....	39
7.1	Getting Acquainted with the Web Interface	39
7.1.1	Computer Requirements.....	39
7.1.2	Accessing the Web Interface	40
7.1.3	Areas of the GUI	41
7.1.4	Toolbar Description.....	42
7.1.5	Navigation Tree	43
7.1.5.1	Displaying Navigation Tree in Basic and Full View.....	43
7.1.5.2	Showing / Hiding the Navigation Pane.....	44
7.1.6	Working with Configuration Pages	45
7.1.6.1	Accessing Pages.....	45
7.1.6.2	Viewing Parameters	46
7.1.6.3	Modifying and Saving Parameters	47
7.1.6.4	Working with Tables	48
7.1.7	Searching for Configuration Parameters	50
7.1.8	Creating a Login Welcome Message.....	52
7.1.9	Getting Help.....	53
7.1.10	Logging Off the Web Interface.....	54
7.2	Viewing the Home Page.....	54
7.2.1	Assigning a Port Name	57
7.3	Configuring Web User Accounts	58
7.3.1	Basic User Accounts Configuration	59
7.3.2	Advanced User Accounts Configuration.....	61
7.4	Displaying Login Information upon Login	64
7.5	Configuring Web Security Settings	65
7.6	Limiting OAMP Access to a Specific WAN Interface.....	66

7.7	Web Login Authentication using Smart Cards	66
7.8	Configuring Web and Telnet Access List	67
7.9	Configuring RADIUS Settings	68
8	CLI-Based Management.....	69
8.1	Enabling CLI using Telnet.....	69
8.2	Enabling CLI using SSH and RSA Public Key	70
8.3	Establishing a CLI Session	72
8.4	Configuring TACACS+ for CLI Login	73
9	EMS-Based Management.....	75
10	SNMP-Based Management	77
10.1	Configuring SNMP Community Strings	77
10.2	Configuring SNMP Trap Destinations	78
10.3	Configuring SNMP Trusted Managers	79
10.4	Configuring SNMP V3 Users.....	80
11	TR-069 CWMP Based Management	83
11.1	TR-069	83
11.2	TR-104	86
11.3	Configuring TR-069.....	88
12	INI File-Based Management.....	89
12.1	INI File Format	89
12.1.1	Configuring Individual ini File Parameters	89
12.1.2	Configuring Table ini File Parameters	89
12.1.3	General ini File Formatting Rules	91
12.2	Loading an ini File	91
12.3	Modifying an ini File	92
12.4	Secured Encoded ini File	92
General System Settings		93
13	Configuring Certificates	95
13.1	Replacing the Device's Certificate	95
13.2	Loading a Private Key	96
13.3	Mutual TLS Authentication	98
13.4	Self-Signed Certificates.....	99
13.5	Configuring Certificate Revocation Checking (OCSP)	99
13.6	TLS Server Certificate Expiry Check.....	100
13.7	Loading Certificate Chain for Trusted Root.....	100
14	Date and Time.....	101
14.1	Configuring Date and Time Manually.....	101
14.2	Automatic Date and Time through SNTP Server	101
15	Configuring Power over Ethernet	103
General VoIP Configuration.....		105

16 Network	107
16.1 Configuring IP Network Interfaces	107
16.1.1 Assigning NTP Services to Application Types	111
16.1.2 Multiple Interface Table Configuration Rules	111
16.1.3 Troubleshooting the Multiple Interface Table	112
16.1.4 Networking Configuration Examples	112
16.1.4.1 One VoIP Interface for All Applications	112
16.1.4.2 VoIP Interface per Application Type	113
16.1.4.3 VoIP Interfaces for Combined Application Types	114
16.1.4.4 VoIP Interfaces with Multiple Default Gateways	114
16.2 Configuring the IP Routing Table	115
16.2.1 Interface Column	117
16.2.2 Routing Table Configuration Summary and Guidelines	117
16.2.3 Troubleshooting the Routing Table	117
16.3 Configuring Quality of Service	118
16.4 DNS	120
16.4.1 Configuring the Internal DNS Table	120
16.4.2 Configuring the Internal SRV Table	122
16.5 Configuring NFS Settings	123
16.6 Network Address Translation Support	125
16.6.1 Device Located behind NAT	125
16.6.1.1 Configuring a Static NAT IP Address for All Interfaces	126
16.6.1.2 Configuring NAT Translation per IP Interface	127
16.6.2 Remote UA behind NAT	128
16.6.2.1 First Incoming Packet Mechanism	129
16.6.2.2 No-Op Packets	129
16.7 Robust Receipt of Media Streams	130
16.8 Multiple Routers Support	130
17 Security	131
17.1 Configuring Firewall Settings	131
17.2 Configuring General Security Settings	135
17.3 Intrusion Detection System	136
17.3.1 Enabling IDS	136
17.3.2 Configuring IDS Policies	137
17.3.3 Assigning IDS Policies	140
17.3.4 Viewing IDS Alarms	142
18 Media	145
18.1 Configuring Voice Settings	145
18.1.1 Configuring Voice Gain (Volume) Control	145
18.1.2 Silence Suppression (Compression)	146
18.1.3 Echo Cancellation	146
18.2 Fax and Modem Capabilities	148
18.2.1 Fax/Modem Operating Modes	149
18.2.2 Fax/Modem Transport Modes	149
18.2.2.1 T.38 Fax Relay Mode	149
18.2.2.2 G.711 Fax / Modem Transport Mode	151
18.2.2.3 Fax Fallback	151
18.2.2.4 Fax/Modem Bypass Mode	152
18.2.2.5 Fax / Modem NSE Mode	153
18.2.2.6 Fax / Modem Transparent with Events Mode	154
18.2.2.7 Fax / Modem Transparent Mode	154

18.2.2.8	RFC 2833 ANS Report upon Fax/Modem Detection	155
18.2.3	V.34 Fax Support.....	155
18.2.3.1	Bypass Mechanism for V.34 Fax Transmission	156
18.2.3.2	Relay Mode for T.30 and V.34 Faxes	156
18.2.3.3	V.34 Fax Relay for SG3 Fax Machines.....	157
18.2.4	V.150.1 Modem Relay	158
18.2.5	Simultaneous Negotiation of Fax (T.38) and Modem (V.150.1) Relay.....	159
18.2.6	V.152 Support.....	160
18.2.7	Fax Transmission behind NAT	160
18.3	Configuring RTP/RTCP Settings.....	161
18.3.1	Configuring the Dynamic Jitter Buffer.....	161
18.3.2	Comfort Noise Generation	162
18.3.3	Dual-Tone Multi-Frequency Signaling	163
18.3.3.1	Configuring DTMF Transport Types.....	163
18.3.3.2	Configuring RFC 2833 Payload	164
18.3.4	Configuring RTP Base UDP Port.....	165
18.4	Configuring IP Media Settings.....	166
18.4.1	Automatic Gain Control (AGC)	166
18.5	Configuring Various Codec Attributes	167
18.6	Configuring Analog Settings.....	167
18.7	Configuring Media Realms.....	168
18.7.1	Configuring Quality of Experience per Media Realm	170
18.7.2	Configuring Bandwidth Management per Media Realm.....	173
18.8	Configuring Server for Media Quality of Experience	175
18.9	Configuring Media Security	176
19	Services	179
19.1	Routing Based on LDAP Active Directory Queries	179
19.1.1	Configuring the LDAP Server	179
19.1.2	Configuring the Device's LDAP Cache.....	180
19.1.3	Active Directory based Tel-to-IP Routing for Microsoft Lync.....	182
19.1.3.1	Querying the AD and Routing Priority	182
19.1.3.2	Configuring AD-Based Routing Rules.....	186
19.1.3.3	Querying the AD for Calling Name	188
19.2	Least Cost Routing.....	189
19.2.1	Overview	189
19.2.2	Configuring LCR	191
19.2.2.1	Enabling the LCR Feature.....	191
19.2.2.2	Configuring Cost Groups.....	193
19.2.2.3	Configuring Time Bands for Cost Groups	194
19.2.2.4	Assigning Cost Groups to Routing Rules.....	196
20	Enabling Applications.....	197
21	Control Network	199
21.1	Configuring SRD Table	199
21.2	Configuring SIP Interface Table	201
21.3	Configuring IP Groups.....	204
21.4	Configuring Proxy Sets Table	213
21.5	Associating WAN Interface with VoIP Traffic	217
22	SIP Definitions.....	219
22.1	Configuring SIP Parameters	219
22.2	Configuring Account Table.....	219

22.3	Configuring Proxy and Registration Parameters	222
22.3.1	SIP Message Authentication Example	223
22.4	Configuring SIP Message Manipulation	224
22.5	Configuring SIP Message Policy Rules	230
23	Coders and Profiles	233
23.1	Configuring Coders	233
23.2	Configuring Coders Groups	236
23.3	Configuring Tel Profile	237
23.4	Configuring IP Profiles	239
Gateway and IP-to-IP Application		251
24	IP-to-IP Routing Overview	253
24.1	Theory of Operation	254
24.1.1	Proxy Sets	255
24.1.2	IP Groups	255
24.1.3	Inbound and Outbound IP Routing Rules	257
24.1.4	Accounts	257
24.2	IP-to-IP Routing Configuration Example	257
24.2.1	Step 1: Enable the IP-to-IP Capabilities	260
24.2.2	Step 2: Configure the Number of Media Channels	260
24.2.3	Step 3: Define a Trunk Group for the Local PSTN	260
24.2.4	Step 4: Configure the Proxy Sets	261
24.2.5	Step 5: Configure the IP Groups	263
24.2.6	Step 6: Configure the Account Table	264
24.2.7	Step 7: Configure IP Profiles for Voice Coders	265
24.2.8	Step 8: Configure Inbound IP Routing	266
24.2.9	Step 9: Configure Outbound IP Routing	268
24.2.10	Step 10: Configure Destination Phone Number Manipulation	270
25	Digital PSTN	271
25.1	Configuring Trunk Settings	271
25.2	TDM and Timing	274
25.2.1	Configuring TDM Bus Settings	274
25.2.2	Clock Settings	274
25.2.2.1	Recovering Clock from PSTN Line Interface	274
25.2.2.2	Configuring Internal Clock as Clock Source	275
25.3	Configuring CAS State Machines	275
25.4	Configuring Digital Gateway Parameters	278
25.5	Tunneling Applications	279
25.5.1	TDM Tunneling	279
25.5.1.1	DSP Pattern Detector	282
25.5.2	QSIG Tunneling	282
25.6	ISDN Non-Facility Associated Signaling (NFAS)	283
25.6.1	NFAS Interface ID	284
25.6.2	Working with DMS-100 Switches	284
25.6.3	Creating an NFAS-Related Trunk Configuration	285
25.6.4	Performing Manual D-Channel Switchover in NFAS Group	286
25.7	ISDN Overlap Dialing	286
25.7.1	Collecting ISDN Digits and Sending Complete Number in SIP	286
25.7.2	Interworking ISDN Overlap Dialing with SIP According to RFC 3578	287

25.8	Redirect Number and Calling Name (Display)	288
26	Trunk Group	289
26.1	Configuring Trunk Group Table	289
26.2	Configuring Hunt Group Settings	291
27	Manipulation	297
27.1	Configuring General Settings	297
27.2	Configuring Source/Destination Number Manipulation Rules	297
27.3	Manipulating Number Prefix	303
27.4	SIP Calling Name Manipulations	304
27.5	Configuring Redirect Number IP to Tel	307
27.6	Manipulating Redirected and Diverted Numbers for Call Diversion	310
27.7	Mapping NPI/TON to SIP Phone-Context	311
27.8	Configuring Release Cause Mapping	313
27.8.1	Fixed Mapping of SIP Response to ISDN Release Reason	314
27.8.2	Fixed Mapping of ISDN Release Reason to SIP Response	316
27.8.3	Reason Header	318
27.8.4	Mapping PSTN Release Cause to SIP Response	318
27.9	Numbering Plans and Type of Number	319
28	Routing	321
28.1	Configuring General Routing Parameters	321
28.2	Configuring Outbound IP Routing Table	321
28.3	Configuring Inbound IP Routing Table	330
28.4	IP Destinations Connectivity Feature	333
28.5	Alternative Routing for Tel-to-IP Calls	334
28.5.1	Alternative Routing Based on IP Connectivity	334
28.5.2	Alternative Routing Based on SIP Responses	336
28.5.3	PSTN Fallback	338
28.6	Alternative Routing for IP-to-Tel Calls	338
28.6.1	Alternative Routing to Trunk upon Q.931 Call Release Cause Code	338
28.6.2	Alternative Routing to an IP Destination upon a Busy Trunk	340
29	Configuring DTMF and Dialing	343
29.1	Dialing Plan Features	344
29.1.1	Digit Mapping	344
29.1.2	External Dial Plan File	346
30	Configuring Supplementary Services	347
30.1	Call Hold and Retrieve	349
30.2	Call Pickup	351
30.3	BRI Suspend and Resume	351
30.4	Consultation Feature	352
30.5	Call Transfer	352
30.5.1	Consultation Call Transfer	352
30.5.2	Consultation Transfer for QSIG Path Replacement	353
30.5.3	Blind Call Transfer	353
30.6	Call Forward	354
30.6.1	Call Forward Reminder Ring	355
30.6.2	Call Forward Reminder (Off-Hook) Special Dial Tone	355
30.6.3	Call Forward Reminder Dial Tone (Off-Hook) upon Spanish SIP Alert-Info	356

30.6.4 BRI Call Forwarding.....	357
30.7 Call Waiting	357
30.8 Message Waiting Indication	358
30.9 Caller ID	360
30.9.1 Caller ID Detection / Generation on the Tel Side	360
30.9.2 Debugging a Caller ID Detection on FXO.....	360
30.9.3 Caller ID on the IP Side	361
30.10 Three-Way Conferencing	362
30.11 Emergency E911 Phone Number Services.....	363
30.11.1 FXS Device Emulating PSAP using DID Loop-Start Lines.....	364
30.11.2 FXO Device Interworking SIP E911 Calls from Service Provider's IP Network to PSAP DID Lines	366
30.11.3 Pre-empting Existing Calls for E911 IP-to-Tel Calls.....	369
30.11.4 Enhanced 9-1-1 Support for Lync Server 2010.....	370
30.11.4.1 About E9-1-1 Services	370
30.11.4.2 Microsoft Lync Server 2010 and E9-1-1.....	371
30.11.4.3 AudioCodes ELIN Gateway for Lync Server 2010 E9-1-1 Calls to PSTN	375
30.11.4.4 Configuring AudioCodes ELIN Gateway	380
30.12 Multilevel Precedence and Preemption.....	382
30.12.1 MLPP Preemption Events in SIP Reason Header	384
30.12.2 Precedence Ring Tone.....	385
30.13 Denial of Collect Calls	385
30.14 Configuring ISDN Supplementary Services	386
30.15 Advice of Charge Services for Euro ISDN	388
30.16 Configuring Voice Mail	389
31 Analog Gateway	391
31.1 Configuring Keypad Features	391
31.2 Configuring Metering Tones.....	392
31.3 Configuring Charge Codes.....	393
31.4 Configuring FXO Settings	394
31.5 Configuring Authentication	395
31.6 Configuring Automatic Dialing.....	396
31.7 Configuring Caller Display Information.....	398
31.8 Configuring Call Forward	399
31.9 Configuring Caller ID Permissions	401
31.10 Configuring Call Waiting.....	402
31.11 Rejecting Anonymous Calls	403
31.12 Configuring FXS Distinctive Ringing and Call Waiting Tones per Source/Destination Number	403
31.13 FXS/FXO Coefficient Types	405
31.14 FXO Operating Modes	406
31.14.1 FXO Operations for IP-to-Tel Calls.....	406
31.14.1.1 One-Stage Dialing	406
31.14.1.2 Two-Stage Dialing	407
31.14.1.3 DID Wink	408
31.14.2 FXO Operations for Tel-to-IP Calls.....	408
31.14.2.1 Automatic Dialing	408
31.14.2.2 Collecting Digits Mode.....	409
31.14.2.3 FXO Supplementary Services.....	409

31.14.3 Call Termination on FXO Devices	410
31.14.3.1 Calls Termination by PBX	410
31.14.3.2 Call Termination before Call Establishment	411
31.14.3.3 Ring Detection Timeout	411
31.15 Remote PBX Extension between FXO and FXS Devices	411
31.15.1 Dialing from Remote Extension (Phone at FXS)	412
31.15.2 Dialing from PBX Line or PSTN	412
31.15.3 Message Waiting Indication for Remote Extensions	413
31.15.4 Call Waiting for Remote Extensions	413
31.15.5 FXS Gateway Configuration	414
31.15.6 FXO Gateway Configuration	415

Session Border Controller Application.....417

32 SBC Overview.....419

32.1 SIP Network Definitions	420
32.2 SIP Dialog Initiation Process	420
32.3 User Registration and Internal Database	422
32.3.1 Initial Registration Request Processing	423
32.3.2 Internal Database	423
32.3.3 Routing using Internal Database	424
32.3.4 Registration Refreshes	424
32.3.5 Notification of Expired User Registration to SIP Proxy / Registrar	424
32.3.6 Registration Restriction Control	425
32.4 SBC Media Handling	425
32.4.1 Media Anchoring without Transcoding (Transparent)	427
32.4.2 Media Anchoring with Transcoding	427
32.4.3 No Media Anchoring	429
32.4.4 Transcoding Modes	431
32.4.5 Restricting Coders	431
32.4.6 Coder Transcoding	432
32.4.7 Prioritizing Coder List in SDP Offer	433
32.4.8 SRTP-RTP and SRTP-SRTP Transcoding	433
32.4.9 Multiple RTP Media Streams per Call Session	434
32.4.10 Interworking DTMF Methods	434
32.5 Fax Negotiation and Transcoding	435
32.6 Limiting SBC Call Duration	435
32.7 SIP Authentication Server for SBC Users	435
32.8 Interworking SIP Signaling	436
32.8.1 Interworking SIP 3xx Redirect Responses	436
32.8.1.1 Resultant INVITE Traversing Device	436
32.8.1.2 Local Handling of SIP 3xx	438
32.8.2 Interworking SIP Diversion and History-Info Headers	438
32.8.3 Interworking SIP REFER Messages	439
32.8.4 Interworking SIP PRACK Messages	439
32.8.5 Interworking SIP Session Timer	440
32.8.6 Interworking SIP Early Media	440
32.8.7 Interworking SIP re-INVITE Messages	442
32.8.8 Interworking SIP UPDATE Messages	442
32.8.9 Interworking SIP re-INVITE to UPDATE	442
32.8.10 Interworking Delayed Offer	442
32.8.11 Interworking Call Hold	443
32.9 Call Survivability	443
32.9.1 Auto-Provisioning of Subscriber-Specific Information for BroadWorks Server for Survivability	443

32.9.2	BroadSoft's Shared Phone Line Call Appearance for SBC Survivability.....	444
32.9.3	Call Survivability for Call Centers	445
32.9.4	Survivability Mode Display on Aastra IP Phones	447
32.10	Call Forking	448
32.10.1	Initiating SIP Call Forking	448
32.10.2	SIP Forking Initiated by SIP Proxy Server.....	448
32.11	Alternative Routing on Detection of Failed SIP Response	449
33	SBC Configuration	451
33.1	Configuring General Settings	451
33.2	Configuring Admission Control.....	452
33.3	Configuring Allowed Coder Groups.....	454
33.4	Routing SBC	455
33.4.1	Configuring Classification Rules.....	456
33.4.1.1	Classification Based on URI of Selected Header Example.....	460
33.4.2	Configuring Condition Rules.....	461
33.4.3	Configuring SBC IP-to-IP Routing	462
33.4.4	Configuring Alternative Routing Reasons.....	468
33.5	SBC Manipulations.....	469
33.5.1	Configuring IP-to-IP Inbound Manipulations.....	472
33.5.2	Configuring IP-to-IP Outbound Manipulations.....	474
	Cloud Resilience Package Application.....	479
34	CRP Overview.....	481
35	CRP Configuration	483
35.1	Enabling the CRP Application	483
35.2	Configuring Call Survivability Mode	484
35.3	Pre-Configured IP Groups.....	485
35.4	Pre-Configured IP-to-IP Routing Rules	486
	Stand-Alone Survivability Application.....	487
36	SAS Overview	489
36.1	SAS Operating Modes	489
36.1.1	SAS Outbound Mode.....	490
36.1.1.1	Normal State	490
36.1.1.2	Emergency State.....	490
36.1.2	SAS Redundant Mode.....	491
36.1.2.1	Normal State	492
36.1.2.2	Emergency State.....	492
36.1.2.3	Exiting Emergency and Returning to Normal State	492
36.2	SAS Routing.....	493
36.2.1	SAS Routing in Normal State	493
36.2.2	SAS Routing in Emergency State.....	495
37	SAS Configuration	497
37.1	General SAS Configuration.....	497
37.1.1	Enabling the SAS Application.....	497
37.1.2	Configuring Common SAS Parameters.....	497

37.2	Configuring SAS Outbound Mode	500
37.3	Configuring SAS Redundant Mode	500
37.4	Configuring Gateway Application with SAS	501
37.4.1	Gateway with SAS Outbound Mode	501
37.4.2	Gateway with SAS Redundant Mode	503
37.5	Advanced SAS Configuration.....	504
37.5.1	Manipulating URI user part of Incoming REGISTER.....	504
37.5.2	Manipulating Destination Number of Incoming INVITE	505
37.5.3	SAS Routing Based on IP-to-IP Routing Table	508
37.5.4	Blocking Calls from Unregistered SAS Users.....	513
37.5.5	Configuring SAS Emergency Calls	513
37.5.6	Adding SIP Record-Route Header to SIP INVITE.....	514
37.5.7	Re-using TCP Connections	515
37.5.8	Replacing Contact Header for SIP Messages	515
37.6	Viewing Registered SAS Users.....	516
38	SAS Cascading.....	517
IP Media Capabilities		519
39	Transcoding using Third-Party Call Control	521
39.1	Using RFC 4117.....	521
Data-Router Configuration.....		523
40	Introduction	525
Maintenance		527
41	Basic Maintenance	529
41.1	Resetting the Device	529
41.2	Remotely Resetting Device using SIP NOTIFY	530

WEEE EU Directive

Pursuant to the WEEE EU Directive, electronic and electrical waste must not be disposed of with unsorted waste. Please contact your local recycling authority for disposal of this product.

Customer Support

Customer technical support and service are generally provided by AudioCodes' Distributors, Partners, and Resellers from whom the product was purchased. For technical support for products purchased directly from AudioCodes, or for customers subscribed to AudioCodes Customer Technical Support (ACTS), contact support@audiocodes.com.

Abbreviations and Terminology

Each abbreviation, unless widely used, is spelled out in full when first used.

Throughout this manual, unless otherwise specified, the term *device* refers to the Mediant 850 MSBR.

Documentation Feedback

AudioCodes continually strives to produce high quality documentation. If you have any comments (suggestions or errors) regarding this document, please fill out the Documentation Feedback form on our Web site at <http://www.audiocodes.com/downloads>.

Notes and Warnings

Note: The scope of this document does not fully cover security aspects for deploying the device in your environment. Security measures should be done in accordance with your organization's security policies. For basic security guidelines, you should refer to AudioCodes *Recommended Security Guidelines* document.

Note: Before configuring the device, ensure that it is installed correctly as instructed in the *Hardware Installation Manual*.

Note: This device is considered an **INDOOR** unit and therefore must be installed only indoors.

Note: The device's Data-Router functionality is configured using CLI. For more information, refer to the document, *MSBR Series CLI Reference Guide for Data Functionality*.

Notes:

- By default, the device supports export-grade (40-bit and 56-bit) encryption due to US government restrictions on the export of security technologies. To enable 128-bit and 256-bit encryption on your device, contact your AudioCodes sales representative.
- This device includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org/>).
- This device includes cryptographic software written by Eric Young (eay@cryptsoft.com).

1 Overview

The Mediant 850 Multi-Service Business Router (MSBR) is a networking device that combines multiple service functions such as a Media Gateway, Session Border Controller (SBC), Data Router and Firewall, LAN switch, WAN access, Stand Alone Survivability (SAS) and an integrated general-purpose server. The device offers enhanced dialing plans and voice routing capabilities along with SIP-to-SIP mediation, allowing enterprises to implement SIP Trunking services (IP-to-IP call routing) and IP-based Unified Communications, as well as flexible PSTN and legacy PBX connectivity.

The device is designed as a secured Voice-over-IP (VoIP) and data platform. Enhanced media gateway security features include, for example, SRTP for media, TLS for SIP control, and IPSec for management. Data security functions include integrated Stateful Firewall, IDS/IPS, SSL for remote user access, and site-to-site VPN. A fully featured enterprise class SBC provides a secured voice network deployment based on a Back-to-Back User Agent (B2BUA) implementation.

The device's SAS and Cloud Resilience Package (CRP) applications offer service continuity to enterprises served by a centralized SIP-based IP-Centrex server or branch offices of distributed enterprises. SAS enables internal office communication between SIP clients, along with PSTN fallback in the case of disconnection from the centralized SIP IP-Centrex server or IP-PBX.

The device provides Foreign Exchange Station (FXS) and/or Foreign Exchange Office (FXO) telephony module interfaces, depending on ordered hardware configuration. The device supports either a combination of FXS and FXO port interfaces, or only FXS or only FXO interfaces. The device can support up to 12 simultaneous VoIP calls. Each FXS or FXO module provides four analog RJ-11 ports. The FXO module can be used to connect analog lines of an enterprise's PBX or the PSTN, to the IP network. The FXS module can be used to connect legacy telephones, fax machines, and modems to the IP network. Optionally, the FXS module can be connected to the external trunk lines of a PBX. When deployed with a combination of FXO and FXS modules, the device can be used as a PBX for Small Office Home Office (SOHO) users, and businesses not equipped with a PBX. The FXS modules also support the Analog Lifeline feature, enabling an FXS port to connect directly to the PSTN upon power and/or network failure.

The device supports up to 8 ISDN Basic Rate Interface (BRI) S/T interfaces (RJ-45 ports), supporting up to 16 voice channels. These connect ISDN terminal equipment such as ISDN telephones. The device also provides an optional, single or dual E1/T1 interface port(s), supporting Transparent, CAS and ISDN protocols. The device supports various ISDN PRI protocols such as Euro ISDN, North American NI-2, Lucent™ 4/5ESS, Nortel™ DMS-100 and others. It also supports various ISDN BRI protocols such as ETSI 5ESS and QSIG over BRI. It also supports different variants of CAS protocols for E1 and T1 spans, including MFC R2, E&M immediate start, E&M delay dial / start, loop start and ground start.

The device provides two USB ports that can be used for an optional, 3G cellular WAN modem and/or USB storage services.

The device's data routing capabilities support static and dynamic routing protocols such as RIP/OSPF and BGP, Virtual Routing and Forwarding (VRF-Lite) where interfaces can be clustered into a VRF to provide segregated routing domains. The device supports various optional WAN interfaces, providing flexibility in connecting to Service Providers. It provides an integrated Gigabit Ethernet (GE) Unshielded Twisted Pair (UTP) interface port, with an option of one or two additional WAN interfaces of the following types (factory assembled option):

- GE UTP
- Optical Fiber SFP form factor, supporting 100 Mbps and 1000 Mbps Ethernet
- ADSL2+ / VDSL2 (RJ-11 port interfaces)
- SHDSL, supporting up to four wire-pairs (two RJ-11 port interfaces) according to G.991.2. This serves as a remote-terminal CPE device. ATM and EFM modes are supported. In the ATM mode, a variety of protocols are supported, including PPPoE,

PPPoA, and RFC 2684 in both bridged (Ethernet-over-ATM) and routed (IP-over-ATM) variants. In the EFM mode, the SHDSL port functions as a logical Ethernet device.

- 1 x Ethernet copper WAN port (10/100/1000Base-T)
- 3G Cellular WAN access (primary or backup) using a USB modem1000Base-T Gigabit Ethernet copper.

The device is optimized for wire-speed delivery of data, providing up to 12 Ethernet LAN ports for connecting equipment such as computers and IP phones. These ports are divided into Gigabit Ethernet and Fast Ethernet interfaces (the number depends on the ordered configuration), and provide power-over-Ethernet (PoE) capabilities.

The device also supports an optional, Wi-Fi interface, providing wireless LAN 802.11n access point at 2.4 GHz, 3xTx / 3xRx enabling data rates of up to 300 Mbps. The Wi-Fi interface also supports 802.11b/802.11g backward compatibility, allowing interoperability of multiple devices with different types of Wi-Fi

The device also provides an integrated Open Solution Network (OSN) Server module. The OSN can host a variety of third-party applications such as IP-PBX, Call Center, and Conferencing.

The device allows full management through its command line interface (CLI) as well as its HTTP/S-based embedded Web server. The user-friendly Web interface allows remote configuration using any standard Web browser (such as Microsoft™ Internet Explorer™).

Figure 1-1: Typical Application

Part I

Getting Started with Initial Connectivity

2 Introduction

This section describes how to initially access the device's management interface and change its IP address to correspond with your networking scheme.

The device is shipped with a factory default IP address for operations, administration, maintenance, and provisioning (OAMP) through the VoIP LAN interface. You can use this address to initially access the device using any of its management tools -- embedded Web server, EMS, or Telnet.

You can also access the device through the console CLI, whereby the device's serial (RS-232) port is connected to the management PC's serial port.

Device management can be done through one of the VoIP LAN OAMP, WAN, and LAN.

Note: By default, the device's embedded DHCP server is enabled. For more information, see Section 'Configuring the Device's DHCP Server' on page [30](#).

Reader's Notes

3 Configuring VoIP-LAN Interface for OAMP

You can configure the VoIP LAN OAMP through the device's Web interface or CLI.

3.1 Web Interface

This procedure describes how to configure the VoIP-LAN IP address for OAMP, through the Web interface.

Default VoIP LAN IP Address for OAMP

IP Address	Value
IP Address	192.168.0.2
Subnet Mask	255.255.255.0
Default Gateway IP Address	192.168.0.1

➤ **To configure the VoIP-LAN IP address for OAMP:**

1. Connect Port 1 (left-most LAN port), located on the front panel, directly to the network interface of your computer, using a straight-through Ethernet cable.

Figure 3-1: Connecting to LAN Port

2. Make sure that your computer is configured to automatically obtain an IP address; the device has an embedded DHCP server which by default allocates IP addresses to computers that are connected to it.

3. On your computer, start a Web browser and in the URL address field, enter the default IP address of the device; the Web interface's Web Login screen appears:

Figure 3-2: Web Login Screen

Web Login

Username
Admin

Password

☒ Remember Me Login

4. In the 'Username' and 'Password' fields, enter the default (case-sensitive) login username ("Admin") and password ("Admin"), and then click **Login**; the device's Web interface appears.
5. Open the Multiple Interface Table page (**Configuration** tab > **VoIP** menu > **Network** > **IP Settings**).

Figure 3-3: Multiple Interface Table with Default OAMP Address

Note: Select row index to modify the relevant row.

2 Add Index Done

Index	Application Type	IP Address	Prefix Length	Gateway	VLAN ID	Interface Name	Primary DNS Server IP Address	Secondary DNS Server IP Address
0	OAMP + Media + Control	192.168.0.2	24	192.168.0.1	1	Voice		0.0.0.0

- a. Select the 'Index' radio button corresponding to the "OAMP + Media + Control" application type, and then click **Edit**.
 - b. Change the IP address to correspond with your network IP addressing scheme, for example:
 - ◆ IP Address: 10.8.6.86
 - ◆ Prefix Length: 24 (for 255.255.255.0)
 - ◆ Gateway: 10.8.6.85
 - c. Click **Apply**, and then click **Done** to validate your settings.
6. Restart the device with a flash burn.
 7. Cable the device to your network. You can now access the management interface using the new IP address for OAMP.

Note: After you have completed the above procedure, change your PC's IP address to correspond with your network requirements.

3.2 CLI

This procedure describes how to configure the VoIP-LAN IP address for OAMP, through the CLI.

➤ **To configure the VoIP-LAN IP address for OAMP:**

1. Connect the RS-232 port of the device to the serial communication port on your computer. For more information, refer to the *Hardware Installation Manual*.

Figure 3-4: Connecting to Serial Port

2. Establish serial communication with the device using a terminal emulator program (such as HyperTerminal) with the following communication port settings:
 - **Baud Rate:** 115,200 bps
 - **Data Bits:** 8
 - **Parity:** None
 - **Stop Bits:** 1
 - **Flow Control:** None
3. At the CLI prompt, type the username (default is "Admin" - case sensitive):
 Username: Admin
4. At the prompt, type the password (default is "Admin" - case sensitive):
 Password: Admin
5. At the prompt, type the following:
enable
6. At the prompt, type the password again:
 Password: Admin
7. Access the VoIP configuration mode:
configure voip
8. Access the Multiple Interface table:
 (config-voip)# **interface network-if 0**
9. Configure the IP address:
 (network-if-0)# **set ip** <IP address>
10. Configure the prefix length:
 (network-if-0)# **set prefix-length** <prefix length, e.g., 16>
11. Configure the Default Gateway address:
 (network-if-0)# **set gateway** <IP address>

12. Exit the Multiple Interface table:
`(network-if-0)# exit`
13. Exit the VoIP configuration mode:
`(config-voip)# exit`
14. Reset the device with a flash burn:
`# reload now`
15. Cable the device to your network. You can now access the management interface using the new IP address for OAMP.

Note: After you have completed the above procedure, change your PC's IP address according to your network requirements.

4 Configuring Data-Router's LAN and WAN

This section describes how to configure the device's data-router LAN and/or WAN interfaces.

Notes:

- Make sure that you configure the LAN IP address of the data-router in the **same** subnet as the LAN IP address for OAMP of the VoIP interface.
- Once you access the device through the default VoIP LAN interface, you can configure Web management access from one of the following interfaces:
 - ✓ Any of the configured data-router LAN interfaces. The default LAN data interface is 192.168.0.1. This interface can be in a different subnet to the VoIP LAN IP address and with a different VLAN ID. This is useful, for example, if you want to separate management from the VoIP traffic.
 - ✓ WAN port interface. In this setup, you need to enable remote access to the WAN port interface, as described in 'Enabling Remote Management from WAN' on page 32.

4.1 Configuring Data-Router's LAN Interface

The default LAN IP address of the device's data-router is listed in the table below.

Default LAN IP Address of Data-Router

Parameter	Default Value
IP Address	192.168.0.1
Subnet Mask	255.255.255.0
Default Gateway	0.0.0.0

➤ To configure LAN IP address of data-router:

1. Establish serial communication with the device.
2. At the prompt, type the following command to access the data-router configuration mode:

```
# configure data
```

3. Access the VLAN 1 LAN switch interface:

```
(config-data)# interface vlan 1
```

4. Configure the IP address and subnet:

```
(conf-if-VLAN 1)# ip address <IP address> <subnet>
```

For example:

```
(conf-if-VLAN 1)# ip address 10.8.6.85 255.255.255.0
```

5. Save your settings with a flash burn:

```
(conf-if-VLAN 1)# do write
```

4.2 Configuring the Device's DHCP Server

By default, the device's embedded DHCP server is enabled for the LAN, and with default IP pool addresses relating to the default subnet LAN. You can disable the DHCP server, or modify the IP address pool. The device's DHCP server allocates this spool of IP addresses to the computers connected to its LAN interface.

➤ **To enable the device's DHCP server:**

1. Establish serial communication with the device.
2. At the prompt, type the following command to access the Data-router configuration mode:

```
# configure data
```

3. Access the data LAN switch interface:

```
(config-data)# interface vlan 1
```

4. To disable the DHCP server:

```
(conf-if-VLAN 1)# no service dhcp
```

5. To enable DHCP server:

- a. Configure the pool of IP addresses:

```
(conf-if-VLAN 1)# ip dhcp-server network 10.8.6.84 10.8.6.89  
255.255.255.0
```

- b. Enable DHCP server functionality:

```
(conf-if-VLAN 1)# service dhcp
```

6. Save your settings with a flash burn:

```
(conf-if-VLAN 1)# do write
```

4.3 Configuring the WAN Interface

This procedure describes how to configure the WAN interface and uses Gigabit Ethernet as an example. If your device uses a different WAN interface, refer to the *MSBR Series CLI Reference Guide for Data*.

Note: Before you configure the WAN interface, make sure that you have all the required information from your Internet Telephony Service Provider (ITSP).

➤ **To configure a WAN IP address:**

1. Connect the WAN port to the WAN network. For information on cabling the WAN port, refer to the *Hardware Installation Manual*.
2. Establish serial communication with the device.
3. At the prompt, type the following command to access the Data-router configuration mode:

```
# configure data
```

4. Access the WAN interface:

```
(config-data)# interface GigabitEthernet 0/0
```

5. Configure the IP address and subnet mask:

```
(config-if-GE 0/0)# ip address 100.33.2.105 255.255.255.0
```

6. Enable Network Address Port Translation (NAPT) on the WAN interface:

```
(config-if-GE 0/0)# napt
```

7. Enable the WAN interface:

```
(config-if-GE 0/0)# no shutdown
```

8. Exit the interface:

```
(config-if-GE 0/0)# exit
```

9. Configure the default route:

```
(config-data)# ip route 0.0.0.0 0.0.0.0 100.33.2.106  
GigabitEthernet 0/0
```

10. Exit the data-router configuration mode:

```
(config-data)# exit
```

11. Save the configuration to flash:

```
# write
```

Reader's Notes

5 Enabling Remote Management from WAN

This section describes how to configure remote device management from the WAN, if necessary.

5.1 Remote Web-based (HTTP/S) Management

This procedure describes how to enable remote Web-based management (HTTP/S) from the WAN.

➤ To enable remote Web (HTTP/S) management from WAN:

■ **CLI:**

1. Access the System configuration mode:
configure system
2. Enable HTTP management from the WAN:
<config-system># **web**
<web># **set wan-http on**
3. Reset the device with a burn to flash:
<cli-terminal># **do reload now**

■ **Web:**

1. Open the WEB Security Settings page (**Configuration** tab > **System** menu > **Management** > **WEB Security Settings**).

Figure 5-1: Enabling Web Management from WAN

General	
Voice Menu Password	12345
HTTP Authentication Mode	Web Based Authentication
Secured Web Connection (HTTPS)	HTTP and HTTPS
Requires Client Certificates for HTTPS connection	Disable
HTTPS Cipher String	RC4:EXP
WAN OAMP Interface	WAN Ethernet
Allow WAN access to HTTP	Disable
Allow WAN access to HTTPS	Enable

2. From the 'WAN OAMP Interface' drop-down list, select the WAN interface (**WAN Ethernet**).
3. From the 'Allow WAN access to HTTPS' drop-down list, select **Enable**.
4. Click **Submit**.
5. Save your settings with a flash burn.

5.2 Remote Telnet-based Management

This procedure describes how to enable remote Telnet-based management from the WAN.

➤ To enable remote Telnet management from WAN:

■ CLI:

1. Access the System configuration mode:

```
# configure system
```

2. Type the following command:

```
<config-system># cli-terminal
```

3. Enable Telnet:

```
<cli-terminal># set telnet
```

4. Enable Telnet from WAN:

```
<cli-terminal># set wan-telnet-allow on
```

5. Reset the device with a burn to flash:

```
<cli-terminal># do reload now
```

■ Web:

1. Open the Telnet/SSH Settings page (**Configuration** tab > **System** menu > **Management** > **Telnet/SSH Settings**).

Figure 5-2: Enabling Telnet Management from WAN

Telnet Settings	
Embedded Telnet Server	Enable Secured
Telnet Server TCP Port	23
Telnet Server Idle Timeout	100
Allow WAN access to Telnet	Enable

2. From the 'Embedded Telnet Server' drop-down list, select **Enable Secured**.
3. From the 'Allow WAN access to Telnet' drop-down list, select **Enable**.
4. Click **Submit**.
5. Save your settings with a flash burn.

Part II

Management Tools

6 Introduction

This part provides an overview of the various management tools that can be used to configure the device. It also provides step-by-step procedures on how to configure the management settings.

The following management tools can be used to configure the device:

- Embedded HTTP/S-based Web server - see 'Web-based Management' on page [39](#)
- Command Line Interface (CLI) - see 'CLI-Based Management' on page [69](#)
- AudioCodes Element Management System - see 'EMS-Based Management' on page [75](#)
- Simple Network Management Protocol (SNMP) browser software - see 'SNMP-Based Management' on page [75](#)
- TR-069 - see TR-069 Based Management on page [83](#)
- Configuration *ini* file - see 'INI File-Based Management' on page [89](#)

**Notes:**

- Some configuration settings can only be done using a specific management tool. For example, some configuration can only be done using the Configuration ini file method.
- Throughout this manual, where a parameter is mentioned, its corresponding Web, CLI, and ini parameter is mentioned. The ini file parameters are enclosed in square brackets [...].
- For a list and description of all the configuration parameters, see 'Configuration Parameters Reference' on page 655.

Reader's Notes

7 Web-Based Management

The device provides an embedded Web server (hereafter referred to as *Web interface*), supporting fault management, configuration, accounting, performance, and security (FCAPS), including the following:

- Full configuration
- Software and configuration upgrades
- Loading auxiliary files, for example, the Call Progress Tones file
- Real-time, online monitoring of the device, including display of alarms and their severity
- Performance monitoring of voice calls, data routing, and various traffic parameters

The Web interface provides a user-friendly, graphical user interface (GUI), which can be accessed using any standard Web browser (e.g., Microsoft™ Internet Explorer).

Access to the Web interface is controlled by various security mechanisms such as login user name and password, read-write privileges, and limiting access to specific IP addresses.

Notes:

- The Web interface allows you to configure most of the device's settings. However, additional configuration parameters may exist that are not available in the Web interface and which can only be configured using other management tools.
- Some Web interface pages and/or parameters are available only for certain hardware configurations or software features. The software features are determined by the installed Software License Key (see 'Software License Key' on page 553).

7.1 Getting Acquainted with the Web Interface

This section provides a description of the Web interface.

7.1.1 Computer Requirements

The client computer requires the following to work with the Web interface of the device:

- A network connection to the device
- One of the following Web browsers:
 - Microsoft™ Internet Explorer™ (Version 6.0 and later)
 - Mozilla Firefox® (Versions 5 through 9.0)
- Recommended screen resolutions: 1024 x 768 pixels, or 1280 x 1024 pixels

Note: Your Web browser must be JavaScript-enabled to access the Web interface.

7.1.2 Accessing the Web Interface

The procedure below describes how to access the Web interface.

➤ **To access the Web interface:**

1. Open a standard Web browser (see 'Computer Requirements' on page 39).
2. In the Web browser, specify the IP address of the device (e.g., <http://10.1.10.10>); the Web interface's Login window appears, as shown below:

Figure 7-1: Web Login Screen

The image shows a web login form titled "Web Login". It contains two input fields: "Username" with the text "Admin" entered, and "Password" which is empty. Below the password field is a checkbox labeled "Remember Me" which is checked. To the right of the checkbox is a blue button labeled "Login".

3. In the 'Username' and 'Password' fields, enter the case-sensitive, user name and password respectively.
4. Click **Login**; the Web interface is accessed, displaying the Home page. For a detailed description of the Home page, see 'Viewing the Home Page' on page 54.

Notes:

- The default username and password is "Admin". To change the login user name and password, see 'Configuring the Web User Accounts' on page 58.
- If you want the Web browser to remember your password, select the 'Remember Me' check box and then agree to the browser's prompt (depending on your browser) to save the password for future logins. On your next login attempt, simply press the Tab or Enter keys to auto-fill the 'Username' and 'Password' fields, and then click **Login**.

7.1.3 Areas of the GUI

The areas of the Web interface's GUI are shown in the figure below and described in the subsequent table.

Description of the Web GUI Areas

Item #	Description
1	Displays AudioCodes (corporate) logo image.
2	Displays the product name.
3	Toolbar, providing frequently required command buttons. For more information, see 'Toolbar Description' on page 42.
4	Displays the username of the Web user that is currently logged in.
5	Navigation bar, providing the following tabs for accessing various functionalities in the Navigation tree: ▪ Configuration, Maintenance, and Status & Diagnostics tabs: Access the configuration menus (see 'Working with Configuration Pages' on page 45) ▪ Search tab: Enables a search engine for searching configuration parameters (see 'Searching for Configuration Parameters' on page 50)
6	Navigation tree, displaying a tree-like structure of elements (configuration menus or search engine) pertaining to the selected tab on the Navigation bar. For more information, see 'Navigation Tree' on page 43.
7	Work pane, displaying the configuration page of the selected menu in the Navigation tree. This is where configuration is done. For more information, see 'Working with Configuration Pages' on page 45.

7.1.4 Toolbar Description

The toolbar provides frequently required command buttons, described in the table below:

Description of Toolbar Buttons

Icon	Button Name	Description
	Submit	Applies parameter settings to the device (see 'Saving Configuration' on page 532). Note: This icon is grayed out when not applicable to the currently opened page.
	Burn	Saves parameter settings to flash memory (see 'Saving Configuration' on page 532).
	Device Actions	Opens a drop-down list with frequently needed commands: ▪ Load Configuration File: Opens the Configuration File page for loading an <i>ini</i> file to the device (see 'Backing Up and Loading Configuration File' on page 559). ▪ Save Configuration File: Opens the Configuration File page for saving the <i>ini</i> file to a folder on a computer (see 'Backing Up and Loading Configuration File' on page 559). ▪ Reset: Opens the Maintenance Actions page for performing various maintenance procedures such as resetting the device (see 'Resetting the Device' on page 529). ▪ Software Upgrade Wizard: starts the Software Upgrade wizard for upgrading the device's software (see 'Software Upgrade Wizard' on page 556).
	Home	Opens the Home page (see 'Viewing the Home Page' on page 54).
	Help	Opens the Online Help topic of the currently opened configuration page (see 'Getting Help' on page 53).
	Log off	Logs off a session with the Web interface (see 'Logging Off the Web Interface' on page 54).

Note: If you modify a parameter that takes effect only after a device reset, after you click the **Submit** button in the configuration page, the toolbar displays "Reset", as shown in the figure below. This is a reminder that you need to later save your settings to flash memory and reset the device.

Figure 7-2: "Reset" Displayed on Toolbar

7.1.5 Navigation Tree

The Navigation tree is located in the Navigation pane and displays a tree-like structure of menus pertaining to the selected tab on the Navigation bar. You can drill-down to the required page item level to open its corresponding page in the Work pane.

The terminology used throughout this manual for referring to the hierarchical structure of the tree is as follows:

- *Menu*: first level (highest level)
- *Submenu*: second level - contained within a menu
- *Page item*: last level (lowest level in a menu) - contained within a menu or submenu

Figure 7-3: Navigating in Hierarchical Menu Tree (Example)

Note: The figure above is used only as an example. The displayed menus depend on supported features based on the Software License Key installed on your device.

7.1.5.1 Displaying Navigation Tree in Basic and Full View

You can view an expanded or reduced display of the Navigation tree. This affects the number of displayed menus and submenus in the tree. The expanded (*Full*) view displays all the menus pertaining to the selected configuration tab; the reduced (*Basic*) view displays only commonly used menus. This is relevant when using the configuration tabs

(i.e., **Configuration**, **Maintenance**, and **Status & Diagnostics**) on the Navigation bar. The advantage of the Basic view is that it prevents "cluttering" of the Navigation tree with menus that may not be required.

➤ **To toggle between Full and Basic view:**

- To display a reduced menu tree, select the **Basic** option (default).
- To display all the menus and submenus in the Navigation tree, select the **Full** option.

Figure 7-4: Basic and Full View Options

Note: After you reset the device, the Web GUI is displayed in Basic view.

7.1.5.2 Showing / Hiding the Navigation Pane

You can hide the Navigation pane to provide more space for elements displayed in the Work pane. This is especially useful when the Work pane displays a wide table. The arrow button located below the Navigation bar is used to hide and show the pane.

➤ **To hide and show the Navigation pane:**

- **To hide the Navigation pane:** Click the left-pointing arrow ; the pane is hidden and the button is replaced by the right-pointing arrow button.

- **To show the Navigation pane:** Click the right-pointing arrow ; the pane is displayed and the button is replaced by the left-pointing arrow button.

Figure 7-5: Show and Hide Button (Navigation Pane in Hide View)

7.1.6 Working with Configuration Pages

The configuration pages contain the parameters for configuring the device and are displayed in the Work pane.

7.1.6.1 Accessing Pages

The configuration pages are accessed by clicking the required page item in the Navigation tree.

➤ **To open a configuration page:**

1. On the Navigation bar, click the required tab (**Configuration**, **Maintenance**, or **Status & Diagnostics**); the menus pertaining to the selected tab appear in the Navigation tree.
2. Navigate to the required page item, by performing the following:
 - Drill-down using the **plus**  sign to expand the menu and submenus.
 - Drill-up using the **minus**  sign to collapse the menu and submenus.
3. Click the required page item; the page opens in the Work pane.

You can also access previously opened pages by clicking the Web browser's **Back** button until you have reached the required page. This is useful if you want to view pages in which you have performed configurations in the current Web session.

Notes:

- You can also access certain pages from the **Device Actions** button located on the toolbar (see 'Toolbar Description' on page 42).
- To view all the menus in the Navigation tree, ensure that the Navigation tree is in Full view (see 'Displaying Navigation Tree in Basic and Full View' on page 43).
- To get Online Help for the currently displayed page, see 'Getting Help' on page 53.
- Certain pages may not be accessible or may be read-only, depending on the access level of your Web user account (see 'Configuring Web User Accounts' on page 58). If a page is read-only, "Read-Only Mode" is displayed at the bottom of the page.

7.1.6.2 Viewing Parameters

Some pages allow you to view a reduced or expanded display of parameters. The Web interface provides two methods for displaying page parameters:

- Displaying "basic" and "advanced" parameters - see 'Displaying Basic and Advanced Parameters' on page 46
- Displaying parameter groups - see 'Showing / Hiding Parameter Groups' on page 46

7.1.6.2.1 Displaying Basic and Advanced Parameters

Some pages provide a toggle button that allows you to show and hide parameters that typically are used only in certain deployments. This button is located on the top-right corner of the page and has two display states:

- **Advanced Parameter List** button with down-pointing arrow: click this button to display all parameters.
- **Basic Parameter List** button with up-pointing arrow: click this button to show only common (*basic*) parameters.

The figure below shows an example of a page displaying basic parameters only. If you click the **Advanced Parameter List** button (shown below), the page will also display the advanced parameters.

Figure 7-6: Toggling between Basic and Advanced View

Notes:

- When the Navigation tree is in Full mode (see 'Navigation Tree' on page 43), configuration pages display all their parameters.
- If a page contains only basic parameters, the **Basic Parameter List** button is not displayed.
- If you reset the device, the Web pages display only the basic parameters.
- The basic parameters are displayed in a dark blue background.

7.1.6.2.2 Showing / Hiding Parameter Groups

Some pages provide groups of parameters, which can be hidden or shown. To toggle between hiding and showing a group, simply click the group title button that appears above

each group. The button appears with a down-pointing or up-pointing arrow, indicating that it can be collapsed or expanded when clicked, respectively.

Figure 7-7: Expanding and Collapsing Parameter Groups

7.1.6.3 Modifying and Saving Parameters

When you modify a parameter value on a page, the **Edit**  symbol appears to the right of the parameter. This indicates that the parameter has been modified, but has yet to be applied (submitted). After you apply your modifications, the  symbol disappears.

Figure 7-8: Edit Symbol after Modifying Parameter Value

- To save configuration changes on a page to the device's volatile memory (RAM), do one of the following:

- On the toolbar, click the **Submit**  button.
- At the bottom of the page, click the **Submit**  button.

When you click **Submit**, modifications to parameters with on-the-fly capabilities are immediately applied to the device and take effect. Parameters displayed on the page with the lightning  symbol take effect only after a device reset. For resetting the device, see 'Resetting the Device' on page 529.

Note: Parameters saved to the volatile memory (by clicking **Submit**), revert to their previous settings after a hardware or software reset, or if the device is powered down. Therefore, to ensure parameter changes (whether on-the-fly or not) are retained, save ('burn') them to the device's non-volatile memory, i.e., flash (see 'Saving Configuration' on page 532).

If you enter an invalid parameter value (e.g., not in the range of permitted values) and then click **Submit**, a message box appears notifying you of the invalid value. In addition, the parameter value reverts to its previous value and is highlighted in red, as shown in the figure below:

Figure 7-9: Value Reverts to Previous Valid Value

7.1.6.4 Working with Tables

This section describes how to work with configuration tables, which are provided in basic or enhanced design, depending on the configuration page.

7.1.6.4.1 Basic Design Tables

A few of the tables in the Web interface are in basic design format. The figure below displays a typical table in the basic design format and the subsequent table describes its command buttons.

Figure 7-10: Adding an Index Entry to a Table

Basic Table Design Description

Item #	Button / Field	
1	Add Index (or Add) button	Adds an index entry row to the table.
2	Edit	Edits the selected row.
3	Delete	Removes the selected row from the table.
4	'Add Index' field	Defines the index number. When adding a new row, enter the required index number in this field, and then click Add Index .
5	Index radio button	Selects the row for editing and deleting.
-	Compact button	Organizes the index entries in ascending, consecutive order, starting from index 0. For example, assume you have three index entries, 0, 4 and 6. After you click Compact ,

Item #	Button / Field	
		index entry 4 is re-assigned to index 1 and index entry 6 is re-assigned to index 2.
-	Apply button	Saves the row configuration. Click this button after you add or edit each index entry.

7.1.6.4.2 Enhanced Design Tables

Most of the tables in the Web interface are designed in the enhanced table format. The figure below displays a typical table in the enhanced design format and the subsequent table describes its command buttons and areas.

Figure 7-11: Displayed Details Pane

Enhanced Table Design Description

Item #	Button	
1	Add	Adds a new index entry row to the table. When you click this button, a dialog box appears with parameters for configuring the new entry. When you have completed configuration, click the Submit button in the dialog box to add it to the table.
2	Edit	Edits the selected row.
3	Delete	Removes the selected row from the table. When you click this button, a confirmation box appears requesting you to confirm deletion. Click Delete to accept deletion.
4	Show/Hide	Toggles between displaying and hiding the full configuration of a selected row. This configuration is displayed below the table (see Item

Item #	Button	
		#6) and is useful for large tables that cannot display all its columns in the work pane.
5	-	Selected index row entry for editing, deleting and showing configuration.
6	-	Displays the full configuration of the selected row when you click the Show/Hide button.
7	-	Links to access additional configuration tables related to the current configuration.

If the configuration of an entry row is invalid, the index of the row is highlighted in red, as shown below:

Figure 7-12: Invalid Configuration with Index Highlighted in Red

The table also enables you to define the number of rows to display on the page and to navigate between pages displaying multiple rows. This is done using the page navigation area located below the table, as shown in the figure below:

Figure 7-13: Viewing Table Rows per Page

Row Display and Page Navigation

Item #	Description
1	Defines the page that you want to view. Enter the required page number or use the following page navigation buttons: ➡ - Displays the next page ➡➡ - Displays the last page ⬅ - Displays the previous page ⬅⬅ - Displays the first page
2	Defines the number of rows to display per page. You can select 5 or 10, where the default is 10.
3	Displays the currently displayed page number.

7.1.7 Searching for Configuration Parameters

You can locate the exact Web page on which a specific parameter appears, by using the device's Search feature. The Web parameter's corresponding *ini* file parameter name is used as the search key. The search key can include the full parameter name (e.g.,

"EnableIPSec") or a substring of it (e.g., "sec"). If you search for a substring, all parameters containing the specified substring in their names are listed in the search result.

Note: If an *ini* file parameter is not configurable in the Web interface, the search fails.

➤ **To search for a parameter:**

1. On the Navigation bar, click the **Search** tab; the Search engine appears in the Navigation pane.
2. In the field alongside the **Search** button, enter the parameter name or a substring of the name for which you want to search. If you have done a previous search for such a parameter, instead of entering the required string, you can use the 'Search History' drop-down list to select the string saved from a previous search.
3. Click **Search**; a list of found parameters based on your search key appears in the Navigation pane. Each searched result displays the following:
 - *ini* file parameter name
 - Link (in green) to the Web page on which the parameter appears
 - Brief description of the parameter
 - Menu navigation path to the Web page on which the parameter appears
4. In the searched list, click the required parameter (green link) to open the page on which the parameter appears; the relevant page opens in the Work pane and the searched parameter is highlighted in the page for easy identification, as shown in the figure below:

Figure 7-14: Searched Result Screen

Search Description

Item #	Description
1	Search field for entering search key and Search button for activating the search process.
2	Search results listed in Navigation pane.
3	Found parameter, highlighted on relevant Web page

7.1.8 Creating a Login Welcome Message

You can create a Welcome message box that is displayed on the Web Login page for logging in to the Web interface. The figure below displays an example of a Welcome message:

Figure 7-15: User-Defined Web Welcome Message after Login

Web Login

Username

Password

☐ Remember Me

To enable and create a Welcome message, use the WelcomeMessage table ini file parameter. If this parameter is not configured, no Welcome message is displayed.

ini File Parameter for Welcome Login Message

Parameter	Description
[WelcomeMessage]	Enables and defines a Welcome message that appears on the Web Login page for logging in to the Web interface. The format of this parameter is as follows: <pre>[WelcomeMessage] FORMAT WelcomeMessage_Index = WelcomeMessage_Text; [WelcomeMessage]</pre> For Example: <pre>[WelcomeMessage] FORMAT WelcomeMessage_Index = WelcomeMessage_Text; WelcomeMessage 1 = "*****"; WelcomeMessage 2 = "***** This is a Welcome message ***"; WelcomeMessage 3 = "*****"; [WelcomeMessage]</pre> Each index row represents a line of text in the Welcome message box. Up to 20 lines (or rows) of text can be defined.

7.1.9 Getting Help

The Web interface provides you with context-sensitive Online Help. The Online Help provides brief descriptions of parameters pertaining to the currently opened page.

- To view the Help topic of a currently opened page:

1. On the toolbar, click the **Help**  button; the Help topic pertaining to the opened page appears, as shown below:

Figure 7-16: Help Topic for Current Page

2. To view a description of a parameter, click the **plus**  sign to expand the parameter. To collapse the description, click the **minus**  sign.
3. To close the Help topic, click the **close**  button located on the top-right corner of the Help topic window or simply click the **Help**  button.

Note: Instead of clicking the **Help** button for each page you open, you can open it once for a page and then simply leave it open. Each time you open a different page, the Help topic pertaining to that page is automatically displayed.

7.1.10 Logging Off the Web Interface

The procedure below describes how to log off the Web interface.

➤ To log off the Web interface:

1. On the toolbar, click the **Log Off**  icon; the following confirmation message box appears:

Figure 7-17: Log Off Confirmation Box

2. Click **OK**; you are logged off the Web session and the Web Login dialog box appears enabling you to re-login, if required.

7.2 Viewing the Home Page

The Home page is displayed when you access the device's Web interface. The Home page provides you with a graphical display of the device's front panel, showing color-coded status icons for various operations device.

➤ To access the Home page:

- On the toolbar, click the **Home**  icon.

Note: The displayed number and type of telephony interfaces, LAN interfaces and WAN interfaces depends on the ordered hardware configuration.

In addition to the color-coded status information depicted on the graphical display of the device, the Home page displays various read-only information in the General Information pane:

- **IP Address:** IP address of the device
- **Subnet Mask:** Subnet mask address of the device
- **Default Gateway Address:** Default gateway used by the device
- **Digital Port Number:** Number of digital PRI ports (depending on ordered hardware configuration)
- **BRI Port Number:** Number of BRI ports (depending on ordered hardware configuration))
- **Analog Port Number:** Number of analog (FXS, FXO) ports (depending on ordered hardware configuration)
- **Firmware Version:** Software version running on the device
- **Protocol Type:** Signaling protocol currently used by the device (i.e. SIP)
- **Gateway Operational State:**
 - "LOCKED": device is locked (i.e. no new calls are accepted)
 - "UNLOCKED": device is not locked
 - "SHUTTING DOWN": device is currently shutting down

To perform these operations, see 'Basic Maintenance' on page 529.

The table below describes the areas of the Home page.

Home Page Description

Item #	Description		
1	Displays the highest severity of an active alarm raised (if any) by the device: ■ Green = No alarms ■ Red = Critical alarm ■ Orange = Major alarm ■ Yellow = Minor alarm To view active alarms, click the Alarms area to open the Active Alarms page (see Viewing Active Alarms on page 579).		
2	Module slot number.		
3	Port (trunk or channel) status icon.		
	Icon	Trunk Description (Digital Module)	Channel Description (Analog Modules)
	 (gray)	Disable: Trunk not configured (not in use)	Idle: Channel is currently on-hook
	 (green)	Active - OK: Trunk synchronized	Call Connected: Active RTP stream
	 (yellow)	RAI Alarm: Remote Alarm Indication (RAI), also known as the Yellow Alarm	-
	 (red)	LOS/LOF Alarm: Loss due to LOS (Loss of Signal) or LOF (Loss of Frame)	Not Connected: No FXO line is connected to this port or port out of service due to Serial Peripheral Interface (SPI) failure (applicable only to FXO interfaces)

Item #	Description														
	 (blue)	AIS Alarm: Alarm Indication Signal (AIS), also known as the Blue Alarm	Handset Offhook: Channel is off-hook, but there is no active RTP session												
	 (orange)	D-Channel Alarm: D-channel alarm	-												
	 (dark orange)	NFAS Alarm	-												
	If you click a port, a shortcut menu appears with commands allowing you to do the following: - Reset channel (Analog ports only): Resets the analog port (see Resetting an Analog Channel on page 533) - Port Settings: Displays trunk status (see 'Viewing Trunk and Channel Status' on page 589) and analog port status (see 'Viewing Analog Port Information' on page 591) - Update Port Info: Assigns a name to the port (see 'Assigning a Port Name' on page 57)														
4	Module interface type.														
5	Module status icon:  (green): Module has been inserted or is correctly configured  (gray): Module was removed and "Reserved" is displayed  (red): Module failure and "Failure" is displayed														
6	Optional, additional WAN ports (up to two). WAN port status icons:  (green): Link is working  (gray): Link is not configured  (red): Link error Depending on ordered hardware configuration, the WAN port can be Gigabit Ethernet copper, SHDSL, or ADSL2+ / VDSL2, and optical fiber: <table border="0"> <tr> <td>Gigabit Ethernet Copper</td><td>SHDSL</td><td>ADSL2+ / VDSL2</td><td>Fiber</td></tr> <tr> <td></td><td></td><td></td><td></td></tr> <tr> <td>One Port</td><td>Four Ports</td><td>One Port</td><td></td></tr> </table>			Gigabit Ethernet Copper	SHDSL	ADSL2+ / VDSL2	Fiber					One Port	Four Ports	One Port	
Gigabit Ethernet Copper	SHDSL	ADSL2+ / VDSL2	Fiber												
															
One Port	Four Ports	One Port													
7	Copper Gigabit Ethernet WAN port. See Item 6 for a description.														
8	Gigabit Ethernet LAN port status icons:  (green): Link is working  (gray): Link is not configured  (red): Link error To view detailed port information, click the port icon (see Viewing Ethernet Port														

Item #	Description
	Information on page 577). If the ports are enabled with Power-over-Ethernet (PoE), the color codes of the status icons are as follows:  (gray with dark gray frame): Link is not connected  (green with dark gray frame): Ethernet delivered  (gray with orange frame): Power delivered  (green with orange frame): Ethernet and power delivered
9	Fast Ethernet LAN port status icons. See Item 8 for a description.
10	RS-232 interface port.
11	USB port for 3G cellular WAN modem for primary or backup WAN: - Gray - USB 3G cellular modem is not configured. - Blue - USB 3G cellular modem is in standby mode (backup mode). - Green - USB 3G cellular modem is active. - Red - USB 3G cellular modem is not active

7.2.1 Assigning a Port Name

The Home page allows you to assign an arbitrary name or a brief description to each port. This description appears as a tooltip when you move your mouse over the port.

Note: Only alphanumerical characters can be used in the port description.

➤ **To add a port description:**

1. Open the Home page.
2. Click the required port icon; a shortcut menu appears.
3. From the shortcut menu, choose **Update Port Info**; a text box appears.
4. Type a brief description for the port, and then click **Apply Port Info**.

7.3 Configuring Web User Accounts

You can create up to 10 Web user accounts for the device. Up to five Web users can simultaneously be logged in to the device's Web interface. Web user accounts prevent unauthorized access to the Web interface, enabling login access only to users with correct credentials (i.e., username and password). Each Web user account is composed of the following attributes:

- **Username and password:** Credentials that enable authorized login access to the Web interface.
- **Access level (user type):** Access privileges specifying what the user can view in the Web interface and its read/write privileges. The table below describes the different types of Web user account access levels:

Access Levels of Web User Accounts

User Access Level	Numeric Representation*	Privileges
Master	220	Read / write privileges for all pages. Can create all user types, including additional Master users and Security Administrators. It can delete all users except the last Security Administrator.
Security Administrator	200	Read / write privileges for all pages. It can create all user types and is the only one that can create the first Master user. Note: There must be at least one Security Administrator.
Administrator	100	Read / write privileges for all pages except security-related pages, which are read-only.
Monitor	50	No access to security-related and file-loading pages; read-only access to other pages.
No Access	0	No access to any page. Note: This access level is not applicable when using advanced Web user account configuration in the Web Users table.

* The numeric representation of the access level is used only to define accounts in a RADIUS server (the access level ranges from 1 to 255).

By default, the device is pre-configured with the following two Web user accounts:

Pre-configured Web User Accounts

User Access Level	Username (Case-Sensitive)	Password (Case-Sensitive)
Security Administrator	Admin	Admin
Monitor	User	User

After you log in to the Web interface, the username is displayed on the toolbar.

If the Web session is idle (i.e., no actions are performed) for more than five minutes, the Web session expires and you are once again requested to login with your username and password. Users can be banned for a period of time upon a user-defined number of

unsuccessful login attempts. Login information (such as how many login attempts were made and the last successful login time) can be presented to the user.

➤ **To prevent user access after a specific number of failed logins:**

1. From the 'Deny Access On Fail Count' drop-down list, select the number of failed logins after which the user is prevented access to the device for a user-defined time (see next step).
2. In the 'Deny Authentication Timer' field, enter the interval (in seconds) that the user needs to wait before a new login attempt from the same IP address can be done after reaching the number of failed login attempts (defined in the previous step).

Notes:

- For security, it's recommended that you change the default username and password.
- The Security Administrator user can change all attributes of all Web user accounts. Web users with access levels other than Security Administrator can change only their password and username.
- To restore the two Web user accounts to default settings (usernames and passwords), set the *ini* file parameter ResetWebPassword to 1.
- To log in to the Web interface with a different Web user, click the **Log off** button and then login with with a different username and password.
- You can set the entire Web interface to read-only (regardless of Web user access levels), by using the *ini* file parameter DisableWebConfig (see 'Web and Telnet Parameters' on page 662).
- You can define additional Web user accounts using a RADIUS server (see 'Configuring RADIUS Settings' on page 68).
- For secured HTTP connection use HTTPS.

7.3.1 Basic User Accounts Configuration

This section describes basic Web user account configuration. This is relevant only if the two default, pre-configured Web user accounts - Security Administrator ("Admin") and Monitor ("User") - are sufficient for your management scheme.

For the Security Administrator, you can change only the username and password; not its access level. For the Monitor user, you can change username and password as well as access level (Administrator, Monitor, or No Access).

Notes:

- The access level of the Security Administrator cannot be modified.
- The access level of the second user account can be modified only by the Security Administrator.
- The username and password can be a string of up to 19 characters. When you log in to the Web interface, the username and password string values are case-sensitive, according to your configuration.
- Up to two users can be logged in to the Web interface at the same time, and they can be of the same user.

- **To configure the two pre-configured Web user accounts:**
- 1. Open the Web User Accounts page (**Configuration** tab > **System** menu > **Web User Accounts**). If you are logged in as Security Administrator, both Web user accounts are displayed (as shown below). If you are logged in with the second user account, only the details of this user account are displayed.

Figure 7-18: WEB User Accounts Page (for Users with 'Security Administrator' Privileges)

Current Logged User: Admin		
▼ Account Data for User: Admin		
User Name	Admin	Change User Name
Access Level	Security Administrator ▼	
▼ Fill in the following 3 fields to change the password		
Current Password		
New Password		
Confirm New Password		Change Password
▼ Account Data for User: User		
User Name	User	Change User Name
Access Level	User Monitor ▼	Change Access Level
▼ Fill in the following 3 fields to change the password		
Current Password		
New Password		
Confirm New Password		Change Password
▼ Web Users Table		
Create Web Users Table	Create Table	

- 2. To change the username of an account:
 - a. In the 'User Name' field, enter the new user name.
 - b. Click **Change User Name**; if you are currently logged in to the Web interface with this account, the 'Web Login' dialog box appears.
 - c. Log in with your new user name.
- 3. To change the password of an account:
 - a. In the 'Current Password' field, enter the current password.
 - b. In the 'New Password' and 'Confirm New Password' fields, enter the new password.
 - c. Click **Change Password**; if you are currently logged in to the Web interface with this account, the 'Web Login' dialog box appears.
 - d. Log in with your new password.
- 4. To change the access level of the optional, second account:
 - a. Under the **Account Data for User: User** group, from the 'Access Level' drop-down list, select a new access level user.
 - b. Click **Change Access Level**; the new access level is applied immediately.

7.3.2 Advanced User Accounts Configuration

This section describes advanced Web user account configuration. This is relevant if you need the following management scheme:

- Enhanced security settings per Web user (e.g., limit session duration)
- More than two Web user accounts (up to 10 Web user accounts)
- Master users

This advanced Web user configuration is done in the Web Users table, which is initially accessed from the Web User Accounts page (see procedure below). Once this table is accessed, subsequent access immediately opens the Web Users table instead of the Web User Accounts page.

Notes:

- Only the Security Administrator user can **initially** access the Web Users table.
- Only Security Administrator and Master users can add, edit, or delete users.
- Admin users have read-only privileges in the Web Users table. Monitor users have no access to this page.
- If you delete a user who is currently in an active Web session, the user is immediately logged off by the device.
- All users can change their own passwords. This is done in the WEB Security Settings page (see 'Configuring Web Security Settings' on page 65).
- To remove the Web Users table and revert to the Web User Accounts page with the pre-configured, default Web user accounts, set the ResetWebPassword *ini* file parameter to 1. This also deletes all other Web users.
- Once the Web Users table is accessed, Monitor users and Admin users can only change their passwords in the Web Security Settings page (see 'Configuring Web Security Settings' on page 65). The new password must have at least four different characters than the previous password. (The Security Administrator users and Master users can change their passwords in the Web Users table and in the Web Security Settings page.)
- This table can only be configured using the Web interface or CLI command web-users.

➤ To add Web user accounts with advanced settings:

1. Open the Web Users Table page:
 - Upon initial access:
 - a. Open the Web User Accounts page (**Configuration** tab > **System** menu > **Web User Accounts**).
 - b. Under the **Web Users Table** group, click the **Create Table** button.
 - Subsequent access: **Configuration** tab > **System** menu > **Web User Accounts**.
- The Web Users table appears, listing the two default, pre-configured Web use accounts - Security Administrator ("Admin") and Monitor ("User"):

Figure 7-19: Web Users Table Page

Index	Username	Password	Status	Password Age	Session Limit	Session Timeout	Block Duration	User Level
0	Admin	*	Valid	0	2	60	60	SecAdmin
1	User	*	Valid	0	2	60	60	Monitor

Page 1 of 1 View 1 - 2 of 2

2. Click the **Add** button; the following dialog box is displayed:

Figure 7-20: Web Users Table - Add Record Dialog Box

Add Record

Index
0

Username

Password

Status
New

Password Age
90

Session Limit
2

Session Timeout
60

Block Duration
60

User Level
Monitor

Submit
Cancel

3. Add a user as required. For a description of the parameters, see the table below.
4. Click **Submit**.

Web User Parameters Description

Parameter	Description
Web: Username CLI: user-name	Defines the Web user's username. The valid value is a string of up to 40 alphanumeric characters, including the period ".", underscore "_", and hyphen "-" signs.
Web: Password CLI: password	Defines the Web user's password. The valid value is a string of 8 to 40 ASCII characters, which must include the following: ▪ At least eight characters ▪ At least two letters that are upper case (e.g., "AA") ▪ At least two letters that are lower case (e.g., "aa")

Parameter	Description
	- At least two numbers - At least two signs (e.g., the dollar "\$" sign) - No spaces in the string - At least four characters different to the previous password
Web: Status CLI: status	Defines the status of the Web user. - New = (Default) User is required to change its password on the next login. When the user logs in to the Web interface, the user is immediately prompted to change the current password. - Valid = User can log in to the Web interface as normal. - Failed Access = This state is automatically set for users that exceed a user-defined number of failed login attempts, set by the 'Deny Access on Fail Count' parameter (see 'Configuring Web Security Settings' on page 65). These users can log in only after a user-defined timeout configured by the 'Block Duration' parameter (see below) or if their status is changed (to New or Valid) by a System Administrator or Master. - Old Account = This state is automatically set for users that have not accessed the Web interface for a user-defined number of days, set by the 'User Inactivity Timer' (see 'Configuring Web Security Settings' on page 65). These users can only log in to the Web interface if their status is changed (to New or Valid) by a System Administrator or Master. Notes: - The Old Account status is applicable only to Admin and Monitor users; System Administrator and Master users can be inactive indefinitely. - For security, it is recommended to set the status of a newly added user to New in order to enforce password change.
Web: Password Age CLI: pw-age-interval	Defines the duration (in days) of the validity of the password. When this duration elapses, the user is prompted to change the password; otherwise, access to the Web interface is blocked. The valid value is 0 to 10000, where 0 means that the password is always valid. The default is 90.
Web: Session Limit CLI: session-limit	Defines the maximum number of Web interface sessions allowed for the user. In other words, this allows the same user account to log in to the device from different sources (i.e., IP addresses). The valid value is 0 to 5. The default is 2. Note: Up to 5 users can be logged in to the Web interface at any given.
Web: Session Timeout CLI: session-timeout	Defines the duration (in minutes) of Web inactivity of a logged-in user, after which the user is automatically logged off the Web interface. The valid value is 0 to 100000. The default is according to the settings of the 'Session Timeout' global parameter (see 'Configuring Web Security Settings' on page 65).

Parameter	Description
Web: Block Duration CLI: block-time	Defines the duration (in seconds) for which the user is blocked when the user exceeds a user-defined number of failed login attempts. This is configured by the 'Deny Access On Fail Count' parameter (see 'Configuring Web Security Settings' on page 65). The valid value is 0 to 100000, where 0 means that the user can do as many login failures without getting blocked. The default is according to the settings of the 'Deny Authentication Timer' parameter (see 'Configuring Web Security Settings' on page 65). Note: The 'Deny Authentication Timer' parameter relates to failed Web logins from specific IP addresses.
Web: User Level CLI: user-level	Defines the user's access level. - Monitor = (Default) Read-only user. This user can only view Web pages and access to security-related pages is denied. - Admin = Read/write privileges for all pages, except security-related pages including the Web Users table where this user has only read-only privileges. - SecAdmin = Read/write privileges for all pages. This user is the Security Administrator. - Master-User = Read/write privileges for all pages. This user also functions as a security administrator. Notes: - At least one Security Administrator must exist. The last remaining Security Administrator cannot be deleted. - The first Master user can be added only by a Security Administrator user. - Additional Master users can be added, edited and deleted only by Master users. - If only one Master user exists, it can be deleted only by itself. - Master users can add, edit, and delete Security Administrators (but cannot delete the last Security Administrator). - Only Security Administrator and Master users can add, edit, and delete Admin and Monitor users.

7.4 Displaying Login Information upon Login

The device can display login information immediately upon Web login.

➤ To enable display of user login information upon a successful login:

1. Open the WEB Security Settings page (**Configuration** tab > **System** menu > **Management** submenu > **WEB Security Settings**).
2. From the 'Display Login Information' drop-down list, select **Yes**.
3. Click **Submit** to apply your changes.

Once enabled, the Login Information window is displayed upon a successful login, as shown in the example below:

Figure 7-21: Login Information Window

Login Information	
Last Login Privilege	Security Administrator
Last Failed Login Time	15: 04: 19
Last Failed Login Date	10/06/2012
Last Failed Login IP	10.13.2.11
Login Attempts Since Last Success	2
Last Success Login Time	15: 03: 32
Last Success Login Date	10/06/2012
Last Success Login IP	10.13.2.11

Close

7.5 Configuring Web Security Settings

The WEB Security Settings page is used to define a secure Web access communication method. For a description of these parameters, see 'Web and Telnet Parameters' on page 662.

➤ **To define Web access security:**

1. Open the WEB Security Settings page (**Configuration** tab > **System** menu > **Management** submenu > **WEB Security Settings**).

Figure 7-22: Web Security Settings Page

▼ General	
HTTP Authentication Mode	Web Based Authentication ▼
⚡ Secured Web Connection (HTTPS)	HTTP and HTTPS ▼
Requires Client Certificates for HTTPS connection	Disable ▼
⚡ HTTPS Cipher String	RC4:EXP
⚡ WAN OAMP Interface	Not Configured ▼
⚡ Allow WAN access to HTTP	Disable ▼
⚡ Allow WAN access to HTTPS	Disable ▼
▼ Session	
Session Timeout (minutes)	15
▼ Access Block Parameters	
Deny Authentication Timer	60
Deny Access On Fail Count	3 ▼
Display Login Information	No ▼

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

7.6 Limiting OAMP Access to a Specific WAN Interface

You can limit the access of OAMP applications (such as HTTP, HTTPS, Telnet, and SSH) to a specific WAN interface. This OAMP-interface binding can then be associated with a Virtual Routing and Forwarding (VRF).

➤ **To limit OAMP access on a specific WAN interface, using CLI.**

1. Enable WAN management access for specific OAMP applications, using any of the following commands:

```
set wan-ssh-allow
set wan-telnet-allow
set wan-snmp-allow
set wan-http-allow
set wan-https-allow
```

2. Define the WAN interface for the OAMP applications, using the OAMPWanInterfaceName ini file parameter or the following CLI command:

```
bind GigabitEthernet <slot/port.vlanId> oamp
bind vlan <vlanId> oamp
```

The following example enables WAN access for Telnet on interface GigabitEthernet 0/0.4 (GigabitEthernet 0/0.4 may be associated with a VRF):

```
(config-system)# cli-terminal
(cli-terminal)# set wan-telnet-allow on
(cli-terminal)# exit
(config-system)# bind GigabitEthernet 0/0.5 oamp
```

➤ **To define the WAN OAMP interface using the Web interface:**

1. Open the WEB Security Settings page (see 'Configuring Web Security Settings' on page 65).
2. From the 'WAN OAMP Interface' drop-down list, select the required WAN interface.
3. Click **Submit** to apply your changes.

7.7 Web Login Authentication using Smart Cards

You can enable Web login authentication using certificates from a third-party, common access card (CAC) with user identification. When a user attempts to access the device through the Web browser (HTTPS), the device retrieves the Web user's login username (and other information, if required) from the CAC. The user attempting to access the device is only required to provide the login password. Typically, a TLS connection is established between the CAC and the device's Web interface, and a RADIUS server is implemented to authenticate the password with the username. Therefore, this feature implements a two-factor authentication - what the user has (i.e., the physical card) and what the user knows (i.e., the login password).

This feature is enabled using the EnableMgmtTwoFactorAuthentication parameter.

Note: For specific integration requirements for implementing a third-party smart card for Web login authentication, contact your AudioCodes representative.

➤ **To log in to the Web interface using CAC:**

1. Insert the Common Access Card into the card reader.
2. Access the device using the following URL: `https://<host name or IP address>`; the device prompts for a username and password.
3. Enter the password only. As some browsers require that the username be provided, it's recommended to enter the username with an arbitrary value.

7.8 Configuring Web and Telnet Access List

The Web & Telnet Access List page is used to define IP addresses (up to ten) that are permitted to access the device's Web, Telnet, and SSH interfaces. Access from an undefined IP address is denied. If no IP addresses are defined, this security feature is inactive and the device can be accessed from any IP address. The Web and Telnet Access List can also be defined using the *ini* file parameter `WebAccessList_x` (see 'Web and Telnet Parameters' on page 662).

➤ **To add authorized IP addresses for Web, Telnet, and SSH interfaces access:**

1. Open the Web & Telnet Access List page (**Configuration** tab > **System** menu > **Management** submenu > **Web & Telnet Access List**).

Figure 7-23: Web & Telnet Access List Page - Add New Entry

2. To add an authorized IP address, in the 'Add an authorized IP address' field, enter the required IP address, and then click **Add New Entry**; the IP address you entered is added as a new entry to the Web & Telnet Access List table.

Figure 7-24: Web & Telnet Access List Table

Delete Row	Authorized IP Address
1 ☐	10.13.2.11
2 ☐	10.13.2.12

3. To delete authorized IP addresses, select the Delete Row check boxes corresponding to the IP addresses that you want to delete, and then click **Delete Selected Addresses**; the IP addresses are removed from the table and these IP addresses can no longer access the Web and Telnet interfaces.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

Notes:

- The first authorized IP address in the list must be your PC's (terminal) IP address; otherwise, access from your PC is denied.
- Delete your PC's IP address last from the 'Web & Telnet Access List' page. If it is deleted before the last, subsequent access to the device from your PC is denied.

7.9 Configuring RADIUS Settings

The RADIUS Settings page is used for configuring the Remote Authentication Dial In User Service (RADIUS) accounting parameters. For a description of these parameters, see 'Configuration Parameters Reference' on page 655.

➤ **To configure RADIUS:**

1. Open the RADIUS Settings page (**Configuration** tab > **System** menu > **Management** submenu > **RADIUS Settings**).

Figure 7-25: RADIUS Parameters Page

General RADIUS Setting	
Enable RADIUS Access Control	Disable
Use RADIUS for Web/Telnet Login	Disable
RADIUS Authentication Server IP Address	0.0.0.0
RADIUS Authentication Server Port	1645
RADIUS Shared Secret	••••••••
General RADIUS Authentication	
Default Access Level	200
Device Behavior Upon RADIUS Timeout	Verify Access Locally
Local RADIUS Password Cache Mode	Reset Timer Upon Access
Local RADIUS Password Cache Timeout [sec]	300
RADIUS VSA Vendor ID	5003
RADIUS VSA Access Level Attribute	35

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

8 CLI-Based Management

This section provides an overview of the CLI-based management and configuration relating to CLI management. The device's CLI-based management interface can be accessed using the RS-232 serial port or by using Secure SHell (SSH) or Telnet through the Ethernet interface.

Notes:

- For security, CLI is disabled by default.
- For information on accessing the CLI interface through the RS-232 port interface, see 'CLI' on page 27.
- For more information on the CLI commands, refer to the following documents:
 - MSBR Series CLI Reference Guide for Data Functionality
 - MSBR Series CLI Reference Guide for System and VoIP Functionality

8.1 Enabling CLI using Telnet

The device's CLI can be accessed using Telnet. Secure Telnet using Secure Socket Layer (SSL) can be configured whereby information is not transmitted in the clear. If SSL is used, a special Telnet client is required on your PC to connect to the Telnet interface over a secured connection; examples include C-Kermit for UNIX and Kermit-95 for Windows.

For security, some organizations require the display of a proprietary notice upon starting a Telnet session. You can use the configuration ini file parameter, WelcomeMessage to configure such a message (see Creating a Login Welcome Message on page 52).

➤ To enable Telnet:

1. Open the Telnet/SSH Settings page (**Configuration** tab > **System** menu > **Management** > **Telnet/SSH Settings**).

Figure 8-1: Telnet Settings on Telnet/SSH Settings Page

▼ Telnet Settings	
Embedded Telnet Server	Enable Unsecured ▼
Telnet Server TCP Port	23
⚡ Telnet Server Idle Timeout	60
⚡ Allow WAN access to Telnet	Enable ▼

2. Set the 'Embedded Telnet Server' parameter to **Enable Unsecured** or **Enable Secured** (i.e, SSL).
3. To enable Telnet from the WAN, set the 'Allow WAN access to Telnet' parameter to **Enable**.
4. Configure the other Telnet parameters as required. For a description of these parameters, see Telnet Parameters on page 665.
5. Click **Submit**.
6. Save the changes to flash memory with a device reset.

8.2 Enabling CLI using SSH and RSA Public Key

The device's CLI can be accessed using Telnet. However, unless configured for TLS, Telnet is not secure as it requires passwords to be transmitted in clear text. To overcome this, Secure SHell (SSH) is used, which is the de-facto standard for secure CLI. SSH 2.0 is a protocol built above TCP, providing methods for key exchange, authentication, encryption, and authorization.

SSH requires appropriate client software for the management PC. Most Linux distributions have OpenSSH pre-installed; Windows-based PCs require an SSH client software such as PuTTY, which can be downloaded from <http://www.chiark.greenend.org.uk/~sgtatham/putty/>.

By default, SSH uses the same username and password as the Telnet and Web server. SSH supports 1024/2048-bit RSA public keys, providing carrier-grade security. Follow the instructions below to configure the device with an administrator RSA key as a means of strong authentication.

➤ To enable SSH and configure RSA public keys for Windows (using PuTTY SSH):

1. Start the PuTTY Key Generator program, and then do the following:
 - a. Under the 'Parameters' group, do the following:
 - ◆ Select the **SSH-2 RSA** option.
 - ◆ In the 'Number of bits in a generated key' field, enter "1024" bits.
 - b. Under the 'Actions' group, click **Generate** and then follow the on-screen instructions.
 - c. Under the 'Actions' group, click **Save private key** to save the new private key to a file (*.ppk) on your PC.
 - d. Under the 'Key' group, select the displayed encoded text between "ssh-rsa" and "rsa-key-....", as shown in the example below:

Figure 8-2: Selecting Public RSA Key in PuTTY

2. Open the Telnet/SSH Settings page (**Configuration** tab > **System** menu > **Management** > **Telnet/SSH Settings**), and then do the following:
 - a. Set the 'Enable SSH Server' parameter to **Enable**.
 - b. Paste the public key that you copied in Step 1.d into the 'Admin Key' field, as shown below:

Figure 8-3: SSH Settings - Pasting Public RSA Key in 'Admin Key' Field

SSH Settings	
Enable SSH Server	Enable
Server Port	22
Admin Key	AAAAB3NzaC1yc2EAAAABJQAAAIB
Require Public Key	Enable
Max Payload Size	32768
Max Binary Packet Size	35000
Enable Last Login Message	Enable
Max Login Attempts	3
Allow WAN access to SSH	Disable

- c. For additional security, you can set the 'Require Public Key' to **Enable**. This ensures that SSH access is only possible by using the RSA key and not by using user name and password.
 - d. To enable SSH from the WAN, set 'Allow WAN access to SSH' to **Enable**.
 - e. Configure the other SSH parameters as required. For a description of these parameters, see SSH Parameters on page 686.
 - f. Click **Submit**.
 3. Start the PuTTY Configuration program, and then do the following:
 - a. In the 'Category' tree, drill down to **Connection**, then **SSH**, and then **Auth**; the 'Options controlling SSH authentication' pane appears.
 - b. Under the 'Authentication parameters' group, click **Browse** and then locate the private key file that you created and saved in Step 4.
 4. Connect to the device with SSH using the username "Admin"; RSA key negotiation occurs automatically and no password is required.
- **To configure RSA public keys for Linux (using OpenSSH 4.3):**
1. Run the following command to create a new key in the admin.key file and to save the public portion to the admin.key.pub file:

```
ssh-keygen -f admin.key -N "" -b 1024
```
 2. Open the admin.key.pub file, and then copy the encoded string from "ssh-rsa" to the white space.
 3. Open the Telnet/SSH Settings page (**Configuration** tab > **System** menu > **Management** > **Telnet/SSH Settings**), and then paste the value copied in Step 2 into the 'Admin Key' field.
 4. Click **Submit**.
 5. Connect to the device with SSH, using the following command:

```
ssh -i admin.key xx.xx.xx.xx
```

 where xx.xx.xx.xx is the device's IP address. RSA-key negotiation occurs automatically and no password is required.

8.3 Establishing a CLI Session

The procedure below describes how to establish a CLI session with the device.

Notes:

- The default login username and password are both "Admin" (case-sensitive).
- Only the primary User Account, which has Security Administration access level (200) can access the device using Telnet. For configuring the username and password, see [Configuring Web User Accounts](#) on page 58.

➤ To establish a CLI session with the device:

1. Establish a Telnet or SSH session with the device using its OAMP IP address.
2. Log in to the session using the username and password assigned to the Admin user of the Web interface:
3. At the Username prompt, type the username, and then press Enter:
Username: Admin
4. At the Password prompt, type the password, and then press Enter:
Password: Admin
5. At the prompt, type the following, and then press Enter:
enable
6. At the prompt, type the password again, and then press Enter:
Password: Admin

Once logged in, you can configure the device by accessing one of the following modes:

- **Basic:** Provides general CLI commands, for example, to display system information and activate debugging. This mode is accessed immediately after you login to the CLI. For example, to access the command shell, type the following command, and then press Enter:

```
cmdshell
```

- **Enable:** Provides the configuration commands and is accessed by typing the following command:

```
# enable
# Password: <password>
```

This mode groups the commands under the following command sets:

- **configure-system:** This contains the general and system related configuration commands, for example, Syslog configuration. This set is accessed by typing the following:
configure system
- **configure-data:** This contains the data-router configuration commands. This set is accessed by typing the following:
configure data
- **configure-voip:** This contains VoIP-related configuration commands, for example, SIP, VoIP network interfaces, and VoIP media configurations. This set is accessed by typing the following:
configure voip

8.4 Configuring TACACS+ for CLI Login

This section describes how to enable and configure Terminal Access Controller Access-Control System (TACACS+). TACACS+ is a security protocol for centralized username and password verification. TACACS+ can be used for validating users attempting to gain access to the device through CLI. TACACS+ services are maintained on a database on a TACACS+ daemon. You must have access to and must configure a TACACS+ server before configuring TACACS+ on your device.

TACACS+ can provide the following services:

- Authentication: provides authentication through login and password dialog
- Authorization: manages user capabilities for the duration of the user's session by placing restrictions on what commands a user may execute
- Accounting: collects and sends information for auditing and reporting to the TACACS+ daemon

The TACACS+ protocol provides authentication between the device and the TACACS+ daemon, and it ensures confidentiality as all protocol exchanges between a network access server and a TACACS+ daemon are encrypted. You need a system running TACACS+ daemon software to use the TACACS+ functionality on your network access server.

When a user attempts a simple ASCII login by authenticating to a network access server using TACACS+, the following typically occurs:

1. When the connection is established, the network access server contacts the TACACS+ daemon to obtain a username prompt, which is then displayed to the user. The user enters a username and the network access server then contacts the TACACS+ daemon to obtain a password prompt. The network access server displays the password prompt to the user, the user enters a password, and the password is then sent to the TACACS+ daemon.
2. The network access server eventually receives one of the following responses from the TACACS+ daemon:
 - ACCEPT: The user is authenticated and service may begin. If the network access server is configured to require authorization, authorization will begin at this time.
 - REJECT: The user has failed to authenticate. The user may be denied further access.
 - ERROR: An error occurred at some time during authentication. This can be at the daemon or in the network connection between the daemon and the network access server. If an ERROR response is received, the device typically attempts to use an alternative method for authenticating the user.
3. If TACACS+ authorization is needed, the TACACS+ daemon is again contacted for each CLI command entered by the user, and it returns an ACCEPT or REJECT authorization response. If an ACCEPT response is returned, the CLI command is allowed; otherwise, it is rejected.

The following CLI commands are used for enabling and configuring TACACS+:

- **aaa authentication login tacacs+:** enables TACACS+
- **tacacs-server host <host-ip>:** defines the IP address of the TACACS+ server (up to two servers can be configured)
- **tacacs-server port <port-num>:** defines the TCP port number for the TACACS+ service
- **tacacs-server key <password>:** defines the shared secret between the TACACS+ server and the device
- **tacacs-server timeout <seconds>:** defines how much time to wait for a TACACS+ response before failing the authentication

The procedure below describes how to configure TACACS+ through CLI.

➤ **To configure TACACS+ through the CLI:**

1. Establish serial communication with the device.
2. At the prompt, type the following command to access the data interface and then press Enter:

```
# configure data
```

3. At the prompt, type the TACACS+ commands, as required, to enable and configure TACACS+. Below shows an example configuration:

```
(config-data)# aaa authentication login tacacs+
(config-data)# tacacs-server host 192.168.1.55
(config-data)# tacacs-server key Tumble
```

9 EMS-Based Management

AudioCodes Element Management System (EMS) is an advanced solution for standards-based management of MSBRs within VoP networks, covering all areas vital for the efficient operation, administration, management and provisioning (OAM&P) of AudioCodes' families of MSBRs. The EMS enables Network Equipment Providers (NEPs) and System Integrators (SIs) the ability to offer customers rapid time-to-market and inclusive, cost-effective management of next-generation networks. The standards-compliant EMS uses distributed SNMP-based management software, optimized to support day-to-day Network Operation Center (NOC) activities, offering a feature-rich management framework. It supports fault management, configuration and security.

Note: For more information on using the EMS tool, refer to the *EMS User's Manual* and *EMS Server IOM Manual*.

Reader's Notes

10 SNMP-Based Management

The device provides an embedded SNMP Agent to operate with a third-party SNMP Manager (e.g., element management system or EMS) for operation, administration, maintenance, and provisioning (OAMP) of the device. The SNMP Agent supports standard Management Information Base (MIBs) and proprietary MIBs, enabling a deeper probe into the interworking of the device. The SNMP Agent can also send unsolicited events (SNMP traps) towards the SNMP Manager. All supported MIB files are supplied to customers as part of the release.

This section provides configuration relating to SNMP management.

Note: For more information on SNMP support such as SNMP traps, refer to the *SNMP User's Guide*.

10.1 Configuring SNMP Community Strings

The SNMP Community String page allows you to configure up to five read-only and up to five read-write SNMP community strings and to configure the community string that is used for sending traps.

For detailed descriptions of the SNMP parameters, see 'SNMP Parameters' on page 666.

➤ **To configure the SNMP community strings:**

1. Open the SNMP Community String page (**Configuration** tab > **System** menu > **Management** submenu > **SNMP** submenu > **SNMP Community String**).

Figure 10-1: SNMP Community String Page

Delete	Community String	Access Level
☐		Read Only
☐		Read Only
☐		Read Only
☐		Read Only
☐		Read Only
☐		Read / Write
☐		Read / Write
☐		Read / Write
☐		Read / Write
☐		Read / Write

▼	
⚡ Disable SNMP	No ▼
Trap Community String	trapuser
Trap Manager Host Name	
⚡ Allow WAN access to SNMP	Disable ▼

2. Configure the SNMP community strings parameters according to the table below.
 3. Click **Submit** to apply your changes.
 4. To save the changes to flash memory, see 'Saving Configuration' on page 532.
- To delete a community string, select the **Delete** check box corresponding to the community string that you want to delete, and then click **Submit**.

SNMP Community String Parameters Description

Parameter	Description
Community String	▪ Read Only [SNMPReadOnlyCommunityString_x]: Up to five read-only community strings (up to 19 characters each). The default string is 'public'. ▪ Read / Write [SNMPReadWriteCommunityString_x]: Up to five read / write community strings (up to 19 characters each). The default string is 'private'.
Trap Community String CLI: configure system > snmp trap > community-string [SNMPTrapCommunityString]	Community string used in traps (up to 19 characters). The default string is 'trapuser'.

10.2 Configuring SNMP Trap Destinations

The SNMP Trap Destinations page allows you to configure up to five SNMP trap managers. You can associate a trap destination with SNMPv2 users and specific SNMPv3 users. Associating a trap destination with SNMPv3 users sends encrypted and authenticated traps to the SNMPv3 destination. By default, traps are sent unencrypted using SNMPv2.

➤ **To configure SNMP trap destinations:**

1. Open the SNMP Trap Destinations page (**Configuration** tab > **System** menu > **Management** submenu > **SNMP** > **SNMP Trap Destinations**).

Figure 10-2: SNMP Trap Destinations Page

		IP Address	Trap Port	Trap User	Trap Enable
☒	SNMP Manager 1	0.0.0.0	162	v2cParams ▾	Enable ▾
☒	SNMP Manager 2	0.0.0.0	162	hq-snmpv3 ▾	Enable ▾
☐	SNMP Manager 3	0.0.0.0	162	v2cParams ▾	Enable ▾
☐	SNMP Manager 4	0.0.0.0	162	v2cParams ▾	Enable ▾
☐	SNMP Manager 5	0.0.0.0	18	v2cParams ▾	Enable ▾

2. Configure the SNMP trap manager parameters according to the table below.
3. Select the check box corresponding to the SNMP Manager that you wish to enable.
4. Click **Submit** to apply your changes.

Note: Only row entries whose corresponding check boxes are selected are applied when clicking **Submit**; otherwise, settings revert to their defaults.

SNMP Trap Destinations Parameters Description

Parameter	Description
Web: SNMP Manager [SNMPManagerIsUsed_x]	Enables the SNMP Manager to receive traps and checks the validity of the configured destination (IP address and port number). [0] (check box cleared) = (Default) Disables SNMP Manager [1] (check box selected) = Enables SNMP Manager
Web: IP Address [SNMPManagerTableIP_x]	Defines the IP address (in dotted-decimal notation, e.g., 108.10.1.255) of the remote host used as the SNMP Manager. The device sends SNMP traps to this IP address.
Trap Port [SNMPManagerTrapPort_x]	Defines the port number of the remote SNMP Manager. The device sends SNMP traps to this port. The valid value range is 100 to 4000. The default is 162.
Web: Trap User [SNMPManagerTrapUser]	Associates a trap user with the trap destination. This determines the trap format, authentication level, and encryption level. - v2cParams (default) = SNMPv2 user community string - SNMPv3 user configured in 'Configuring SNMP V3 Users' on page 80
Trap Enable [SNMPManagerTrapSendingEnable_x]	Activates the sending of traps to the SNMP Manager. [0] Disable [1] Enable (Default)

10.3 Configuring SNMP Trusted Managers

The SNMP Trusted Managers page allows you to configure up to five SNMP Trusted Managers, based on IP addresses. By default, the SNMP agent accepts SNMP Get and Set requests from any IP address, as long as the correct community string is used in the request. Security can be enhanced by using Trusted Managers, which is an IP address from which the SNMP agent accepts and processes SNMP requests.

Notes: The SNMP Trusted Managers table can also be configured using the table ini file parameter, SNMPTrustedMgr_x (see 'SNMP Parameters' on page 666) or CLI command, configure system > snmp > trusted-managers.

➤ **To configure SNMP Trusted Managers:**

1. Open the SNMP Trusted Managers page (**Configuration** tab > **System** menu > **Management** submenu > **SNMP** submenu > **SNMP Trusted Managers**).

Figure 10-3: SNMP Trusted Managers

Delete	Trusted Managers IP Address	
☐	SNMP Trusted Manager 1	0.0.0.0
☐	SNMP Trusted Manager 2	0.0.0.0
☐	SNMP Trusted Manager 3	0.0.0.0
☐	SNMP Trusted Manager 4	0.0.0.0
☐	SNMP Trusted Manager 5	0.0.0.0

2. Select the check box corresponding to the SNMP Trusted Manager that you want to enable and for whom you want to define an IP address.
3. Define an IP address in dotted-decimal notation.
4. Click **Submit** to apply your changes.
5. To save the changes, see 'Saving Configuration' on page 532.

10.4 Configuring SNMP V3 Users

The SNMP v3 Users page allows you to configure authentication and privacy for up to 10 SNMP v3 users.

➤ **To configure SNMP v3 users:**

1. Open the SNMP v3 Users page (**Configuration** tab > **System** menu > **Management** submenu > **SNMP** submenu > **SNMP V3 Users**).
2. Click **Add**; the following dialog box appears:

Figure 10-4: SNMP V3 Setting Page - Add Record Dialog Box

The dialog box titled "Add Record" contains the following fields and controls:

- Index:** A text input field with the value "5".
- User Name:** An empty text input field.
- Authentication Protocol:** A dropdown menu with "None" selected.
- Privacy Protocol:** A dropdown menu with "None" selected.
- Authentication Key:** An empty text input field.
- Privacy Key:** An empty text input field.
- Group:** A dropdown menu with "Read-Write" selected.
- Buttons:** "Submit" and "Cancel" buttons at the bottom right.

3. Configure the SNMP V3 Setting parameters according to the table below.
4. Click **Submit** to apply your settings.
5. To save the changes, see 'Saving Configuration' on page 532.

**Notes:**

- If you delete a user that is associated with a trap destination (in 'Configuring SNMP Trap Destinations' on page 78), the configured trap destination becomes disabled and the trap user reverts to default (i.e., SNMPv2).
- The SNMP v3 Users table can also be configured using the table ini file parameter, SNMPUsers (see 'SNMP Parameters' on page 666) or CLI command, configure system > snmp v3-users.

SNMP V3 Users Parameters

Parameter	Description
Index [SNMPUsers_Index]	The table index. The valid range is 0 to 9.
User Name CLI: username [SNMPUsers_Username]	Name of the SNMP v3 user. This name must be unique.
Authentication Protocol CLI: auth-protocol [SNMPUsers_AuthProtocol]	Authentication protocol of the SNMP v3 user. ▪ [0] None (default) ▪ [1] MD5 ▪ [2] SHA-1
Privacy Protocol CLI: priv-protocol [SNMPUsers_PrivProtocol]	Privacy protocol of the SNMP v3 user. ▪ [0] None (default) ▪ [1] DES ▪ [2] 3DES ▪ [3] AES-128 ▪ [4] AES-192 ▪ [5] AES-256
Authentication Key CLI: auth-key [SNMPUsers_AuthKey]	Authentication key. Keys can be entered in the form of a text password or long hex string. Keys are always persisted as long hex strings and keys are localized.
Privacy Key CLI: priv-key [SNMPUsers_PrivKey]	Privacy key. Keys can be entered in the form of a text password or long hex string. Keys are always persisted as long hex strings and keys are localized.
Group CLI: group [SNMPUsers_Group]	The group with which the SNMP v3 user is associated. ▪ [0] Read-Only (default) ▪ [1] Read-Write ▪ [2] Trap Note: All groups can be used to send traps.

Reader's Notes

11 TR-069 CWMP Based Management

The device supports TR-069 CPE WAN Management Protocol (CWMP) based management, which is used for remote management of CPE devices. This allows the device to be configured and monitored from a management application running on a remote Auto-Configuration Server (ACS).

11.1 TR-069

TR-069 (Technical Report 069) is a specification published by Broadband Forum (www.broadband-forum.org) entitled CPE WAN management protocol (CWMP). It defines an application layer protocol for remote management of end-user devices.

TR-069 uses a bi-directional SOAP/HTTP protocol for communication between the customer premises equipment (CPE) and the Auto Configuration Servers (ACS). The TR-069 connection to the ACS can be done on the LAN or WAN interface.

The protocol stack looks as follows:

TR-069 Protocol Stack

CPE/ACS Management Application
RPC Methods
SOAP
HTTP
SSL/TLS
TCP/IP

Communication is typically established by the CPE; hence, messages from CPE to ACS are typically carried in HTTP requests, and messages from ACS to CPE in HTTP responses.

Figure 11-1: TR-069 Session Example

Communication between ACS and CPE is defined via Remote Procedure Call (RPC) methods. TR-069 defines a generic mechanism by which an ACS can read or write parameters to configure a CPE and monitor CPE status and statistics. It also defines the mechanism for file transfer and firmware/software management. However, it does not define individual parameters; these are defined in separate documents, as described below.

Some of the RPC methods are Configuration File Download, Firmware upgrade, Get Parameter Value, Set Parameter Value, Reboot, and the upload and download files.

TR-106 defines the “data model” template for TR-069 enabled devices. The Data Model consists of objects and parameters hierarchically organized in a tree with a single Root Object, typically named *Device*. Arrays of objects are supported by appending a numeric index to the object name (e.g. ABCService.1 in the example below); such objects are called “multi-instance objects”.

Figure 11-2: TR-069 Model Data Example

Below is a list of some of the TR-069 methods:

■ CPE Methods:

- GetRPCMethods: Used by the CPE or ACS to discover the set of methods supported by the Server or CPE it is in communication with.
- SetParameterValues: Used by the ACS to modify the value of CPE parameter(s).
- GetParameterValues: Used by the ACS to obtain the value of CPE parameter(s).
- GetParameterNames: Used by the ACS to discover the parameters accessible on a particular CPE.

- **SetParameterAttributes:** Used by the ACS to modify attributes associated with CPE parameter(s).
- **GetParameterAttributes:** Used by the ACS to read the attributes associated with CPE parameter(s).
- **AddObject:** Used by the ACS to create a new instance of a multi-instance object—a collection of parameters and/or other objects for which multiple instances are defined.
- **DeleteObject:** Removes a particular instance of an object.
- **Download:** Used by the ACS to cause the CPE to download the following file(s) from a designated location:
 - ◆ Firmware Upgrade Image (File Type = 1) - cmp file.
 - ◆ Vendor Configuration File (File Type = 3) - output of show running-config CLI command, which includes Data and Voice configuration.

The CPE responds to the Download method, indicating successful or unsuccessful completion via one of the following:

- ◆ A DownloadResponse with the Status argument set to zero (indicating success), or a fault response to the Download request (indicating failure).
- ◆ A TransferComplete message sent later in the same session as the Download request (indicating either success or failure). In this case, the Status argument in the corresponding DownloadResponse has a value of one.
- ◆ A TransferComplete message sent in a subsequent session (indicating success or failure). In this case, the Status argument in the corresponding DownloadResponse has a value of one.

Figure 11-3: Download Method Execution Example

- Upload: Used by the ACS to cause the CPE to upload (to the ACS) the following files to a designated location:
 - ◆ Vendor Configuration File (File Type = 1 or 3): Output of show running-config CLI command, which includes Data and Voice configuration. For File Type 3 (where index is included – see below) only one instance of the file is supported.
 - ◆ Vendor Log File (File Type = 2 or 4): “Aggregated” log file. For File Type 2, the last file is supported. For File Type 4 (where index is included – see below), multiple files is supported.

The CPE responds to the Upload method, indicating successful or unsuccessful completion via the UploadResponse or TransferComplete method.

For a complete description of the Upload method, refer to TR-069 Amendment 3 section A.4.1.5.

- Reboot: Reboots the CPE. The CPE sends the method response and completes the remainder of the session prior to rebooting.
- X_0090F8_CommandResponse: Runs CLI commands.
- ACS Methods:
 - Inform: A CPE must call this method to initiate a transaction sequence whenever a connection to an ACS is established.
 - TransferComplete: Informs the ACS of the completion (either successful or unsuccessful) of a file transfer initiated by an earlier Download or Upload method call.

11.2 TR-104

The device supports TR-104 for configuration. This support is for the SIP (VoIP) application layer and applies to FXS interfaces (lines) only. TR-104 defines a "data model" template for TR-069 enabled devices. The "data model" that is applicable to the AudioCodes device is defined in the DSL Forum TR-104 – "DSLHome™ Provisioning Parameters for VoIP CPE" at <http://www.broadband-forum.org/technical/download/TR-104.pdf>.

The hierarchical tree structure of the supported TR-104 objects is shown below:

Figure 11-4: Hierarchical Tree Structure of TR-104 Objects

- InternetGatewayDevice.Services.VoiceService: Top-level object.
- InternetGatewayDevice.Services.VoiceService.1.Capabilities: (Read-Only) Displays the overall capabilities of the device.
 - InternetGatewayDevice.Services.VoiceService.1.Capabilities.Codecs: (Read-Only) Lists supported codecs (according to devices installed Software Feature Key).
 - InternetGatewayDevice.Services.VoiceService.1.Capabilities.SIP: (Read-Only) Displays various SIP settings such as SIP transport type.
- InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1: Corresponds to one or more FXS lines that share the same basic configuration:
 - InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.FaxT38: Configures fax T.38 relay.
 - InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.Line: Corresponds to an FXS line (as configured in the Trunk Group table). It enables and configures each FXS line (number).
 - ◆ InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.Line.{i}.Code c.List.{i}: Configures voice coder used by specific FXS line.
 - ◆ InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.Line.{i}.Callin gFeatures: Configures voice parameters per FXS line such as caller ID.
 - ◆ InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.Line.{i}.SIP: Configures username/password per FXS line. AudioCodes maps this object to the corresponding entry in the Authentication table
 - InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.SIP: Configures SIP parameters specific to the UA such as Proxy server.
 - InternetGatewayDevice.Services.VoiceService.1.VoiceProfile.1.RTP: Configures various RTP parameters for the FXS lines such as RTCP and SRTP.

11.3 Configuring TR-069

The CWMP/TR-069 Settings page is used to enable and configure TR-069.

Notes: For a description of the TR-069 parameters, see 'TR-069 Parameters' on page 669.

➤ **To configure TR-069:**

1. Open the CWMP/TR-069 Settings page (**Configuration** tab > **System** menu > **Management** submenu > **CWMP**).

Figure 11-5: CWMP/TR-069 Settings Page

▼ TR069	
TR069	Enable
Interface Name	WAN Ethernet
Protocol	HTTP
Port	82
URL	http://10.31.4.115:82/tr069/
▼ ACS	
URL	http://10.37.5.5:8080/dps-basic/TR/
User Name	tr069
Password	tr069
▼ CPE	
User Name	dps
Password	dps
Inform Interval	20
▼ ACS Connection Status	
Session with ACS ended successfully.	

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

12 INI File-Based Management

The device can be configured using an ini file, which is a text-based file with an *ini* file extension name that can be created using any standard text-based editor such as Notepad. Each configuration element of the device has a corresponding ini file parameter that you can use in the ini file for configuring the device. When you have created the ini file with your ini file parameter settings, you apply these settings to the device by installing (loading) the ini file to the device.

Notes:

- For a list and description of the *ini* file parameters, see 'Configuration Parameters Reference' on page [655](#).
- To restore the device to default settings using the *ini* file, see 'Restoring Factory Defaults' on page [571](#).

12.1 INI File Format

The *ini* file can be configured with any number of parameters. These *ini* file parameters can be one of the following types:

- Individual parameters - see 'Configuring Individual ini File Parameters' on page [89](#)
- Table parameters - see 'Configuring Table ini File Parameters' on page [89](#)

12.1.1 Configuring Individual ini File Parameters

The syntax for configuring individual *ini* file parameters in the ini file is as follows:

- An optional, subsection name (or group name) enclosed in square brackets "[...]". **This** is used to conveniently group similar parameters by their functionality.
- Parameter name, followed by an equal "=" sign and then its value.
- Comments must be preceded by a semicolon ";".

```
[subsection name]
parameter name = value
parameter name = value
; this is a comment line
; for example:
[System Parameters]
SyslogServerIP = 10.13.2.69
EnableSyslog = 1
```

For general *ini* file formatting rules, see 'General ini File Formatting Rules' on page [91](#).

12.1.2 Configuring Table ini File Parameters

The table ini file parameters allow you to configure tables, which include multiple parameters (*columns*) and row entries (*indices*). When loading an *ini* file to the device, it's recommended to include only tables that belong to applications that are to be configured (dynamic tables of other applications are empty, but static tables are not).

The table ini file parameter is composed of the following elements:

- **Title of the table:** The name of the table in square brackets, e.g., [MY_TABLE_NAME].
- **Format line:** Specifies the columns of the table (by their string names) that are to be

configured.

- The first word of the Format line must be "FORMAT", followed by the Index field name and then an equal "=" sign. After the equal sign, the names of the columns are listed.
- Columns must be separated by a comma ",".
- The Format line must only include columns that can be modified (i.e., parameters that are not specified as read-only). An exception is Index fields, which are mandatory.
- The Format line must end with a semicolon ";".
- **Data line(s):** Contain the actual values of the columns (parameters). The values are interpreted according to the Format line.
 - The first word of the Data line must be the table's string name followed by the Index field.
 - Columns must be separated by a comma ",".
 - A Data line must end with a semicolon ";".
- **End-of-Table Mark:** Indicates the end of the table. The same string used for the table's title, preceded by a backslash "\", e.g., [**MY_TABLE_NAME**].

The following displays an example of the structure of a table ini file parameter.

```
[Table_Title]
; This is the title of the table.
FORMAT Index = Column_Name1, Column_Name2, Column_Name3;
; This is the Format line.
Index 0 = value1, value2, value3;
Index 1 = value1, $$, value3;
; These are the Data lines.
[\\Table_Title]
; This is the end-of-the-table-mark.
```

The table ini file parameter formatting rules are listed below:

- Indices (in both the Format and the Data lines) must appear in the same order. The Index field must never be omitted.
- The Format line can include a subset of the configurable fields in a table. In this case, all other fields are assigned with the pre-defined default values for each configured line.
- The order of the fields in the Format line isn't significant (as opposed to the Index fields). The fields in the Data lines are interpreted according to the order specified in the Format line.
- The double dollar sign (\$\$) in a Data line indicates the default value for the parameter.
- The order of the Data lines is insignificant.
- Data lines must match the Format line, i.e., it must contain exactly the same number of Indices and Data fields and must be in exactly the same order.
- A row in a table is identified by its table name and Index field. Each such row may appear only once in the *ini* file.
- Table dependencies: Certain tables may depend on other tables. For example, one table may include a field that specifies an entry in another table. This method is used to specify additional attributes of an entity, or to specify that a given entity is part of a larger entity. The tables must appear in the order of their dependency (i.e., if Table X is referred to by Table Y, Table X must appear in the *ini* file before Table Y).

For general *ini* file formatting rules, see 'General ini File Formatting Rules' on page 91.

The table below displays an example of a table ini file parameter:

```
[ CodersGroup0 ]
FORMAT CodersGroup0_Index = CodersGroup0_Name, CodersGroup0_pTime,
CodersGroup0_rate, CodersGroup0_PayloadType, CodersGroup0_Sce;
```

```
CodersGroup0 0 = g711Alaw64k, 20, 0, 255, 0;  
CodersGroup0 1 = eg711Ulaw, 10, 0, 71, 0;  
[ \CodersGroup0 ]
```

Note: Do not include read-only parameters in the table ini file parameter as this can cause an error when attempting to load the file to the device.

12.1.3 General ini File Formatting Rules

The *ini* file must adhere to the following formatting rules:

- The *ini* file name must not include hyphens "-" or spaces; if necessary, use an underscore "_" instead.
- Lines beginning with a semi-colon ";" are ignored. These can be used for adding remarks in the *ini* file.
- A carriage return (i.e., Enter) must be done at the end of each line.
- The number of spaces before and after the equals sign "=" is irrelevant.
- Subsection names for grouping parameters are optional.
- If there is a syntax error in the parameter name, the value is ignored.
- Syntax errors in the parameter's value can cause unexpected errors (parameters may be set to the incorrect values).
- Parameter string values that denote file names (e.g., CallProgressTonesFileName) must be enclosed with inverted commas, e.g., CallProgressTonesFileName = 'cpt_usa.dat'.
- The parameter name is not case-sensitive.
- The parameter value is not case-sensitive, except for coder names.
- The *ini* file must end with at least one carriage return.

12.2 Loading an ini File

You can load an *ini* file to the device using the following methods:

- Web interface, using any of the following pages:
 - Configuration File - see 'Backing Up and Loading Configuration File' on page [559](#)
 - Load Auxiliary Files - see 'Loading Auxiliary Files' on page [535](#)

When loaded to the device, the configuration settings of the *ini* file are saved to the device's non-volatile memory. If a parameter is not included in the loaded *ini* file, the following occurs:

- Using the Load Auxiliary Files page: Current settings for parameters that were not included in the loaded ini file are retained.
- All other methods: The default is assigned to the parameters that were not included in the loaded ini file and thereby, overriding values previously configured for these parameters.

Notes:

- For a list and description of the *ini* file parameters, see 'Configuration Parameters Reference' on page [655](#).
- Some parameters are configurable only through the *ini* file (and not the Web interface).
- To restore the device to default settings using the *ini* file, see 'Restoring Factory Defaults' on page [571](#).

12.3 Modifying an ini File

You can modify an *ini* file currently used by the device. Modifying an *ini* file instead of loading an entirely new *ini* file preserves the device's current configuration.

➤ **To modify an *ini* file:**

1. Save the device's configuration as an *ini* file on your computer, using the Web interface (see 'Loading an ini File' on page [91](#)).
2. Open the *ini* file using a text file editor such as Notepad, and then modify the *ini* file parameters as required.
3. Save the modified *ini* file, and then close the file.
4. Load the modified *ini* file to the device (see 'Loading an ini File' on page [91](#)).

Tip: Before loading the *ini* file to the device, verify that the file extension of the file is *.ini*.

12.4 Secured Encoded ini File

The *ini* file contains sensitive information that is required for the functioning of the device. The file may be loaded to the device using HTTP. These protocols are not secure and are vulnerable to potential hackers. To overcome this security threat, the AudioCodes DConvert utility allows you to binary-encode (encrypt) the *ini* file before loading it to the device. For more information, refer to *DConvert Utility User's Guide*.

Notes:

- The procedure for loading an encoded *ini* file is identical to the procedure for loading an unencoded *ini* file (see 'Loading an ini File' on page [91](#)).
- If you download from the device (to a folder on your computer) an *ini* file that was loaded encoded to the device, the file is saved as a regular *ini* file (i.e., unencoded).

Part III

General System Settings

13 Configuring Certificates

The Certificates page allows you to configure X.509 certificates, which are used for secure management of the device, secure SIP transactions, and other security applications.

Note: The device is shipped with an active TLS setup. Thus, configure certificates only if required.

13.1 Replacing the Device's Certificate

The device is supplied with a working TLS configuration consisting of a unique self-signed server certificate. If an organizational Public Key Infrastructure (PKI) is used, you may wish to replace this certificate with one provided by your security administrator.

➤ **To replace the device's certificate:**

1. Your network administrator should allocate a unique DNS name for the device (e.g., dns_name.corp.customer.com). This DNS name is used to access the device and therefore, must be listed in the server certificate.
2. If the device is operating in HTTPS mode, then set the 'Secured Web Connection (HTTPS)' parameter (HTTPSOnly) to **HTTP and HTTPS** (see 'Configuring Web Security Settings' on page 65). This ensures that you have a method for accessing the device in case the new certificate does not work. Restore the previous setting after testing the configuration.
3. Open the Certificates page (**Configuration** tab > **System** menu > **Certificates**).
4. Under the **Certificate Signing Request** group, do the following:
 - a. In the 'Subject Name [CN]' field, enter the DNS name.
 - b. Fill in the rest of the request fields according to your security provider's instructions.
 - c. Click the **Create CSR** button; a textual certificate signing request is displayed in the area below the button:

Figure 13-1: Certificate Signing Request Group

Certificate Signing Request	
Subject Name [CN]	audio.com
Organizational Unit [OU] (optional)	Headquarters
Company name [O] (optional)	Corporate
Locality or city name [L] (optional)	Poughkeepsie
State [ST] (optional)	New York
Country code [C] (optional)	US
Create CSR	
After creating the CSR, copy the text below (including the BEGIN/END lines) and send it to your Certification Authority for signing.	
<pre>-----BEGIN CERTIFICATE REQUEST----- MIIBtjCCAR8CAQAwZjESMBAGA1UEAxMJYXVkaW8uY29tMRUwEwYDVQQLZwxiZWZk cXVhcnR1cnMxZjAQBGNVBAOTCUNvbnBvcnF0ZTEVMBMGA1UEBxMMUG91Z2hrZWVw c211MRUwEwYDVQQIEWhOZXcgW9yazELMAkGA1UEBhMCVVMwZ28wDQYJKoZIhvcN AQEBBQADgY0AMIGJAoGBAPhpf2t4OLy3FRk5Bw7F1ZFWCXq7nvuochtu7Nns071M xL7of8YoL63eeIK2eDo8nm6rJo677z/AHWJmF65pAK1CboIFgoZNS0g6+5JAmJAA 1LNUnocjEsK7CF32uvolH//gFkhy5z1eNvObI+25Pn38aJzEXc8DkGwZ19rROqRZ AgMBAAGgADANBgkqhkiG9w0BAQQAQFAOBgQDihdqbci1kHdLFr+5BRuscKyGUXBM6 q7FGjFXAfZk1MmgnBMc/MYf8GTbawrQF7p6dNj60D1vmuCPf6Gzz5m2uqC6LqoIi nLnQpVcmdbva/B1QyEpPbQhZqpULJ8CSe8rrY3ru23AZeDUbYyho90IkRbAp//+3 ZvnZze5M5CB3Lg== -----END CERTIFICATE REQUEST-----</pre>	

5. Copy the text and send it to your security provider. The security provider, also known as Certification Authority or CA, signs this request and then sends you a server certificate for the device.
6. Save the certificate to a file (e.g., cert.txt). Ensure that the file is a plain-text file containing the "BEGIN CERTIFICATE" header, as shown in the example of a Base64-Encoded X.509 Certificate below:

```
-----BEGIN CERTIFICATE-----
MIIDkzCCAnugAwIBAgIEAgAAADANBgkqhkiG9w0BAQQFADA/MQswCQYDVQQGEw
JGUjETMBEGA1UEChMKQ2VydG1wb3N0ZTEbMBkGA1UEAxMSQ2VydG1wb3N0ZSBT

UEBhMCRlIxZzARBgNVBAoTCKNlcnRpcG9zdGUxGzAZBgNVBAMTEkNlcnRpcG9z
dGUgU2VydM1cjcCAwEwDQYJKoZIhvcNAQEBBQADggE0ADCCAQkCggEAPqd4Mz
iR4spWldGRx8bQrhZkonWnNm`+Yhb7+4Q67ecf1janH7GcN/SXsfx7jJpreWUL
f7v7Cvpr4R7qIJcmdHIntmf7JPM5n6cDBv17uSW63er7NkVnMFHwK1QaGFLMyb
FkzaeGrvFm4k3lRefiXDmuOe+FhJgHYeZYHf44LvPRPwhSrzi9+Aq3o8pWDguJ
uZDIUP1F1jMa+LPwvREXfFcUW+w==
-----END CERTIFICATE-----
```

7. Scroll down to the **Upload certificates files from your computer** group, click the **Browse** button corresponding to the 'Send Device Certificate...' field, navigate to the cert.txt file, and then click **Send File**.
8. After the certificate successfully loads to the device, save the configuration with a device reset (see 'Saving Configuration' on page 532); the Web interface uses the provided certificate.
9. Open the Certificates page again and verify that under the **Certificate information** group (at the top of the page), the 'Private key' read-only field displays "OK"; otherwise, consult your security administrator:

Figure 13-2: Private key "OK" in Certificate Information Group

▼ Certificate information	
Certificate subject:	/CN=ACL_3845462
Certificate issuer:	/CN=ACL_3845462
Time to expiration:	7261 days
Key size:	1024 bits
Private key:	OK

10. If the device was originally operating in HTTPS mode and you disabled it in Step 2, then return it to HTTPS by setting the 'Secured Web Connection (HTTPS)' parameter to **HTTPS Only**, and then reset the device with a flash burn.

Notes:

- The certificate replacement process can be repeated when necessary (e.g., the new certificate expires).
- It is possible to use the IP address of the device (e.g., 10.3.3.1) instead of a qualified DNS name in the Subject Name. This is not recommended since the IP address is subject to change and may not uniquely identify the device.
- The device certificate can also be loaded via the Automatic Update Facility by using the HTTPSCertFileName *ini* file parameter.

13.2 Loading a Private Key

The device is shipped with a self-generated random private key, which cannot be extracted from the device. However, some security administrators require that the private key be generated externally at a secure facility and then loaded to the device through configuration. Since private keys are sensitive security parameters, take precautions to

load them over a physically-secure connection such as a back-to-back Ethernet cable connected directly to the managing computer.

➤ **To replace the device's private key:**

1. Your security administrator should provide you with a private key in either textual PEM (PKCS #7) or PFX (PKCS #12) format. The file may be encrypted with a short pass-phrase, which should be provided by your security administrator.
2. If the device is operating in HTTPS mode, then set the 'Secured Web Connection (HTTPS)' field (HTTPSOnly) to **HTTP and HTTPS** (see 'Configuring Web Security Settings' on page 65). This ensures that you have a method for accessing the device in case the new configuration does not work. Restore the previous setting after testing the configuration.
3. Open the Certificates page (**Configuration** tab > **System** menu > **Certificates**) and scroll down to the **Upload certificate files from your computer** group.

Figure 13-3: Upload Certificate Files from your Computer Group

4. Fill in the 'Private key pass-phrase' field, if required.
5. Click the **Browse** button corresponding to the 'Send Private Key' field, navigate to the key file, and then click **Send File**.
6. If the security administrator has provided you with a device certificate file, load it using the 'Send Device Certificate' field.
7. After the files successfully load to the device, save the configuration with a device reset (see 'Saving Configuration' on page 532); the Web interface uses the new configuration.
8. Open the Certificates page again, and verify that under the **Certificate information** group (at the top of the page) the 'Private key' read-only field displays "OK"; otherwise, consult your security administrator.
9. If the device was originally operating in HTTPS mode and you disabled it in Step 2, then enable it by setting the 'Secured Web Connection (HTTPS)' field to **HTTPS Only**.

13.3 Mutual TLS Authentication

By default, servers using TLS provide one-way authentication. The client is certain that the identity of the server is authentic. When an organizational PKI is used, two-way authentication may be desired - both client and server should be authenticated using X.509 certificates. This is achieved by installing a client certificate on the managing PC and loading the root CA's certificate to the device's Trusted Root Certificate Store. The Trusted Root Certificate file may contain more than one CA certificate combined, using a text editor.

Since X.509 certificates have an expiration date and time, the device must be configured to use NTP (see 'Simple Network Time Protocol Support' on page 101) to obtain the current date and time. Without the correct date and time, client certificates cannot work.

➤ **To enable mutual TLS authentication for HTTPS:**

1. Set the 'Secured Web Connection (HTTPS)' field to **HTTPS Only** (see 'Configuring Web Security Settings' on page 65) to ensure you have a method for accessing the device in case the client certificate does not work. Restore the previous setting after testing the configuration.
2. Open the Certificates page (see 'Replacing the Device's Certificate' on page 95).
3. In the **Upload certificate files from your computer** group, click the **Browse** button corresponding to the 'Send Trusted Root Certificate Store ...' field, navigate to the file, and then click **Send File**.
4. When the operation is complete, set the 'Requires Client Certificates for HTTPS connection' field to **Enable** (see 'Configuring Web Security Settings' on page 65).
5. Save the configuration with a device reset (see 'Saving Configuration' on page 532).

When a user connects to the secured Web interface of the device:

- If the user has a client certificate from a CA that is listed in the Trusted Root Certificate file, the connection is accepted and the user is prompted for the system password.
- If both the CA certificate and the client certificate appear in the Trusted Root Certificate file, the user is not prompted for a password (thus, providing a single-sign-on experience - the authentication is performed using the X.509 digital signature).
- If the user does not have a client certificate from a listed CA or does not have a client certificate, the connection is rejected.

Notes:

- The process of installing a client certificate on your PC is beyond the scope of this document. For more information, refer to your operating system documentation, and/or consult your security administrator.
- The root certificate can also be loaded via the Automatic Update facility, using the HTTPSRootFileName *ini* file parameter.
- You can enable the device to check whether a peer's certificate has been revoked by an Online Certificate Status Protocol (OCSP) server (see Configuring Certificate Revocation Checking (OCSP) on page 99).

13.4 Self-Signed Certificates

The device is shipped with an operational, self-signed server certificate. The subject name for this default certificate is 'ACL_nnnnnnn', where *nnnnnnn* denotes the serial number of the device. However, this subject name may not be appropriate for production and can be changed while still using self-signed certificates.

➤ **To change the subject name and regenerate the self-signed certificate:**

- Before you begin, ensure the following:
 - You have a unique DNS name for the device (e.g., `dns_name.corp.customer.com`). This name is used to access the device and should therefore, be listed in the server certificate.
 - No traffic is running on the device. The certificate generation process is disruptive to traffic and should be executed during maintenance time.
- Open the Certificates page (see 'Replacing the Device's Certificate' on page 95).
- In the 'Subject Name **[CN]**' field, enter the fully-qualified DNS name (FQDN) as the certificate subject, select the desired private key size (in bits), and then click **Generate self-signed**; after a few seconds, a message appears displaying the new subject name.
- Save the configuration with a device reset (see 'Saving Configuration' on page 532) for the new certificate to take effect.

13.5 Configuring Certificate Revocation Checking (OCSP)

Some Public-Key Infrastructures (PKI) can revoke a certificate after it has been issued. You can configure the device to check whether a peer's certificate has been revoked, using the Online Certificate Status Protocol (OCSP). When OCSP is enabled, the device queries the OCSP server for revocation information whenever a peer certificate is received (IPSec, TLS client mode, or TLS server mode with mutual authentication).

➤ **To configure OCSP:**

- Open the General Security Settings page (**Configuration** tab > **VoIP** menu > **Security** > **General Security Settings**).

Figure 13-4: OCSP Parameters

OCSP Settings	
Enable OCSP Server	Enable
Primary Server IP	212.10.5.6
Secondary Server IP	0.0.0.0
Server Port	2560
Default Response When Server Unreachable	Reject

- Configure the OCSP parameters as required. For a description of these parameters, see OCSP Parameters on page 687.
- Click **Submit**.

Notes:

- The device does not query OCSP for its own certificate.
- Some PKIs do not support OCSP but generate Certificate Revocation Lists (CRLs). For such cases, set up an OCSP server such as OCSPD.

13.6 TLS Server Certificate Expiry Check

The device can periodically check the validation date of the installed TLS server certificate. This periodic check interval is user-defined. In addition, within a user-defined number of days before the installed TLS server certificate expires, the device can be configured to send the SNMP trap, acCertificateExpiryNotification to notify of the impending certificate expiration.

➤ **To configure TLS certificate expiry checks and notification:**

1. Open the Certificates page (see 'Replacing the Device's Certificate' on page 95).
2. In the 'TLS Expiry Check Start' field, enter the number of days before the installed TLS server certificate is to expire at which the device must send a trap to notify of this.

Figure 13-5: TLS Expiry Settings Group

TLS Expiry Settings	
TLS Expiry Check Start (days)	60
TLS Expiry Check Period (days)	7
Submit TLS Expiry Settings	

3. In the 'TLS Expiry Check Period' field, enter the periodical interval (in days) for checking the TLS server certificate expiry date. By default, the device checks the certificate every 7 days.
4. Click the **Submit TLS Expiry Settings** button.

13.7 Loading Certificate Chain for Trusted Root

A certificate chain is a sequence of certificates where each certificate in the chain is signed by the subsequent certificate. The last certificate in the list of certificates is the Root CA certificate, which is self-signed. The purpose of a certificate chain is to establish a chain of trust from a child certificate to the trusted root CA certificate. The CA vouches for the identity of the child certificate by signing it. A client certificate is considered trusted if one of the CA certificates up the certificate chain is found in the server certificate directory.

Figure 13-6: Certificate Chain Hierarchy

For the device to trust a whole chain of certificates, you need to combine the certificates into one text file (using a text editor). Once done, upload the file using the 'Trusted Root Certificate Store' field in the Certificates page.

Notes: The maximum supported size of the combined file of trusted chain of certificates is 100,000 bytes (including the certificate's headers).

14 Date and Time

The date and time of the device can be configured manually or it can be obtained automatically from a Simple Network Time Protocol (SNTP) server.

14.1 Configuring Date and Time Manually

The date and time of the device can be configured manually.

➤ **To manually configure the device's date and time, using the Web interface:**

1. Open the Regional Settings page (**Configuration** tab > **System** menu > **Regional Settings**).

Figure 14-1: Regional Settings Page

Year	Month	Day	Hour	Minutes	Seconds
2010	2	4	10	21	46

2. Enter the current date and time of the geographical location in which the device is installed.
3. Click the **Submit** button.

Notes:

- If the device is configured to obtain the date and time from an SNTP server, the fields on this page are read-only, displaying the received date and time.
- After performing a hardware reset, the date and time are returned to their defaults and thus, should be updated.

14.2 Automatic Date and Time through SNTP Server

The Simple Network Time Protocol (SNTP) client functionality generates requests and reacts to the resulting responses using the NTP version 3 protocol definitions (according to RFC 1305). Through these requests and responses, the NTP client synchronizes the system time to a time source within the network, thereby eliminating any potential issues should the local system clock 'drift' during operation. By synchronizing time to a network time source, traffic handling, maintenance, and debugging become simplified for the network administrator.

The NTP client follows a simple process in managing system time: the NTP client requests an NTP update, receives an NTP response, and then updates the local system clock based on a configured NTP server within the network.

The client requests a time update from a specified NTP server at a specified update interval. In most situations, this update interval is every 24 hours based on when the system was restarted. The NTP server identity (as an IP address or FQDN) and the update interval are user-defined, or an SNMP MIB object.

When the client receives a response to its request from the identified NTP server, it must be interpreted based on time zone or location offset that the system is to a standard point of reference called the Universal Time Coordinate (UTC). The time offset that the NTP client uses is configurable.

If required, the clock update is performed by the client as the final step of the update process. The update is performed in such a way as to be transparent to the end users. For instance, the response of the server may indicate that the clock is running too fast on the client. The client slowly robs bits from the clock counter to update the clock to the correct

time. If the clock is running too slow, then in an effort to catch the clock up, bits are added to the counter, causing the clock to update quicker and catch up to the correct time. The advantage of this method is that it does not introduce any disparity in the system time that is noticeable to an end user or that could corrupt call timeouts and timestamps.

The procedure below describes how to configure SNTP.

➤ **To configure SNTP using the Web interface:**

1. Open the Application Settings page (**Configuration** tab > **System** menu > **Application Settings**).

Figure 14-2: SNTP Configuration in Application Settings Page

NTP Settings					
NTP Server DN/IP	212.13.4.5				
NTP UTC Offset	Hours: 0	Minutes: 0			
NTP Updated Interval	Hours: 24	Minutes: 0			
NTP Secondary Server IP					

Day Light Saving Time					
Day Light Saving Time	Enable				
DST Mode	Day of month				
Start Time	Sep	02	0	:	0
End Time	Apr	07	0	:	0
Offset [min]	60				
Day of Month Start	Sep	Sunday	First	0	: 0
Day of Month End	Apr	Sunday	First	0	: 0

2. Configure the NTP parameters:
 - 'NTP Server DN/IP' (NTPServerIP) - defines the IP address or FQDN of the NTP server.
 - 'NTP UTC Offset' (NTPServerUTCOffset) - defines the time offset in relation to the UTC. For example, if your region is 2 hours ahead of the UTC, enter "2".
 - 'NTP Updated Interval' (NTPUpdateInterval) - defines the period after which the date and time of the device is updated.
 - 'NTP Secondary Server IP' (NTPSecondaryServerIP) - defines the secondary NTP server.
3. Configure daylight saving, if required:
 - 'Day Light Saving Time' (DayLightSavingTimeEnable) - enables daylight saving time.
 - 'DST Mode' - Determines the range type for configuring the start and end date for daylight saving:
 - ◆ **Day of Year:** The range is configured by date of month, for example, from January 4 to August 31.
 - ◆ **Day of month:** The range is configured by day of month, for example, from the second Sunday of May January to the last Sunday of August.
 - 'Start Time' (DayLightSavingTimeStart) and 'End Time' (DayLightSavingTimeEnd) - defines the period for which daylight saving time is relevant.
 - 'Offset' (DayLightSavingTimeOffset) - defines the offset in minutes to add to the time for daylight saving. For example, if your region has daylight saving of one hour, the time received from the NTP server is 11:00, and the UTC offset for your region is +2 (i.e., 13:00), you need to enter "60" to change the local time to 14:00.
4. Verify that the device is set to the correct date and time. You can do this by viewing the date and time in the Regional Settings page, as described in 'Configuring Date and Time Manually' on page 101.

15 Configuring Power over Ethernet

The device supports Power over Ethernet (PoE) according to the IEEE 802.3af-2003 and IEEE 802.3at standards, providing power on the Ethernet lines through all the LAN ports. The ports can transfer electrical power, along with the usual data, over the Ethernet cable to connected equipment (e.g., IP phones) that are capable of receiving PoE.

The LAN ports automatically detect the presence of IEEE 802.3 compliant equipment. Upon plugging in a PoE client to one of the ports, the device also automatically detects the class to which the client belongs and consequently, the maximum power allowed:

- IEEE 802.3af-2003: The device can supply up to 15.4W per port, and a total budget of 50W or 120W (depending on model) for all ports:
 - Class 0: configurable, up to 15.4W
 - Class 1: up to 4W
 - Class 2: up to 7W
 - Class 3: up to 15.4W
- IEEE 802.3at – Class 4: The device can supply up to 30W per port to the connected equipment and a total budget of 50W, 120W, or 200W (depending on model) for all ports.

PoE is supplied on Pins 4,5: (+), pins 7,8: (-).

You can enable PoE per port and set the maximum port power consumption (up to 15.4W) when the plugged-in client is detected as Class 0. If the plugged-in client is detected as Class 0, the device saves the user-defined wattage from the total wattage budget (i.e., 15.4W). If the plugged-in client is detected as Class 1, Class 2, or Class 3, the device saves 4W, 7W, or 15.4W respectively from the total wattage budget. If the power budget has been exhausted and a new client is plugged in, power is unavailable to this client. You can also enable Class 4 PoE per port.

Notes:

- PoE is a customer ordered feature.
- Upon device startup, PoE is enabled on all LAN ports.
- The power is always taken off the total budget according to the class detected, regardless of what is actually consumed per port.
- To view allocated power per port and various PoE allocation information, see 'Viewing Ethernet Port Information' on page 577.
- You can also configure PoE, using the ini file parameter POETable, or CLI command, **configure system/poe**.

The procedure below describes how to configure PoE through the Web interface.

➤ **To configure PoE through the Web interface:**

1. Open the Power Over Ethernet Settings page (**Configuration** tab > **System** menu > **Power over Ethernet Settings**).

Figure 15-1: Power Over Ethernet Settings Page

Index	Port Enable	Max Power	AT Enable
1 ☒	Enable ▼	15400	Disable ▼
2 ☐	Enable	15400	Disable
3 ☐	Enable	15400	Disable
4 ☐	Enable	15400	Disable
5 ☐	Enable	15400	Disable
6 ☐	Enable	15400	Disable
7 ☐	Enable	15400	Disable
8 ☐	Enable	15400	Disable
9 ☐	Enable	15400	Disable
10 ☐	Enable	15400	Disable
11 ☐	Enable	15400	Disable
12 ☐	Enable	15400	Disable

2. Select the 'Index' radio button corresponding to the required LAN port.
3. Click the **Edit** button.
4. From the 'Port Enable' drop-down list, select whether you want to enable or disable PoE.
5. In the 'Max Power' field, enter the required maximum power consumption for the port.
6. From the 'AT Enable' drop-down list, select whether you want to enable PoE according to IEEE 802.3at.
7. Click **Apply**.

Part IV

General VoIP Configuration

16 Network

This section describes the network-related configuration.

16.1 Configuring IP Network Interfaces

You can configure a single VoIP network interface for all applications, which includes OAMP (management traffic), call control (SIP messages), and media (RTP traffic), or you can configure multiple logical, IP network interfaces for these applications. A need often arises to have logically separated network segments for these applications for administration and security. This can be achieved by employing Layer-2 VLANs and Layer-3 subnets.

The figure below illustrates a typical network architecture where the device is configured with three network interfaces for the OAMP, call control, and media applications. The device is connected to a VLAN-aware switch for directing traffic from and to the device to the three separated Layer-3 broadcast domains according to VLAN tags (middle pane).

Figure 16-1: Multiple Network Interfaces

The Multiple Interface Table page allows you to configure these network interfaces. Each row of the table defines a logical IP interface with the following attributes:

- Application type allowed on the interface:
 - Control - call control signaling traffic (i.e., SIP)
 - Media - RTP traffic
 - Operations, Administration, Maintenance and Provisioning (OAMP) - management (such as Web- and SNMP-based management)
- IP address and subnet mask represented by prefix length
- VLAN ID
- Default Gateway - traffic from this interface destined to a subnet that does not meet any of the routing rules, local or static routes, are forwarded to this gateway
- Primary and secondary DNS IP address (optional)

You can configure up to 12 interfaces, consisting of up to 11 Control and Media interfaces and 1 OAMP interface.

The default VoIP interface is as follows:

- Application type: OAMP + Media + Control
- IP address: 192.168.0.2 with prefix length 24 (i.e., subnet mask 255.255.255.0)
- Default gateway: 192.168.0.1
- Name: "Voice"
- VLAN ID: 1

Complementing this network configuration is the On-Board Ethernet Switch configuration. This enables you to configure the VLAN IDs accessible through each physical port, as well as the Native VLAN ID of each physical port. Layer3 (DiffServ) and Layer 2 (VLAN priority) Quality of Service parameters are also configurable. For configuring Quality of Service (QoS), see 'Configuring the QoS Settings' on page 118.

Complementing the Multiple Interface table is the IP Routing table, which allows you to define VoIP network static routing rules for non-local hosts/subnets. For more information, see 'Configuring the IP Routing Table' on page 115.

Notes:

- When using data-routing functionality, the network interfaces for the data-router are configured using the Data Settings menu (see Data Router Configuration on page 525).
- When operating with both voice and data-routing functionalities, it is recommended to define the default gateway IP address for the VoIP network interfaces in the same subnet and with the same VLAN ID as the IP address defined in the data-routing configuration section.
- To configure firewall rules (access list) for allowing or blocking packets received from specific IP network interfaces, see 'Configuring Firewall Settings' on page 131.
- IPv6 is currently not supported (even though it may appear in the Web interface).
- The Multiple Interface table can also be configured using the table ini file parameter, InterfaceTable (see 'Networking Parameters' on page 655) or CLI command, configure voip/interface network-if.

➤ To configure VoIP network interfaces:

1. Open the Multiple Interface Table page (**Configuration** tab > **VoIP** menu > **Network** submenu > **IP Settings**).

Figure 16-2: Multiple Interface Table

Index	Application Type	IP Address	Prefix Length	Gateway	VLAN ID	Interface Name	Primary DNS Server IP Address	Secondary DNS Server IP Address	Underlying Interface
0	OAMP + Media + Control	10.13.4.12	16	10.13.0.1	1	Mng	0.0.0.0	0.0.0.0	None

2. In the 'Add Index' field, enter the desired index number for the new interface, and then click **Add Index**; the index row is added to the table.
3. Configure the interface according to the table below.
4. Click the **Apply** button; the interface is added to the table and the **Done** button appears.
5. Click **Done** to validate the interface. If the interface is not valid (e.g., if it overlaps with

another interface in the table or if it does not adhere to the other rules as summarized in 'Multiple Interface Table Configuration Summary and Guidelines' on page 111), a warning message is displayed.

6. Save the changes to flash memory and reset the device (see 'Saving Configuration' on page 532).

Multiple Interface Table Parameters Description

Parameter	Description
Table parameters	
Index CLI: network-if [InterfaceTable_Index]	Table index row of the interface. The range is 0 to 11.
Web: Application Type EMS: Application Types CLI: application-type [InterfaceTable_ApplicationTypes]	Defines the applications allowed on the interface. ▪ [0] OAMP = Operations, Administration, Maintenance and Provisioning (OAMP) applications (e.g., Web, Telnet, SSH, and SNMP). ▪ [1] Media = Media (i.e., RTP streams of voice). ▪ [2] Control = Call Control applications (e.g., SIP). ▪ [3] OAMP + Media = OAMP and Media applications. ▪ [4] OAMP + Control = OAMP and Call Control applications. ▪ [5] Media + Control = Media and Call Control applications. ▪ [6] OAMP + Media + Control = All application types are allowed on the interface. Note: For valid configuration, see Multiple Interface Table Configuration Rules on page 111.
Web/EMS: IP Address CLI: ip-address [InterfaceTable_IPAddress]	Defines the IPv4 IP address in dotted-decimal notation. Note: For valid configuration, see Multiple Interface Table Configuration Rules on page 111.
Web/EMS: Prefix Length CLI: prefix-length [InterfaceTable_PrefixLength]	Defines the prefix length of the related IP address. This is a Classless Inter-Domain Routing (CIDR)-style representation of a dotted-decimal subnet notation. The CIDR-style representation uses a suffix indicating the number of bits which are set in the dotted-decimal format. For example, 192.168.0.0/16 is synonymous with 192.168.0.0 and subnet 255.255.0.0. This CIDR lists the number of '1' bits in the subnet mask (i.e., replaces the standard dotted-decimal representation of the subnet mask for IPv4 interfaces). For example, a subnet mask of 255.0.0.0 is represented by a prefix length of 8 (i.e., 11111111 00000000 00000000 00000000) and a subnet mask of 255.255.255.252 is represented by a prefix length of 30 (i.e., 11111111 11111111 11111111 11111100). The prefix length is a Classless Inter-Domain Routing (CIDR) style presentation of a dotted-decimal subnet notation. The CIDR-style presentation is the latest method for interpretation of IP addresses. Specifically, instead of using eight-bit address blocks, it uses the variable-length subnet masking technique to allow allocation on arbitrary-length prefixes. The prefix length for IPv4 can range from 0 to 30. Note: For valid configuration, see Multiple Interface Table Configuration Rules on page 111.
Web/EMS: Gateway CLI: gateway	Defines the IP address of the default gateway for the interface. When traffic is sent from this interface to an unknown destination (i.e., not in the

Parameter	Description
[InterfaceTable_Gateway]	same subnet and not defined for any static routing rule), it is forwarded to this default gateway. Note: For valid configuration, see Multiple Interface Table Configuration Rules on page 111.
Web/EMS: VLAN ID CLI: vlan-id [InterfaceTable_VlanID]	Defines a VLAN ID for the interface. Note: For valid configuration, see Multiple Interface Table Configuration Rules on page 111.
Web/EMS: Interface Name CLI: name [InterfaceTable_InterfaceName]	Defines a name for this interface. This name is used in various configuration tables to associate this network interface with other configuration entities such as Media Realms. It is also displayed in management interfaces (Web, CLI, and SNMP) for clarity where it has no functional use. The valid value is a string of up to 16 characters. Note: For valid configuration, see Multiple Interface Table Configuration Rules on page 111.
Web/EMS: Primary DNS Server IP address CLI: primary-dns [InterfaceTable_PrimaryDNSServerIPAddress]	(Optional) Defines the primary DNS server's IP address (in dotted-decimal notation), which is used for translating domain names into IP addresses for the interface. By default, no IP address is defined.
Web/EMS: Secondary DNS Server IP address CLI: secondary-dns [InterfaceTable_SecondaryDNSServerIPAddress]	(Optional) Defines the secondary DNS server's IP address (in dotted-decimal notation), which is used for translating domain names into IP addresses for the interface. By default, no IP address is defined.
[WanInterfaceName]	Assigns a WAN interface to the VoIP traffic (i.e., SIP signaling and media / RTP interfaces). The available WAN interface options depends on the hardware configuration (e.g., Ethernet, T1, or SHDSL) and/or whether VLANs are defined for the WAN interface. If VLANs are configured, for example, for the Ethernet WAN interface (see Data Settings on page 525), then you can select the WAN VLAN on which you want to run these SIP signaling and/or media interfaces. The WAN interface can be assigned to SIP signaling and media interfaces in the SIP Interface table (see Configuring SIP Interface Table on page 201) and Media Realm table (see Configuring Media Realms on page 168), where the WAN interface is denoted as "WAN". Once this association is set, VoIP traffic is sent via the WAN and incoming traffic is identified as coming from the WAN. The device also automatically configures the required port forwarding and static NAT rules. Notes: - For this parameter to take effect, a device reset is required. - If you do not assign the WAN interface to SIP and media interfaces, then the WAN interface may not be used for VoIP traffic. In such scenarios, the VoIP traffic can be sent and received within the LAN, or sent to the WAN via a third-party LAN router. If a third-party router is used as the interface to the WAN, then you need to define NAT rules (using the NATTranslation parameter) to translate the VoIP LAN IP

Parameter	Description
	addresses (defined in the Multiple Interface table and associated with SIP and media interfaces) into global, public IP addresses. This parameter is applicable only if the data-routing functionality is supported (i.e., relevant Software License Key is installed on the device).

16.1.1 Assigning NTP Services to Application Types

You can associate the Network Time Protocol (NTP) application with the OAMP or Control application type. This is done using the EnableNTPasOAM ini file parameter.

16.1.2 Multiple Interface Table Configuration Rules

The Multiple Interface table configuration must adhere to the following rules:

- Multiple Control and Media interfaces can be configured with overlapping IP addresses and subnets.
- The prefix length replaces the dotted-decimal subnet mask presentation and must have a value of 0-30 for IPv4 addresses.
- Only one OAMP interface must be configured and this must be an IPv4 address. This OAMP interface can be combined with Media and Control.
- At least one Control interface must be configured with an IPv4 address.
- At least one Media interface must be configured with an IPv4 address.
- The network interface types can be combined:
 - Example 1:
 - ◆ One combined OAMP-Media-Control interface with an IPv4 address
 - Example 2:
 - ◆ One OAMP interface with an IPv4 address
 - ◆ One or more Control interfaces with IPv4 addresses
 - ◆ One or more Media interfaces with IPv4 interfaces
 - Example 3:
 - ◆ One combined OAMP-Media interface with an IPv4 address
 - ◆ One or more combined Media-Control interfaces with IPv4 addresses
- Each network interface can be configured with a Default Gateway. The address of the Default Gateway must be in the same subnet as the associated interface. Additional static routing rules can be configured in the IP Routing table.
- The interface name must be configured (mandatory) and unique for each interface, and can include up to 16 characters.
- For IPv4 addresses, the 'Interface Mode' column must be set to IPv4 Manual (numeric value 10).
- For network configuration to take effect, you must save the configuration to the device's flash memory (burn) with a device reset.

Notes:

- When configuring the network interfaces and VLANs in the Multiple Interface table using the Web interface, it is recommended to check that your configuration is valid, by clicking the Done button in the Multiple Interface Table page.
- Upon device start up, the Multiple Interface table is parsed and passes comprehensive validation tests. If any errors occur during this validation phase, the device sends an error message to the Syslog server and falls back to a "safe mode", using a single interface and no VLANs. Ensure that you view the Syslog messages that the device sends in system startup to see if any errors occurred.

16.1.3 Troubleshooting the Multiple Interface Table

If any of the Multiple Interface table guidelines are violated, the device falls back to a "safe mode" configuration, working temporarily with IP address 192.168.0.2. For more information on validation failures, consult the Syslog messages.

Validation failures may be caused by one of the following:

- One of the Application Types (OAMP, Control, or Media) are missing in the IPv4 interfaces.
- There are too many interfaces for Application Type, OAMP. There is only one interface defined, but the 'Application Types' column is not set to **OAMP + Media + Control** (numeric value 6).
- An IPv4 interface was defined with 'Interface Type' other than **IPv4 Manual** (10).
- Two interfaces have the same VLAN ID value.
- Two interfaces have the same name.

Apart from these validation errors, connectivity problems may be caused by one of the following:

- Trying to access the device with untagged traffic when VLANs are on and Native VLAN is not configured properly.
- The IP Routing table is not configured properly.

16.1.4 Networking Configuration Examples

This section provides configuration examples of networking interfaces.

16.1.4.1 One VoIP Interface for All Applications

This example describes the configuration of a single VoIP interface for all applications:

1. **Multiple Interface table:** Configured with a single interface for OAMP, Media and Control:

Example of Single VoIP Interface in Multiple Interface Table

Index	Application Type		IP Address	Prefix Length	Default	VLAN ID	Interface Name
0	OAMP, Media & Control		192.168.0.2	16	192.168.0.1	1	myInterface

2. **IP Routing table:** Two routes are configured for directing traffic for subnet 201.201.0.0/16 to 192.168.11.10, and all traffic for subnet 202.202.0.0/16 to 192.168.11.1:

Example of IP Routing Table

Destination IP Address	Prefix Length	Gateway IP Address	Metric	Interface Name
201.201.0.0	16	192.168.11.10	1	-
202.202.0.0	16	192.168.11.1	1	-

3. The NTP applications remain with their default application types.

16.1.4.2 VoIP Interface per Application Type

This example describes the configuration of three VoIP interfaces; one for each application type:

1. **Multiple Interface table:** Configured with three interfaces, each for a different application type, i.e., one for OAMP, one for Call Control, and one for RTP Media, and each with a different VLAN ID and default gateway:

Example of VoIP Interfaces per Application Type in Multiple Interface Table

Index	Application Type		IP Address	Prefix Length	Gateway	VLAN ID	Interface Name
0	OAMP		192.168.0.2	16	192.168.0.1	1	ManagementIF
1	Control		200.200.85.14	24	200.200.85.1	200	myControlIF
2	Media		211.211.85.14	24	211.211.85.1	211	myMediaIF

2. **IP Routing table:** A routing rule is required to allow remote management from a host in 176.85.49.0 / 24:

Example IP Routing Table

Destination IP Address	Prefix Length	Gateway IP Address	Metric	Interface Name
176.85.49.0	24	192.168.11.1	1	-

3. All other parameters are set to their respective default values. The NTP application remains with its default application types.

16.1.4.3 VoIP Interfaces for Combined Application Types

This example describes the configuration of multiple interfaces for the following applications:

- One interface for the OAMP application.
- Interfaces for Call Control and Media applications.

1. Multiple Interface table:

Example of VoIP Interfaces of Combined Application Types in Multiple Interface Table

Index	Application Type		IP Address	Prefix Length	Gateway	VLAN ID	Interface Name
0	OAMP		192.168.0.2	16	192.168.0.1	1	Mgmt
1	Media & Control		200.200.85.14	24	200.200.85.1	201	MediaCntrl1
2	Media & Control		200.200.86.14	24	200.200.86.1	202	MediaCntrl2

- #### 2. IP Routing table:
- A routing rule is required to allow remote management from a host in 176.85.49.0/24:

Example of IP Routing Table

Destination IP Address	Prefix Length	Gateway IP Address	Metric	Interface Name
176.85.49.0	24	192.168.0.10	1	-

- #### 3.
- The NTP application is configured (using the ini file) to serve as OAMP applications:
- ```
EnableNTPasOAM = 1
```

### 16.1.4.4 VoIP Interfaces with Multiple Default Gateways

Below is a configuration example using default gateways per IP network interface. In this example, the default gateway for OAMP is 192.168.0.1 and for Media and Control it is 200.200.85.1.

**Configured Default Gateway Example**

| Index | Application Type |  | IP Address    | Prefix Length | Gateway      | VLAN ID | Interface Name |
|-------|------------------|--|---------------|---------------|--------------|---------|----------------|
| 0     | OAMP             |  | 192.168.0.2   | 16            | 192.168.0.1  | 100     | Mgmt           |
| 1     | Media & Control  |  | 200.200.85.14 | 24            | 200.200.85.1 | 200     | CntrlMedia     |

A separate IP routing table enables you to configure static routing rules. Configuring the following static routing rules enables OAMP applications to access peers on subnet 17.17.0.0 through the gateway 192.168.10.1 (which is not the default gateway of the interface), and Media & Control applications to access peers on subnet 171.79.39.0 through the gateway 200.200.85.10 (which is not the default gateway of the interface).

### Separate Routing Table Example

| Destination IP Address | Prefix Length | Gateway IP Address | Metric | Interface Name | Status |
|------------------------|---------------|--------------------|--------|----------------|--------|
| 17.17.0.0              | 16            | 192.168.10.1       | 1      | 0              | Active |
| 171.79.39.0            | 24            | 200.200.85.10      | 1      | 1              | Active |

## 16.2 Configuring the IP Routing Table

The IP Routing Table page allows you to define up to 30 static IP routing rules for the device. These rules can be associated with a network interface (defined in the Multiple Interface table) and therefore, the routing decision is based on the source subnet/VLAN. If not associated with an IP interface, the static IP rule is based on destination IP address. Traffic destined to the subnet specified in the routing rule is re-directed to the defined gateway, reachable through the specified interface.

➤ **To configure static IP routing:**

1. Open the IP Routing Table page (**Configuration** tab > **VoIP** menu > **Network** submenu > **IP Routing Table**).

**Figure 16-3: IP Routing Table Page**

| # | Delete Row               | Destination IP Address | Prefix Length | Gateway IP Address | Metric | Interface Name | Status |
|---|--------------------------|------------------------|---------------|--------------------|--------|----------------|--------|
| 1 | <input type="checkbox"/> | 169.254.254.252        | 30            | 0.0.0.0            | 0      | InternalIF     | Active |
| 2 | <input type="checkbox"/> | 10.9.0.0               | 16            | 0.0.0.0            | 0      | Voice          | Active |
| 3 | <input type="checkbox"/> | 0.0.0.0                | 0             | 10.9.0.1           | 1      | Voice          | Active |
| 4 | <input type="checkbox"/> | 0.0.0.0                | 0             | 169.254.254.253    | 2      | InternalIF     | Active |

**Delete Selected Entries**

**Add a new table entry**

| Destination IP Address | Prefix Length | Gateway IP Address | Metric | Interface Name |
|------------------------|---------------|--------------------|--------|----------------|
|                        | 16            |                    | 1      |                |

**Add New Entry**

2. In the Add a new table entry table, add a new static routing rule according to the parameters described in the table below.
3. Click **Add New Entry**; the new routing rule is added to the IP routing table.

To delete a routing rule from the table, select the 'Delete Row' check box corresponding to the required routing rule, and then click **Delete Selected Entries**.

**Notes:**

- You can delete only inactive routing rules.
- The IP Routing table can also be configured using the table ini file parameter, StaticRouteTable or the CLI command, configure voip/routing static.

### IP Routing Table Description

| Parameter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Destination IP Address<br>CLI: destination<br>[StaticRouteTable_Destination]                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | Defines the IP address of the destination host/network. The destination can be a single host or a whole subnet, depending on the Prefix Length configured for this routing rule.                                                                                                                                                                                                                 |
| Prefix Length<br>CLI: prefix-length<br>[StaticRouteTable_PrefixLength]                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Defines the Classless Inter-Domain Routing (CIDR)-style representation of a dotted-decimal subnet notation, of the destination host/network. The CIDR-style representation uses a suffix indicating the number of bits that are set in the dotted-decimal format. For example, 16 is synonymous with subnet 255.255.0.0.                                                                         |
| The address of the host/network you want to reach is determined by an AND operation that is applied to the fields 'Destination IP Address' and 'Prefix Length'. For example, to reach the network 10.8.x.x, enter 10.8.0.0 in the 'Destination IP Address' field and 16 in the 'Prefix Length'. As a result of the AND operation, the value of the last two octets in the 'Destination IP Address' field is ignored. To reach a specific host, enter its IP address in the 'Destination IP Address' field and 32 in the 'Prefix Length' field. |                                                                                                                                                                                                                                                                                                                                                                                                  |
| Gateway IP Address<br>CLI: gateway<br>[StaticRouteTable_Gateway]                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Defines the IP address of the router (next hop) used for traffic destined to the subnet/host as defined in the 'Destination IP Address' / 'Prefix Length' field.<br><b>Note:</b> The Gateway address must be in the same subnet as the IP address of the interface over which you configure this static routing rule.                                                                            |
| Metric                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Defines the number of hops needed to reach the specified destination.<br><b>Note:</b> The recommended value for this parameter is 1. This parameter must be set to a number greater than 0 for the routing rule to be valid. Routing entries with Hop Count equals 0 are local routes set automatically by the device.                                                                           |
| Interface Name<br>CLI: interface-name<br>[StaticRouteTable_InterfaceName]                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | Assigns a network interface through which the 'Gateway IP Address' is reached. This is the string value as configured for the network interface in the 'Interface Name' field of the Multiple Interface table (see 'Configuring IP Network Interfaces' on page 107).<br><b>Note:</b> The IP address of the 'Gateway IP Address' field must be in the same subnet as this interface's IP address. |
| Status                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Read-only field displaying the status of the static IP route: <ul style="list-style-type: none"> <li>"Active" - routing rule is used by the device.</li> <li>"Inactive" - routing rule is not applied. When the destination IP address is not on the same segment with the next hop or the interface does not exist, the route state changes to "Inactive".</li> </ul>                           |

## 16.2.1 Interface Column

This example describes the configuration of static IP routing rules.

1. Configure network interfaces in the Multiple Interface table, as shown below:

**Configured Network Interfaces in Multiple Interface Table**

| Index | Application Type | IP Address   | Prefix Length | Gateway     | VLAN ID | Interface Name |
|-------|------------------|--------------|---------------|-------------|---------|----------------|
| 0     | OAMP             | 192.168.0.2  | 16            | 192.168.0.1 | 501     | Mng            |
| 1     | Media & Control  | 10.32.174.50 | 24            | 10.32.174.1 | 2012    | MediaCntrl     |
| 2     | Media            | 10.33.174.50 | 24            | 10.33.174.1 | 2013    | Media1         |
| 3     | Control          | 10.34.174.50 | 24            | 10.34.174.1 | 2014    | Cntrl1         |

2. Configure static IP Routing rules in the IP Routing table, as shown below:

**Configured Static IP Routing Rules in IP Routing Table**

| Destination IP Address | Prefix Length | Gateway IP Address | Metric | Interface Name |
|------------------------|---------------|--------------------|--------|----------------|
| 10.31.174.0            | 24            | 192.168.11.1       | 1      | Mng            |
| 174.96.151.15          | 24            | 10.32.174.12       | 1      | MediaCntrl     |
| 10.35.174.0            | 24            | 10.34.174.240      | 1      | Cntrl1         |

Note that the IP address configured in the 'Gateway IP Address' field (i.e., next hop) must reside on the same subnet as the IP address of the associated network interface that is specified in the 'Interface Name' field.

## 16.2.2 Routing Table Configuration Summary and Guidelines

The Routing table configurations must adhere to the following rules:

- Up to 30 different static routing rules can be configured.
- The 'Prefix Length' replaces the dotted-decimal subnet mask presentation. This column must have a value of 0-31 for IPv4 interfaces.
- The 'Gateway IP Address' field must be on the same subnet as the IP address of the associated interface specified in the 'Interface Name' field.
- The 'Metric' field must be set to 1.
- For the configuration settings to take effect, you must reset the device with a "burn" to flash memory.

## 16.2.3 Troubleshooting the Routing Table

When adding a new static routing rule, the added rule passes a validation test. If errors are found, the routing rule is rejected and is not added to the IP Routing table. Failed routing validations may result in limited connectivity (or no connectivity) to the destinations specified in the incorrect routing rule. For any error found in the Routing table or failure to

configure a routing rule, the device sends a notification message to the Syslog server reporting the problem.

Common routing rule configuration errors may include the following:

- The IP address specified in the 'Gateway IP Address' field is unreachable from the interface specified in the 'Interface Name' field.
- The same destination is configured in two different routing rules.
- More than 30 routing rules have been configured.

**Note:** If an IP routing rule is required to access OAMP applications (for remote management, for example) and the route is not configured correctly, the route is not added and the device is not accessible remotely. To restore connectivity, the device must be accessed locally from the OAMP subnet and the required routes be configured.

## 16.3 Configuring Quality of Service

The Diff Serv Table page is used for configuring the Layer-2 and Layer-3 Quality of Service (QoS) parameters for VoIP. Differentiated Services (DiffServ) is an architecture providing different types or levels of service for IP traffic. DiffServ (according to RFC 2474), prioritizes certain traffic types based on their priority, thereby, accomplishing a higher-level QoS at the expense of other traffic types. By prioritizing packets, DiffServ routers can minimize transmission delays for time-sensitive packets such as VoIP packets.

You can assign DiffServ to four classes of traffic and assign VLAN priorities (IEEE 802.1p) to various values of DiffServ:

- Premium Media service class – used for RTP media traffic
- Premium Control service class – used for call control (i.e., SIP) traffic
- Gold service class – used for streaming applications
- Bronze service class – used for OAMP applications

The Layer-3 QoS parameters define the values of the DiffServ field in the IP header of the frames related to a specific service class. The Layer-2 QoS parameters define the values for the 3 priority bits in the VLAN tag (according to the IEEE 802.1p standard) according to the value of the DiffServ field found in the packet IP header.

The DiffServ Table (DiffServToVlanPriority) allows you to configure up to 64 DiffServ-to-VLAN Priority mapping (Layer 2 class of service). For each packet sent to the LAN, the VLAN Priority of the packet is set according to the DiffServ value in the IP header of the packet.

The mapping of an application to its CoS and traffic type is shown in the table below:

**Traffic/Network Types and Priority**

| Application         | Traffic / Network Types | Class-of-Service (Priority) |
|---------------------|-------------------------|-----------------------------|
| Debugging interface | Management              | Bronze                      |
| Telnet              | Management              | Bronze                      |
| DHCP                | Management              | Network                     |
| Web server (HTTP)   | Management              | Bronze                      |
| SNMP GET/SET        | Management              | Bronze                      |
| Web server (HTTPS)  | Management              | Bronze                      |
| RTP traffic         | Media                   | Premium media               |

| Application         | Traffic / Network Types                                                                                                                                                                             | Class-of-Service (Priority)                                                                                                     |
|---------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| RTCP traffic        | Media                                                                                                                                                                                               | Premium media                                                                                                                   |
| T.38 traffic        | Media                                                                                                                                                                                               | Premium media                                                                                                                   |
| SIP                 | Control                                                                                                                                                                                             | Premium control                                                                                                                 |
| SIP over TLS (SIPS) | Control                                                                                                                                                                                             | Premium control                                                                                                                 |
| Syslog              | Management                                                                                                                                                                                          | Bronze                                                                                                                          |
| SNMP Traps          | Management                                                                                                                                                                                          | Bronze                                                                                                                          |
| DNS client          | Varies according to DNS settings: <ul style="list-style-type: none"> <li>OAMP</li> <li>Control</li> </ul>                                                                                           | Depends on traffic type: <ul style="list-style-type: none"> <li>Control: Premium Control</li> <li>Management: Bronze</li> </ul> |
| NTP                 | Varies according to the interface type associated with NTP (see 'Assigning NTP Services to Application Types' on page 111): <ul style="list-style-type: none"> <li>OAMP</li> <li>Control</li> </ul> | Depends on traffic type: <ul style="list-style-type: none"> <li>Control: Premium control</li> <li>Management: Bronze</li> </ul> |

**Notes:**

- For the QoS settings to take effect, a device reset is required.
- You can also configure the DiffServ table using the table ini file parameter DiffServToVlanPriority or CLI command, configure voip > qos vlan-mapping.

➤ **To configure QoS:**

- Open the Diff Serv Table page (**Configuration** tab > **VoIP** menu > **Network** submenu > **QoS Settings**).

**Figure 16-4: DiffServ Table Page**

| Index | Differentiated Services | VLAN Priority |
|-------|-------------------------|---------------|
| 1     | 6                       | 1             |

▼ Differentiated Services

|                     |    |
|---------------------|----|
| Media Premium QoS   | 46 |
| Control Premium QoS | 40 |
| Gold QoS            | 26 |
| Bronze QoS          | 10 |

- Configure DiffServ to VLAN priority mapping (Layer-2 QoS):
  - Enter an index entry, and then click Add.
  - In the 'Differentiated Services' field, enter the DiffServ value (0-63) and its corresponding VLAN priority level (0-7).
  - Click Submit.

3. Configure the desired DiffServ (Layer-3 QoS) values for the following traffic classes:
  - Media Premium QoS: this affects Media RTP packets sent by the VoIP towards the LAN.
  - Control Premium QoS: this affects Control Protocol (SIP) packets sent by the VoIP towards the LAN.
  - Gold QoS: this affects HTTP Streaming packets sent by the VoIP towards the LAN.
  - Bronze QoS: this affects OAMP packets sent by the VoIP towards the LAN.
4. Click **Submit** to apply your changes.
5. Save the changes to flash memory and reset the device (see 'Saving Configuration' on page 532).

## 16.4 DNS

You can use the device's embedded domain name server (DNS) or an external, third-party DNS to translate domain names into IP addresses. This is useful if domain names are used as the destination in call routing. The device supports the configuration of the following DNS types:

- Internal DNS table - see 'Configuring the Internal DNS Table' on page 120
- Internal SRV table - see 'Configuring the Internal SRV Table' on page 122

### 16.4.1 Configuring the Internal DNS Table

The Internal DNS Table page, similar to a DNS resolution, translates up to 20 host (domain) names into IP addresses. This functionality can be used when a domain name (FQDN) is configured as an IP destination for Tel-to-IP or IP-to-IP routing in the Outbound IP Routing Table or SBC IP-to-IP Routing table. Up to four different IP addresses can be assigned to the same host name. This is typically needed for alternative Tel-to-IP call routing.

#### Notes:

- The IP addresses can be configured as IPv4 and/or IPv6 addresses.
- The device initially attempts to resolve a domain name using the Internal DNS table. If the domain name isn't listed in the table, the device performs a DNS resolution using an external DNS server for the related IP network interface, configured in the Multiple Interface table (see 'Configuring IP Network Interfaces' on page 107).
- You can also configure the DNS table using the table ini file parameter, DNS2IP (see 'DNS Parameters' on page 659) or CLI command, `configure voip > control-network dns dns-to-ip`.

➤ **To configure the internal DNS table:**

1. Open the Internal DNS Table page (**Configuration** tab > **VoIP** menu > **Network** submenu > **DNS** submenu > **Internal DNS Table**).
2. Click **Add**; the following dialog box appears:

**Figure 16-5: Internal DNS Table - Add Record Dialog Box**

| Field             | Value          |
|-------------------|----------------|
| Index             | 0              |
| Domain Name       | dnscompany.com |
| First IP Address  | 10.8.2.15      |
| Second IP Address | 10.8.4.20      |
| Third IP Address  | 10.8.16.17     |
| Fourth IP Address | 0.0.0.0        |

3. Configure the DNS rule, as required. For a description of the parameters, see the table below.
4. Click **Submit**; the DNS rule is added to the table.

**Internal DNS Table Parameter Description**

| Parameter                                                               | Description                                                                                             |
|-------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Domain Name<br>CLI: domain-name<br>[Dns2Ip_DomainName]                  | Defines the host name to be translated.<br>The valid value is a string of up to 31 characters.          |
| First IP Address<br>CLI: first-ip-address<br>[Dns2Ip_FirstIpAddress]    | Defines the first IP address (in dotted-decimal format notation) to which the host name is translated.  |
| Second IP Address<br>CLI: second-ip-address<br>[Dns2Ip_SecondIpAddress] | Defines the second IP address (in dotted-decimal format notation) to which the host name is translated. |
| Third IP Address<br>CLI: third-ip-address<br>[Dns2Ip_ThirdIpAddress]    | Defines the third IP address (in dotted-decimal format notation) to which the host name is translated.  |
| Fourth IP Address<br>CLI: fourth-ip-address<br>[Dns2Ip_FourthIpAddress] | Defines the fourth IP address (in dotted-decimal format notation) to which the host name is translated. |

## 16.4.2 Configuring the Internal SRV Table

The Internal SRV Table page resolves host names to DNS A-Records. Three different A-Records can be assigned to each host name, where each A-Record contains the host name, priority, weight, and port.

### Notes:

- If the Internal SRV table is configured, the device initially attempts to resolve a domain name using this table. If the domain name isn't found, the device performs a Service Record (SRV) resolution using an external DNS server configured in the Multiple Interface table (see 'Configuring IP Network Interfaces' on page 107).
- The Internal SRV table can also be configured using the table ini file parameter, SRV2IP (see 'DNS Parameters' on page 659) or CLI command, configure voip > control-network dns srv2ip.

### ➤ To configure the Internal SRV table:

1. Open the Internal SRV Table page (**Configuration** tab > **VoIP** menu > **Network** submenu > **DNS** submenu > **Internal SRV Table**).
2. Click **Add**; the following dialog box appears:

**Figure 16-6: Internal SRV Table Page**

| Add Record                                                                  |     |
|-----------------------------------------------------------------------------|-----|
| Index                                                                       | 0   |
| Domain Name                                                                 |     |
| Transport Type                                                              | UDP |
| DNS Name 1                                                                  |     |
| Priority 1                                                                  | 0   |
| Weight 1                                                                    | 0   |
| Port 1                                                                      | 0   |
| DNS Name 2                                                                  |     |
| Priority 2                                                                  | 0   |
| Weight 2                                                                    | 0   |
| Port 2                                                                      | 0   |
| DNS Name 3                                                                  |     |
| Priority 3                                                                  | 0   |
| Weight 3                                                                    | 0   |
| Port 3                                                                      | 0   |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |     |

3. Configure the SRV rule, as required. For a description of the parameters, see the table below.
4. Click **Submit**; the SRV rule is added to the table.

Internal SRV Table Parameter Description

| Parameter                                                       | Description                                                                                                                             |
|-----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Domain Name<br>CLI: domain-name<br>[Srv2lp_InternalDomain]      | Defines the host name to be translated.<br>The valid value is a string of up to 31 characters.                                          |
| Transport Type<br>CLI: transport-type<br>[Srv2lp_TransportType] | Defines the transport type. <ul style="list-style-type: none"> <li>▪ [0] UDP (default)</li> <li>▪ [1] TCP</li> <li>▪ [2] TLS</li> </ul> |
| DNS Name (1-3)<br>CLI: dns-name-1 2 3<br>[Srv2lp_Dns1/2/3]      | Defines the first, second or third DNS A-Record to which the host name is translated.                                                   |
| Priority (1-3)<br>CLI: priority-1 2 3<br>[Srv2lp_Priority1/2/3] | Defines the priority of the target host. A lower value means that it is more preferred.                                                 |
| Weight (1-3)<br>CLI: weight-1 2 3<br>[Srv2lp_Weight1/2/3]       | Defines a relative weight for records with the same priority.                                                                           |
| Port (1-3)<br>CLI: port-1 2 3<br>[Srv2lp_Port1/2/3]             | Defines the TCP or UDP port on which the service is to be found.                                                                        |

## 16.5 Configuring NFS Settings

Network File System (NFS) enables the device to access a remote server's shared files and directories and to handle them as if they're located locally. The device can use NFS to load *cmp*, *ini*, and auxiliary files through the Automatic Update mechanism (see 'Automatic Update' on page 561).

You can configure up to 16 different NFS file systems. As a file system, the NFS is independent of machine types, operating systems and network architectures. Note that an NFS file server can share multiple file systems. There must be a separate row for each remote file system shared by the NFS file server that needs to be accessed by the device.

### ➤ To add remote NFS file systems:

1. Open the Application Settings page (**Configuration** tab > **System** menu > **Application Settings**).
2. Under the 'NFS Settings' group, click the **NFS Table**  button; the NFS Table page appears.

3. Click the **Add** button; the Add Record dialog box appears:

**Figure 16-7: Add Record Dialog Box for NFS**

The dialog box titled 'Add Record' contains the following fields and controls:

- Index:** Text input field with value '1'.
- Host Or IP:** Text input field with value '10.13.4.5'.
- Root Path:** Text input field with value '/audio\_files'.
- NFS Version:** Dropdown menu with 'NFS Version 3' selected.
- Authentication Type:** Dropdown menu with 'Null' selected.
- User ID:** Text input field with value '0'.
- Group ID:** Text input field with value '1'.
- Vlan Type:** Dropdown menu with 'MEDIA' selected.
- Buttons:** 'Submit' and 'Cancel' buttons at the bottom right.

4. Configure the NFS parameters according to the table below.
5. Click the **Submit** button; the remote NFS file system is immediately applied, which can be verified by the appearance of the 'NFS mount was successful' message in the Syslog server.
6. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**Notes:**

- To avoid terminating current calls, a row must not be deleted or modified while the device is currently accessing files on that remote NFS file system.
- The combination of 'Host Or IP' and 'Root Path' must be unique for each row in the table. For example, the table must include only one row with a Host/IP of 192.168.1.1 and Root Path of /audio.
- The NFS table can also be configured using the table ini file parameter NFSServers (see 'NFS Parameters' on page 658) or CLI command, configure system > nfs > servers.

**NFS Settings Parameters**

| Parameter                                              | Description                                                                                                                     |
|--------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| Index                                                  | The row index of the remote file system.<br>The valid range is 1 to 16.                                                         |
| Host Or IP<br>CLI: host<br>[NFSServers_HostOrIP]       | The domain name or IP address of the NFS server. If a domain name is provided, a DNS server must be configured.                 |
| Root Path<br>CLI: root-path<br>[NFSServers_RootPath]   | Path to the root of the remote file system in the format: <b>/[path]</b> . For example, '/audio'.                               |
| NFS Version<br>CLI: version<br>[NFSServers_NfsVersion] | NFS version used to access the remote file system. <ul style="list-style-type: none"> <li>▪ <b>[2]</b> NFS Version 2</li> </ul> |

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ]                                                                        | <ul style="list-style-type: none"> <li>[3] NFS Version 3 (default)</li> </ul>                                                                                                                                                                                                                    |
| Authentication Type<br>CLI: authentication-type<br>[NFSServers_AuthType] | Authentication method used for accessing the remote file system. <ul style="list-style-type: none"> <li>[0] Null</li> <li>[1] Unix (default)</li> </ul>                                                                                                                                          |
| User ID<br>CLI: uid<br>[NFSServers_UID]                                  | User ID used in authentication when using Unix.<br>The valid range is 0 to 65537. The default is 0.                                                                                                                                                                                              |
| Group ID<br>CLI: gid<br>[NFSServers_GID]                                 | Group ID used in authentication when using Unix.<br>The valid range is 0 to 65537. The default is 1.                                                                                                                                                                                             |
| VLAN Type<br>CLI: vlan-type<br>[NFSServers_VlanType]                     | The VLAN type for accessing the remote file system. <ul style="list-style-type: none"> <li>[0] OAM</li> <li>[1] MEDIA (default)</li> </ul> <b>Note:</b> This parameter applies only if VLANs are enabled or if Multiple IPs is configured (see 'Configuring IP Network Interfaces' on page 107). |

## 16.6 Network Address Translation Support

Network Address Translation (NAT) is a mechanism that maps internal IP addresses (and ports) used within a private network to global IP addresses and vice versa, providing transparent routing to end hosts. The primary advantages of NAT include (1) reduction in the number of global IP addresses required in a private network (global IP addresses are only used to connect to the Internet) and (2) better network security by hiding the internal architecture.

The design of SIP creates a problem for VoIP traffic to pass through NAT. SIP uses IP addresses and port numbers in its message body. However, the NAT server is unable to modify the SIP messages and thus, can't change local addresses to global addresses.

This section discusses the device's solutions for overcoming NAT traversal issues.

### 16.6.1 Device Located behind NAT

Two different streams traverse through NAT - signaling and media. A device located behind a NAT, that initiates a signaling path has problems receiving incoming signaling responses as they are blocked by the NAT server. Therefore, the initiating device must inform the receiving device where to send the media. To resolve this NAT problem, the following solutions are provided by the device, listed in priority of the selected method used by the device:

- a. If configured, uses the single Static NAT IP address for all interfaces - see 'Configuring a Static NAT IP Address for All Interfaces' on page 126.
- b. If configured, uses the NAT Translation table which configures NAT per interface - see 'Configuring NAT Translation per IP Interface' on page 127.

If NAT is not configured by any of the above-mentioned methods, the device sends the packet according to its IP address configured in the Multiple Interface table.

**Note:** The priority list above is applicable only to the Gateway/IP-to-IP application.

The figure below illustrates the NAT problem faced by the SIP networks where the device is located behind a NAT:

**Figure 16-8: Device behind NAT and NAT Issues**

### 16.6.1.1 Configuring a Static NAT IP Address for All Interfaces

You can configure a global (public) IP address of the router to enable static NAT between the device and the Internet for all network interfaces. Thus, the device replaces the source IP address for media of all outgoing SIP messages sent on any of its network interfaces to this public IP address.

**Note:** The NAT IP address can also be configured using the ini file parameter, StaticNATIP or CLI command, configure voip > sip-definition general-settings > nat-ip-addr.

#### ➤ To configure a single static NAT IP address for all interfaces:

1. Open the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **General Parameters**).

**Figure 16-9: Configuring Static NAT IP Address in SIP General Parameters Page**

The screenshot shows the 'SIP General' configuration page. Under the 'NAT IP Address' field, the value '0.0.0.0' is entered.

2. In the 'NAT IP Address' field, enter the NAT IP address in dotted-decimal notation.
3. Click **Submit**.
4. Save the setting to the device's flash memory with a device reset (see 'Saving Configuration' on page 532).

### 16.6.1.2 Configuring NAT Translation per IP Interface

The NAT Translation table defines network address translation (NAT) rules for translating source IP addresses per VoIP interface (SIP control and RTP media traffic) into NAT IP addresses (*global* or *public*), when the device is located behind NAT. This allows, for example, the separation of VoIP traffic between different ITSP's, and topology hiding of internal IP addresses to the "public" network. Each IP interface (configured in the Multiple Interface table) can be associated with a NAT rule in this table, translating the source IP address and port of the outgoing packet into the NAT address (IP address and port range). The device's NAT traversal mechanism replaces the source IP address of SIP messages sent from a specified VoIP interface to a public IP address.

If the device is configured with two network interfaces, for example, one LAN and one WAN, only one NAT rule is required and without specifying ports. This rule is defined with the network interface representing the WAN and with a public IP address.

If the device is configured with only one network interface (e.g., "Voice") and you have an SRD configured for WAN and LAN, then you need to specify ports in order to differentiate between these SRDs. In such a scenario, the device replaces the source IP address only for messages sent from the WAN SRD, not from the LAN SRD.

**Note:** The NAT Translation table can also be configured using the table ini file parameter, NATTranslation or CLI command, control-network NATTranslation.

➤ **To configure NAT translation rules:**

1. Open the NAT Translation Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **NAT Translation Table**).
2. Click the **Add** button; the following dialog box appears:

**Figure 16-10: NAT Translation Table Page**

| Add Record                                                                  |                |
|-----------------------------------------------------------------------------|----------------|
| Index                                                                       | 0              |
| Source Interface Name                                                       | Voice          |
| Target IP Address                                                           | 212.199.200.90 |
| Source Start Port                                                           | 5070           |
| Source End Port                                                             | 5070           |
| Target Start Port                                                           | 5070           |
| Target End Port                                                             | 5070           |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |                |

3. Configure the parameters as required. For a description of the parameters, see the table below:
4. Click **Submit** to apply your changes.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

### NAT Translation Table Parameters

| Parameter                                                                                            | Description                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>CLI: index<br><b>[NATTranslation_Index]</b>                                                 | Defines the table index entry. This table can include up to 32 entries.                                                                                                                                                                                                             |
| Source Interface Name<br>CLI: SourceIPInterfaceName<br><b>[NATTranslation_SourceIPInterfaceName]</b> | Defines the name of the IP interface, as appears in the Multiple Interface table.                                                                                                                                                                                                   |
| Target IP Address<br>CLI: TargetIPAddress<br><b>[NATTranslation_TargetIPAddress]</b>                 | Defines the global IP address. This address is set in the SIP Via and Contact headers as well as in the o= and c= SDP fields.                                                                                                                                                       |
| Source Start Port<br>CLI: SourceStartPort<br><b>[NATTranslation_SourceStartPort]</b>                 | Defines the optional starting port range (1-65536) of the IP interface, used as matching criteria for this NAT rule. If not configured, the match is done on the entire port range. Only IP addresses and ports of matched source ports will be replaced.                           |
| Source End Port<br>CLI: SourceEndPort<br><b>[NATTranslation_SourceEndPort]</b>                       | Defines the optional ending port range (1-65536) of the IP interface, used as matching criteria for this NAT rule. If not configured, the match is done on the entire port range. Only IP addresses and ports of matched source ports will be replaced.                             |
| Target Start Port<br>CLI: TargetStartPort<br><b>[NATTranslation_TargetStartPort]</b>                 | Defines the optional, starting port range (1-65536) of the global address. If not configured, the ports are not replaced. Matching source ports are replaced with the target ports. This address is set in the SIP Via and Contact headers, as well as in the o= and c= SDP fields. |
| Target End Port<br>CLI: TargetEndPort<br><b>[NATTranslation_TargetEndPort]</b>                       | Defines the optional, ending port range (1-65536) of the global address. If not configured, the ports are not replaced. Matching source ports are replaced with the target ports. This address is set in the SIP Via and Contact headers, as well as in the o= and c= SDP fields.   |

## 16.6.2 Remote UA behind NAT

If the remote User Agent with which the device needs to communicate with is located behind NAT, the device can resolve the problem of activating the RTP/RTCP/T.38 streams to an invalid IP address / UDP port.

To resolve this NAT traversal issue, the device offers the following features:

- First Incoming Packet Mechanism - see 'First Incoming Packet Mechanism' on page 129
- RTP No-Op packets according to the avt-rtp-noop draft - see 'No-Op Packets' on page 129

The figure below illustrates a typical network architecture where the remote UA is located behind NAT:

**Figure 16-11: Remote UA behind NAT**

### 16.6.2.1 First Incoming Packet Mechanism

If the remote device resides behind a NAT device, it's possible that the device can activate the RTP/RTCP/T.38 streams to an invalid IP address / UDP port. To avoid such cases, the device automatically compares the source address of the first received incoming RTP/RTCP/T.38 stream with the IP address and UDP port of the remote device when the session was initially opened. If the two are not identical, then the destination IP address of the outgoing RTP packets is set to the source IP address of the first incoming packet. The RTP, RTCP and T.38 can thus have independent destination IP addresses and UDP ports.

➤ **To enable NAT resolution using the First Incoming Packet mechanism:**

1. Open the General Media Settings page (**Configuration** tab > **VoIP** menu > **Media** > **General Media Settings**).
2. Set the 'NAT Traversal' parameter to **Enable**.
3. Click **Submit**.

### 16.6.2.2 No-Op Packets

The device's No-Op packet support can be used to verify Real-Time Transport Protocol (RTP) and T.38 connectivity, and to keep NAT bindings and Firewall pinholes open. The No-Op packets are available for sending in RTP and T.38 formats.

You can control the activation of No-Op packets by using the *ini* file parameter NoOpEnable. If No-Op packet transmission is activated, you can control the time interval in which No-Op packets are sent in the case of silence (i.e., no RTP or T.38 traffic). This is done using the *ini* file parameter NoOpInterval. For a description of the RTP No-Op *ini* file parameters, see 'Networking Parameters' on page 655.

- **RTP No-Op:** The RTP No-Op support complies with IETF Internet-Draft draft-wing-avt-rtp-noop-03 ("A No-Op Payload Format for RTP"). This IETF document defines a No-Op payload format for RTP. The draft defines the RTP payload type as dynamic. You can control the payload type with which the No-Op packets are sent. This is performed using the RTPNoOpPayloadType *ini* parameter (see 'Networking Parameters' on page 655). The default payload type is 120.
- **T.38 No-Op:** T.38 No-Op packets are sent only while a T.38 session is activated. Sent packets are a duplication of the previously sent frame (including duplication of the sequence number).

**Note:** Receipt of No-Op packets is always supported.

## 16.7 Robust Receipt of Media Streams

The “robust-media” mechanism is an AudioCodes proprietary mechanism to filter out unwanted media (i.e., RTP, RTCP, and T.38) streams that are sent to the same port number on the device. In practice, the media RTP/RTCP ports may receive additional multiple unwanted media streams as result of traces of previous calls, call control errors, or deliberate attacks. When more than one media stream reaches the device on the same port number, the “robust-media” mechanism detects the valid media stream and ignores the rest.

The “robust-media” mechanism can be disabled by setting the `InboundMediaLatchMode` parameter to 0.

## 16.8 Multiple Routers Support

Multiple routers support is designed to assist the device when it operates in a multiple routers network. The device learns the network topology by responding to Internet Control Message Protocol (ICMP) redirections and caches them as routing rules (with expiration time).

When a set of routers operating within the same subnet serve as devices to that network and intercommunicate using a dynamic routing protocol, the routers can determine the shortest path to a certain destination and signal the remote host the existence of the better route. Using multiple router support, the device can utilize these router messages to change its next hop and establish the best path.

**Note:** Multiple Routers support is an integral feature that doesn't require configuration.

# 17 Security

This section describes the VoIP security-related configuration.

## 17.1 Configuring Firewall Settings

The device provides an internal firewall that enables you to configure network traffic filtering rules (*access list*). You can add up to 50 firewall rules. The access list offers the following firewall possibilities:

- Block traffic from known malicious sources
- Allow traffic only from known "friendly" sources, and block all other traffic
- Mix allowed and blocked network sources
- Limit traffic to a user-defined rate (blocking the excess)
- Limit traffic to specific protocols, and specific port ranges on the device

For each packet received on the network interface, the table is scanned from top to bottom until the first matching rule is found. This rule can either permit (*allow*) or deny (*block*) the packet. Once a rule in the table is located, subsequent rules further down the table are ignored. If the end of the table is reached without a match, the packet is accepted.

### Notes:

- This firewall applies to a very low-level network layer and overrides all your other security-related configuration. Thus, if you have configured higher-level security features (e.g., on the Application level), you must also configure firewall rules to permit this necessary traffic. For example, if you have configured IP addresses to access the Web and Telnet interfaces in the Web Access List (see 'Configuring Web and Telnet Access List' on page 67), you must configure a firewall rule that permits traffic from these IP addresses.
- Only Security Administrator users or Master users can configure firewall rules.
- Setting the 'Prefix Length' field to **0** means that the rule applies to **all** packets, regardless of the defined IP address in the 'Source IP' field. Therefore, it is highly recommended to set this parameter to a value other than 0.
- It is recommended to add a rule at the end of your table that blocks all traffic and to add firewall rules above it that allow required traffic (with bandwidth limitations). To block all traffic, use the following firewall rule:
  - Source IP: 0.0.0.0
  - Prefix Length: 0 (i.e., rule matches all IP addresses)
  - Start Port - End Port: 0-65535
  - Protocol: **Any**
  - Action Upon Match: **Block**
- You can also configure the firewall settings using the table ini file parameter, AccessList (see 'Security Parameters' on page 679) or the CLI command, configure voip/access-list.

➤ **To add firewall rules:**

1. Open the Firewall Settings page (**Configuration** tab > **VoIP** menu > **Security** submenu > **Firewall Settings**).
2. Click the **Add** button; the following dialog box appears:

**Figure 17-1: Firewall Settings Page - Add Record**

|                        |         |
|------------------------|---------|
| Index                  | 0       |
| Source IP              | 0.0.0.0 |
| Prefix Length          | 0       |
| Start Port             | 0       |
| End Port               | 65535   |
| Protocol               | Any     |
| Use Specific Interface | Disable |
| Interface Name         | None    |
| Packet Size            | 0       |
| Byte Rate              | 0       |
| Byte Burst             | 0       |
| Action Upon Match      | Allow   |
| Match Count            |         |
| Source Port            | 0       |

Submit Cancel

3. Configure the firewall parameters, as required. For a description of the parameters, see the table below.
4. Click **Submit** to add the new firewall rule to the table.
5. Reset the device to activate the rules.

The table below provides an example of configured firewall rules:

**Firewall Rule Examples**

| Parameter               | Value per Rule |              |         |           |         |
|-------------------------|----------------|--------------|---------|-----------|---------|
|                         | 1              | 2            | 3       | 4         | 5       |
| Source IP               | 12.194.231.76  | 12.194.230.7 | 0.0.0.0 | 192.0.0.0 | 0.0.0.0 |
| Prefix Length           | 16             | 16           | 0       | 8         | 0       |
| Start Port and End Port | 0-65535        | 0-65535      | 0-65535 | 0-65535   | 0-65535 |
| Protocol                | Any            | Any          | icmp    | Any       | Any     |
| Use Specific Interface  | Enable         | Enable       | Disable | Enable    | Disable |
| Interface Name          | WAN            | WAN          | None    | Voice-Lan | None    |
| Byte Rate               | 0              | 0            | 40000   | 40000     | 0       |
| Burst Bytes             | 0              | 0            | 50000   | 50000     | 0       |
| Action Upon Match       | Allow          | Allow        | Allow   | Allow     | Block   |

The firewall rules in the above configuration example do the following:

- **Rules 1 and 2:** Typical firewall rules that allow packets ONLY from specified IP addresses (e.g., proxy servers). Note that the prefix length is configured.
- **Rule 3:** A more "advanced" firewall rule - bandwidth rule for ICMP, which allows a maximum bandwidth of 40,000 bytes/sec with an additional allowance of 50,000 bytes. If, for example, the actual traffic rate is 45,000 bytes/sec, then this allowance would be consumed within 10 seconds, after which all traffic exceeding the allocated 40,000 bytes/sec is dropped. If the actual traffic rate then slowed to 30,000 bytes/sec, the allowance would be replenished within 5 seconds.
- **Rule 4:** Allows traffic from the LAN voice interface and limits bandwidth.
- **Rule 5:** Blocks all other traffic.

#### Internal Firewall Parameters

| Parameter                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Source IP<br>CLI: source-ip<br>[AccessList_Source_IP]     | Defines the IP address (or DNS name) or a specific host name of the source network (i.e., from where the incoming packet is received).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Source Port<br>CLI: src-port<br>[AccessList_Source_Port]  | Defines the source UDP/TCP ports (of the remote host) from where packets are sent to the device.<br>The valid range is 0 to 65535.<br><b>Note:</b> When set to 0, this field is ignored and any source port matches the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Prefix Length<br>CLI: prefixLen<br>[AccessList_PrefixLen] | <b>(Mandatory)</b> Defines the IP network mask - 32 for a single host or the appropriate value for the source IP addresses. <ul style="list-style-type: none"> <li>■ A value of 8 corresponds to IPv4 subnet class A (network mask of 255.0.0.0).</li> <li>■ A value of 16 corresponds to IPv4 subnet class B (network mask of 255.255.0.0).</li> <li>■ A value of 24 corresponds to IPv4 subnet class C (network mask of 255.255.255.0).</li> </ul> The IP address of the sender of the incoming packet is trimmed in accordance with the prefix length (in bits) and then compared to the parameter 'Source IP'.<br>The default is 0 (i.e., applies to all packets). You <b>must</b> change this value to any of the above options.<br><b>Note:</b> A value of 0 applies to <b>all</b> packets, regardless of the defined IP address. Therefore, you must set this parameter to a value other than 0. |
| Start Port<br>CLI: start-port<br>[AccessList_Start_Port]  | Defines the destination UDP/TCP start port (on this device) to where packets are sent.<br>The valid range is 0 to 65535.<br><b>Note:</b> When the protocol type isn't TCP or UDP, the entire range must be provided.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| End Port<br>CLI: end-port<br>[AccessList_End_Port]        | Defines the destination UDP/TCP end port (on this device) to where packets are sent.<br>The valid range is 0 to 65535.<br><b>Note:</b> When the protocol type isn't TCP or UDP, the entire range must be provided.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Protocol<br>CLI: protocol<br><b>[AccessList_Protocol]</b>                                           | Defines the protocol type (e.g., UDP, TCP, ICMP, ESP or 'Any') or the IANA protocol number in the range of 0 (Any) to 255.<br><b>Note:</b> This field also accepts the abbreviated strings 'SIP' and 'HTTP'. Specifying these strings implies selection of the TCP or UDP protocols, and the appropriate port numbers as defined on the device.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Use Specific Interface<br>CLI: use-specific-interface<br><b>[AccessList_Use_Specific_Interface]</b> | Determines whether you want to apply the rule to a specific network interface defined in the Multiple Interface table (i.e., packets received from that defined in the Source IP field and received on this network interface): <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable (default)</li> <li>▪ <b>[1]</b> Enable</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ If enabled, then in the 'Interface Name' field (described below), select the interface to which the rule is applied.</li> <li>▪ If disabled, then the rule applies to all interfaces.</li> </ul>                                                                                                                                                                                                                          |
| Interface Name<br>CLI: network-interface-name<br><b>[AccessList_Interface_ID]</b>                   | Defines the network interface to which you want to apply the rule. This is applicable if you enabled the 'Use Specific Interface' field. The list displays interface names as defined in the Multiple Interface table in 'Configuring IP Network Interfaces' on page 107.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Packet Size<br>CLI: packet-size<br><b>[AccessList_Packet_Size]</b>                                  | Defines the maximum allowed packet size.<br>The valid range is 0 to 65535.<br><b>Note:</b> When filtering fragmented IP packets, this field relates to the overall (re-assembled) packet size, and not to the size of each fragment.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Byte Rate<br>CLI: byte-rate<br><b>[AccessList_Byte_Rate]</b>                                        | Defines the expected traffic rate (bytes per second), i.e., the allowed bandwidth for the specified protocol. In addition to this field, the 'Burst Bytes' field provides additional allowance such that momentary bursts of data may utilize more than the defined byte rate, without being interrupted.<br><br>For example, if 'Byte Rate' is set to 40000 and 'Burst Bytes' to 50000, then this implies the following: the allowed bandwidth is 40000 bytes/sec with extra allowance of 50000 bytes; if, for example, the actual traffic rate is 45000 bytes/sec, then this allowance would be consumed within 10 seconds, after which all traffic exceeding the allocated 40000 bytes/sec is dropped. If the actual traffic rate then slowed to 30000 bytes/sec, then the allowance would be replenished within 5 seconds. |
| Burst Bytes<br>CLI: byte-burst<br><b>[AccessList_Byte_Burst]</b>                                    | Defines the tolerance of traffic rate limit (number of bytes).<br>The default is 0.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Action Upon Match<br>CLI: allow-type<br><b>[AccessList_Allow_Type]</b>                              | Defines the firewall action to be performed upon rule match. <ul style="list-style-type: none"> <li>▪ "Allow" = (Default) Permits these packets</li> <li>▪ "Block" = Rejects these packets</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Match Count<br><b>[AccessList_MatchCount]</b>                                                       | (Read-only) Displays the number of packets accepted or rejected by the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## 17.2 Configuring General Security Settings

The General Security Settings page is used to configure various security features. For a description of the parameters appearing on this page, refer 'Configuration Parameters Reference' on page 655.

➤ **To configure the general security parameters:**

1. Open the General Security Settings page (**Configuration** tab > **VoIP** menu > **Security** submenu > **General Security Settings**).

**Figure 17-2: General Security Settings Page**

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, refer to 'Saving Configuration' on page 532.

## 17.3 Intrusion Detection System

The device can be configured to detect malicious attacks on its system and send SNMP traps if malicious activity is identified. The Intrusion Detection System (IDS) is an important feature for Enterprises to ensure legitimate calls are not being adversely affected by attacks and to prevent Theft of Service and unauthorized access. If, for example, you identify the source (IP address) of the attack, you can add that source to your blacklist to prevent it from accessing your device.

There are many types of malicious attacks, the most common being:

- **Denial of service:** This can be Denial of Service (DoS) where an attacker wishing to prevent a server from functioning correctly directs a large amount of requests – sometimes meaningless and sometimes legitimate, or it can be Distributed Denial of Service (DDoS) where the attacker controls a large group of systems to coordinate a large scale DoS attack against a system:
  - Message payload tampering: Attacker may inject harmful content into a message, e.g., by entering meaningless or wrong information, with the goal of exploiting a buffer overflow at the target. Such messages can be used to probe for vulnerabilities at the target.
  - Message flow tampering: This is a special case of DoS attacks. These attacks disturb the ongoing communication between users. An attacker can then target the connection by injecting fake signaling messages into the communication channel (such as CANCEL messages).
  - Message Flooding: The most common DoS attack is where an attacker sends a huge amount of messages (e.g., INVITES) to a target. The goal is to overwhelm the target's processing capabilities, thereby rendering the target inoperable.
- **SPAM over Internet Telephony (SPIT):** VoIP spam is unwanted, automatically dialed, pre-recorded phone calls using VoIP. It is similar to e-mail spam.
- **Theft of Service (ToS):** Service theft can be exemplified by phreaking, which is a type of hacking that steals service (i.e., free calls) from a service provider, or uses a service while passing the cost to another person.

The IDS configuration is based on IDS Policies, where each policy can be configured with a set of IDS rules. Each rule defines a type of malicious attack to detect and the number of attacks during an interval (threshold) before an SNMP trap is sent. Each policy is then applied to a target under attack (SIP interface) and/or source of attack (Proxy Set and/or subnet address).

### 17.3.1 Enabling IDS

The procedure below describes how to enable IDS.

#### ➤ To enable IDS:

1. Open the IDS Global Parameters page (**Configuration** tab > **VoIP** menu > **Security** > **Intrusion Detection and Prevention** > **Global Parameters**).

**Figure 17-3: Enabling IDS on IDS Global Parameters Page**

2. From the 'Intrusion Detection System' drop-down list, select **Enable**.
3. Reset the device with a burn-to-flash for the setting to take effect (see Saving Configuration).

## 17.3.2 Configuring IDS Policies

Configuring IDS policies is a two-stage process done in the following tables:

1. **IDS Policy table:** Defines a name and description for the policy. You can define up to 20 policies.
2. **IDS Rules table:** Defines the actual IDS rules per policy. Each policy can be configured with up to 20 rules.

**Note:** A maximum of 100 IDS rules can be configured (regardless of how many rules are assigned to each policy).

By default and for your convenience, the device provides three pre-configured IDS policies with rules that can be used in your deployment if they meet your requirements:

- "DEFAULT\_FEU": Policy for far-end users in the WAN
- "DEFAULT\_PROXY": Policy for proxy server
- "DEFAULT\_GLOBAL": Policy with global thresholds

These default policies are read-only.

➤ **To configure IDS policies:**

1. Open the IDS Policy Table page (**Configuration** tab > **VoIP** menu > **Security** > **Intrusion Detection and Prevention** > **Policy Table**).

**Figure 17-4: IDS Policy Table with Default Rules**

| Add + Edit ✎ Delete – Show/Hide ☏                                                              |                |                                 |
|------------------------------------------------------------------------------------------------|----------------|---------------------------------|
| Index                                                                                          | Name           | Description                     |
| 0                                                                                              | DEFAULT_FEU    | Default policy for FEU          |
| 1                                                                                              | DEFAULT_PROXY  | Default policy for proxies      |
| 2                                                                                              | DEFAULT_GLOBAL | Default policy for global scope |
| Page 1 of 1 Show 10 records per page View 1 - 3 of 3                                           |                |                                 |

2. Add a Policy name:
  - a. Click **Add**.

**Figure 17-5: IDS Policy Table - Add Record**

| Add Record                                                                  |                            |
|-----------------------------------------------------------------------------|----------------------------|
| Index                                                                       | 3                          |
| Name                                                                        | SIP-Trunk                  |
| Description                                                                 | for attacks from SIP Trunk |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |                            |

- b. Configure the parameters as described in the following table, and then click **Submit**.

**Table 17-1: IDS Policy Table Parameters**

| Parameter                                    | Description                                                                                             |
|----------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Index<br>CLI: policy<br>[IDSPolicy_Index]    | Defines the table row number for the policy.                                                            |
| Name<br>CLI: rule<br>[IDSPolicy_Description] | Defines a name for the policy.<br>The valid value is a string of up to 20 characters.                   |
| Description<br>[IDSPolicy_Name]              | Defines an arbitrary description of the policy.<br>The valid value is a string of up to 100 characters. |

1. Add rules to the policy:
  - a. In the IDS Policy table, select the required policy and then click the **IDS Rule Table** link located below the table:

**Figure 17-6: IDS Rule Table of Selected IDS Policy**

| Index | Reason                   | Threshold Scope | Threshold Window | Minor Alarm Threshold | Major Alarm Threshold | Critical Alarm Threshold |
|-------|--------------------------|-----------------|------------------|-----------------------|-----------------------|--------------------------|
| 0     | Connection abuse         | IP              | 30               | 5                     | 0                     | 0                        |
| 1     | Malformed message        | IP              | 30               | 15                    | 0                     | 0                        |
| 2     | Authentication failure   | IP              | 600              | 20                    | 0                     | 0                        |
| 3     | Dialog establish failure | IP              | 300              | 30                    | 0                     | 0                        |
| 4     | Abnormal flow            | IP              | 30               | 15                    | 0                     | 0                        |

| Major-Alarm Threshold    | 20                |
| Critical-Alarm Threshold | 25                |

Submit Cancel

- c. Configure the parameters as required, and then click **Submit**. For a description of these parameters, see the table below. The figure above shows an example configuration where if 15 malformed SIP messages are received within a period of 30 seconds, a minor alarm is sent. Every 30 seconds, the rule's counters are cleared.
  - a. To add more rules to the policy, repeat steps 1.b to 1.c.

Table 17-2: IDS Rule Table Parameters

| Parameter                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Parameter                                                                                    | Description                                                                                                                                       |
|----------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| Minor-Alarm Threshold<br>CLI: minor-alm-thr<br><b>[IDSRule_MinorAlarmThreshold]</b>          | Defines the threshold that if crossed a minor severity alarm is sent. The valid range is 1 to 1,000,000. A value of 0 or -1 means not defined.    |
| Major-Alarm Threshold<br>CLI: major-alm-thr<br><b>[IDSRule_MajorAlarmThreshold]</b>          | Defines the threshold that if crossed a major severity alarm is sent. The valid range is 1 to 1,000,000. A value of 0 or -1 means not defined.    |
| Critical-Alarm Threshold<br>CLI: critical-alm-thr<br><b>[IDSRule_CriticalAlarmThreshold]</b> | Defines the threshold that if crossed a critical severity alarm is sent. The valid range is 1 to 1,000,000. A value of 0 or -1 means not defined. |

### 17.3.3 Assigning IDS Policies

The IDS Match table enables you to use your configured IDS policies. This is done by assigning them to any or a combination of the following entities:

- **SIP Interface:** Detects malicious attacks (according to specified IDS Policy) on specific SIP Interface(s)
- **Proxy Sets:** Detects malicious attacks (according to specified IDS Policy) from specified Proxy Set(s)
- **Subnet addresses:** Detects malicious attacks (according to specified IDS Policy) from specified subnet address

Up to 20 IDS policy-matching rules can be configured.

➤ **To assign an IDS policy:**

1. Open the IDS Match Table page (**Configuration** tab > **VoIP** menu > **Security** > **Intrusion Detection and Prevention** > **Match Table**).
2. Click **Add**.

**Figure 17-8: IDS Match Table - Add Record**

The figure above shows a configuration example where the IDS Policy, "SIP Trunk" is applied to SIP Interfaces 1 and 2, and all source IP addresses outside of subnet 10.1.0.0/16 and IP address 10.2.2.2.

3. Configure the IDS matching parameters. For a description of these parameters, see the following table.
4. Click **Submit**.

Table 17-3: IDS Match Table Parameters

| Parameter                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Index<br>CLI: sip-interface<br>[IDSMATCH_Index]                | Defines the table row number for the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| SIP Interface<br>CLI: sip-interface<br>[IDSMATCH_SIPInterface] | <p>Defines the SIP Interface(s) to which you want to assign the IDS policy. This indicates the SIP Interfaces that are being attacked. The entered value must be the ID of the SIP Interface. The following syntax is supported:</p> <ul style="list-style-type: none"> <li>A comma-separated list of SIP Interface IDs (e.g., 1,3,4)</li> <li>A hyphen "-" indicates a range of SIP Interfaces (e.g., 3,4-7 means IDs 3, and 4 through 7)</li> <li>A prefix of an exclamation mark "!" means negation of the set (e.g., !3,4-7 means all indexes excluding 3, and excluding 4 through 7)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| ProxySet<br>CLI: proxy-set<br>[IDSMATCH_ProxySet]              | <p>Defines the Proxy Set(s) to which the IDS policy is assigned. This indicates the Proxy Sets from where the attacks are coming from. The following syntax is supported:</p> <ul style="list-style-type: none"> <li>A comma-separated list of Proxy Set IDs (e.g., 1,3,4)</li> <li>A hyphen "-" indicates a range of Proxy Sets (e.g., 3,4-7 means IDs 3, and 4 through 7)</li> <li>A prefix of an exclamation mark "!" means negation of the set (e.g., !3,4-7 means all indexes excluding 3, and excluding 4 through 7)</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>Only the IP address of the Proxy Set is considered (not the port).</li> <li>If a Proxy Set has multiple IP addresses, the device considers the Proxy Set as one entity and includes all its IP addresses in the same IDS count.</li> </ul>                                                                                                                                                                                                                                                                                           |
| Subnet<br>CLI: subnet<br>[IDSMATCH_Subnet]                     | <p>Defines the subnet(s) to which the IDS policy is assigned. This indicates the subnets from where the attacks are coming from. The following syntax can be used:</p> <ul style="list-style-type: none"> <li>Basic syntax is a subnet in CIDR notation (e.g., 10.1.0.0/16 means all sources with IP address in the range 10.1.0.0–10.1.255.255)</li> <li>An IP address can be specified without the prefix length to refer to the specific IP address.</li> <li>Each subnet can be negated by prefixing it with "!", which means all IP addresses outside that subnet.</li> <li>Multiple subnets can be specified by separating them with "&amp;" (and) or " " (or) operations. For example: <ul style="list-style-type: none"> <li>✓ 10.1.0.0/16   10.2.2.2: includes subnet 10.1.0.0/16 and IP address 10.2.2.2.</li> <li>✓ !10.1.0.0/16 &amp; !10.2.2.2: includes all addresses except those of subnet 10.1.0.0/16 and IP address 10.2.2.2. Note that the exclamation mark "!" appears before each subnet.</li> <li>✓ 10.1.0.0/16 &amp; !10.1.1.1: includes subnet 10.1.0.0/16, except IP address 10.1.1.1.</li> </ul> </li> </ul> |
| Policy<br>CLI: policy<br>[IDSMATCH_Policy]                     | Selects the IDS policy, configured in 'Configuring IDS Policies' on page 137.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 17.3.4 Viewing IDS Alarms

The device uses SNMP (and Syslog) to notify the detection of malicious attacks. The trap displays the IDS Policy and Rule, and the Policy-Match index.

The device sends the SNMP alarm, acIDSPolicyAlarm whenever a threshold of a specific IDS Policy rule is crossed. For each scope that crosses this threshold, the device sends an additional SNMP event (trap) - acIDSThresholdCrossNotification - indicating the specific details (IP address or IP address:port). If the trap severity level is raised, the alarm of the former severity is cleared and the device then sends a new alarm with the new severity.

The SNMP alarm is cleared after a user-defined period (configured by the ini file parameter, IDSAAlarmClearPeriod) during which no thresholds have been crossed. However, this "quiet" period must be at least twice the Threshold Window value (configured in 'Configuring IDS Policies' on page 137). For example, if IDSAAlarmClearPeriod is set to 20 sec and the Threshold Window is set to 15 sec, the IDSAAlarmClearPeriod parameter is ignored and the alarm is cleared only after 30 seconds (2 x 15 sec).

The figure below shows an example of IDS alarms in the Active Alarms table (Viewing Active Alarms), where a minor threshold alarm is cleared and replaced by a major threshold alarm:

**Figure 17-9: IDS Alarms in Active Alarms Table**

|    |         |                              |                                                                                         |                      |
|----|---------|------------------------------|-----------------------------------------------------------------------------------------|----------------------|
| 17 | Minor   | Board#1/IDSMATCH#2/IDSRULE#0 | Policy 2 (Proxy): minor threshold (5) of signaling-msg cross in ip scope                | 24.10.2012 , 9:48:53 |
| 18 | cleared | Board#1/IDSMATCH#2/IDSRULE#0 | Alarm cleared: Policy 2 (Proxy): minor threshold (5) of signaling-msg cross in ip scope | 24.10.2012 , 9:48:53 |
| 19 | Major   | Board#1/IDSMATCH#2/IDSRULE#0 | Policy 2 (Proxy): major threshold (10) of signaling-msg cross in ip scope               | 24.10.2012 , 9:48:53 |

You can also view the IDS alarms in the CLI:

- To view active IDS alarms:

```
show voip security ids active-alarm all
```

- To view all IP addresses that crossed the threshold for an active IDS alarm:

```
show voip security ids active-alarm match * rule *
```

The device also sends IDS notifications in Syslog messages to a Syslog server (if enabled - see Configuring Syslog). The table below shows the Syslog text message per malicious event:

**Table 17-4: Types of Malicious Events and Syslog Text String**

| Type                          | Description                                                                                                                                                                                                                                                                                | Syslog String                                                                                                                                                                                                                                      |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Connection Abuse</b>       | TLS authentication failure                                                                                                                                                                                                                                                                 | abuse-tls-auth-fail                                                                                                                                                                                                                                |

## Reader's Notes

## 18 Media

This section describes the media-related configuration.

### 18.1 Configuring Voice Settings

The Voice Settings page configures various voice parameters such as voice volume, silence suppression, and DTMF transport type. For a detailed description of these parameters, see 'Configuration Parameters Reference' on page 655.

➤ **To configure the voice parameters:**

1. Open the Voice Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Voice Settings**).

|                             |                    |   |
|-----------------------------|--------------------|---|
| ▼                           |                    |   |
| Voice Volume (-32 to 31 dB) | 0                  |   |
| Input Gain (-32 to 31 dB)   | 0                  |   |
| Silence Suppression         | Disable            | ▼ |
| DTMF Transport Type         | RFC2833 Relay DTMF | ▼ |
| DTMF Volume (-31 to 0 dB)   | -11                |   |
| NTE Max Duration            | -1                 |   |
| CAS Transport Type          | CASEventsOnly      | ▼ |
| ⚡ DTMF Generation Twist     | 0                  |   |
| Echo Canceller              | Enable             | ▼ |

2. Configure the Voice parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

#### 18.1.1 Configuring Voice Gain (Volume) Control

The device allows you to configure the level of the received (input gain) Tel-to-IP signal and the level of the transmitted (output gain) IP-to-Tel signal. The gain can be set between -32 and 31 decibels (dB).

The procedure below describes how to configure gain control using the Web interface:

➤ **To configure gain control using the Web interface:**

1. Open the Voice Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Voice Settings**).

**Figure 18-1: Voice Volume Parameters in Voice Settings Page**

|                             |   |
|-----------------------------|---|
| Voice Volume (-32 to 31 dB) | 0 |
| Input Gain (-32 to 31 dB)   | 0 |

2. Configure the following parameters:
  - 'Voice Volume' (*VoiceVolume*) - Defines the voice gain control (in decibels) for IP-to-Tel
  - 'Input Gain' (*InputGain*) - Defines the PCM input gain control (in decibels) for Tel-to-IP
3. Click **Submit** to apply your settings.

## 18.1.2 Silence Suppression (Compression)

Silence suppression (compression) is a method for conserving bandwidth on VoIP calls by not sending packets when silence is detected. The device uses its VAD feature to detect periods of silence in the voice channel during an established call. When silence is detected, it stops sending packets in the channel.

The procedure below describes how to enable silence suppression using the Web interface.

➤ **To enable silence suppression using the Web interface:**

1. Open the Voice Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Voice Settings**).

**Figure 18-2: Enabling Silence Suppression in Voice Settings Page**

The screenshot shows a web interface for 'Voice Settings'. A table with a light blue header contains the following information:

| Silence Suppression | Enable |
|---------------------|--------|
|                     | Enable |

There is a blue circular icon with a white 'Z' in the top right corner of the table.

2. Set the 'Silence Suppression' (*EnableSilenceCompression*) field to **Enable**.
3. Click **Submit** to apply your changes.

## 18.1.3 Echo Cancellation

The device supports adaptive linear (line) echo cancellation according to G.168-2002. Echo cancellation is a mechanism that removes echo from the voice channel. Echoes are reflections of the transmitted signal.

In this line echo, echoes are generated when two-wire telephone circuits (carrying both transmitted and received signals on the same wire pair) are converted to a four-wire circuit. Echoes are reflections of the transmitted signal, which result from impedance mismatch in the hybrid (bi-directional 2-wire to 4-wire converting device).

An estimated echo signal is built by feeding the decoder output signal to an RLS-like adaptive filter, which adapts itself to the characteristics of the echo path. The 'estimated echo signal' (the output of this filter) is then subtracted from the input signal (which is the sum of the desired input signal and the undesired echo) to provide a clean signal. To suppress the remaining residual echo, a Non Linear Processor (NLP) is used, as well as a double-talk (two people speak at the same time) detector that prevents false adaptation during near-end speech.

The device also supports acoustic echo cancellation for SBC calls. These echoes are composed of undesirable acoustical reflections (non-linear) of the received signal (i.e., from the speaker) which find their way from multiple reflections such as walls and windows into the transmitted signal (i.e., microphone). Therefore, the party at the far end hears his / her echo. The device removes these echoes and sends only the near-end's desired speech signal to the network (i.e., to the far-end party). The echo is composed of a linear part and a nonlinear part. However, in the Acoustic Echo Canceller, a substantial part of the echo is non-linear echo. To support this feature, the Forced Transcoding feature must be enabled so that the device uses DSPs.

The procedure below describes how to configure echo cancellation using the Web interface:

➤ **To configure echo cancellation using the Web interface:**

**1.** Configure line echo cancellation:

- a.** Open the Voice Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Voice Settings**).

|                                     |                     |
|-------------------------------------|---------------------|
| Echo Canceller                      | Enable              |
| ▼ Acoustic Echo Suppressor Settings |                     |
| ⚡ Network Echo Suppressor Enable    | Disable             |
| Echo Canceller Type                 | Line echo canceller |
| Attenuaion Intensity                | 0                   |
| Max ERL Threshold - DB              | 0                   |
| Min Reference Delay x10 msec        | 0                   |
| Max Reference Delay x10 msec        | 40                  |

- b.** Set the 'Echo Canceller' field (*EnableEchoCanceller*) to **Enable**.

**2.** Enable acoustic echo cancellation for SBC calls:

- a.** In the Voice Settings page, configure the following parameters:

- ◆ 'Network Echo Suppressor Enable' (*AcousticEchoSuppressorSupport*) - enables the network Acoustic Echo Suppressor
- ◆ 'Echo Canceller Type' (*EchoCancellerType*) - defines the echo canceller type
- ◆ 'Attenuation Intensity' (*AcousticEchoSuppAttenuationIntensity*) - defines the acoustic echo suppressor signals identified as echo attenuation intensity
- ◆ 'Max ERL Threshold' (*AcousticEchoSuppMaxERLThreshold*) - defines the acoustic echo suppressor maximum ratio between signal level and returned echo from the phone
- ◆ 'Min Reference Delay' (*AcousticEchoSuppMinRefDelayx10ms*) - defines the acoustic echo suppressor minimum reference delay
- ◆ 'Max Reference Delay' (*AcousticEchoSuppMaxRefDelayx10ms*) - defines the acoustic echo suppressor maximum reference delay

- b.** Open the IP Profile Settings page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** submenu > **IP Profile Settings**), and set the 'Echo Canceller' field to **Acoustic**.

- c.** Enable the Forced Transcoding feature (using the *TranscodingMode* parameter) to allow the device to use DSP channels, which are required for acoustic echo cancellation.

**Note:** The following additional echo cancellation parameters are configurable only through the *ini* file:

- *ECHybridLoss* - defines the four-wire to two-wire worst-case Hybrid loss
- *ECNLPMode* - defines the echo cancellation Non-Linear Processing (NLP) mode
- *EchoCancellerAggressiveNLP* - enables Aggressive NLP at the first 0.5 second of the call

## 18.2 Fax and Modem Capabilities

This section describes the device's fax and modem capabilities and corresponding configuration. The fax and modem configuration is done in the Fax/Modem/CID Settings page.

### Notes:

- Unless otherwise specified, the configuration parameters mentioned in this section are available on this page.
- Some SIP parameters override these fax and modem parameters. For example, the IsFaxUsed parameter and V.152 parameters in Section 'V.152 Support' on page 160).
- For a detailed description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page 655.

### ➤ To access the fax and modem parameters:

1. Open the Fax/Modem/CID Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Fax/Modem/CID Settings**).

| General Settings          |                   |
|---------------------------|-------------------|
| Fax Transport Mode        | RelayEnable       |
| Caller ID Transport Type  | Mute              |
| Caller ID Type            | Standard Bellcore |
| V.21 Modem Transport Type | Disable           |
| V.22 Modem Transport Type | Enable Bypass     |
| V.23 Modem Transport Type | Enable Bypass     |
| V.32 Modem Transport Type | Enable Bypass     |
| V.34 Modem Transport Type | Enable Bypass     |
| Fax CNG Mode              | Disable           |
| CNG Detector Mode         | Disable           |

| Fax Relay Settings                  |                |
|-------------------------------------|----------------|
| Fax Relay Redundancy Depth          | 0              |
| Fax Relay Enhanced Redundancy Depth | 4              |
| Fax Relay ECM Enable                | Enable         |
| Fax Relay Max Rate (bps)            | 33600bps       |
| T38 Version                         | T.38 version 0 |

| Bypass Settings                 |             |
|---------------------------------|-------------|
| Fax/Modem Bypass Coder Type     | G711Alaw_64 |
| Fax/Modem Bypass Packing Factor | 1           |
| Fax Bypass Output Gain          | 0           |
| Modem Bypass Output Gain        | 0           |

| V.150.1 Modem Relay Settings         |     |
|--------------------------------------|-----|
| SSE Payload Type Rx                  | 105 |
| SSE Payload Type Tx                  | 105 |
| SSE Redundancy Depth                 | 3   |
| SPRT Payload Type Rx                 | 115 |
| SPRT Payload Type Tx                 | 115 |
| SPRT Transport Ch.0 Max Payload Size | 140 |
| SPRT Transport Ch.2 Max Payload Size | 132 |
| SPRT Transport Ch.2 Max Window Size  | 8   |
| SPRT Transport Ch.3 Max Payload Size | 140 |

2. Configure the parameters, as required.
3. Click **Submit** to apply your changes.

## 18.2.1 Fax/Modem Operating Modes

The device supports two modes of operation:

- Fax/modem negotiation that is not performed during the establishment of the call.
- Voice-band data (VBD) mode for V.152 implementation (see 'V.152 Support' on page 160): fax/modem capabilities are negotiated between the device and the remote endpoint at the establishment of the call. During a call, when a fax/modem signal is detected, transition from voice to VBD (or T.38) is automatically performed and no additional SIP signaling is required. If negotiation fails (i.e., no match is achieved for any of the transport capabilities), fallback to existing logic occurs (according to the parameter `IsFaxUsed`).

## 18.2.2 Fax/Modem Transport Modes

The device supports the following transport modes for fax per modem type (V.22/V.23/Bell/V.32/V.34):

- T.38 fax relay (see 'T.38 Fax Relay Mode' on page 149)
- G.711 Transport: switching to G.711 when fax/modem is detected (see 'G.711 Fax / Modem Transport Mode' on page 151)
- Fax fallback to G.711 if T.38 is not supported (see 'Fax Fallback' on page 151)
- Fax and modem bypass: a proprietary method that uses a high bit rate coder (see 'Fax/Modem Bypass Mode' on page 152)
- NSE Cisco's Pass-through bypass mode for fax and modem (see 'Fax / Modem NSE Mode' on page 153)
- Transparent with events: passing the fax / modem signal in the current voice coder with adaptations (see 'Fax / Modem Transparent with Events Mode' on page 154)
- Transparent: passing the fax / modem signal in the current voice coder (see 'Fax / Modem Transparent Mode' on page 154)
- RFC 2833 ANS Report upon Fax/Modem Detection (see 'RFC 2833 ANS Report upon Fax/Modem Detection' on page 155)

'Adaptations' refer to automatic reconfiguration of certain DSP features for handling fax/modem streams differently than voice.

### 18.2.2.1 T.38 Fax Relay Mode

In Fax Relay mode, fax signals are transferred using the T.38 protocol. T.38 is an ITU standard for sending fax across IP networks in real-time mode. The device currently supports only the T.38 UDP syntax.

T.38 can be configured in the following ways:

- Switching to T.38 mode using SIP Re-INVITE messages (see 'Switching to T.38 Mode using SIP Re-INVITE' on page 150)
- Automatically switching to T.38 mode without using SIP Re-INVITE messages (see 'Automatically Switching to T.38 Mode without SIP Re-INVITE' on page 150)

When fax transmission ends, the reverse switching from fax relay to voice is automatically performed at both the local and remote endpoints.

You can change the fax rate declared in the SDP, using the 'Fax Relay Max Rate' parameter (`FaxRelayMaxRate`). This parameter does not affect the actual transmission rate. You can also enable or disable Error Correction Mode (ECM) fax mode using the 'Fax Relay ECM Enable' parameter (`FaxRelayECMEnable`).

When using T.38 mode, you can define a redundancy feature to improve fax transmission over congested IP networks. This feature is activated using the 'Fax Relay Redundancy Depth' parameter (FaxRelayRedundancyDepth) and the 'Fax Relay Enhanced Redundancy Depth' parameter (FaxRelayEnhancedRedundancyDepth). Although this is a proprietary redundancy scheme, it should not create problems when working with other T.38 decoders.

### 18.2.2.1.1 Switching to T.38 Mode using SIP Re-INVITE

In the Switching to T.38 Mode using SIP Re-INVITE mode, upon detection of a fax signal the terminating device negotiates T.38 capabilities using a Re-INVITE message. If the far-end device doesn't support T.38, the fax fails. In this mode, the 'Fax Transport Mode' parameter (FaxTransportMode) is ignored.

➤ **To configure T.38 mode using SIP Re-INVITE messages:**

1. In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **T.38 Relay** (IsFaxUsed = 1).
2. In the Fax/Modem/CID Settings page, configure the following optional parameters:
  - 'Fax Relay Redundancy Depth' (FaxRelayRedundancyDepth)
  - 'Fax Relay Enhanced Redundancy Depth' (FaxRelayEnhancedRedundancyDepth)
  - 'Fax Relay ECM Enable' (FaxRelayECMEnable)
  - 'Fax Relay Max Rate' (FaxRelayMaxRate)

**Note:** The terminating gateway sends T.38 packets immediately after the T.38 capabilities are negotiated in SIP. However, the originating device by default, sends T.38 (assuming the T.38 capabilities are negotiated in SIP) only after it receives T.38 packets from the remote device. This default behavior cannot be used when the originating device is located behind a firewall that blocks incoming T.38 packets on ports that have not yet received T.38 packets from the internal network. To resolve this problem, the device should be configured to send CNG packets in T.38 upon CNG signal detection (CNGDetectorMode = 1).

### 18.2.2.1.2 Automatically Switching to T.38 Mode without SIP Re-INVITE

In the Automatically Switching to T.38 Mode without SIP Re-INVITE mode, when a fax signal is detected, the channel automatically switches from the current voice coder to answer tone mode and then to T.38-compliant fax relay mode.

➤ **To configure automatic T.38 mode:**

1. In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **No Fax** (IsFaxUsed = 0).
2. In the Fax/Modem/CID Settings page, set the 'Fax Transport Mode' parameter to **RelayEnable** (FaxTransportMode = 1).
3. Configure the following optional parameters:
  - 'Fax Relay Redundancy Depth' (FaxRelayRedundancyDepth)
  - 'Fax Relay Enhanced Redundancy Depth' (FaxRelayEnhancedRedundancyDepth)
  - 'Fax Relay ECM Enable' (FaxRelayECMEnable)
  - 'Fax Relay Max Rate' (FaxRelayMaxRate)

### 18.2.2.2 G.711 Fax / Modem Transport Mode

In this mode, when the terminating device detects fax or modem signals (CED or AnsAM), it sends a Re-INVITE message to the originating device, requesting it to re-open the channel in G.711 VBD with the following adaptations:

- Echo Canceller = off
- Silence Compression = off
- Echo Canceller Non-Linear Processor Mode = off
- Dynamic Jitter Buffer Minimum Delay = 40
- Dynamic Jitter Buffer Optimization Factor = 13

After a few seconds upon detection of fax V.21 preamble or super G3 fax signals, the device sends a second Re-INVITE enabling the echo canceller (the echo canceller is disabled only on modem transmission).

A 'gpmmd' attribute is added to the SDP according to the following format:

- **For G.711 A-law:**

```
a=gpmmd:0 vbd=yes;ecan=on (or off for modems)
```

- **For G.711  $\mu$ -law:**

```
a=gpmmd:8 vbd=yes;ecan=on (or off for modems)
```

The following parameters are ignored and automatically set to **Events Only**:

- 'Fax Transport Mode' (FaxTransportMode)
- 'Vxx ModemTransportType' (VxxModemTransportType)

➤ **To configure fax / modem transparent mode:**

- In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **G.711 Transport** (IsFaxUsed = 2).

### 18.2.2.3 Fax Fallback

In this mode, when the terminating device detects a fax signal, it sends a Re-INVITE message to the originating device with T.38. If the remote device doesn't support T.38 (replies with SIP response 415 "Media Not Supported"), the device sends a new Re-INVITE with G.711 VBD with the following adaptations:

- Echo Canceller = on
- Silence Compression = off
- Echo Canceller Non-Linear Processor Mode = off
- Dynamic Jitter Buffer Minimum Delay = 40
- Dynamic Jitter Buffer Optimization Factor = 13

When the device initiates a fax session using G.711, a 'gpmmd' attribute is added to the SDP according to the following format:

- **For G.711A-law:**

```
a=gpmmd:0 vbd=yes;ecan=on
```

- **For G.711  $\mu$ -law:**

```
a=gpmmd:8 vbd=yes;ecan=on
```

In this mode, the 'Fax Transport Mode' (FaxTransportMode) parameter is ignored and automatically set to **Disable** (transparent mode).

➤ **To configure fax fallback mode:**

- In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **Fax Fallback** (IsFaxUsed = 3).

#### 18.2.2.4 Fax/Modem Bypass Mode

In this proprietary mode, when fax or modem signals are detected, the channel automatically switches from the current voice coder to a high bit-rate coder, according to the 'Fax/Modem Bypass Coder Type' parameter (FaxModemBypassCoderType). The channel is also automatically reconfigured with the following fax / modem adaptations:

- Disables silence suppression
- Enables echo cancellation for fax
- Disables echo cancellation for modem
- Performs certain jitter buffering optimizations

The network packets generated and received during the bypass period are regular voice RTP packets (per the selected bypass coder), but with a different RTP payload type according to the following parameters:

- 'Fax Bypass Payload Type' (FaxBypassPayloadType)
- ModemBypassPayloadType (ini file)

During the bypass period, the coder uses the packing factor, configured by the 'Fax/Modem Bypass Packing Factor' parameter (FaxModemBypassM). The packing factor determines the number of coder payloads (each the size of FaxModemBypassBasicRTTPacketInterval) that are used to generate a single fax/modem bypass packet. When fax/modem transmission ends, the reverse switching, from bypass coder to regular voice coder is performed.

➤ **To configure fax / modem bypass mode:**

1. In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **No Fax** (IsFaxUsed = 0).
2. In the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'Fax Transport Mode' parameter to **Bypass** (FaxTransportMode = 2).
  - b. Set the 'V.21 Modem Transport Type' parameter to **Enable Bypass** (V21ModemTransportType = 2).
  - c. Set the 'V.22 Modem Transport Type' parameter to **Enable Bypass** (V22ModemTransportType = 2).
  - d. Set the 'V.23 Modem Transport Type' parameter to **Enable Bypass** (V23ModemTransportType = 2).
  - e. Set the 'V.32 Modem Transport Type' parameter to **Enable Bypass** (V32ModemTransportType = 2).
  - f. Set the 'V.34 Modem Transport Type' parameter to **Enable Bypass** (V34ModemTransportType = 2).
3. Set the ini file parameter, BellModemTransportType to 2 (Bypass).
4. Configure the following optional parameters:
  - 'Fax/Modem Bypass Coder Type' (FaxModemBypassCoderType).
  - 'Fax Bypass Payload Type' (FaxBypassPayloadType) - in the RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** > **RTP/RTCP Settings**).
  - ModemBypassPayloadType (ini file).
  - FaxModemBypassBasicRTTPacketInterval (ini file).
  - FaxModemBypasDJBufMinDelay (ini file).

**Note:** When the device is configured for modem bypass and T.38 fax, V.21 low-speed modems are not supported and fail as a result.

**Tip:** When the remote (non-AudioCodes) gateway uses the G.711 coder for voice and doesn't change the coder payload type for fax or modem transmission, it is recommended to use the Bypass mode with the following configuration:

- EnableFaxModemInbandNetworkDetection = 1.
- 'Fax/Modem Bypass Coder Type' = same coder used for voice.
- 'Fax/Modem Bypass Packing Factor'(FaxModemBypassM) = same interval as voice.
- ModemBypassPayloadType = 8 if voice coder is A-Law or 0 if voice coder is Mu-Law.

### 18.2.2.5 Fax / Modem NSE Mode

In this mode, fax and modem signals are transferred using Cisco-compatible Pass-through bypass mode. Upon detection of fax or modem answering tone signal, the terminating device sends three to six special NSE RTP packets (configured by the NSEpayloadType parameter; usually to 100). These packets signal the remote device to switch to G.711 coder, according to the 'Fax/Modem Bypass Packing Factor' parameter. After a few NSE packets are exchanged between the devices, both devices start using G.711 packets with standard payload type (8 for G.711 A-Law and 0 for G.711 Mu-Law). In this mode, no Re-INVITE messages are sent. The voice channel is optimized for fax/modem transmission (same as for usual bypass mode).

The parameters defining payload type for AudioCodes proprietary Bypass mode -- 'Fax Bypass Payload Type' (RTP/RTCP Settings page) and ModemBypassPayloadType (ini file) -- are not used with NSE Bypass.

When configured for NSE mode, the device includes in its SDP the following line:

```
a=rtpmap:100 X-NSE/8000
```

Where 100 is the NSE payload type.

The Cisco gateway must include the following definition:

```
modem passthrough nse payload-type 100 codec g711alaw
```

#### ➤ To configure NSE mode:

1. In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **No Fax** (IsFaxUsed = 0).
2. In the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'Fax Transport Mode' parameter to **Bypass** (FaxTransportMode = 2).
  - b. Set the 'V.21 Modem Transport Type' parameter to **Enable Bypass** (V21ModemTransportType = 2).
  - c. Set the 'V.22 Modem Transport Type' parameter to **Enable Bypass** (V22ModemTransportType = 2).
  - d. Set the 'V.23 Modem Transport Type' parameter to **Enable Bypass** (V23ModemTransportType = 2).
  - e. Set the 'V.32 Modem Transport Type' parameter to **Enable Bypass** (V32ModemTransportType = 2).

- d. Set the 'V.23 Modem Transport Type' parameter to **Disable** (V23ModemTransportType = 0).
- e. Set the 'V.32 Modem Transport Type' parameter to **Disable** (V32ModemTransportType = 0).
- f. Set the 'V.34 Modem Transport Type' parameter to **Disable** (V34ModemTransportType = 0).
3. Set the ini file parameter, BellModemTransportType to 0 (transparent mode).
4. Configure the following optional parameters:
  - a. Coders table - (**Configuration** tab > **VoIP** menu > **Coders and Profiles** > **Coders**).
  - b. 'Dynamic Jitter Buffer Optimization Factor' (DJBufOptFactor) - RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** > **RTP/RTCP Settings**).
  - c. 'Silence Suppression' (EnableSilenceCompression) - Voice Settings page (**Configuration** tab > **VoIP** menu > **Media** > **Voice Settings**).
  - d. 'Echo Cancellor' (EnableEchoCancellor) - Voice Settings page.

**Note:** This mode can be used for fax, but is not recommended for modem transmission. Instead, use the Bypass (see 'Fax/Modem Bypass Mode' on page 152) or Transparent with Events modes (see 'Fax / Modem Transparent with Events Mode' on page 154) for modem.

#### 18.2.2.8 RFC 2833 ANS Report upon Fax/Modem Detection

The device (terminator gateway) sends RFC 2833 ANS/ANSam events upon detection of fax and/or modem answer tones (i.e., CED tone). This causes the originator to switch to fax/modem. This parameter is applicable only when the fax or modem transport type is set to bypass, Transparent-with-Events, V.152 VBD, or G.711 transport. When the device is located on the originator side, it ignores these RFC 2833 events

##### ➤ To configure RFC 2833 ANS Report upon fax/modem detection:

1. In the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**), set the 'Fax Signaling Method' parameter to **No Fax** or **Fax Fallback** (IsFaxUsed = 0 or 3).
2. In the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'Fax Transport Mode' parameter to **Bypass** (FaxTransportMode = 2).
  - b. Set the 'V.xx Modem Transport Type' parameters to **Enable Bypass** (VxxModemTransportType = 2).
3. Set the ini file parameter, FaxModemNTEMode to 1 (enables this feature).

### 18.2.3 V.34 Fax Support

V.34 fax machines can transmit data over IP to the remote side using various methods. The device supports the following modes for transporting V.34 fax data over IP:

- T38 Version 3 - V.34 fax relay mode
- Bypass mechanism for V.34 fax transmission (see 'Bypass Mechanism for V.34 Fax Transmission' on page 156)
- T38 Version 0 relay mode, i.e., fallback to T.38 (see 'Relay Mode for T.30 and V.34 Faxes' on page 156)

To configure whether to pass V.34 over T38 fax relay, or use Bypass over the High Bit Rate coder (e.g. PCM A-Law), use the 'V.34 Fax Transport Type' parameter (V34FaxTransportType).

You can use the 'SIP T38 Version' parameter (SIPT38Version) in the Advanced Parameters page (Configuration tab > VoIP menu > SIP Definitions > Advanced Parameters) to configure one of the following:

- Pass V.34 over T.38 fax relay using bit rates of up to 33,600 bps ('SIP T38 Version' is set to Version 3).
- Use Fax-over-T.38 fallback to T.30, using up to 14,400 bps ('SIP T38 Version' is set to Version 0).

**Note:** The CNG detector is disabled in all the subsequent examples. To disable the CNG detector, set the 'CNG Detector Mode' parameter (CNGDetectorMode) to **Disable**.

### 18.2.3.1 Bypass Mechanism for V.34 Fax Transmission

In this proprietary scenario, the device uses bypass (or NSE) mode to transmit V.34 faxes, enabling the full utilization of its speed.

#### ➤ To use bypass mode for T.30 and V.34 faxes:

1. In the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'Fax Transport Mode' parameter to **Bypass** (FaxTransportMode = 2).
  - b. Set the 'V.22 Modem Transport Type' parameter to **Enable Bypass** (V22ModemTransportType = 2).
  - c. Set the 'V.23 Modem Transport Type' parameter to **Enable Bypass** (V23ModemTransportType = 2).
  - d. Set the 'V.32 Modem Transport Type' parameter to **Enable Bypass** (V32ModemTransportType = 2).
  - e. Set the 'V.34 Modem Transport Type' parameter to **Enable Bypass** (V34ModemTransportType = 2).
2. Set the ini file parameter, V34FaxTransportType to 2 (Bypass).

#### ➤ To use bypass mode for V.34 faxes, and T.38 for T.30 faxes:

1. In the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'Fax Transport Mode' parameter to **Relay** (FaxTransportMode = 1).
  - b. Set the 'V.22 Modem Transport Type' parameter to **Enable Bypass** (V22ModemTransportType = 2).
  - c. Set the 'V.23 Modem Transport Type' parameter to **Enable Bypass** (V23ModemTransportType = 2).
  - d. Set the 'V.32 Modem Transport Type' parameter to **Enable Bypass** (V32ModemTransportType = 2).
  - e. Set the 'V.34 Modem Transport Type' parameter to **Enable Bypass** (V34ModemTransportType = 2).
2. Set the ini file parameter, V34FaxTransportType to 2 (Bypass).

### 18.2.3.2 Relay Mode for T.30 and V.34 Faxes

In this scenario, V.34 fax machines are forced to use their backward compatibility with T.30 faxes and operate in the slower T.30 mode.

➤ **To use T.38 mode for V.34 and T.30 faxes:**

1. In the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'Fax Transport Mode' parameter to **Relay** (FaxTransportMode = 1).
  - b. Set the 'V.22 Modem Transport Type' parameter to **Disable** (V22ModemTransportType = 0).
  - c. Set the 'V.23 Modem Transport Type' parameter to **Disable** (V23ModemTransportType = 0).
  - d. Set the 'V.32 Modem Transport Type' parameter to **Disable** (V32ModemTransportType = 0).
  - e. Set the 'V.34 Modem Transport Type' parameter to **Disable** (V34ModemTransportType = 0).
2. Set the ini file parameter, V34FaxTransportType to 1 (Relay).

➤ **To allow V.34 fax relay over T.38:**

- In the Advanced Parameters page (Configuration tab > VoIP menu > SIP Definitions > Advanced Parameters), set the 'SIP T38 Version' parameter to Version 3 (SIPT38Version = 3).

➤ **To force V.34 fax machines to use their backward compatibility with T.30 faxes and operate in the slower T.30 mode:**

- Set the 'SIP T38 Version' parameter to Version 0 (SIPT38Version = 0).

### 18.2.3.3 V.34 Fax Relay for SG3 Fax Machines

Super Group 3 (SG3) is a standard for fax machines that support speeds of up to 33.6 kbps through V.34 half duplex (HD) modulation. This procedure below describes how to configure V.34 (SG3) fax relay support based on ITU Specification T.38 version 3.

➤ **To enable support for V.34 fax relay (T.38) at SG3 speed:**

1. In the IP Profile table (**Configuration** tab > **VoIP** menu > **Coders and Profiles** > **IP Profile Settings**), configure an IP Profile with the 'Fax Signaling Method' parameter (IpProfile\_IsFaxUsed) set to **T.38 Relay**.
2. In the Coders Table (**Configuration** tab > **VoIP** menu > **Coders and Profiles** > **Coders**), set the coder used by the device to G.729 (or any other supported codec).
3. On the Fax/Modem/CID Settings page, do the following:
  - a. Set the 'SIP T38 Version' parameter to Version 3 (SIPT38Version = 3).
  - b. Set the 'Fax Relay Max Rate' parameter (RelayMaxRate) to **33,600bps** (default).
  - c. Set the 'CNG Detector Mode' parameter (CNGDetectorMode) to **Disable** (default).
  - d. Set the 'V.21 Modem Transport Type' parameter to **Disable** (V21ModemTransportType = 0).
  - e. Set the 'V.22 Modem Transport Type' parameter to **Disable** (V22ModemTransportType = 0).
  - f. Set the 'V.23 Modem Transport Type' parameter to **Disable** (V23ModemTransportType = 0).
  - g. Set the 'V.32 Modem Transport Type' parameter to **Disable** (V32ModemTransportType = 0).
  - h. Set the 'V.34 Modem Transport Type' parameter to **Disable** (V34ModemTransportType = 0).
4. Set the ini file parameter, V34FaxTransportType to 1 (i.e., relay).
5. Set the ini file parameter, T38MaxDatagramSize to 560 (default).

6. Set the ini file parameter, CEDTransferMode to 0 (default).

**Notes:**

- The T.38 negotiation should be completed at call start according to V.152 procedure (as shown in the INVITE example below).
- T.38 mid-call Re-INVITES are supported.
- If the remote party supports only T.38 Version 0, the device "downgrades" the T.38 Version 3 to T.38 Version 0.

For example, the device sends or receives the following INVITE message, negotiating both audio and image media:

```

INVITE sip:2001@10.8.211.250;user=phone SIP/2.0

## 18.2.4 V.150.1 Modem Relay

The device can be configured to transfer modem calls using a subset of the ITU-T V.150.1 Modem Relay protocol. The device also supports V.150.1 modem relay coder negotiation in the initial SIP INVITE and 200 OK using the SDP body (according to the UCR-2008,

Change 2 specification). This eliminates the need for sending a re-INVITE to negotiate V.150.1. The device sends an INVITE's SDP offer in a format to negotiate V.150 modem relay using the same port as RTP, as shown in the example below:

```
a=csrc:1 audio udpsprt 114\r\n
a=cpar:a=sprtmap:114 v150mr/8000\r\n
a=cpar:a=fmtp:114
mr=1;mg=0;CDSCselect=1;mrmod=1,3;jmdelay=no;versn=1.1\r\n\r\n
```

You can configure the payload type for the outgoing SDP offer, using the NoAudioPayloadType parameter. You can set this parameter to "NoAudio", whereby RTP is not sent and the device adds an audio media only for the Modem Relay purpose. This is also in accordance to DOD UCR 2008 specification: "The AS-SIP signaling appliance MUST advertise the "NoAudio" payload type to interoperate with a "Modem Relay-Preferred" endpoint that immediately transitions to the Modem Relay state without first transmitting voice information in the Audio state."

**Notes:**

- The V.150.1 Modem Relay feature support is a subset of the full V.150.1 protocol and is designed according to the US DOD requirement document. It therefore, cannot be used for general purposes.
- The V.150.1 Modem Relay feature is available only if the device is installed with the V.150.1 Software License Key.
- The V.150.1 feature has been tested with certain IP phones. For more details, please contact your AudioCodes sales representative.
- The V.150.1 SSE Tx payload type is according to the offered SDP of the remote side.
- The V.150.1 SPRT Rx payload type is according to the 'Payload Type' field in the Coders table.
- The V.150.1 SPRT Tx payload type is according to the remote side offered SDP.

➤ **To configure V.150.1 Modem relay:**

1. In the Coders Table (**Configuration** tab > **VoIP** menu > **Coders and Profiles** > **Coders**), set the coder to **V.150**.
2. On the Fax/Modem/CID Settings page, configure the V.150.1 parameters appearing under the 'V.150.1 Modem Relay Settings' group:
  - a. Set the 'SSE Payload Type Rx' parameter to the V.150.1 SSE payload type that the device uses when it offers the SDP.
  - b. Set the 'SSE Redundancy Depth' parameter to the number of sent SSE redundant packets. This parameter is important in case of network impairments.
  - c. For additional V.150.1 related parameters, see 'Fax and Modem Parameters' on page 748.

## 18.2.5 Simultaneous Negotiation of Fax (T.38) and Modem (V.150.1) Relay

The device can negotiate fax relay (T.38) and modem relay (V.150.1) sessions in the same, already established call channel. Fax relay sessions require bypass answering tone (CED) while modem relay requires RFC 2833 answering tone. As the device is not always aware at the start of the session whether the answering tone is fax or modem, it uses both methods for CED tone transfer and sends both answering tone types. Only when the answering tone is detected, does the device send the fax or modem.

To support this functionality, you need to configure a Coders Group (in the Coders Group table - see 'Configuring Coder Groups' on page 236) that includes the T.38, V.150, and G.711/VBD coders.

## 18.2.6 V.152 Support

The device supports the ITU-T recommendation V.152 (Procedures for Supporting Voice-Band Data over IP Networks). Voice-band data (VBD) is the transport of modem, facsimile, and text telephony signals over a voice channel of a packet network with a codec appropriate for such signals.

For V.152 capability, the device supports T.38 as well as VBD codecs (i.e., G.711 A-law and G.711  $\mu$ -law). The selection of capabilities is performed using the coders table (see 'Configuring Coders' on page 233).

When in VBD mode for V.152 implementation, support is negotiated between the device and the remote endpoint at the establishment of the call. During this time, initial exchange of call capabilities is exchanged in the outgoing SDP. These capabilities include whether VBD is supported and associated RTP payload types ('gpmd' SDP attribute), supported codecs, and packetization periods for all codec payload types ('ptime' SDP attribute). After this initial negotiation, no Re-INVITE messages are necessary as both endpoints are synchronized in terms of the other side's capabilities. If negotiation fails (i.e., no match was achieved for any of the transport capabilities), fallback to existing logic occurs (according to the parameter IsFaxUsed).

Below is an example of media descriptions of an SDP indicating support for V.152. In the example, V.152 implementation is supported (using the dynamic payload type 96 and G.711 u-law as the VBD codec) as well as the voice codecs G.711  $\mu$ -law and G.729.

```
v=0
o=- 0 0 IN IPV4 <IPAdressA>
s=-
t=0 0
p=+1
c=IN IP4 <IPAdressA>
m=audio <udpPort A> RTP/AVP 18 0
a=ptime:10
a=rtpmap:96 PCMU/8000
a=gpmd: 96 vbd=yes
```

Instead of using VBD transport mode, the V.152 implementation can use alternative relay fax transport methods (e.g., fax relay over IP using T.38). The preferred V.152 transport method is indicated by the SDP 'pmft' attribute. Omission of this attribute in the SDP content means that VBD mode is the preferred transport mechanism for voice-band data. To configure T.38 mode, use the CodersGroup parameter.

**Note:** You can also configure the device to handle G.711 coders received in INVITE SDP offers as VBD coders, using the HandleG711asVBD parameter. For example, if the device is configured with G.729 and G.711 VBD coders and it receives an INVITE with an SDP offer containing G.729 and "regular" G.711 coders, it sends an SDP answer containing G.729 and G.711 VBD coders, allowing subsequent bypass (passthrough) sessions if fax / modem signals are detected during the call.

## 18.2.7 Fax Transmission behind NAT

The device supports transmission from fax machines (connected to the device) located inside (behind) a Network Address Translation (NAT). Generally, the firewall blocks T.38 (and other) packets received from the WAN, unless the device behind the NAT sends at least one IP packet from the LAN to the WAN through the firewall. If the firewall blocks T.38 packets sent from the termination IP fax, the fax fails.

To overcome this, the device sends No-Op ("no-signal") packets to open a pinhole in the NAT for the answering fax machine. The originating fax does not wait for an answer, but immediately starts sending T.38 packets to the terminating fax machine upon receipt of a re-INVITE with T.38 only in the SDP, or T.38 and audio media in the SDP. This feature is configured using the `T38FaxSessionImmediateStart` parameter. The No-Op packets are enabled using the `NoOpEnable` and `NoOpInterval` parameters.

## 18.3 Configuring RTP/RTCP Settings

This section describes configuration relating to Real-Time Transport Protocol (RTP) and RTP Control Protocol (RTCP).

### 18.3.1 Configuring the Dynamic Jitter Buffer

Voice frames are transmitted at a fixed rate. If the frames arrive at the other end at the same rate, voice quality is perceived as good. However, some frames may arrive slightly faster or slower than the other frames. This is called jitter (delay variation) and degrades the perceived voice quality. To minimize this problem, the device uses a jitter buffer. The jitter buffer collects voice packets, stores them and sends them to the voice processor in evenly spaced intervals.

The device uses a dynamic jitter buffer that can be configured with the following:

- **Minimum delay:** Defines the starting jitter capacity of the buffer. For example, at 0 msec, there is no buffering at the start. At the default level of 10 msec, the device always buffers incoming packets by at least 10 msec worth of voice frames.
- **Optimization Factor:** Defines how the jitter buffer tracks to changing network conditions. When set at its maximum value of 12, the dynamic buffer aggressively tracks changes in delay (based on packet loss statistics) to increase the size of the buffer and doesn't decay back down. This results in the best packet error performance, but at the cost of extra delay. At the minimum value of 0, the buffer tracks delays only to compensate for clock drift and quickly decays back to the minimum level. This optimizes the delay performance but at the expense of a higher error rate.

The default settings of 10 msec Minimum delay and 10 Optimization Factor should provide a good compromise between delay and error rate. The jitter buffer 'holds' incoming packets for 10 msec before making them available for decoding into voice. The coder polls frames from the buffer at regular intervals in order to produce continuous speech. As long as delays in the network do not change (jitter) by more than 10 msec from one packet to the next, there is always a sample in the buffer for the coder to use. If there is more than 10 msec of delay at any time during the call, the packet arrives too late. The coder tries to access a frame and is not able to find one. The coder must produce a voice sample even if a frame is not available. It therefore compensates for the missing packet by adding a Bad-Frame-Interpolation (BFI) packet. This loss is then flagged as the buffer being too small. The dynamic algorithm then causes the size of the buffer to increase for the next voice session. The size of the buffer may decrease again if the device notices that the buffer is not filling up as much as expected. At no time does the buffer decrease to less than the minimum size configured by the Minimum delay parameter.

In certain scenarios, the **Optimization Factor is set to 13**: One of the purposes of the Jitter Buffer mechanism is to compensate for clock drift. If the two sides of the VoIP call are not synchronized to the same clock source, one RTP source generates packets at a lower rate, causing under-runs at the remote Jitter Buffer. In normal operation (optimization factor 0 to 12), the Jitter Buffer mechanism detects and compensates for the clock drift by occasionally dropping a voice packet or by adding a BFI packet.

Fax and modem devices are sensitive to small packet losses or to added BFI packets. Therefore, to achieve better performance during modem and fax calls, the Optimization Factor should be set to 13. In this special mode the clock drift correction is performed less

frequently - only when the Jitter Buffer is completely empty or completely full. When such condition occurs, the correction is performed by dropping several voice packets simultaneously or by adding several BFI packets simultaneously, so that the Jitter Buffer returns to its normal condition.

The procedure below describes how to configure the jitter buffer using the Web interface.

➤ **To configure jitter buffer using the Web interface:**

1. Open the RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **RTP/RTCP Settings**). The relevant parameters are listed under the 'General Settings' group, as shown below:

**Figure 18-3: Jitter Buffer Parameters in the RTP/RTCP Settings Page**

| ▼ General Settings                        |                                 |
|-------------------------------------------|---------------------------------|
| Dynamic Jitter Buffer Minimum Delay       | <input type="text" value="10"/> |
| Dynamic Jitter Buffer Optimization Factor | <input type="text" value="10"/> |

2. Set the 'Dynamic Jitter Buffer Minimum Delay' parameter (DJBufMinDelay) to the minimum delay (in msec) for the Dynamic Jitter Buffer.
3. Set the 'Dynamic Jitter Buffer Optimization Factor' parameter (DJBufOptFactor) to the Dynamic Jitter Buffer frame error/delay optimization factor.
4. Click **Submit** to apply your settings.

## 18.3.2 Comfort Noise Generation

The device can generate artificial background noise, called *comfort* noise, in the voice channel during periods of silence (i.e. when no call party is speaking). This is useful in that it reassures the call parties that the call is still connected. The device detects silence using its Voice Activity Detection (VAD) mechanism. When the Calling Tone (CNG) is enabled and silence is detected, the device transmits Silence Identifier Descriptors (SIDs) parameters to reproduce the local background noise at the remote (receiving) side.

The Comfort Noise Generation (CNG) support also depends on the silence suppression (SCE) setting for the coder used in the voice channel. For more information, see the description of the CNG-related parameters.

The procedure below describes how to configure CNG using the Web interface.

➤ **To configure CNG using the Web interface:**

1. Open the RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **RTP/RTCP Settings**). The relevant parameters are listed under the 'General Settings' group, as shown below:

**Figure 18-4: Comfort Noise Parameter in RTP/RTCP Settings Page**

|                                      |                                     |
|--------------------------------------|-------------------------------------|
| Comfort Noise Generation Negotiation | <input type="text" value="Enable"/> |
|--------------------------------------|-------------------------------------|

2. Set the 'Comfort Noise Generation Negotiation' parameter (ComfortNoiseNegotiation) to **Enable**.
3. Click **Submit** to apply your changes.

## 18.3.3 Dual-Tone Multi-Frequency Signaling

This section describes the configuration of Dual-Tone Multi-Frequency (DTMF) signaling.

### 18.3.3.1 Configuring DTMF Transport Types

The device supports various methods for transporting DTMF digits over the IP network to the remote endpoint. These methods and their configuration are configured in the DTMF & Dialing page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **DTMF and Supplementary** > **DTMF & Dialing**):

- **Using INFO message according to Nortel IETF draft:** DTMF digits are sent to the remote side in INFO messages. To enable this mode, define the following:
  - a. Set the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Set the '1st Tx DTMF Option' parameter to **INFO (Nortel)** (TxDTMFOption = 1).**Note:** In this mode, DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).
- **Using INFO message according to Cisco's mode:** DTMF digits are sent to the remote side in INFO messages. To enable this mode, define the following:
  - a. Set the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Set the '1st Tx DTMF Option' parameter to **INFO (Cisco)** (TxDTMFOption = 3).**Note:** In this mode, DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).
- **Using NOTIFY messages according to IETF Internet-Draft draft-mahy-sipping-signaled-digits-01:** DTMF digits are sent to the remote side using NOTIFY messages. To enable this mode, define the following:
  - a. Set the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Set the '1st Tx DTMF Option' parameter to **NOTIFY** (TxDTMFOption = 2).**Note:** In this mode, DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).
- **Using RFC 2833 relay with Payload type negotiation:** DTMF digits are sent to the remote side as part of the RTP stream according to RFC 2833. To enable this mode, define the following:
  - a. Set the 'Declare RFC 2833 in SDP' parameter to **Yes** (RxDTMFOption = 3).
  - b. Set the '1st Tx DTMF Option' parameter to **RFC 2833** (TxDTMFOption = 4).**Note:** To set the RFC 2833 payload type with a value other than its default, use the RFC2833PayloadType parameter. The device negotiates the RFC 2833 payload type using local and remote SDP and sends packets using the payload type from the received SDP. The device expects to receive RFC 2833 packets with the same payload type as configured by this parameter. If the remote side doesn't include 'telephony-event' in its SDP, the device sends DTMF digits in transparent mode (as part of the voice stream).
- **Sending DTMF digits (in RTP packets) as part of the audio stream (DTMF Relay is disabled):** This method is typically used with G.711 coders. With other low-bit rate (LBR) coders, the quality of the DTMF digits is reduced. To enable this mode, define the following:
  - a. Set the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Set the '1st Tx DTMF Option' parameter to **Not Supported** (TxDTMFOption = 0).
  - c. Set the ini file parameter, DTMFTransportType to 2 (i.e., transparent).

- **Using INFO message according to Korea mode:** DTMF digits are sent to the remote side in INFO messages. To enable this mode, define the following:
  - a. Set the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Set the '1st Tx DTMF Option' parameter to **INFO (Cisco)** (TxDTMFOption = 3).

**Note:** In this mode, DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).

**Notes:**

- The device is always ready to receive DTMF packets over IP in all possible transport modes: INFO messages, NOTIFY, and RFC 2833 (in proper payload type) or as part of the audio stream.
- To exclude RFC 2833 Telephony event parameter from the device's SDP, set the 'Declare RFC 2833 in SDP' parameter to **No**.

The following parameters affect the way the device handles the DTMF digits:

- TxDTMFOption, RxDTMFOption, RFC2833TxPayloadType, and RFC2833RxPayloadType
- MGCPDTMFDetectionPoint, DTMFVolume, DTMFTransportType, DTMFDigitLength, and DTMFInterDigitInterval

### 18.3.3.2 Configuring RFC 2833 Payload

The procedure below describes how to configure the RFC 2833 payload using the Web interface:

➤ **To configure RFC 2833 payload using the Web interface:**

1. Open the RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **RTP/RTCP Settings**). The relevant parameters are listed under the 'General Settings' group, as shown below:

**Figure 18-5: RFC 2833 Payload Parameters in RTP/RTCP Settings Page**

|                                 |         |   |
|---------------------------------|---------|---|
| RTP Redundancy Depth            | 0       |   |
| Packing Factor                  | 1       |   |
| Basic RTP Packet Interval       | Default | ▼ |
| RFC 2833 TX Payload Type        | 96      |   |
| RFC 2833 RX Payload Type        | 96      |   |
| RFC 2198 Payload Type           | 104     |   |
| Fax Bypass Payload Type         | 102     |   |
| Enable RFC 3389 CN Payload Type | Enable  | ▼ |

2. Configure the following parameters:
  - 'RTP Redundancy Depth' (RTPRedundancyDepth) - enables the device to generate RFC 2198 redundant packets.
  - 'Enable RTP Redundancy Negotiation' (EnableRTPRedundancyNegotiation) - enables the device to include the RTP redundancy dynamic payload type in the SDP, according to RFC 2198.
  - 'RFC 2833 TX Payload Type' (RFC2833TxPayloadType) - defines the Tx RFC 2833 DTMF relay dynamic payload type.
  - 'RFC 2833 RX Payload Type' (RFC2833RxPayloadType) - defines the Rx RFC 2833 DTMF relay dynamic payload type.
  - 'RFC 2198 Payload Type' (RFC2198PayloadType) - defines the RTP redundancy packet payload type according to RFC 2198.
3. Click **Submit** to apply your settings.

### 18.3.4 Configuring RTP Base UDP Port

You can configure the range of UDP ports for RTP, RTCP, and T.38. The UDP port range can be configured using media realms in the Media Realm table, allowing you to assign different port ranges (media realms) to different interfaces. However, if you do not use media realms, you can configure the lower boundary of the UDP port used for RTP, RTCP (RTP port + 1) and T.38 (RTP port + 2), using the 'RTP Base UDP Port' (BaseUDPPort) parameter. For example, if the BaseUDPPort is set to 6000, then one channel may use the ports RTP 6000, RTCP 6001, and T.38 6002, while another channel may use RTP 6010, RTCP 6011, and T.38 6012.

The range of possible UDP ports is 6,000 to 64,000 (default base UDP port is 6000). The port range is calculated using the BaseUDPPort parameter as follows: **BaseUDPPort to (BaseUDPPort + <channels -1> \* 10)**

The default local UDP ports for audio and fax media streams is calculated using the following formula: **BaseUDPPort + (Channel ID \* 10) + Port Offset**

Where the port offsets are as follows:

- **Audio RTP:** 0
- **Audio RTCP:** 1
- **Fax T.38:** 2

For example, the local T.38 UDP port for channel 30 is calculated as follows: **6000 + (30\*10) + 2 = 6302**

The maximum (when all channels are required) UDP port range is calculated as follows:

- BaseUDPPort to (BaseUDPPort + 255\*10) - for example, if the BaseUDPPort is set to 6,000, then the UDP port range is 6,000 to 8,550

#### Notes:

- The device allocates the UDP ports randomly to the channels.
- To configure the device to use the same port for both RTP and T.38 packets, set the T38UseRTPPort parameter to 1.
- If you are using Media Realms (see 'Configuring Media Realms' on page 168), the port range configured for the Media Realm must be within this range defined by the BaseUDPPort parameter.

The procedure below describes how to configure the RTP base UDP port using the Web interface.

#### ➤ To configure the RTP base UDP port:

1. Open the RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **RTP/RTCP Settings**). The relevant parameter is listed under the 'General Settings' group, as shown below:

**Figure 18-6: RTP Based UDP Port in RTP/RTCP Settings Page**

|                     |      |
|---------------------|------|
| ⚡ RTP Base UDP Port | 6000 |
|---------------------|------|

2. Set the 'RTP Base UDP Port' parameter to the required value.
3. Click **Submit**.
4. Reset the device for the settings to take effect.

## 18.4 Configuring IP Media Settings

This section describes the configuration of various IP media features.

### 18.4.1 Automatic Gain Control (AGC)

Automatic Gain Control (AGC) adjusts the energy of the output signal to a required level (volume). This feature compensates for near-far gain differences. AGC estimates the energy of the incoming signal from the IP or PSTN, determined by the 'AGC Redirection' parameter, calculates the essential gain, and then performs amplification. Feedback ensures that the output signal is not clipped. You can configure the required Gain Slope in decibels per second using the 'AGC Slope' parameter and the required signal energy threshold using the 'AGC Target Energy' parameter.

When the AGC first detects an incoming signal, it begins operating in Fast Mode, which allows the AGC to adapt quickly when a conversation starts. This means that the Gain Slope is 8 dB/sec for the first 1.5 seconds. After this period, the Gain Slope is changed to the user-defined value. You can disable or enable the AGC's Fast Mode feature, using the *ini* file parameter AGCDisableFastAdaptation. After Fast Mode is used, the signal should be off for two minutes in order to have the feature turned on again.

**Note:** AGC is a customer ordered feature and thus, must be included in the Software License Key installed on the device.

The procedure below describes how to configure AGC using the Web interface:

➤ **To configure AGC using the Web interface:**

1. Open the IPMedia Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **IPMedia Settings**). The AGC parameters are shown in the figure below:

**Figure 18-7: AGC Parameters in IPMedia Settings Page**

|                   |        |
|-------------------|--------|
| Enable AGC        | Enable |
| AGC Slope         | 3      |
| AGC Redirection   | 0      |
| AGC Target Energy | 19     |

2. Configure the following parameters:
  - 'Enable AGC' (*EnableAGC*) - Enables the AGC mechanism.
  - 'AGC Slope' (*AGCGainSlope*) - Determines the AGC convergence rate.
  - 'AGC Redirection' (*AGCRedirection*) - Determines the AGC direction.
  - 'AGC Target Energy' - Defines the signal energy value (dBm) that the AGC attempts to attain.
3. Click **Submit** to apply your settings.

**Note:** Below are additional AGC parameters:

- AGCMinGain - Defines the minimum gain (in dB) by the AGC when activated
- AGCMaxGain - Defines the maximum gain (in dB) by the AGC when activated.
- AGCDisableFastAdaptation - Enables the AGC Fast Adaptation mode

## 18.5 Configuring Various Codec Attributes

The following codec attributes can be configured in the General Media Settings page:

- AMR coder:
  - 'Payload Format': Defines the AMR payload format type.
- SILK coder (Skype's default audio codec):
  - 'Silk Tx Inband FEC': Enables forward error correction (FEC) for the SILK coder.
  - 'Silk Max Average Bit Rate': Defines the maximum average bit rate for the SILK coder.

For a detailed description of these parameters and for additional codec parameters, see 'Coder Parameters' on page 741.

➤ **To configure general media parameters:**

1. Open the General Media Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **General Media Settings**).

**Figure 18-8: Coder Attribute Configuration in General Media Settings Page**

|                                         |               |
|-----------------------------------------|---------------|
| ▲ General Settings                      |               |
| ▼ SILK Coders Settings                  |               |
| Silk Tx Inband FEC                      | Disable       |
| Silk Max Average Bit Rate               | 16000         |
| ▼ AMR Bandwidth Efficient Configuration |               |
| AMR Payload Format                      | Octet Aligned |

2. Configure the parameters as required, and then click **Submit**.
3. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 18.6 Configuring Analog Settings

The Analog Settings page allows you to configure various analog parameters. For a detailed description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page 655.

This page also selects the type (USA or Europe) of FXS and/or FXO coefficient information. The FXS coefficient contains the analog telephony interface characteristics such as DC and AC impedance, feeding current, and ringing voltage.

➤ **To configure the analog parameters:**

1. Open the Analog Settings page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Analog Settings**).

**Figure 18-9: Analog Settings Page**

| FXS_FXO Settings                          |                          |
|-------------------------------------------|--------------------------|
| ⚡ Analog TTX Voltage Level                | 0.5V                     |
| ⚡ Analog Metering Type                    | 12 kHz sinusoidal bursts |
| ⚡ Min. Hook-Flash Detection Period [msec] | 300                      |
| Max. Hook-Flash Detection Period [msec]   | 700                      |
| ⚡ FXS Coefficient Type                    | USA                      |
| ⚡ FXO Coefficient Type                    | USA                      |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 18.7 Configuring Media Realms

The Media Realm Table page allows you to define a pool of up to 64 SIP media interfaces, termed *Media Realms*. Media Realms allow you to divide a Media-type interface, which is configured in the Multiple Interface table, into several realms, where each realm is specified by a UDP port range. You can also define the maximum number of sessions per Media Realm. Once configured, Media Realms can be assigned to IP Groups (see 'Configuring IP Groups' on page 204) or SRDs (see 'Configuring SRD Table' on page 199).

Once you have configured a Media Realm, you can configure it with the following:

- Quality of Experience parameters for reporting to AudioCodes SEM server used for monitoring the quality of calls (see Configuring Quality of Experience Parameters per Media Realm on page 170)
- Bandwidth management (see 'Configuring Bandwidth Management per Media Realm' on page 173)

**Notes:**

- If different Media Realms are assigned to an IP Group and to an SRD, the IP Group's Media Realm takes precedence.
- For this setting to take effect, a device reset is required.
- The Media Realm table can also be configured using the table ini file parameter, CpMediaRealm or CLI command, configure voip/media realm.

➤ **To define a Media Realm:**

1. Open the Media Realm Table page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Media Realm Configuration**).
2. Click the **Add** button; the following appears:

**Figure 18-10: Media Realm Page - Add Record Dialog Box**

3. Configure the parameters as required. See the table below for a description of each parameter
4. Click **Submit** to apply your settings.
5. Reset the device to save the changes to flash memory (see 'Saving Configuration' on page 532).

**Media Realm Table Parameter Descriptions**

| Parameter                                                                  | Description                                                                                                                                                                                                                                                                                                                                                    |
|----------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>[CpMediaRealm_Index]                                              | Defines the required table index number.                                                                                                                                                                                                                                                                                                                       |
| Media Realm Name<br>CLI: name<br>[CpMediaRealm_MediaRealmName]             | Defines an arbitrary, identifiable name for the Media Realm.<br>The valid value is a string of up to 40 characters.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>▪ This parameter is mandatory.</li> <li>▪ The name assigned to the Media Realm must be unique.</li> <li>▪ This Media Realm name is used in the SRD and IP Groups table.</li> </ul> |
| IPv4 Interface Name<br>CLI: ipv4<br>[CpMediaRealm_IPv4IF]                  | Assigns an IPv4 interface to the Media Realm. This is name of the interface as configured for the Interface Name field in the Multiple Interface table.                                                                                                                                                                                                        |
| Port Range Start<br>CLI: port-range-start<br>[CpMediaRealm_PortRangeStart] | Defines the starting port for the range of Media interface UDP ports.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>▪ You must either configure all media realms with port ranges or all without; not some with and some without.</li> <li>▪ The available UDP port range is calculated using the BaseUDPport parameter:</li> </ul>                  |

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                    | <ul style="list-style-type: none"> <li>✓ BaseUDPport to BaseUDPport + 255*10</li> <li>▪ Port ranges over 60,000 must not be used.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Number of Media Session Legs<br>CLI: session-leg<br>[CpMediaRealm_MediaSessionLeg] | Defines the number of media sessions associated with the range of ports. This is the number of media sessions available in the port range. For example, 100 ports correspond to 10 media sessions, since ports are allocated in chunks of 10.                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Port Range End<br>CLI: port-range-end<br>[CpMediaRealm_PortRangeEnd]               | Read-only field displaying the ending port for the range of Media interface UDP ports. This field is calculated by adding the 'Media Session Leg' field (multiplied by the port chunk size) to the 'Port Range Start' field. A value appears once a row has been successfully added to the table.                                                                                                                                                                                                                                                                                                                                                                 |
| Is Default<br>CLI: is-default<br>[CpMediaRealm_IsDefault]                          | <p>Defines the Media Realm as the default Media Realm. This default Media Realm is used when no Media Realm is configured for an IP Group or SRD for a specific call.</p> <ul style="list-style-type: none"> <li>▪ [0] No (default)</li> <li>▪ [1] Yes</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ This parameter can be set to <b>Yes</b> for only <b>one</b> defined Media Realm.</li> <li>▪ If this parameter is not configured, then the first Media Realm in the table is used as the default.</li> <li>▪ If the table is not configured, then the default Media Realm includes all the configured media interfaces.</li> </ul> |

## 18.7.1 Configuring Quality of Experience per Media Realm

You can configure Quality of Experience (QoE) per Media Realm. This enables you to monitor and analyze media and signaling traffic, allowing you to detect problems causing service degradation. The device can save call information and statistics at call start, at call end, or at specific changes in the call. The information is stored as call records on an external server. The device connects, as a client, to the server using TLS over TCP.

You can specify the call parameters to monitor and configure their upper and lower thresholds. If these thresholds are exceeded, the device can be configured to do the following:

- Reports the change in the monitored parameter to the monitoring server (default).
- Sends RFC 2198 RTP redundancy packets on the call leg that crossed the threshold. This enables the device to adapt to the changed network status. In this option, you can also configure the redundancy depth. The channel configuration is unchanged if the change requires channel reopening. Currently, this option is applicable only when the monitored parameter is remote packet loss.

The device can be configured to monitor the following parameters on the local (i.e., at the device) or remote side:

- Packet loss
- Mean Opinion Score (MOS)
- Jitter
- Packet delay
- Residual Echo Return Loss (RERL)

At any given time during a call, each of these parameters can be in one of the following states according to its value in the last RTCP / RTCP XR packet:

- Gray - indicates that the value is unknown
- Green - indicates good call quality
- Yellow - indicates medium call quality
- Red - indicates poor call quality

The mapping between the values of the parameters and the color is according to the configured threshold of these parameters, per Media Realm. The call itself also has a state (color), which is the worst-state color of all the monitored parameters. Each time a color of a parameter changes, the device sends a report to the external server. A report is also sent at the end of each call.

**Notes:**

- The QoE feature is available only if the device is installed with the relevant Software License Key.
- To configure the address of the AudioCodes Session Experience Manager (SEM) server to where the device reports the QoE, see 'Configuring SEM Server for Media Quality of Experience' on page 175.
- You can also configure QoE per Media Realm using the table *ini* file parameter QOERules or CLI command, media qoe-rules.

➤ **To configure QoE per Media Realm:**

1. Open the Media Realm Table page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Media Realm Configuration**).
2. Select the Media Realm for which you want to configure Quality of Experience, and then click the **Quality Of Experience** link; the Quality Of Experience page appears.
3. Click the **Add** button; the following dialog box appears:

**Figure 18-11: Quality of Experience Page - Add Record Dialog Box**

| Add Record                                                                               |                 |
|------------------------------------------------------------------------------------------|-----------------|
| Index                                                                                    | 1               |
| Monitored Parameter                                                                      | MOS             |
| Direction                                                                                | Device Side     |
| Profile                                                                                  | Low Sensitivity |
| Green Yellow Threshold                                                                   | 3.4             |
| Green Yellow Hysteresis                                                                  | 0.1             |
| Yellow Red Threshold                                                                     | 2.7             |
| Yellow Red Hysteresis                                                                    | 0.1             |
| Green Yellow Operation                                                                   | Notify          |
| Green Yellow Operation Details                                                           | 1               |
| Yellow Red Operation                                                                     | Notify          |
| Yellow Red Operation Details                                                             | 1               |
| <div> <input type="button" value="Submit"/> <input type="button" value="Cancel"/> </div> |                 |

The figure above shows value thresholds for the MOS parameter, which are assigned using pre-configured values of the Low Sensitivity profile. In this example setting, if the

MOS value changes by 0.1 (hysteresis) to 3.3 or 3.5, the device sends a report to the SEM indicating this change. If the value changes to 3.3, it sends a yellow state (i.e., medium quality); if the value changes to 3.5, it sends a green state.

4. Configure the parameters as required. See the table below for a description of each parameter.
5. Click **Submit** to apply your settings.

#### Quality of Experience Parameter Descriptions

| Parameter                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>CLI: index<br>[QOERules_RuleIndex]                                                    | Defines the table index entry. Up to four table row entries can be configured per Media Realm.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Monitored Parameter<br>CLI: monitored-parameter<br>[QOERules_MonitoredParam]                   | Defines the parameter to monitor and report. <ul style="list-style-type: none"> <li>▪ [0] MOS (default)</li> <li>▪ [1] Delay</li> <li>▪ [2] Packet Loss</li> <li>▪ [3] Jitter</li> <li>▪ [4] RERL</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Direction<br>CLI: direction<br>[QOERules_Direction]                                            | Defines the monitoring direction. <ul style="list-style-type: none"> <li>▪ [0] Device Side (default)</li> <li>▪ [1] Remote Side</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Profile<br>CLI: profile<br>[QOERules_Profile]                                                  | Defines the pre-configured threshold profile to use. <ul style="list-style-type: none"> <li>▪ [0] No Profile = No profile is used and you need to define the thresholds in the parameters described below.</li> <li>▪ [1] Low Sensitivity = Automatically sets the thresholds to low sensitivity values. Therefore, reporting is done only if changes in parameters' values is significant.</li> <li>▪ [2] Default Sensitivity = Automatically sets the thresholds to a medium sensitivity.</li> <li>▪ [3] High Sensitivity = Automatically sets the thresholds to high sensitivity values. Therefore, reporting is done for small fluctuations in parameters' values.</li> </ul> |
| Green Yellow Threshold<br>CLI: green-yellow-threshold<br>[QOERules_GreenYellowThres<br>hold]   | Defines the parameter threshold values between green (good quality) and yellow (medium quality) states.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Green Yellow Hysteresis<br>CLI: green-yellow-hysteresis<br>[QOERules_GreenYellowHyste<br>rsis] | Defines the hysteresis (fluctuation) for the green-yellow threshold. When the threshold is exceeded by this hysteresis value, the device sends a report to the SEM indicating this change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Yellow Red Threshold<br>CLI: yellow-red-threshold<br>[QOERules_YellowRedThresho<br>ld]         | Defines the parameter threshold values between yellow (medium quality) and red (poor quality). When this threshold is exceeded, the device sends a report to the SEM indicating this change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Yellow Red Hysteresis<br>CLI: yellow-red-hysteresis<br>[QOERules_YellowRedHystersi<br>s]       | Defines the hysteresis (fluctuation) for the yellow-red threshold. When the threshold is exceeded by this hystersis value, the device sends a report to the SEM indicating this change.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Parameter                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## 18.7.2 Configuring Bandwidth Management per Media Realm

Bandwidth management enables you to configure bandwidth utilization thresholds per Media Realm which when exceeded, the device can do one of the following:

- Generate an appropriate SNMP alarm, which is cleared when the bandwidth utilization returns to normal.
- Block any additional calls on the Media Realm.

Bandwidth management includes the following bandwidth utilization states:

- Normal
- High threshold
- Critical threshold

When a transition occurs between two bandwidth threshold states, based on threshold and hysteresis values, the device executes the configured action. The transition possibilities include Normal-High threshold state changes and High-Critical threshold state changes.

Thus, up to two thresholds can be configured per Media Realm; one for each state transition.

#### Notes:

- This feature is available only if the device is installed with the relevant Software License Key.
- For your bandwidth management settings to take effect, you must reset the device.
- You can also use the BWManagement *ini* file parameter to configure bandwidth management per Media Realm.

#### ➤ To configure bandwidth management rules per Media Realm:

1. Open the Media Realm Table page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Media Realm Configuration**).
2. Select the Media Realm for which you want to configure bandwidth management rules, and then click the **Bandwidth Management** link; the Bandwidth Management page appears.
3. Click the **Add** button; the following dialog box appears:

**Figure 18-12: Bandwidth Management Page - Add record Dialog Box**

The figure above shows an example where if the bandwidth for this Media Realm reaches 41,000 Bps (i.e., 40,000 plus 1,000 hysteresis), the device blocks any additional calls. If the bandwidth later decreases to 39,000 Bps (i.e., 40,000 minus 1,000 hysteresis), the device allows additional calls.

4. Configure the parameters as required. See the table below for a description of each parameter.
5. Click **Submit** to apply your settings.
6. Reset the device for your settings to take effect.

#### Bandwidth Management Parameter Descriptions

| Parameter                                                      | Description                                                                                                                                                                                                                                 |
|----------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>CLI: status<br><b>BWManagement_ThresholdIndex</b>     | Defines the index of the table row entry. This index determines the bandwidth threshold type for the rule: <ul style="list-style-type: none"> <li>▪ <b>[0]</b> High Threshold Rule</li> <li>▪ <b>[1]</b> Critical Threshold Rule</li> </ul> |
| Rule Action<br>CLI: action<br><b>[BWManagement_RuleAction]</b> | Defines the action that the device performs when the configured threshold is exceeded: <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Report Only (default)</li> <li>▪ <b>[1]</b> No more calls</li> </ul>                             |

| Parameter                                                  | Description                                                                                                                                  |
|------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| Threshold<br>CLI: threshold<br>[BWManagement_Threshold]    | Defines the bandwidth threshold in bytes per second (Bps).<br>The default is 0.                                                              |
| Hysteresis<br>CLI: hysteresis<br>[BWManagement_Hysteresis] | Defines the bandwidth fluctuation (change) from the threshold value at which the device performs the configured action.<br>The default is 0. |

## 18.8 Configuring Server for Media Quality of Experience

The device can be configured to report voice (media) quality of experience to AudioCodes Session Experience Manager (SEM) server, a plug-in for AudioCodes EMS. The reports include real-time metrics of the quality of the actual call experience and processed by the SEM.

### Notes:

- To support this feature, the device must be installed with the relevant Software License Key.
- To configure the parameters to report and their thresholds per Media Realm, see 'Configuring Quality of Experience per Media Realm' on page 170.
- For information on the SEM server, refer to the *EMS User's Manual*.

### ➤ To configure QoE reporting of media:

1. Open the Media Quality of Experience page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Media Quality of Experience**).

Figure 18-13: Media Quality of Experience Page

| Quality of Experience |            |
|-----------------------|------------|
| ⚡ Server Ip           | 0.0.0.0    |
| Port                  | 5000       |
| ⚡ Interface Name      | DEFAULT    |
| Connection Mode       | VQMClient  |
| Information Level     | VQStandard |
| Use Mos LQ            | Disable    |

2. Configure the parameters as required
  - 'Server Ip' (QOEServerIP) - defines the IP address of the SEM server
  - 'Port' (QOEPort) - defines the port of the SEM server
  - 'Interface Name' (QOEInterfaceName) - defines the device's IP network interface on which the SEM reports are sent
  - 'Use Mos LQ' (QOEUseMosLQ) - defines the reported MOS type (listening or conversational)
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 18.9 Configuring Media Security

The device supports Secured RTP (SRTP) according to RFC 3711. SRTP is used to encrypt RTP and RTCP transport for protecting VoIP traffic. SRTP requires a key exchange mechanism that is performed according to RFC 4568 – “Session Description Protocol (SDP) Security Descriptions for Media Streams”. The key exchange is done by adding a 'crypto' attribute to the SDP. This attribute is used (by both sides) to declare the various supported cipher suites and to attach the encryption key. If negotiation of the encryption data is successful, the call is established.

SRTP supports the following cipher suites (all other suites are ignored):

- AES\_CM\_128\_HMAC\_SHA1\_32
- AES\_CM\_128\_HMAC\_SHA1\_80
- ARIA\_CM\_128\_HMAC\_SHA1\_80
- ARIA\_CM\_192\_HMAC\_SHA1\_80

When the device is the offering side, it generates an MKI of a size configured by the 'Master Key Identifier (MKI) Size' parameter. The length of the MKI is limited to four bytes. If the remote side sends a longer MKI, the key is ignored. The key lifetime field is not supported. However, if it is included in the key it is ignored and the call does not fail.

The device supports the following session parameters (as defined in RFC 4568, SDP Security Descriptions for Media Streams):

- UNENCRYPTED\_SRTP
- UNENCRYPTED\_SRTCP
- UNAUTHENTICATED\_SRTP

Session parameters should be the same for the local and remote sides. When the device is the offering side, the session parameters are configured by the following parameter - 'Authentication On Transmitted RTP Packets', 'Encryption On Transmitted RTP Packets', and 'Encryption On Transmitted RTCP Packets'. When the device is the answering side, the device adjusts these parameters according to the remote offering. Unsupported session parameters are ignored, and do not cause a call failure.

Below is an example of crypto attributes usage:

```
a=crypto:1 AES_CM_128_HMAC_SHA1_80
inline:PsKoMpHlCg+b5X0YLuSvNrImEh/dAe
a=crypto:2 AES_CM_128_HMAC_SHA1_32
inline:IsPtLoGkBf9a+c6XVzRuMqHlDnEiAd
```

The device also supports symmetric MKI negotiation, whereby it can be configured to forward the MKI size received in the SDP offer crypto line in the SDP answer crypto line.

To configure the device's mode of operation if negotiation of the cipher suite fails, use the 'Media Security Behavior' parameter. This parameter can be set to enforce SRTP, whereby incoming calls that don't include encryption information are rejected.

### Notes:

- For a detailed description of the SRTP parameters, see SRTP Parameters on page 681.
- When SRTP is used, the channel capacity may be reduced.

➤ **To configure media security:**

1. Open the Media Security page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Media Security**).

**Figure 18-14: Media Security Page**

| ▼ General Media Security Settings         |                                     |   |
|-------------------------------------------|-------------------------------------|---|
| ⚡ Media Security                          | Disable                             | ▼ |

| CIPHER SUITES ARIA CM 192 HMAC SHA1 80    | <input checked="" type="checkbox"/> |   |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## Reader's Notes

## 19 Services

This section describes configuration for various supported services.

### 19.1 Routing Based on LDAP Active Directory Queries

The device supports Lightweight Directory Access Protocol (LDAP), enabling call routing decisions based on information stored on a third-party LDAP server (or Microsoft's Active Directory™ enterprise directory server). This feature enables the usage of a single common, popular database to manage and maintain information regarding user's availability, presence, and location.

#### 19.1.1 Configuring the LDAP Server

The basic LDAP mechanism is described below:

- **Connection:** The device connects and binds to the remote LDAP server either during the service's initialization (at device start-up) or whenever the LDAP server's IP address and port is changed. Service makes 10 attempts to connect and bind to the remote LDAP server with a timeout of 20 seconds between attempts. If connection fails, the service remains in disconnected state until either the LDAP server's IP address or port is changed.

If connection to the LDAP server later fails, the service attempts to reconnect, as described previously. The SNMP alarm `acLDAPLostConnection` is sent when connection is broken. Upon successful reconnection, the alarm is cleared.

Binding to the LDAP server can be anonymous or not. For anonymous binding, the `LDAPBindDN` and `LDAPPassword` parameters must not be defined or set to an empty string.

The address of the LDAP server can be a DNS name / FQDN configured by the `LDAPServerDomainName` parameter, or an IP address configured by the `LDAPServerIP` parameter.

**Note:** If you configure an FQDN, make sure that the `LDAPServerIP` parameter is left empty.

- **Search:** For the device to run a search using the LDAP service, the path to the directory's subtree (or DN) where the search is to be done must be configured using the `LDAPSearchDN` parameter. Up to three DNs can be configured. The search key, or *filter* in LDAP references, which defines the exact DN to be found and one or more attributes whose values should be returned, must also be defined.

If connection to the LDAP server is disrupted during the search, all search requests are dropped and an alarm indicating a failed status is sent to client applications.

The LDAP Settings page is used for configuring the LDAP server parameters. For a full description of these parameters, see 'Configuration Parameters Reference' on page [655](#).

➤ **To configure the LDAP server parameters:**

1. Open the LDAP Settings page (**Configuration** tab > **VoIP** menu > **Services** submenu > **LDAP Settings**).

**Figure 19-1: LDAP Settings Page**

|                              |                   |
|------------------------------|-------------------|
| LDAP Server Status           | Connection Broken |
| LDAP Service                 | Disable           |
| LDAP Server IP               | 0.0.0.0           |
| LDAP Server Port             | 389               |
| LDAP Server Max Respond Time | 3000              |
| LDAP Server Domain Name      |                   |
| LDAP Search Dn               |                   |
| LDAP Password                | .....             |
| LDAP Bind DN                 |                   |

The read-only 'LDAP Server Status' field displays one of the following possibilities:

- "Not Applicable"
  - "Connection Broken"
  - "Connecting"
  - "Connected"
2. Configure the parameters as required.
  3. Click **Submit** to apply your changes.
  4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 19.1.2 Configuring the Device's LDAP Cache

The device provides an option for storing recent LDAP queries and responses in its local cache. The cache is used for subsequent queries and/or in case of LDAP server failure. The advantage of enabling this feature includes the following:

- Improves routing decision performance by using local cache for subsequent LDAP queries
- Reduces number of queries performed on an LDAP server and corresponding bandwidth consumption
- Provides partial survivability in case of intermittent LDAP server failure (or network isolation)

The handling of LDAP queries with the LDAP cache is shown in the flowchart below:

**Figure 19-2: LDAP Query Process with Local LDAP Cache**

The LDAP Settings page is used for configuring the LDAP cache parameters.

**Notes:**

- The LDAP cache parameters are available only if you have enabled the LDAP service (see 'Configuring the LDAP Server' on page 179).
- If on the first LDAP query, the result fails for at least one attribute and is successful for at least one, the partial result is cached. However, for subsequent queries, the device does not use the partially cached result, but does a new query with the LDAP server again.
- For a full description of the cache parameters, see 'Configuration Parameters Reference' on page 655.

➤ **To configure the LDAP cache parameters:**

1. Open the LDAP Settings page (**Configuration** tab > **VoIP** menu > **Services** submenu > **LDAP Settings**).

**Figure 19-3: LDAP Settings Page - Cache Parameters**

|                                  |                                          |
|----------------------------------|------------------------------------------|
| LDAP Cache                       |                                          |
| LDAP Cache Service               | Enable                                   |
| LDAP Cache Entry Timeout         | 1200                                     |
| LDAP Cache Entry Removal Timeout | 0                                        |
| LDAP Cache Actions               |                                          |
| LDAP Refresh Cache By Key        | <input type="text"/>                     |
|                                  | <input type="button" value="Refresh"/>   |
| LDAP Clear All Cache             | <input type="button" value="Clear All"/> |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

The LDAP Settings page also provides you with the following buttons:

- **LDAP Refresh Cache By Key:** Refreshes a saved LDAP entry response in the cache of a specified LDAP search key. If a request with the specified key exists in the cache, the request is resent to the LDAP server.
- **LDAP Clear All Cache:** Removes all LDAP entries in the cache.

### 19.1.3 Active Directory based Tel-to-IP Routing for Microsoft Lync

Typically, enterprises wishing to deploy Microsoft® Lync™ Server 2010 (formerly known as Office Communication Server 2007) are faced with a complex, call routing dial plan when migrating users from their existing PBX or IP PBX to the Lync Server 2010 platform. As more and more end-users migrate to the new voice system, dialing plan management and PBX link capacity can be adversely impacted. To resolve this issue, enterprises can employ Microsoft's Active Directory (AD), which provides a central database to manage and maintain information regarding user's availability, presence, and location.

The device supports Tel-to-IP call routing decisions based on information stored on the AD. Based on queries sent to the AD, the device can route the Tel call to one of the following IP domains:

- Lync client (formally OCS) - users connected to Lync Server 2010 through the Mediation Server
- PBX or IP PBX - users not yet migrated to Lync Server 2010
- Mobile - mobile number
- Private - private telephone line for Lync users (in addition to the primary telephone line)

#### 19.1.3.1 Querying the AD and Routing Priority

The device queries the AD using the initial destination number (i.e., called number). The query can return up to four user phone numbers, each pertaining to one of the IP domains (i.e., private number, Lync / OCS number, PBX / IP PBX number, and mobile number). The configuration parameters listed in the table below are used to configure the query attribute keys that defines the AD attribute that you wish to query in the AD:

## Parameters for Configuring Query Attribute Key

| Parameter                            | Queried User Domain (Attribute) in AD                                                                                    | Query or Query Result Example        |
|--------------------------------------|--------------------------------------------------------------------------------------------------------------------------|--------------------------------------|
| <b>MSLDAPPBXNumAttributeName</b>     | PBX or IP PBX number (e.g., "telephoneNumber" - default)                                                                 | telephoneNumber=+3233554447          |
| <b>MSLDAPOCSNumAttributeName</b>     | Mediation Server / Lync client number (e.g., "msRTCSIP-line")                                                            | msRTCSIP-line=john.smith@company.com |
| <b>MSLDAPMobileNumAttributeName</b>  | Mobile number (e.g., "mobile")                                                                                           | mobile=+3247647156                   |
| <b>MSLDAPPrivateNumAttributeName</b> | Any attribute (e.g., "msRTCSIP-PrivateLine")<br><b>Note:</b> Used only if set to same value as Primary or Secondary key. | msRTCSIP-PrivateLine=+3233554480     |
| <b>MSLDAPPrimaryKey</b>              | Primary Key query search instead of PBX key - can be any AD attribute                                                    | msRTCSIP-PrivateLine=+3233554480     |
| <b>MSLDAPSecondaryKey</b>            | Secondary Key query key search if Primary Key fails - can be any attribute                                               | -                                    |

The process for querying the AD and subsequent routing based on the query results is as follows:

1. If the Primary Key is configured, it uses the defined string as a primary key instead of the one defined in MSLDAPPBXNumAttributeName. It requests the attributes which are described below.
2. If the primary query is not found in the AD and the Secondary Key is configured, it does a second query for the destination number using a second AD attribute key name, configured by the MSLDAPSecondaryKey parameter.
3. If none of the queries are successful, it routes the call to the original dialed destination number according to the routing rule matching the "LDAP\_ERR" destination prefix number value, or rejects the call with a SIP 404 "Not Found" response.
4. For each query (primary or secondary), it requests to query the following attributes (if they're not configured as an empty string):
  - MSLDAPPBXNumAttributeName
  - MSLDAPOCSNumAttributeName
  - MSLDAPMobileNumAttributeName

In addition, it queries the special attribute defined in MSLDAPPrivateNumAttributeName, only if the query key (primary or secondary) is equal to its value.
5. If the query is found: The AD returns up to four attributes - Lync / OCS, PBX / IP PBX, private (only if it equals Primary or Secondary key), and mobile.
6. The device adds unique prefix keywords to the query results in order to identify the query type (i.e., IP domain). These prefixes are used as the prefix destination number value in the Outbound IP Routing table to denote the IP domains:
  - "PRIVATE" (PRIVATE:<private\_number>): used to match a routing rule based on query results of the private number (MSLDAPPrivateNumAttributeName)
  - "OCS" (OCS:<Lync\_number>): used to match a routing rule based on query results of the Lync client number (MSLDAPOCSNumAttributeName)

- "PBX" (PBX:<PBX\_number>): used to match a routing rule based on query results of the PBX / IP PBX number (MSLDAPPBXNumAttributeName)
- "MOBILE" (MOBILE:<mobile\_number>): used to match a routing rule based on query results of the mobile number (MSLDAPMobileNumAttributeName)
- "LDAP\_ERR": used to match a routing rule based on a failed query result when no attribute is found in the AD

**Note:** These prefixes are involved only in the routing and manipulation processes; they are not used as the final destination number.

7. The device uses the Outbound IP Routing table to route the call based on the LDAP query result. The device routes the call according to the following priority:
  6. **Private line:** If the query is done for the private attribute and it's found, then the device routes the call according to this attribute.
  7. **Mediation Server SIP address (Lync / OCS):** If the private attribute does not exist or is not queried, then the device routes the call to the Mediation Server (which then routes the call to the Lync client).
  8. **PBX / IP PBX:** If the Lync / OCS client is not found in the AD, it routes the call to the PBX / IP PBX.
  9. **Mobile number:** If the Lync / OCS client (or Mediation Server) is unavailable (e.g., SIP response 404 "Not Found" upon INVITE sent to Lync client), and the PBX / IP PBX is also unavailable, then the device routes the call to the user's mobile number (if exists in the AD).
  10. **Alternative route:** If the call routing to all the above fails (e.g., due to unavailable destination - call busy), the device can route the call to an alternative destination if an alternative routing rule is configured.
  11. **"Redundant" route:** If the query failed (i.e., no attribute found in the AD), the device uses the routing rule matching the "LDAP\_ERR" prefix destination number value.

**Note:** For Enterprises implementing a PBX / IP PBX system, but yet to migrate to Lync Server 2010, if the PBX / IP PBX system is unavailable or has failed, the device uses the AD query result for the user's mobile phone number, routing the call through the PSTN to the mobile destination.

The flowchart below summarizes the device's process for querying the AD and routing the call based on the query results:

**Figure 19-4: LDAP Query Flowchart**

**Note:** If you are using the device's local LDAP cache, see 'Configuring the Device's LDAP Cache' on page 180 for the LDAP query process.

### 19.1.3.2 Configuring AD-Based Routing Rules

The procedure below describes how to configure Tel-to-IP routing based on LDAP queries.

➤ **To configure LDAP-based Tel-to-IP routing for Lync Server 2010:**

1. Configure the LDAP server parameters, as described in 'Configuring the LDAP Server' on page 179.
2. Configure the AD attribute names used in the LDAP query:
  - a. Open the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **Advanced Parameters**).

**Figure 19-5: LDAP Parameters for Microsoft Lync Server 2010**

| MS LDAP Settings                     |                             |
|--------------------------------------|-----------------------------|
| MS LDAP OCS Number attribute name    | msRTCSIP-PrimaryUserAddress |
| MS LDAP PBX Number attribute name    | telephoneNumber             |
| MS LDAP MOBILE Number attribute name | mobile                      |

- b. Configure the LDAP attribute names as desired.
3. For the Gateway/IP-to-IP application: Configure AD-based Tel-to-IP routing rules:
  - a. Open the Outbound IP Routing Table page (Configuration tab > VoIP menu > GW and IP to IP submenu > Routing > Tel to IP Routing). For more information, see Configuring Outbound IP Routing Table on page 321.
  - b. Configure query-result routing rules for each IP domain (private, PBX / IP PBX, Lync / OCS clients, and mobile), using the LDAP keywords (case-sensitive) for the prefix destination number:
    - ◆ PRIVATE: Private number
    - ◆ OCS: Lync / OCS client number
    - ◆ PBX: PBX / IP PBX number
    - ◆ MOBILE: Mobile number
    - ◆ LDAP\_ERR: LDAP query failure
  - c. Configure a routing rule for routing the initial Tel call to the LDAP server, using the value "LDAP" for denoting the IP address of the LDAP server.
  - d. For alternative routing, enable the alternative routing mechanism and configure corresponding SIP reasons for alternative routing. For this feature, alternative routing starts from the table row located under the LDAP query row.
4. For the SBC application: Configure AD-based IP-to-IP routing rules:
  - a. Open the IP-to-IP Routing Table page (Configuration tab > VoIP menu > SBC submenu > Routing SBC > IP to IP Routing Table). For more information, see Configuring SBC IP-to-IP Routing on page 462.
  - b. Configure query-result routing rules for each IP domain (private, PBX / IP PBX, Lync / OCS clients, and mobile), using the LDAP keywords (case-sensitive) in the Destination Username Prefix field:
    - ◆ PRIVATE: Private number
    - ◆ OCS: Lync / OCS client number
    - ◆ PBX: PBX / IP PBX number
    - ◆ MOBILE: Mobile number
    - ◆ LDAP\_ERR: LDAP query failure

- c. Configure a routing rule for routing the initial call (LDAP query) to the LDAP server, by setting the 'Destination Type' field to LDAP for denoting the IP address of the LDAP server.
- d. For alternative routing, enable the alternative routing mechanism and configure corresponding SIP reasons for alternative routing. For this feature, alternative routing starts from the table row located under the LDAP query row.

The table below shows an example for configuring AD-based Tel-to-IP routing rules in the Outbound IP Routing Table:

#### AD-Based Tel-to-IP Routing Rule Configuration Examples

| Index | Dest. Phone Prefix | Dest. IP Address |
|-------|--------------------|------------------|
| 1     | PRIVATE:           | 10.33.45.60      |
| 2     | PBX:               | 10.33.45.65      |
| 3     | OCS:               | 10.33.45.68      |
| 4     | MOBILE:            | 10.33.45.100     |
| 5     | LDAP_ERR           | 10.33.45.80      |
| 6     | *                  | LDAP             |
| 7     | *                  | 10.33.45.72      |

The table below shows an example for configuring AD-based SBC routing rules in the IP-to-IP Routing Table:

#### AD-Based SBC IP-to-IP Routing Rule Configuration Examples

| Index | Destination Username Prefix | Destination Type | Destination Address |
|-------|-----------------------------|------------------|---------------------|
| 1     | PRIVATE:                    | Dest Address     | 10.33.45.60         |
| 2     | PBX:                        | Dest Address     | 10.33.45.65         |
| 3     | OCS:                        | Dest Address     | 10.33.45.68         |
| 4     | MOBILE:                     | Dest Address     | 10.33.45.100        |
| 5     | LDAP_ERR                    | Dest Address     | 10.33.45.80         |
| 6     | *                           | LDAP             |                     |
| 7     | *                           | Dest Address     | 10.33.45.72         |

The configured routing rule example is explained below:

- **Rule 1:** Sends call to private telephone line (at 10.33.45.60) upon successful AD query result for the private attribute.
- **Rule 2:** Sends call to IP PBX (at 10.33.45.65) upon successful AD query result for the PBX attribute.
- **Rule 3:** Sends call to Lync client (i.e., Mediation Server at 10.33.45.68) upon successful AD query result for the Lync attribute.
- **Rule 4:** Sends call to user's mobile phone number (to PSTN through the device's IP address at 10.33.45.100) upon successful AD query result for the Mobile attribute.
- **Rule 5:** Sends call to IP address of device (10.33.45.80) if AD query failure (e.g., no response from LDAP server or attribute not found).

- **Rule 6:** Sends query for original destination number of received call to the LDAP server.
- **Rule 7:** Alternative routing rule that sends the call of original dialed number to IP destination 10.33.45.72. This rule is applied in any of the following cases
  - LDAP functionality is disabled.
  - LDAP query is successful but call fails (due to, for example, busy line) to all the relevant attribute destinations (private, Lync, PBX, and mobile), and a relevant Tel-to-IP Release Reason (see Alternative Routing for Tel-to-IP Calls on page 334) or SBC Alternative Routing Reason (see Configuring Alternative Routing Reasons on page 468) has been configured.

Once the device receives the original incoming call, the first rule that it uses is Rule 6, which queries the AD server. When the AD replies, the device searches the table, from the first rule down, for the matching destination phone prefix (i.e., "PRIVATE:", "PBX:", "OCS:", "MOBILE:", and "LDAP\_ERR:"), and then sends the call to the appropriate destination.

### 19.1.3.3 Querying the AD for Calling Name

The device can be configured to retrieve the calling name (display name) from Microsoft Active Directory (AD) for Tel-to-IP calls that are received without a calling name. The device queries the AD, based on the Calling Number search key and searches for the calling name attribute configured by the parameter, MSLDAPDisplayNameAttrName (e.g., "displayName"). The device uses the resultant calling name as the display name in the SIP From header of the sent INVITE message.

To configure this feature, the following keywords are used in the Calling Name Manipulation Table for Tel -> IP Calls table for the 'Prefix/Suffix to Add' fields, which can be combined with other characters:

- "\$LDAP-PBX": starts LDAP query using the MSLDAPPBXAttrName parameter as the search key
- "\$LDAP-MOBILE": starts LDAP query using MSLDAPMobileAttrName parameter as the search key

If the source (calling) number of the Tel-to-IP call matches the PBX / MOBILE (e.g., "telephoneNumber" and "mobile") number in the AD server, the device uses the resultant Display Name instead of the keyword(s).

For example, assume the following configuration in the Calling Name Manipulation Table for Tel -> IP Calls:

- 'Source Prefix' field is set to "4".
- 'Prefix to Add' field is set to "\$LDAP-PBX Office".

If the calling number is 4046 and the resultant LDAP query display name is "John Doe", the device sends the INVITE message with the following From header:

```
From: John Doe <sip:4064@company.com>\
```

#### Notes:

- The Calling Name Manipulation Table for Tel -> IP Calls table uses the numbers before manipulation, as inputs.
- The LDAP query uses the calling number after source number manipulation, as the search key value.

## 19.2 Least Cost Routing

This section provides a description of the device's least cost routing (LCR) feature and how to configure it.

### 19.2.1 Overview

The LCR feature enables the device to choose the outbound IP destination routing rule based on lowest call cost. This is useful in that it enables service providers to optimize routing costs for customers. For example, you may wish to define different call costs for local and international calls, or different call costs for weekends and weekdays (specifying even the time of call). The device sends the calculated cost of the call to a Syslog server (as Information messages), thereby enabling billing by third-party vendors.

LCR is implemented by defining Cost Groups and assigning them to routing rules in the Outbound IP Routing table. The device searches this routing table for matching routing rules, and then selects the rule with the lowest call cost. If two routing rules have identical costs, then the rule appearing higher up in the table is used (i.e., first-matched rule). If a selected route is unavailable, the device selects the next least-cost routing rule. However, even if a matched rule is not assigned a Cost Group, the device can select it as the preferred route over other matched rules with Cost Groups. This is determined according to the settings of the Default Cost parameter in the Routing Rule Groups table.

The Cost Group defines a fixed connection cost (*connection cost*) and a charge per minute (*minute cost*). Cost Groups can also be configured with time segments (*time bands*), which define connection cost and minute cost based on specific days of the week and time of day (e.g., from Saturday through Sunday, between 6:00 and 18:00). If multiple time bands are configured per Cost Group and a call spans multiple time bands, the call cost is calculated using only the time band in which the call was initially established.

In addition to Cost Groups, the device can calculate the call cost using an optional, user-defined average call duration value. The logic in using this option is that a Cost Group may be cheap if the call duration is short, but due to its high minute cost, may prove very expensive if the duration is lengthy. Thus, together with Cost Groups, the device can use this option to determine least cost routing. The device calculates the Cost Group call cost as follows: Total Call Cost = Connection Cost + (Minute Cost \* Average Call Duration).

The below table shows an example of call cost when taking into consideration call duration. This example shows four defined Cost Groups and the total call cost if the average call duration is 10 minutes:

**Call Cost Comparison between Cost Groups for different Call Durations**

| Cost Group | Connection Cost | Minute Cost | Total Call Cost per Duration |            |
|------------|-----------------|-------------|------------------------------|------------|
|            |                 |             | 1 Minute                     | 10 Minutes |
| <b>A</b>   | 1               | 6           | 7                            | 61         |
| <b>B</b>   | 0               | 10          | 10                           | 100        |
| <b>C</b>   | 0.3             | 8           | 8.3                          | 80.3       |
| <b>D</b>   | 6               | 1           | 7                            | <b>16</b>  |

If four matching routing rules are located in the routing table and each one is assigned a different Cost Group as listed in the table above, then the rule assigned Cost Group "D" is selected. Note that for one minute, Cost Groups "A" and "D" are identical, but due to the average call duration, Cost Group "D" is cheaper. Therefore, average call duration is an important factor in determining the cheapest routing role.

Below are a few examples of how you can implement LCR:

- **Example 1:** This example uses two different Cost Groups for routing local calls and international calls:

Two Cost Groups are configured as shown below:

| Cost Group               | Connection Cost | Minute Cost |
|--------------------------|-----------------|-------------|
| 1. "Local Calls"         | 2               | 1           |
| 2. "International Calls" | 6               | 3           |

The Cost Groups are assigned to routing rules for local and international calls in the Outbound IP Routing table:

| Routing Index | Dest Phone Prefix | Destination IP | Cost Group ID           |
|---------------|-------------------|----------------|-------------------------|
| 1             | 2000              | x.x.x.x        | 1 "Local Calls"         |
| 2             | 00                | x.x.x.x        | 2 "International Calls" |

- **Example 2:** This example shows how the device determines the cheapest routing rule in the Outbound IP Routing table:

The Default Cost parameter (global) in the Routing Rule Groups table is set to **Min**, meaning that if the device locates other matching LCR routing rules (with Cost Groups assigned), the routing rule without a Cost Group is considered the lowest cost route.

- The following Cost Groups are configured:

| Cost Group | Connection Cost | Minute Cost |
|------------|-----------------|-------------|
| 1. "A"     | 2               | 1           |
| 2. "B"     | 6               | 3           |

- The Cost Groups are assigned to routing rules in the Outbound IP Routing table:

| Routing Index | Dest Phone Prefix | Destination IP | Cost Group ID |
|---------------|-------------------|----------------|---------------|
| 1             | 201               | x.x.x.x        | "A"           |
| 2             | 201               | x.x.x.x        | "B"           |
| 3             | 201               | x.x.x.x        | 0             |
| 4             | 201               | x.x.x.x        | "B"           |

The device calculates the optimal route in the following index order: 3, 1, 2, and then 4, due to the following logic:

- Index 1 - Cost Group "A" has the lowest connection cost and minute cost
- Index 2 - Cost Group "B" takes precedence over Index 4 entry based on the first-matched method rule
- Index 3 - no Cost Group is assigned, but as the Default Cost parameter is set to **Min**, it is selected as the cheapest route
- Index 4 - Cost Group "B" is only second-matched rule (Index 1 is the first)

- **Example 3:** This example shows how the cost of a call is calculated if the call spans over multiple time bands:

Assume a Cost Group, "CG Local" is configured with two time bands, as shown below:

| Cost Group | Time Band | Start Time | End Time | Connection Cost | Minute Cost |
|------------|-----------|------------|----------|-----------------|-------------|
| CG Local   | TB1       | 16:00      | 17:00    | 2               | 1           |
|            | TB2       | 17:00      | 18:00    | 7               | 2           |

Assume that the call duration is 10 minutes, occurring between 16:55 and 17:05. In other words, the first 5 minutes occurs in time band "TB1" and the next 5 minutes occurs in "TB2", as shown below:

**Figure 19-6: LCR using Multiple Time Bands (Example)**

The device calculates the call using the time band in which the call was initially established, regardless of whether the call spans over additional time bands:

**Total call cost** = "TB1" Connection Cost + ("TB1" Minute Cost x call duration) = 2 + 1 x 10 min = 12

## 19.2.2 Configuring LCR

The following main steps need to be done to configure LCR:

1. Enable the LCR feature and configure the average call duration and default call connection cost - see 'Enabling LCR and Configuring Default LCR' on page 191.
2. Configure Cost Groups - see 'Configuring Cost Groups' on page 193.
3. Configure Time Bands for a Cost Group - see 'Configuring Time Bands for Cost Groups' on page 194.
4. Assign Cost Groups to outbound IP routing rules - see 'Assigning Cost Groups to Routing Rules' on page 196.

### 19.2.2.1 Enabling the LCR Feature

The procedure below describes how to enable the LCR feature. This also includes configuring the average call duration and default call cost for routing rules that are not assigned Cost Groups in the Outbound IP Routing table.

**Note:** The Routing Rule Groups table can also be configured using the table ini file parameter, RoutingRuleGroups or CLI command, configure voip > services least-cost-routing routing-rule-groups.

➤ **To enable LCR:**

1. Open the Routing Rule Groups Table page (**Configuration** tab > **VoIP** menu > **Services** submenu > **Least Cost Routing** > **Routing Rule Groups Table**).
2. Click the **Add** button; the Add Record dialog box appears:

**Figure 19-7: Routing Rule Groups Table - Add Record**

3. Configure the parameters as required. For a description of the parameters, see the table below.
4. Click **Submit**; the entry is added to the Routing Rule Groups table.

**Routing Rule Groups Table Description**

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>[RoutingRuleGroups_Index]                                                  | Defines the table index entry.<br><b>Note:</b> Only one index entry can be configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| LCR Enable<br>CLI: lcr-enable<br>[RoutingRuleGroups_LCREnable]                      | Enables the LCR feature: <ul style="list-style-type: none"> <li>▪ [0] Disabled (default)</li> <li>▪ [1] Enabled</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| LCR Call Length<br>CLI: lcr-call-length<br>[RoutingRuleGroups_LCRAverageCallLength] | Defines the average call duration (in minutes) and is used to calculate the variable portion of the call cost. This is useful, for example, when the average call duration spans over multiple time bands. The LCR is calculated as follows: cost = call connect cost + (minute cost * average call duration)<br>The valid value range is 0-65533. the default is 1.<br>For example, assume the following Cost Groups: <ul style="list-style-type: none"> <li>▪ "Weekend A": call connection cost is 1 and charge per minute is 6. Therefore, a call of 1 minute cost 7 units.</li> <li>▪ "Weekend_B": call connection cost is 6 and charge per minute is 1. Therefore, a call of 1 minute cost 7 units.</li> </ul> Therefore, for calls under one minute, "Weekend A" carries the lower cost. However, if the average call duration is more than one minute, then "Weekend B" carries the lower cost. |

| Parameter                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Default Cost<br>CLI: lcr-default-cost<br>[RoutingRuleGroups_LCRDefaultCost] | <p>Determines whether routing rules in the Outbound IP Routing table without an assigned Cost Group are considered a higher cost or lower cost route compared to other matched routing rules that are assigned Cost Groups.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Lowest Cost = If the device locates other matching LCR routing rules, this routing rule is considered the lowest cost route and therefore, it is selected as the route to use (default.)</li> <li>▪ <b>[1]</b> Highest Cost = If the device locates other matching LCR routing rules, this routing rule is considered as the highest cost route and therefore, is not used or used only if the other cheaper routes are unavailable.</li> </ul> <p><b>Note:</b> If more than one valid routing rule without a defined Cost Group exists, the device selects the first-matched rule.</p> |

### 19.2.2.2 Configuring Cost Groups

The procedure below describes how to configure Cost Groups. Cost Groups are defined with a fixed call connection cost and a call rate (charge per minute). Once configured, you can configure Time Bands for each Cost Group. Up to 10 Cost Groups can be configured.

**Note:** The Cost Group table can also be configured using the table ini file parameter, CostGroupTable or CLI command, configure voip > services least-cost-routing cost-group.

➤ **To configure Cost Groups:**

1. Open the Cost Group Table page (**Configuration** tab > **VoIP** menu > **Services** submenu > **Least Cost Routing** > **Cost Group Table**).
2. Click the **Add** button; the Add Record dialog box appears:

3. Configure the parameters as required. For a description of the parameters, see the table below.
4. Click **Submit**; the entry is added to the Cost Group table.

#### Cost Group Table Description

| Parameter                       | Description                    |
|---------------------------------|--------------------------------|
| Index<br>[CostGroupTable_Index] | Defines the table index entry. |

| Parameter                                                                                             | Description                                                                                                                                                                                                                                                                                                                                               |
|-------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cost Group Name<br>CLI: cost-group-name<br><b>[CostGroupTable_CostGroupName]</b>                      | Defines an arbitrary name for the Cost Group.<br>The valid value is a string of up to 30 characters.<br><b>Note:</b> Each Cost Group must have a unique name.                                                                                                                                                                                             |
| Default Connect Cost<br>CLI: default-connection-cost<br><b>[CostGroupTable_DefaultConnectionCost]</b> | Defines the call connection cost (added as a fixed charge to the call) for a call outside the time bands.<br>The valid value range is 0-65533. The default is 0.<br><b>Note:</b> When calculating the cost of a call, if the current time of the call is not within a time band configured for the Cost Group, then this default connection cost is used. |
| Default Time Cost<br>CLI: default-minute-cost<br><b>[CostGroupTable_DefaultMinuteCost]</b>            | Defines the call charge per minute for a call outside the time bands.<br>The valid value range is 0-65533. The default is 0.<br><b>Note:</b> When calculating the cost of a call, if the current time of the call is not within a time band configured for the Cost Group, then this default charge per minute is used.                                   |

### 19.2.2.3 Configuring Time Bands for Cost Groups

The procedure below describes how to configure Time Bands for a Cost Group. The time band defines the day and time range for which the time band is applicable (e.g., from Saturday 05:00 to Sunday 24:00) as well as the fixed call connection charge and call rate per minute for this interval. Up to 70 time bands can be configured, and up to 21 time bands can be assigned to each Cost Group.

#### Notes:

- You cannot define overlapping time bands.
- The Time Band table can also be configured using the table ini file parameter, CostGroupTimebands or CLI command, configure voip >services least-cost-routing cost-group-time-bands.

➤ **To configure Time Bands for a Cost Group:**

1. Open the Cost Group Table page (**Configuration** tab > **VoIP** menu > **Services** submenu > **Least Cost Routing** > **Cost Group Table**).
2. Select a Cost Group for which you want to assign Time Bands, and then click the **Time Band** link located below the table; the Time Band table for the selected Cost Group appears.
3. Click the **Add** button; the Add Record dialog box appears:

4. Configure the parameters as required. For a description of the parameters, see the table below.
5. Click **Submit**; the entry is added to the Time Band table for the relevant Cost Group.

**Time Band Table Description**

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>CLI: timeband-index<br>[CostGroupTimebands<br>_TimebandIndex]             | Defines the table index entry.                                                                                                                                                                                                                                                                                                             |
| Start Time<br>CLI: start-time<br>[CostGroupTimebands<br>_StartTime]                | Defines the day and time of day from when this time band is applicable. The format is ddd:hh:mm (e.g., sun:06:00), where: <ul style="list-style-type: none"> <li>ddd is the day (i.e., sun, mon, tue, wed, thu, fri, or sat)</li> <li>hh and mm denote the time of day, where hh is the hour (00-23) and mm the minutes (00-59)</li> </ul> |
| End Time<br>CLI: end-time<br>[CostGroupTimebands<br>_EndTime]                      | Defines the day and time of day until when this time band is applicable. For a description of the valid values, see the parameter above.                                                                                                                                                                                                   |
| Connection Cost<br>CLI: connection-cost<br>[CostGroupTimebands<br>_ConnectionCost] | Defines the call connection cost during this time band. This is added as a fixed charge to the call.<br>The valid value range is 0-65533. The default is 0.<br><b>Note:</b> The entered value must be a whole number (i.e., not a decimal).                                                                                                |
| Minute Cost<br>CLI: minute-cost<br>[CostGroupTimebands<br>_MinuteCost]             | Defines the call cost per minute charge during this timeband.<br>The valid value range is 0-65533. The default is 0.<br><b>Note:</b> The entered value must be a whole number (i.e., not a decimal).                                                                                                                                       |

#### 19.2.2.4 Assigning Cost Groups to Routing Rules

Once you have configured your Cost Groups, you need to assign them to routing rules:

- Gateway/IP-to-IP application: Outbound IP Routing table - see Configuring Outbound IP Routing Table on page [321](#)
- SBC application: IP-to-IP Routing table - see Configuring SBC IP-to-IP Routing on page [462](#)

## 20 Enabling Applications

The device supports the following main applications:

- Stand-Alone Survivability (SAS) application (see SAS Overview on page 489)
- Session Border Control (SBC) application (see SBC Overview on page 419)
- Cloud Resilience Package (see CRP Overview on page 481)
- IP-to-IP application (see IP-to-IP Routing Overview on page 253)

The procedure below describes how to enable these applications. Once an application is enabled, the Web GUI provides menus and parameter fields relevant to the application.

### Notes:

- This page displays the application only if the device is installed with the relevant Software License Key supporting the application (see 'Software License Key' on page 553).
- For enabling an application, a device reset is required.
- In some Web pages, the Gateway and IP-to-IP applications are denoted as "GW" and "IP2IP" respectively.

### ➤ To enable an application:

1. Open the Applications Enabling page (**Configuration** tab > **VoIP** menu > **Applications Enabling** submenu > **Applications Enabling**).

|                        |        |
|------------------------|--------|
| ⚡ SAS Application      | Enable |
| ⚡ SBC Application      | Enable |
| ⚡ IP to IP Application | Enable |

2. From the relevant application drop-down list, select **Enable**.
3. Save (burn) the changes to the device's flash memory with a device reset (see 'Saving Configuration' on page 532).

## Reader's Notes

## 21 Control Network

This section describes configuration of the network at the SIP control level.

### 21.1 Configuring SRD Table

The SRD Settings page allows you to configure up to 32 signaling routing domains (SRD). An SRD is configured with a unique name and assigned a Media Realm. Additional SBC attributes such as media anchoring and user registration can also be configured.

An SRD is a set of definitions together creating multiple, virtual multi-service IP gateways:

- Multiple and different SIP signaling interfaces (SRD associated with a SIP Interface) and RTP media (associated with a Media Realm) for multiple Layer-3 networks. Due to the B2BUA nature of the SBC application, different interfaces can be assigned to each leg of the call, and between the LAN and WAN side.
- Can operate with multiple gateway customers that may reside either in the same or in different Layer-3 networks as the device. This allows separation of signaling traffic between different customers. In such a scenario, the device is configured with multiple SRD's.

Typically, one SRD is defined for each group of SIP UAs (e.g. proxies, IP phones, application servers, gateways, and softswitches) that communicate with each other. This provides these entities with VoIP services that reside on the same Layer-3 network (must be able to communicate without traversing NAT devices and must not have overlapping IP addresses). One SRD is generally configured for the LAN and one for the WAN. Routing from one SRD to another is possible, whereby each routing destination (IP Group or destination address) indicates the SRD to which it belongs.

Once configured, you can use the SRD as follows:

- Associate it with a SIP Interface (see 'Configuring SIP Interface Table' on page 201)
- Associate it with an IP Group (see 'Configuring IP Groups' on page 204)
- Associate it with a Proxy Set (see 'Configuring Proxy Sets Table' on page 213)
- Apply an Admission Control rule to it (see 'Configuring Admission Control Table' on page 452)
- Define it as a Classification rule for the incoming SIP request (see 'Configuring Classification Rules' on page 456)
- Use it as a destination IP-to-IP routing rule (see 'Configuring SBC IP-to-IP Routing' on page 462)

The SRD Settings page also displays the IP Groups, Proxy Sets, and SIP Interfaces associated with a selected SRD index.

#### Notes:

- On the SRD Settings page, you can also configure a SIP Interface in the SIP Interface table, instead of navigating to the SIP Interface Table page as described in 'Configuring SIP Interface Table' on page 201.
- The SRD table can also be configured using the table ini file parameter, SRD or CLI command, `configure voip > control-network srd`.

➤ **To configure SRDs:**

1. Open the SRD Settings page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **SRD Table**).

**Figure 21-1: SRD Settings Page**

|                                       |                      |
|---------------------------------------|----------------------|
| ▼                                     |                      |
| SRD Index                             | 0 - Not Exist ▼      |
| ▼ Common Parameters                   |                      |
| SRD Name                              | <input type="text"/> |
| Media Realm                           | <input type="text"/> |
| ▼ SBC Parameters                      |                      |
| Internal SRD Media Anchoring          | Anchor Media ▼       |
| Block Unregistered Users              | No ▼                 |
| Max Number Of Registered Users        | -1                   |
| Enable Un-Authenticated Registrations | Yes ▼                |

2. From the 'SRD Index' drop-down list, select an index for the SRD, and then configure it according to the table below.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**SRD Table Parameters**

| Parameter                                                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## 21.2 Configuring SIP Interface Table

The SIP Interface table allows you to configure up to 32 SIP Interfaces. The SIP Interface defines a listening port and type (UDP, TCP, or TLS) for SIP signaling traffic on a specific logical IP network interface configured for the device (in the Multiple Interface table).

The SIP Interface is configured for a specific application (i.e., Gateway/IP-to-IP, SAS, and SBC) and associated with an SRD. For each SIP Interface, you can assign a SIP message policy, enable TLS mutual authentication, enable TCP keepalive, and determine the SIP response sent upon classification failure.

SIP Interfaces can be used, for example, for the following:

- Using SIP signaling interfaces per call leg (i.e., each SIP entity communicates with a specific SRD).
- Using different SIP listening ports for a single or for multiple IP network interfaces.

- Differentiating between applications by creating SIP Interfaces per application.
- Separating signaling traffic between networks (e.g., different customers) to use different routing tables, manipulations, SIP definitions, and so on.

**Note:** The SIP Interface table can also be configured using the table *ini* file parameter, SIPInterface or the CLI command, configure voip > control-network sip-interface.

➤ **To configure the SIP Interface table:**

1. Open the SIP Interface Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **SIP Interface Table**).
2. Click the **Add** button; the following dialog box appears:

3. Click **Submit** to apply your settings.

#### SIP Interface Table Parameters

| Parameter                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Network Interface<br><b>[SIPInterface_NetworkInterface]</b><br>CLI: network-interface | <p>Defines the Control-type IP network interface that you want to associate with the SIP Interface. This value string must be identical (including case-sensitive) to that configured in the 'Interface Name' field of the Multiple Interface table (see 'Configuring IP Network Interfaces' on page 107).</p> <p>The default is not configured.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ SIP Interfaces that are assigned to a specific SRD must be defined with the same network interface. For example, if you define three SIP Interfaces for SRD ID #8, all these SIP Interfaces must be defined with the same network interface (e.g., "SIP1").</li> <li>■ To create a SIP interface on the WAN interface, enter the string "WAN". This WAN interface is selected in the Multiple Interface table (or use the WANInterfaceName parameter), which is the WAN interface address. If VLANs are defined for the WAN interface and one of the VLANs is selected as the VoIP WAN interface, then the defined SIP Interface uses this interface.</li> </ul> |

| Parameter                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Classification Failure Response Type<br><b>[SIPInterface_ClassificationFailureResponseType]</b><br>CLI:<br>classification_fail_response_type | <p>Defines the SIP response code that the device sends if a received SIP request (OPTIONS, REGISTER, or INVITE) has failed the SBC classification process.</p> <p>The valid value can be a SIP response code from 400 through 699, or it can be set to 0 to not send any response at all. The default response code is 500 (Server Internal Error).</p> <p>This feature is important for preventing Denial of Service (DoS) attacks, typically initiated from the WAN. Malicious attackers can use SIP scanners to detect ports used by SIP devices. These scanners scan devices by sending UDP packets containing a SIP request to a range of specified IP addresses, listing those that return a valid SIP response. Once the scanner finds a device that supports SIP, it extracts information from the response and identifies the type of device (IP address and name) and can execute DoS attacks. A way to defend the device against such attacks is to not send a SIP reject response to these unclassified "calls" so that the attacker assumes that no device exists at such an IP address and port.</p> <p><b>Note:</b> This parameter is applicable only if the device is set to reject unclassified calls. This is configured using the 'Unclassified Calls' parameter on the General Settings page (<b>Configuration</b> tab &gt; <b>VoIP</b> menu &gt; <b>SBC</b> &gt; <b>General Settings</b>).</p> |

## 21.3 Configuring IP Groups

The IP Group Table page allows you to create up to 32 IP Groups. The IP Group represents a SIP entity on the network with which the device communicates. This can be a server (e.g., IP PBX or ITSP) or it can be a group of users (e.g., LAN IP phones). For servers, the IP Group is typically used to define the server's IP address by associating it with a Proxy Set (see 'Configuring Proxy Sets Table' on page 213).

For the SBC application, this table can also be used to classify incoming SIP dialog-initiating requests (e.g., INVITE messages) to specific IP Groups based on the associated Proxy Set ID. However, it is highly recommended to use the Classification table for classifying incoming SIP dialogs to the IP Groups (see 'Configuring Classification Rules' on page 456). See the 'Classify by Proxy Set' parameter below for a detailed description of this feature and for important recommendations.

For the SBC application, IP Groups are used for IP-to-IP routing rules where they represent the source and destination of the call (see 'Configuring SBC IP-to-IP Routing' on page 462).

For the Gateway/IP-to-IP application, IP Groups are used for the following:

- SIP dialog registration and authentication (digest user/password) of a specific IP Group (Served IP Group, e.g., corporate IP-PBX) with another IP Group (Serving IP Group, e.g., ITSP). This is configured in the Account table (see Configuring Account Table on page 219).

- Call routing rules:
  - Outgoing IP calls (IP-to-IP or Tel-to-IP): The IP Group identifies the source of the call and is used as the destination of the outgoing IP call (defined in the Outbound IP Routing Table). For Tel-to-IP calls, the IP Group (Serving IP Group) can be used as the IP destination to where all SIP dialogs that are initiated from a Trunk Group are sent (defined in Configuring Hunt Group Settings on page 291).
  - Incoming IP calls (IP-to-IP or IP-to-Tel): The IP Group identifies the source of the IP call.
  - Number Manipulation rules to IP: The IP Group is used to associate the rule with specific calls identified by IP Group.

**Notes:**

- IP Group ID 0 cannot be used. This IP Group is set to default values and is used by the device when IP Groups are not implemented.
- When operating with multiple IP Groups, the default Proxy server must not be used (i.e., the parameter IsProxyUsed must be set to 0).
- If different SRDs are configured in the IP Group and Proxy Set tables, the SRD defined for the Proxy Set takes precedence.
- You can also configure the IP Groups table using the table ini file parameter, IPGroup (see 'Configuration Parameters Reference' on page 655) or CLI command, configure voip > control- network ip-group.

➤ **To configure IP Groups:**

1. Open the IP Group Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **IP Group Table**).
2. Click the **Add** button: the following dialog box appears:

**Figure 21-2: IP Group Table - Add Dialog Box**

| Common                                                                      |        |
|-----------------------------------------------------------------------------|--------|
| Index                                                                       | 0      |
| Type                                                                        | Server |
| Description                                                                 |        |
| Proxy Set ID                                                                | -1     |
| SIP Group Name                                                              |        |
| Contact User                                                                |        |
| Local Host Name                                                             |        |
| SRD                                                                         | 0      |
| Media Realm Name                                                            |        |
| IP Profile ID                                                               | 0      |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |        |

3. Configure the IP Group parameters according to the table below.
4. Click **Submit**.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

### IP Group Parameters

| Parameter                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Common Parameters</b>                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Type<br>CLI: type<br>[IPGroup_Type]                      | <p>Defines the type of IP Group:</p> <ul style="list-style-type: none"> <li>▪ <b>[0] Server</b> = Used when the destination address, configured by the Proxy Set, of the IP Group (e.g., ITSP, Proxy, IP-PBX, or Application server) is known.</li> <li>▪ <b>[1] User</b> = Represents a group of users such as IP phones and softphones where their location is dynamically obtained by the device when REGISTER requests and responses traverse (or are terminated) by the device. These users are considered remote (far-end) users.</li> </ul> <p>Typically, this IP Group is configured with a Serving IP Group that represents an IP-PBX, Application or Proxy server that serves this User-type IP Group. Each SIP request sent by a user of this IP Group is proxied to the Serving IP Group. For registrations, the device updates its internal database with the AOR and contacts of the users. Digest authentication using SIP 401/407 responses (if needed) is performed by the Serving IP Group. The device forwards these responses directly to the SIP users.</p> <p>To route a call to a registered user, a rule must be configured in the Outbound IP Routing Table or SBC IP-to-IP Routing table. The device searches the dynamic database (by using the request URI) for an entry that matches a registered AOR or Contact. Once an entry is found, the IP destination is obtained from this entry, and a SIP request is sent to the destination.</p> <p>The device also supports NAT traversal for the SIP clients located behind NAT. In this case, the device must be defined with a global IP address.</p> <ul style="list-style-type: none"> <li>▪ <b>[2] Gateway</b> = This is applicable only to the SBC application in scenarios where the device receives requests to and from a gateway representing multiple users. This IP Group type is necessary as the other IP Group types are not suitable: <ul style="list-style-type: none"> <li>✓ The IP Group cannot be defined as a Server since its destination address is unknown during configuration.</li> <li>✓ The IP Group cannot be defined as a User since the SIP Contact header of the incoming REGISTER does not represent a specific user. The Request-URI user part can change and therefore, the device is unable to identify an already registered user and therefore, adds an additional record to the database.</li> </ul> </li> </ul> <p>The IP address of the Gateway IP Group is obtained dynamically from the host part of the Contact header in the REGISTER request received from the IP Group. Therefore, routing to this IP Group is possible only once a REGISTER request is received. If a REGISTER refresh request arrives, the device updates the new location (i.e., IP address) of the IP Group. If the REGISTER fails, no update is performed. If an UN-REGISTER request arrives, the IP address associated with the IP Group is deleted and therefore, no routing to the IP Group is done.</p> <p><b>Note:</b> This field is applicable only to the SBC or IP-to-IP application.</p> |
| Description<br>CLI: description<br>[IPGroup_Description] | <p>Defines a brief description for the IP Group.</p> <p>The valid value is a string of up to 29 characters. The default is an empty field.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| Parameter                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Proxy Set ID<br>CLI: proxy-set-id<br><b>[IPGroup_ProxySetId]</b>        | Assigns a Proxy Set ID to the IP Group. All INVITE messages destined to this IP Group are sent to the IP address configured for the Proxy Set.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>Proxy Set ID 0 must <b>not</b> be used; this is the device's default Proxy.</li> <li>The Proxy Set is applicable only to Server-type IP Groups.</li> <li>The SRD configured for this Proxy Set in the Proxy Set table is automatically assigned to this IP Group (see the 'SRD' field below).</li> <li>To configure Proxy Sets, see 'Configuring Proxy Sets Table' on page <a href="#">213</a>.</li> </ul>                                                                                                                                                                                                                                                                                                                      |
| SIP Group Name<br>CLI: sip-group-name<br><b>[IPGroup_SIPGroupName]</b>  | Defines the SIP Request-URI host name used in INVITE and REGISTER messages sent to this IP Group, or the host name in the From header of INVITE messages received from this IP Group.<br>The valid value is a string of up to 100 characters. The default is an empty field.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>If this parameter is not configured, the value of the global parameter, ProxyName is used instead (see 'Configuring Proxy and Registration Parameters' on page <a href="#">222</a>).</li> <li>If the IP Group is of User type, this parameter is used internally as a host name in the Request-URI for Tel-to-IP initiated calls. For example, if an incoming call from the device's T1 trunk is routed to a User-type IP Group, the device first creates the Request-URI (&lt;destination_number&gt;@&lt;SIP Group Name&gt;), and then it searches the internal database for a match.</li> </ul> |
| Contact User<br>CLI: contact-user<br><b>[IPGroup_ContactUser]</b>       | Defines the user part of the From, To, and Contact headers of SIP REGISTER messages, and the user part of the Contact header of INVITE messages received from this IP Group and forwarded by the device to another IP Group.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>This parameter is applicable only to Server-type IP Groups.</li> <li>This parameter is overridden by the 'Contact User' parameter in the 'Account' table (see 'Configuring Account Table' on page <a href="#">219</a>).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                |
| Local Host Name<br>CLI: local-host-name<br><b>[IPGroup_ContactName]</b> | Defines the host name (string) that the device uses in the SIP message's Via and Contact headers. This is typically used to define an FQDN as the host name. The device uses this string for Via and Contact headers in outgoing INVITE messages to a specific IP Group, and the Contact header in SIP 18x and 200 OK responses for incoming INVITE messages from a specific IP Group. The Inbound IP Routing table can be used to identify the source IP Group from where the INVITE message was received.<br>If this parameter is not configured (default), these headers are populated with the device's dotted-decimal IP address of the network interface on which the message is sent.<br><b>Note:</b> To ensure proper device handling, this parameter should be a valid FQDN.                                                                                                                                                  |

| Parameter                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Classify By Proxy Set<br>CLI: classify-by-proxy-set<br><b>[IPGroup_ClassifyByProxySet]</b>       | <p>Defines whether the incoming INVITE is classified to an IP Group according to its associated Proxy Set ID.</p> <ul style="list-style-type: none"> <li><b>[0]</b> Disable</li> <li><b>[1]</b> Enable (default)</li> </ul> <p>This classification occurs only if classification according to the device's database fails to (i.e., received INVITE is not from a registered user). The classification proceeds with checking whether the INVITE's IP address (if host names, then according to the dynamically resolved IP address list) is defined for a Proxy Set ID (in the Proxy Set table). If a Proxy Set ID has such an IP address, the device classifies the INVITE as belonging to the IP Group associated with this Proxy Set. The Proxy Set ID is assigned to the IP Group using the IP Group table's 'Proxy Set ID' parameter (see above).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>In cases where multiple IP Groups are associated with the same Proxy Set ID, do not enable this feature. If enabled, the device is unable to correctly classify the incoming INVITES to the appropriate IP Groups.</li> <li>To enhance security, it is highly recommended to disable this parameter so that the device can use the Classification table rules to classify the call. If this parameter is enabled, the Classification table is not used if an associated Proxy Set is found.</li> <li>This parameter is applicable only to Server-type IP Groups.</li> </ul> |
| Max Number Of Registered Users<br>CLI: max-num-of-reg-users<br><b>[IPGroup_MaxNumOfRegUsers]</b> | <p>Defines the maximum number of users in this IP Group that can register with the device. | Authentication Mode<br>CLI: authentication-mode<br><b>[IPGroup_AuthenticationMode]</b>                | <p>Defines the authentication mode.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> User Authenticates = (Default) The device does not handle the authentication, but simply passes the authentication messages between the SIP user agents.</li> <li>▪ <b>[1]</b> SBC as client = The device authenticates as a client. It receives the 401/407 response from the proxy requesting for authentication. The device sends the proxy the authorization credentials (i.e., user name and password) according to one of the following: 1) account defined in the Account table (only if authenticating Server-type IP Group), 2) global username and password parameters (only if authenticating Server-type IP Group), 3) User Information file, or 4) sends request to users requesting credentials (only if authenticating User-type IP Group).</li> <li>▪ <b>[2]</b> SBC as Server = The device authenticates as a server (using the User Information file).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Authentication Method List<br>CLI: authentication-method-list<br><b>[IPGroup_MethodList]</b>          | <p>Defines SIP methods that the device must challenge. Multiple entries are separated by the backslash "\". If you set this parameter to an empty value, no methods are challenged.</p> <p>The default value is "INVITE\REGISTER".</p> <p><b>Note:</b> This parameter is applicable only if the 'Authentication Mode' parameter is set to SBC as Server [2].</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| SBC Client Forking Mode<br>CLI: enable-sbc-client-forking<br><b>[IPGroup_EnableSBCCClientForking]</b> | <p>Defines call forking of INVITE messages to up to five separate SIP outgoing legs for User-type IP Groups. This occurs if multiple contacts are registered under the same AoR in the device's registration database.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Sequential = (Default) Sequentially sends the INVITE to each contact. If there is no answer from the first contact, it sends the INVITE to the second contact, and so on until a contact answers. If no contact answers, the call fails or is routed to an alternative destination, if configured.</li> <li>▪ <b>[1]</b> Parallel = Sends the INVITE simultaneously to all contacts. The call is established with the first contact that answers.</li> <li>▪ <b>[2]</b> Sequential Available Only = Sequentially sends the INVITE only to available contacts (i.e., not busy). If there is no answer from the first available contact, it sends the INVITE to the second contact, and so on until a contact answers. If no contact answers, the call fails or is routed to an alternative destination, if configured.</li> </ul> <p><b>Note:</b> The device can also fork INVITE messages received for a Request-URI of a specific contact (user) registered in the database to all other users located under the same AoR as the specific contact. This is configured using the SBCSendInviteToAllContacts parameter.</p> |

## 21.4 Configuring Proxy Sets Table

The Proxy Sets Table page allows you to define *Proxy Sets*. A Proxy Set is a group of Proxy servers defined by IP address or fully qualified domain name (FQDN). You can define up to 32 Proxy Sets, each with up to five Proxy server addresses. For each Proxy server address you can define the transport type (i.e., UDP, TCP, or TLS). In addition, Proxy load balancing and redundancy mechanisms can be applied per Proxy Set if it contains more than one Proxy address.

Proxy Sets can later be assigned to Server-type IP Groups (see 'Configuring IP Groups' on page 204). When the device sends an INVITE message to an IP Group, it is sent to the IP address or domain name defined for the Proxy Set that is associated with the IP Group. In other words, the Proxy Set represents the **destination** of the call. Typically, for IP-to-IP call routing, at least two Proxy Sets are defined for call destination – one for each leg (IP Group) of the call (i.e., both directions). For example, one Proxy Set for the Internet Telephony Service provider (ITSP) interfacing with one 'leg' of the device and another Proxy Set for the second SIP entity (e.g., ITSP) interfacing with the other 'leg' of the device.

### Notes:

- Proxy Sets can be assigned only to Server-type IP Groups.
- To enable classification of IP Groups according to Proxy Set ID, in the IP Group table, set the 'Classify By Proxy Set' parameter to Enable.
- The Proxy Set table can also be configured using two complementary tables:
  - Proxy Set ID with IP addresses: Table ini file parameter, ProxyIP or CLI command, configure voip > control-network proxy-ip > proxy-set-id.
  - Attributes for the Proxy Set: Table ini file parameter, ProxySet or CLI command, configure voip > control-network proxy-set.

### ➤ To configure Proxy Sets:

1. Open the Proxy Sets Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **Proxy Sets Table**).

Figure 21-3: Proxy Sets Table Page

| Proxy Set ID |   |
|--------------|---|
| Proxy Set ID | 1 |

|   | Proxy Address | Transport Type |
|---|---------------|----------------|
| 1 | 100.33.2.26   | UDP            |
| 2 |               |                |
| 3 |               |                |
| 4 |               |                |
| 5 |               |                |

|                             |                |
|-----------------------------|----------------|
| Enable Proxy Keep Alive     | Disable        |
| Proxy Keep Alive Time       | 10             |
| Proxy Load Balancing Method | Round Robin    |
| Is Proxy Hot Swap           | No             |
| Proxy Redundancy Mode       | Not Configured |
| SRD Index                   | 1              |
| Classification Input        | IP only        |

2. From the 'Proxy Set ID' drop-down list, select an ID for the desired group.
3. Configure the Proxy parameters, as required. For a description of the parameters, see the table below.
4. Click **Submit**.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**Proxy Sets Table Parameters**

| Parameter                                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Web: Proxy Set ID<br>EMS: Index<br>CLI: configure voip ><br>control-network proxy-<br>set<br><b>[ProxySet_Index]</b> | <p>Defines the Proxy Set identification number.</p> <p>The valid value is 0 to 31. Proxy Set ID 0 is used as the default Proxy Set.</p> <p><b>Note:</b> Although not recommended, you can use both default Proxy Set (ID 0) and IP Groups for call routing. For example, in the Trunk Group Settings page (see Configuring Hunt Group Settings on page 291) you can configure a Serving IP Group to where you want to route specific Trunk Group channels, and all other device channels then use the default Proxy Set. You can also use IP Groups in the Outbound IP Routing Table (see Configuring the Outbound IP Routing Table on page 321) to configure the default Proxy Set if the parameter PreferRouteTable is set to 1.</p> <p>To summarize, if the default Proxy Set is used, the INVITE message is sent according to the following preferences:</p> <ul style="list-style-type: none"> <li>▪ To the Trunk Group's Serving IP Group ID, as defined in the Trunk Group Settings table.</li> <li>▪ According to the Outbound IP Routing Table if the parameter PreferRouteTable is set to 1.</li> <li>▪ To the default Proxy.</li> </ul> <p>Typically, when IP Groups are used, there is no need to use the default Proxy and all routing and registration rules can be configured using IP Groups and the Account tables (see 'Configuring Account Table' on page 219).</p>                                                                                                                                                                                                                                              |
| Proxy Address<br>CLI: control-network<br>proxy-ip > proxy-<br>address<br><b>[ProxyIp_IpAddress]</b>                  | <p>Defines the address (and optionally, port number) of the Proxy server. Up to five addresses can be configured per Proxy Set.</p> <p>The address can be defined as an IP address in dotted-decimal notation (e.g., 201.10.8.1) or as an FQDN. You can also specify the selected port in the format, &lt;IP address&gt;:&lt;port&gt;.</p> <p>If you enable Proxy Redundancy (by setting the parameter EnableProxyKeepAlive to 1 or 2), the device can operate with multiple Proxy servers. If there is no response from the first (<i>primary</i>) Proxy defined in the list, the device attempts to communicate with the other (<i>redundant</i>) Proxies in the list. When a redundant Proxy is located, the device either continues operating with it until the next failure occurs or reverts to the primary Proxy (refer to the parameter ProxyRedundancyMode). If none of the Proxy servers respond, the device goes over the list again.</p> <p>The device also provides real-time switching (Hot-Swap mode) between the primary and redundant proxies (refer to the parameter IsProxyHotSwap). If the first Proxy doesn't respond to the INVITE message, the same INVITE message is immediately sent to the next Proxy in the list. The same logic applies to REGISTER messages (if RegistrarIP is not defined).</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ If EnableProxyKeepAlive is set to 1 or 2, the device monitors the connection with the Proxies by using keep-alive messages (OPTIONS or REGISTER).</li> <li>▪ To use Proxy Redundancy, you must specify one or more redundant</li> </ul> |

| Parameter                                                                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|---------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Method<br>CLI: control-network<br>proxy-set > proxy-<br>load-balancing-<br>method<br><b>[ProxySet_ProxyLoadBalancingMethod]</b>       | <ul style="list-style-type: none"> <li>▪ <b>[2] Random Weights</b></li> </ul> <p>When the Round Robin algorithm is used, a list of all possible Proxy IP addresses is compiled. This list includes all IP addresses per Proxy Set, after necessary DNS resolutions (including NAPTR and SRV, if configured). After this list is compiled, the Proxy Keep-Alive mechanism (according to parameters EnableProxyKeepAlive and ProxyKeepAliveTime) tags each entry as 'offline' or 'online'. Load balancing is only performed on Proxy servers that are tagged as 'online'.</p> <p>All outgoing messages are equally distributed across the list of IP addresses. REGISTER messages are also distributed unless a RegistrarIP is configured.</p> <p>The IP addresses list is refreshed according to ProxyIPListRefreshTime. If a change in the order of the entries in the list occurs, all load statistics are erased and balancing starts over again.</p> <p>When the Random Weights algorithm is used, the outgoing requests are not distributed equally among the Proxies. The weights are received from the DNS server by using SRV records. The device sends the requests in such a fashion that each Proxy receives a percentage of the requests according to its assigned weight. A single FQDN should be configured as a Proxy IP address. The Random Weights Load Balancing is not used in the following scenarios:</p> <ul style="list-style-type: none"> <li>▪ The Proxy Set includes more than one Proxy IP address.</li> <li>▪ The only Proxy defined is an IP address and not an FQDN.</li> <li>▪ SRV is not enabled (DNSQueryType).</li> <li>▪ The SRV response includes several records with a different Priority value.</li> </ul> |

## 21.5 Associating WAN Interface with VoIP Traffic

If you are using the WAN interface, you need to associate it with VoIP traffic (i.e., SIP signaling and media interfaces). The available WAN interfaces depend on the hardware configuration and/or whether VLANs are configured for the WAN interface. If VLANs are configured, then you can select the WAN VLAN on which you want to run the SIP signaling and media interfaces.

Once this association is set, VoIP traffic is sent through the WAN and incoming traffic is identified as coming from the WAN. The device automatically configures the required port forwarding and static NAT rules.

**Note:** If you do not assign the WAN interface to SIP and media interfaces, then the WAN interface may not be used for VoIP traffic. In such cases, the VoIP traffic can be sent and received within the LAN or sent to the WAN through a third-party LAN router. If a third-party router is used as the interface to the WAN, then you need to configure NAT rules (in the NAT Translation table) to translate the VoIP LAN IP addresses (configured in the Multiple Interface table and associated with SIP and media interfaces) into global, public IP addresses.

### ➤ To assign a WAN interface to VoIP traffic:

1. Select the WAN interface:
  - a. Open the Multiple Interface Table page (**Configuration** tab > **VoIP** menu > **Network** > **IP Settings**).

**Figure 21-4: Selecting WAN Interface for VoIP Traffic**

Multiple Interface Table

Note: Select row index to modify the relevant row.

Index:  Add Index Done

| Index | Application Type       | IP Address | Prefix Length | Gateway  | VLAN ID | Interface Name | Primary DNS Server IP Address | Secondary DNS Server IP Address | Underlying Interface |
|-------|------------------------|------------|---------------|----------|---------|----------------|-------------------------------|---------------------------------|----------------------|
| 0     | OAMP + Media + Control | 10.8.6.86  | 16            | 10.8.0.1 | 1       | Voice_Mng      | 0.0.0.0                       | 0.0.0.0                         | None                 |

WAN Interface Name: WAN Ethernet

- b. From the 'WAN Interface Name' drop-down list, select the WAN interface for VoIP traffic.

- c. Click **Done**, and then reset the device for your setting to take effect.
2. Assign the selected WAN interface to SIP signaling and RTP (media) interfaces in the SIP Interface and Media Realm tables, respectively. To denote the WAN interface, use the string value "WAN":
  - a. Open the SIP Interface Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **SIP Interface Table**) and configure SIP interfaces on the WAN interface.

**Figure 21-5: Assigning SIP Interface to WAN**

| SIP Interface Table |                   |                  |          |          |          |     |                |
|---------------------|-------------------|------------------|----------|----------|----------|-----|----------------|
| Add +               |                   |                  |          |          |          |     |                |
| Index               | Network Interface | Application Type | UDP Port | TCP Port | TLS Port | SRD | Message Policy |

- b. Open the Media Realm Table page (**Configuration** tab > **VoIP** menu > **Media** submenu > **Media Realm Configuration**) and configure media interfaces on the WAN interface.

**Figure 21-6: Assigning WAN Interface to Media Realm**

| Media Realm Table |                  |                     |                     |
|-------------------|------------------|---------------------|---------------------|
| Add               |                  |                     |                     |
| Index             | Media Realm Name | IPv4 Interface Name | IPv6 Interface Name |
| 1                 | Media_1          | Voice_Mng           | None                |
| 2                 | Media_2          | WAN                 | None                |

Page 1 of 1 Show 10 records per page View 1 - 2 of 2

- c. Configure SRDs and associate them with these SIP signaling and media interfaces.
  - d. Configure other SIP settings as required.

## 22 SIP Definitions

This section describes configuration of SIP parameters.

### 22.1 Configuring SIP Parameters

Many of the stand-alone SIP parameters associated with various features can be configured in the following pages:

- **SIP General Parameters page:** Provides SIP parameters for configuring general SIP features. To access this page, use the following path: **Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**.
- **SIP Advanced Parameters page:** Provides SIP parameters for configuring advanced SIP features. To access this page, use the following path: **Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**.

For a description of these parameters, refer to the section corresponding to the feature or see 'Configuration Parameters Reference' on page [655](#).

### 22.2 Configuring Account Table

The Account Table page lets you define up to 32 Accounts per ("served") Trunk Group or source ("served") IP Group. Accounts are used to register and/or digest authenticate a Trunk Group or served IP Group, using a username and password, to a destination ("serving") IP Group. For example, the device can use the Account table to register an IP PBX, which is connected to the device, to an ITSP. The device sends the registration requests to the Proxy Set ID (see 'Configuring Proxy Sets Table' on page [213](#)) that is associated with the serving IP Group.

A Trunk Group or served IP Group can register to more than one serving IP Group (e.g., multiple ITSPs). This is done by configuring multiple entries in the Account table for the same Trunk Group or served IP Group, but with different serving IP Groups, user name/password, host name, and contact user values.

When using the Account table to register a Trunk Group, if all trunks belonging to the Trunk Group are down, the device un-registers the trunks. If any trunk belonging to the Trunk Group is returned to service, the device registers them again. This ensures, for example, that the Proxy does not send INVITEs to trunks that are out of service.

If registration to an IP Group fails for all accounts of a specific Trunk Group and if this Trunk Group includes all the channels in the Trunk Group, the Trunk Group is set to Out-Of-Service if the OOSOnRegistrationFail parameter is set to 1 (see 'Proxy & Registration Parameters' on page [222](#)).

#### Notes:

- For viewing Account registration status, see Viewing Endpoint Registration Status on page [596](#).
- The Account table can also be configured using the table ini file parameter, Account or CLI command, configure voip > sip-definition account.

➤ **To configure Accounts:**

1. Open the Account Table page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **Account Table**).

| <input type="text"/> <input type="button" value="Add"/> <input type="button" value="Compact"/> <input type="button" value="Delete"/> <input type="button" value="Apply"/> |                    |                 |                  |          |          |           |          |             |

2. In the 'Add' field, enter the desired table row index, and then click **Add**. A new row appears.
3. Configure the Account parameters according to the table below.
4. Click the **Apply** button to save your changes.
5. To save the changes, see 'Saving Configuration' on page 532.
6. To perform registration, click the **Register** button; to unregister, click **Unregister**. The registration method for each Trunk Group is according to the setting of the 'Registration Mode' parameter in the Trunk Group Settings page.

#### Account Table Parameters Description

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Served Trunk Group<br>CLI: served-trunk-group<br><b>[Account_ServedTrunkGroup]</b> | Defines the Trunk Group ID that you want to register and/or authenticate to a destination IP Group (i.e., Serving IP Group). <ul style="list-style-type: none"> <li>For Tel-to-IP calls, the Served Trunk Group is the source Trunk Group from where the call originated.</li> <li>For IP-to-Tel calls, the Served Trunk Group is the HuntTrunk Group ID to which the call is sent.</li> </ul> <b>Note:</b> This parameter is applicable only to the Gateway application.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Served IP Group<br>CLI: served-ip-group<br><b>[Account_ServedIPGroup]</b>          | Defines the Source IP Group (e.g., IP-PBX) for which registration and/or authentication is done. <b>Note:</b> This parameter is applicable only to the SBC and IP-to-IP applications (not Gateway application).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Serving IP Group<br>CLI: serving-ip-group<br><b>[Account_ServingIPGroup]</b>       | Defines the destination IP Group ID to where the SIP REGISTER requests, if enabled, are sent and authentication is done. The actual destination to where the REGISTER requests are sent is the IP address configured for the Proxy Set ID that is associated with the IP Group.           Registration occurs only if: <ul style="list-style-type: none"> <li><b>Gateway application only:</b> The 'Registration Mode' parameter is set to 'Per Account' in the Hunt Group Settings table (see Configuring Hunt Group Settings on page 291).</li> <li>The 'Register' parameter in the Account table is set to <b>Yes</b>.</li> </ul> For the Gateway and IP-to-IP applications: <ul style="list-style-type: none"> <li>For Tel-to-IP calls, the serving IP Group is the destination IP Group defined in the Trunk Group Settings table or Outbound IP Routing Table (see Configuring the Outbound IP Routing Table on page 321).</li> <li>For IP-to-Tel calls, the Serving IP Group is the 'Source IP Group ID' defined in the Inbound IP Routing Table (see Configuring the Inbound IP Routing Table on page 330).</li> </ul> <b>Note:</b> If no match is found in this table for incoming or outgoing calls, the username and password is taken from the following: <ul style="list-style-type: none"> <li>FXS interfaces: Authentication table (see Configuring Authentication)</li> <li>UserName and Password parameters on the Proxy &amp; Registration page.</li> </ul> |

| Parameter                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Username<br>CLI: user-name<br><b>[Account_Username]</b>                       | Defines the digest MD5 Authentication user name.<br>The valid value is a string of up to 50 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Password<br>CLI: password<br><b>[Account_Password]</b>                        | Defines the digest MD5 Authentication password.<br>The valid value is a string of up to 50 characters.<br><b>Note:</b> After you click the <b>Apply</b> button, this password is displayed as an asterisk (*).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Host Name<br>CLI: host-name<br><b>[Account_HostName]</b>                      | Defines the Address of Record (AOR) host name. It appears in REGISTER From/To headers as ContactUser@HostName. For successful registrations, this host name is also included in the INVITE request's From header URI.<br>This parameter can be up to 49 characters.<br><b>Note:</b> If this parameter is not configured or if registration fails, the 'SIP Group Name' parameter configured in the IP Group table is used instead.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Register<br>CLI: register<br><b>[Account_Register]</b>                        | Enables registration. <ul style="list-style-type: none"> <li><b>[0]</b> No (Default)</li> <li><b>[1]</b> Yes</li> </ul> <p>When enabled, the device sends REGISTER requests to the Serving IP Group. The host name (i.e., host name in SIP From/To headers) and Contact User (user in From/To and Contact headers) are taken from this table upon successful registration. See the example below:</p> <pre>REGISTER sip:xyz SIP/2.0 Via: SIP/2.0/UDP 10.33.37.78;branch=z9hG4bKac1397582418 From: &lt;sip:ContactUser@HostName&gt;;tag=1c1397576231 To: &lt;sip: ContactUser@HostName &gt; Call-ID: 1397568957261200022256@10.33.37.78 CSeq: 1 REGISTER Contact: &lt;sip:ContactUser@10.33.37.78&gt;;expires=3600 Expires: 3600 User-Agent: Sip-Gateway/v.6.00A.008.002 Content-Length: 0</pre> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>To activate registration, you also need to set the parameter 'Registration Mode' to 'Per Account' in the Trunk Group Settings table for the specific Trunk Group.</li> <li>The Trunk Group account registration is not affected by the parameter IsRegisterNeeded.</li> </ul> |
| Contact User<br>CLI: contact-user<br><b>[Account_ContactUser]</b>             | Defines the AOR user name. This appears in REGISTER From/To headers as ContactUser@HostName, and in INVITE/200 OK Contact headers as ContactUser@<device's IP address>.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>If this parameter is not configured, the 'Contact User' parameter in the IP Group table is used instead.</li> <li>If registration fails, then the user part in the INVITE Contact header contains the source party number.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Application Type<br>CLI: application-type<br><b>[Account_ApplicationType]</b> | Defines the application type: <ul style="list-style-type: none"> <li><b>[0]</b> GW/IP2IP = (Default) Gateway and IP-to-IP application.</li> <li><b>[2]</b> SBC = SBC application.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## 22.3 Configuring Proxy and Registration Parameters

The Proxy & Registration page [allows](#) you to configure the Proxy server and registration parameters. For a description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page [655](#).

**Note:** To view the registration status of endpoints with a SIP Registrar/Proxy server, see Viewing Endpoint Registration Status on page [596](#).

➤ **To configure the Proxy and registration parameters:**

1. Open the Proxy & Registration page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **Proxy & Registration**).

**Figure 22-1: Proxy & Registration Page**

|                                               |                                                                                   |
|-----------------------------------------------|-----------------------------------------------------------------------------------|
| Use Default Proxy                             | Yes                                                                               |
| Proxy Set Table                               |  |
| Proxy Name                                    |                                                                                   |
| Redundancy Mode                               | Homing                                                                            |
| Proxy IP List Refresh Time                    | 60                                                                                |
| Enable Fallback to Routing Table              | Disable                                                                           |
| Prefer Routing Table                          | No                                                                                |
| Use Routing Table for Host Names and Profiles | Disable                                                                           |
| Always Use Proxy                              | Disable                                                                           |
| Redundant Routing Mode                        | Disable                                                                           |

| Number of RTX Before Hot-Swap                 | 3                                                                                 |
| Use Gateway Name for OPTIONS                  | No                                                                                |
| User Name                                     |                                                                                   |
| Password                                      | Default_Passwd                                                                    |
| Cnonce                                        | Default_Cnonce                                                                    |
| Registration Mode                             | Per FXS                                                                           |
| Set Out-Of-Service On Registration Failure    | Disable                                                                           |
| Challenge Caching Mode                        | None                                                                              |
| Mutual Authentication Mode                    | Optional                                                                          |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.

➤ **To register or un-register the device to a Proxy/Registrar:**

- Click the **Register** button to register.
- Click **Un-Register** button to un-register.

Instead of registering the entire device, you can register specific entities as listed below by using the **Register** button located on the page in which these entities are configured:

- FXS/FXO endpoints, BRI endpoints, Trunk Groups - Trunk Group Table page (see Configuring Trunk Group Table on page [289](#))
- Accounts - Account table (see 'Configuring Account Table' on page [219](#))

Click the **Proxy Set Table**  button to Open the Proxy Sets Table page to configure groups of proxy addresses. Alternatively, you can open this page from the **Proxy Sets**

**Table** page item (see 'Configuring Proxy Sets Table' on page 213 for a description of this page).

### 22.3.1 SIP Message Authentication Example

The device supports basic and digest (MD5) authentication types, according to SIP RFC 3261 standard. A proxy server might require authentication before forwarding an INVITE message. A Registrar/Proxy server may also require authentication for client registration. A proxy replies to an unauthenticated INVITE with a 407 Proxy Authorization Required response, containing a Proxy-Authenticate header with the form of the challenge. After sending an ACK for the 407, the user agent can then re-send the INVITE with a Proxy-Authorization header containing the credentials.

User agents, Redirect or Registrar servers typically use the SIP 401 Unauthorized response to challenge authentication containing a WWW-Authenticate header, and expect the re-INVITE to contain an Authorization header.

The following example shows the Digest Authentication procedure, including computation of user agent credentials:

1. The REGISTER request is sent to a Registrar/Proxy server for registration:

```
REGISTER sip:10.2.2.222 SIP/2.0
Via: SIP/2.0/UDP 10.1.1.200
From: <sip: 122@10.1.1.200>;tag=1c17940
To: <sip: 122@10.1.1.200>
Call-ID: 634293194@10.1.1.200
User-Agent: Sip-Gateway/Mediant 850 MSBR/v.6.60.010.006
CSeq: 1 REGISTER
Contact: sip:122@10.1.1.200:
Expires:3600
```

2. Upon receipt of this request, the Registrar/Proxy returns a 401 Unauthorized response:

```
SIP/2.0 401 Unauthorized
Via: SIP/2.0/UDP 10.2.1.200
From: <sip:122@10.2.2.222 >;tag=1c17940
To: <sip:122@10.2.2.222 >
Call-ID: 634293194@10.1.1.200
Cseq: 1 REGISTER
Date: Mon, 30 Jul 2012 15:33:54 GMT
Server: Columbia-SIP-Server/1.17
Content-Length: 0
WWW-Authenticate: Digest realm="audiocodes.com",
nonce="11432d6bce58ddf02e3b5e1c77c010d2",
stale=FALSE,
algorithm=MD5
```

3. According to the sub-header present in the WWW-Authenticate header, the correct REGISTER request is created.
4. Since the algorithm is MD5:
  - The username is equal to the endpoint phone number "122".
  - The realm return by the proxy is "audiocodes.com".
  - The password from the *ini* file is "AudioCodes".
  - The equation to be evaluated is "122:audiocodes.com:AudioCodes". According to the RFC, this part is called A1.
  - The MD5 algorithm is run on this equation and stored for future usage.
  - The result is "a8f17d4b41ab8dab6c95d3c14e34a9e1".
5. The par called A2 needs to be evaluated:

- The method type is "REGISTER".
- Using SIP protocol "sip".
- Proxy IP from *ini* file is "10.2.2.222".
- The equation to be evaluated is "REGISTER:sip:10.2.2.222".
- The MD5 algorithm is run on this equation and stored for future usage.
- The result is "a9a031cfddcb10d91c8e7b4926086f7e".

#### 6. Final stage:

- A1 result: The nonce from the proxy response is "11432d6bce58ddf02e3b5e1c77c010d2".
- A2 result: The equation to be evaluated is "A1:11432d6bce58ddf02e3b5e1c77c010d2:A2".
- The MD5 algorithm is run on this equation. The outcome of the calculation is the response needed by the device to register with the Proxy.
- The response is "b9c45d0234a5abf5ddf5c704029b38cf".

At this time, a new REGISTER request is issued with the following response:

```
REGISTER sip:10.2.2.222 SIP/2.0
Via: SIP/2.0/UDP 10.1.1.200
From: <sip: 122@10.1.1.200>;tag=1c23940
To: <sip: 122@10.1.1.200>
Call-ID: 654982194@10.1.1.200
Server: Audiocodes-Sip-Gateway/Mediant 850 MSBR/v.6.60.010.006
CSeq: 1 REGISTER
Contact: sip:122@10.1.1.200:
Expires:3600
Authorization: Digest, username: 122,
realm="audiocodes.com",
nonce="11432d6bce58ddf02e3b5e1c77c010d2",
uri="10.2.2.222",
response="b9c45d0234a5abf5ddf5c704029b38cf"
```

#### 7. Upon receiving this request and if accepted by the Proxy, the Proxy returns a 200 OK response, completing the registration transaction:

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 10.1.1.200
From: <sip: 122@10.1.1.200>;tag=1c23940
To: <sip: 122@10.1.1.200>
Call-ID: 654982194@10.1.1.200
Cseq: 1 REGISTER
Date: Thu, 26 Jul 2012 09:34:42 GMT
Server: Columbia-SIP-Server/1.17
Content-Length: 0
Contact: <sip:122@10.1.1.200>; expires="Thu, 26 Jul 2012
10:34:42 GMT"; action=proxy; q=1.00
Contact: <122@10.1.1.200:>; expires="Tue, 19 Jan 2038 03:14:07
GMT"; action=proxy; q=0.00
Expires: Thu, 26 Jul 2012 10:34:42 GMT
```

## 22.4 Configuring SIP Message Manipulation

The Message Manipulations page allows you to define up to 100 SIP message manipulation rules. Each manipulation rule can be assigned any Manipulation Set ID (0 to 19), enabling you to create groups (sets) of manipulation rules whereby rules of a group are configured with the same Manipulation Set ID number. To use these Manipulation Sets, you need to assign them to IP Groups in the IP Group table (see 'Configuring IP Groups' on page 204) where they can be applied to inbound and/or outbound SIP messages.

SIP message manipulation enables the normalization of SIP messaging fields between communicating network segments. For example, it allows service providers to design their own policies on the SIP messaging fields that must be present before a SIP call enters their network. Similarly, enterprises and small businesses may have policies for the information that can enter or leave their networks for policy or security reasons from a service provider. The manipulations can also be implemented to resolve incompatibilities between SIP devices inside the enterprise network.

SIP message manipulation supports the following:

- Addition of new headers.
- Removal of headers ("Black list").
- Modification of header components - value, header value (e.g., URI value of the P-Asserted-Identity header can be copied to the From header), call's parameter values.
- Deletion of SIP body (e.g., if a message body isn't supported at the destination network this body is removed).
- Translating one SIP response code to another.
- Topology hiding (generally present in SIP headers such as Via, Record Route, Route and Service-Route).
- Configurable identity hiding (information related to identity of subscribers for example, P-Asserted-Identity, Referred-By, Identity and Identity-Info).
- Apply conditions per rule - the condition can be on parts of the message or call's parameters.
- Multiple manipulation rules on the same SIP message.

The manipulation is performed on SIP messages according to the Classification table (source/destination of username/host prefixes, and source IP address). The manipulation can be performed on message type (Method, Request/Response, and Response type) and multiple manipulation rules can be configured for the same SIP message.

For the Gateway / IP-to-IP application, manipulation rules can be assigned as follows:

- Manipulating inbound SIP INVITE messages: The Manipulation Set ID is selected using the "global" parameter, GWInboundManipulationSet. If this parameter is not configured, then no manipulation is done.
- Manipulating outbound SIP INVITE messages: The Manipulation Set ID is selected using the following logic:
  - a. According to the settings of the 'Outbound Message Manipulation Set' parameter configured for the destination IP Group (in the IP Group table). In other words, manipulation can be done per destination IP Group. If this parameter is not configured, see below.
  - b. According to the settings of the "global" parameter, GWOutboundManipulationSet. If this parameter is not configured, no manipulation is done.

The figure below illustrates a SIP message manipulation example:

**Figure 22-2: SIP Header Manipulation Example**

**Notes:**

- For a detailed description of the syntax for configuring SIP message manipulation rules, refer to *SIP Message Manipulations Quick Reference Guide*.
- For the IP-to-IP application, the outgoing message is re-created and thus, SIP headers that are not relevant to the outgoing SIP session (e.g., Referred-By) are not included in the outgoing message. Therefore, if required, manipulations on such headers should be handled in inbound manipulation.
- The values entered in the table are not case-sensitive.
- For the SBC application, SIP message manipulation is done only after the Classification, inbound/outbound number manipulations, and routing processes.
- Each message can be manipulated twice - on the source leg and on the destination leg (i.e., source and destination IP Groups).
- Unknown SIP parts can only be added or removed.
- SIP manipulations do not allow you to remove or add mandatory SIP headers. They can only be modified and only on requests that initiate new dialogs. Mandatory SIP headers include To, From, Via, CSeq, Call-Id, and Max-Forwards.
- The Message Manipulations table can also be configured using the table *ini* file parameter, MessageManipulations or CLI command, configure voip > sbc manipulations message-manipulations.

➤ **To configure SIP message manipulation rules:**

1. Open the Message Manipulations page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **Msg Policy & Manipulation** > **Message Manipulations**).
2. Click the **Add** button; the following dialog box appears:

**Figure 22-3: Message Manipulations Table - Add Record Dialog Box**

|                                                                             |                       |
|-----------------------------------------------------------------------------|-----------------------|
| Add Record                                                                  |                       |
| Index                                                                       | 0                     |
| Manipulation Set ID                                                         | 0                     |
| Message Type                                                                |                       |
| Condition                                                                   |                       |
| Action Subject                                                              |                       |
| Action Type                                                                 | Add                   |
| Action Value                                                                |                       |
| Row Role                                                                    | Use Current Condition |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |                       |

3. Configure the SIP message manipulation rule as required. See the table below for a description of each parameter.
4. Click **Submit** to apply your changes.

The figure below displays an example of configured message manipulation rules:

- Index 0 - adds the suffix ".com" to the host part of the To header.
- Index 1 - changes the user part of the From header to the user part of the P-Asserted-ID.
- Index 2 - changes the user part of the SIP From header to "200".
- Index 3 - if the user part of the From header equals "unknown", then it is changed according to the srcIPGroup call's parameter.
- Index 4 - removes the Priority header from an incoming INVITE message.

**Figure 22-4: Message Manipulations Page**

| Index | Manipulation Set ID | Message Type        | Condition                  | Action Subject       | Action Type | Action Value                  |
|-------|---------------------|---------------------|----------------------------|----------------------|-------------|-------------------------------|
| 0     | 0                   | invite.response.200 |                            | header.to.url.user   | Add Prefix  | '.com'                        |
| 1     | 1                   | invite.response.200 |                            | header.from.url.user | Modify      | header.p-asserted-id.url.user |
| 2     | 2                   | invite.request      |                            | header.from.url.user | Modify      | '200'                         |
| 3     | 3                   | invite.request      | header.from.url.user=='Unk | header.from.url.user | Modify      | param.ipq.src.user            |
| 4     | 4                   | invite.request      |                            | header.priority      | Remove      |                               |

### Message Manipulations Parameters

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Index<br>[MessageManipulations_Index]                                              | Defines the table row index for the rule.<br>The valid value is 0 to 99. The default is 0.<br><b>Note:</b> Each rule must be configured with a unique index.                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Manipulation Set ID<br>CLI: manipulation-set-id<br>[MessageManipulations_ManSetID] | Defines a Manipulation Set ID for the rule. You can define the same Manipulation Set ID for multiple rules to create a group of rules. The Manipulation Set ID is used to assign the manipulation rules to an IP Group (in the IP Group table) for inbound and/or outbound messages.<br>The valid value is 0 to 19. The default is 0.                                                                                                                                                                                                                                                   |
| <b>Matching Characteristics</b>                                                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Message Type<br>CLI: message-type<br>[MessageManipulations_MessageType]            | Defines the SIP message type that you want to manipulate.<br>The valid value is a string denoting the SIP message.<br>For example: <ul style="list-style-type: none"> <li>■ Empty = rule applies to all messages</li> <li>■ Invite = rule applies to all INVITE requests and responses</li> <li>■ Invite.Request = rule applies to INVITE requests</li> <li>■ Invite.Response = rule applies to INVITE responses</li> <li>■ subscribe.response.2xx = rule applies to SUBSCRIBE confirmation responses</li> </ul> <b>Note:</b> Currently, SIP 100 Trying messages cannot be manipulated. |
| Condition<br>CLI: condition<br>[MessageManipulations_Condition]                    | Defines the condition that must exist for the rule to apply.<br>The valid value is a string.<br>For example: <ul style="list-style-type: none"> <li>■ header.from.url.user== '100' (indicates that the user part of the From header must have the value "100")</li> <li>■ header.contact.param.expires &gt; '3600'</li> <li>■ header.to.url.host contains 'domain'</li> <li>■ param.call.dst.user != '100'</li> </ul>                                                                                                                                                                   |

| Parameter                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Action Subject<br>CLI: action-subject<br><b>[MessageManipulations_ActionSubject]</b> | Defines the SIP header upon which the manipulation is performed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Action Type<br>CLI: action-type<br><b>[MessageManipulations_ActionType]</b>          | <p>Defines the type of manipulation.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Add (default) = adds new header/param/body (header or parameter elements).</li> <li>▪ <b>[1]</b> Remove = removes header/param/body (header or parameter elements).</li> <li>▪ <b>[2]</b> Modify = sets element to the new value (all element types).</li> <li>▪ <b>[3]</b> Add Prefix = adds value at the beginning of the string (string element only).</li> <li>▪ <b>[4]</b> Add Suffix = adds value at the end of the string (string element only).</li> <li>▪ <b>[5]</b> Remove Suffix = removes value from the end of the string (string element only).</li> <li>▪ <b>[6]</b> Remove Prefix = removes value from the beginning of the string (string element only).</li> </ul> |
| Action Value<br>CLI: action-value<br><b>[MessageManipulations_ActionValue]</b>       | <p>Defines a value (string) that you want to use in the manipulation. The syntax is as follows:</p> <ul style="list-style-type: none"> <li>▪ string/&lt;message-element&gt;/&lt;call-param&gt; +</li> <li>▪ string/&lt;message-element&gt;/&lt;call-param&gt;</li> </ul> <p>For example:</p> <ul style="list-style-type: none"> <li>▪ 'itsp.com'</li> <li>▪ header.from.url.user</li> <li>▪ param.call.dst.user</li> <li>▪ param.call.dst.host + '.com'</li> <li>▪ param.call.src.user + '&lt;' + header.from.url.user + '@' + header.p-asserted-id.url.host + '&gt;'</li> </ul> <p><b>Note:</b> Only single quotation marks must be used.</p>                                                                                                                                    |
| Row Role<br>CLI: row-role<br><b>[MessageManipulations_RowRole]</b>                   | <p>Determines which condition must be used for the rule of this table row.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Use Current Condition = The condition entered in this row must be matched in order to perform the defined action (default).</li> <li>▪ <b>[1]</b> Use Previous Condition = The condition of the rule configured directly above this row must be used in order to perform the defined action. This option allows you to configure multiple actions for the same condition.</li> </ul> <p><b>Note:</b> When multiple manipulations rules apply to the same header, the next rule applies to the result string of the previous rule.</p>                                                                                                          |

## 22.5 Configuring SIP Message Policy Rules

You can configure SIP message policy rules for blocking (blacklist) unwanted incoming SIP messages or allowing (whitelist) receipt of desired messages. This feature allows you to define legal and illegal characteristics of a SIP message. Message policies can be applied globally (default) or per signaling domain by assigning it to a SIP interface in the SIP Interface table (see 'Configuring SIP Interface Table' on page 201).

This feature is helpful against VoIP fuzzing (also known as robustness testing), which sends different types of packets to its "victims" for finding bugs and vulnerabilities. For example, the attacker might try sending a SIP message containing either an over-sized parameter or too many occurrences of a parameter.

Each message policy rule can be configured with the following:

- Maximum message length
- Maximum SIP header length
- Maximum message body length
- Maximum number of headers
- Maximum number of bodies
- Option to send 400 "Bad Request" response if message request is rejected
- Blacklist and whitelist for defined SIP methods (e.g., INVITE)
- Blacklist and whitelist for defined SIP bodies

**Note:** The Message Policy table can also be configured using the table ini file parameter, MessagePolicy or the CLI command, configure voip > sbc message-policy.

### ➤ To configure SIP message policy rules:

1. Open the Message Policy Table page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Msg Policy & Manipulation** > **Message Policy Table**).
2. Click the **Add** button; the Add Record dialog box appears:

**Figure 22-5: Message Policy Table - Add Record Dialog Box**

|                                                                             |                  |
|-----------------------------------------------------------------------------|------------------|
| Add Record                                                                  |                  |
| Index                                                                       | 1                |
| Max Message Length                                                          | 1400             |
| Max Header Length                                                           | 300              |
| Max Body Length                                                             | 300              |
| Max Num Headers                                                             | 20               |
| Max Num Bodies                                                              | 5                |
| Send Rejection                                                              | Policy Reject    |
| Method List                                                                 | INVITE\REFER     |
| Method List Type                                                            | Policy Blacklist |
| Body List                                                                   |                  |
| Body List Type                                                              | Policy Blacklist |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |                  |

The policy defined above limits SIP messages to 32,768 characters, headers to 256 characters, bodies to 512 characters, number of headers to 16, and only permits two bodies. Invalid requests are rejected. Only INVITE and BYE requests are permitted and there are no restrictions on bodies.

3. Configure the SIP message policy rule as required. See the table below for a description of each parameter.
4. Click **Submit** to apply your changes.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**SIP Message Policy Parameters**

| Parameter                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                       |

| Index<br>[MessagePolicy_Index]                                                    | Defines the table index entry.                                                                                                                                                                                                                                                                                                                                                    |
| Max Message Length<br>CLI: max-message-length<br>[MessagePolicy_MaxMessageLength] | Defines the maximum SIP message length.<br>The valid value is up to 32,768 characters. The default is 32,768.                                                                                                                                                                                                                                                                     |
| Max Header Length<br>CLI: max-header-length<br>[MessagePolicy_MaxHeaderLength]    | Defines the maximum SIP header length.<br>The valid value is up to 512 characters. The default is 512.                                                                                                                                                                                                                                                                            |
| Max Body Length<br>CLI: max-body-length<br>[MessagePolicy_MaxBodyLength]          | Defines the maximum SIP message body length. This is the value of the Content-Length header.<br>The valid value is up to 1,024 characters. The default is 1,024.                                                                                                                                                                                                                  |
| Max Num Headers<br>CLI: max-num-headers<br>[MessagePolicy_MaxNumHeaders]          | Defines the maximum number of SIP headers.<br>The valid value is any number up to 32. The default is 32.<br><b>Note:</b> The device supports up to 20 SIP Record-Route headers that can be received in a SIP INVITE request or 200 OK response. If it receives more than this, it responds with a SIP 513 'Message Too Large' response.                                           |
| Max Num Bodies<br>CLI: max-num-bodies<br>[MessagePolicy_MaxNumBodies]             | Defines the maximum number of bodies (e.g., SDP) in the SIP message.<br>The valid value is any number up to 8. The default is 8.                                                                                                                                                                                                                                                  |
| Send Rejection<br>CLI: send-rejection<br>[MessagePolicy_SendRejection]            | Determines whether the device sends a 400 "Bad Request" response if a message request is rejected. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Policy Reject = (Default) If the message is a request, then the device sends a response to reject the request.</li> <li>▪ <b>[1]</b> Policy Drop = The device ignores the message without sending any response.</li> </ul> |
| Method List<br>CLI: method-list<br>[MessagePolicy_MethodList]                     | Defines the SIP methods (e.g., INVITE\BYE) to which the rule applies.<br>The syntax for entering the methods is as follows: <ul style="list-style-type: none"> <li>▪ Methods must be separated by a backslash (\).</li> <li>▪ The entered value is not case sensitive.</li> </ul>                                                                                                 |

| Parameter                                                                          | Description                                                                                                                                                                                                                                                                                                                                |
|------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Method List Type<br>CLI: method-list-type<br><b>[MessagePolicy_MethodListType]</b> | Determines the policy for the SIP methods. <ul style="list-style-type: none"><li>▪ <b>[0]</b> Policy Blacklist = The specified methods (in the 'Method List' field) are rejected by the policy.</li><li>▪ <b>[1]</b> Policy Whitelist = (Default) The specified methods (in the 'Method List' field) are allowed by the policy.</li></ul>  |
| Body List<br>CLI: body-list<br><b>[MessagePolicy_BodyList]</b>                     | Defines the SIP body (i.e., value of the Content-Type header) to which the rule applies.                                                                                                                                                                                                                                                   |
| Body List Type<br>CLI: body-list-type<br><b>[MessagePolicy_BodyListType]</b>       | Determines the policy for the defined SIP body. <ul style="list-style-type: none"><li>▪ <b>[0]</b> Policy Blacklist = The specified SIP body (in the 'Body List' field) is rejected by the policy.</li><li>▪ <b>[1]</b> Policy Whitelist = (Default) The specified SIP body (in the 'Body List' field) is allowed by the policy.</li></ul> |

## 23 Coders and Profiles

This section describes configuration of the coders and SIP profiles parameters.

### 23.1 Configuring Coders

The Coders page allows you to configure up to 10 voice coders for the device. Each coder can be configured with packetization time (ptime), bit rate, payload type, and silence suppression. The first coder configured in the table has the highest priority and is used by the device whenever possible. If the remote side cannot use the first coder, the device attempts to use the next coder in the table, and so on.

#### Notes:

- A specific coder can only be configured once in the table.
- If packetization time and/or rate are not specified, the default is applied.
- Only the packetization time of the first coder in the coder list is declared in INVITE/200 OK SDP, even if multiple coders are defined.
- The device always uses the packetization time requested by the remote side for sending RTP packets. If not specified, the packetization time is assigned the default value.
- The value of several fields is hard-coded according to common standards (e.g., payload type of G.711 U-law is always 0). Other values can be set dynamically. If no value is specified for a dynamic field, a default is assigned. If a value is specified for a hard-coded field, the value is ignored.
- If silence suppression is not configured for a coder, the settings of the EnableSilenceCompression parameter is used.
- The G.722 coder provides Packet Loss Concealment (PLC) capabilities, ensuring higher voice quality.
- For G.729, it's also possible to select silence suppression without adaptations.
- If G.729 is selected and silence suppression is disabled, the device includes 'annexb=no' in the SDP of the relevant SIP messages. If silence suppression is enabled or set to 'Enable w/o Adaptations', 'annexb=yes' is included. An exception to this logic is when the remote gateway is a Cisco device (IsCiscoSCEMode).
- For defining groups of coders, which can be assigned to Tel and IP Profiles, see 'Configuring Coder Groups' on page [236](#).
- For information on V.152 and implementation of T.38 and VBD coders, see 'Supporting V.152 Implementation' on page [160](#).
- The Coders table can also be configured using the table *ini* file parameter, CodersGroup or CLI command, configure voip > coders-and-profiles coders-group-<index>.

➤ **To configure the device's coders:**

1. Open the Coders page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** submenu > **Coders**).

**Figure 23-1: Coders Table Page**

| Coder Name | Packetization Time | Rate | Payload Type | Silence Suppression |
|------------|--------------------|------|--------------|---------------------|
| G.723.1    | 30                 | 5.3  | 4            | Disabled            |
|            |                    |      |              |                     |
|            |                    |      |              |                     |
|            |                    |      |              |                     |
|            |                    |      |              |                     |

2. From the 'Coder Name' drop-down list, select the required coder.
3. From the 'Packetization Time' drop-down list, select the packetization time (in msec) for the selected coder. The packetization time determines how many coder payloads are combined into a single RTP packet.
4. From the 'Rate' drop-down list, select the bit rate (in kbps) for the selected coder.
5. In the 'Payload Type' field, if the payload type (i.e., format of the RTP payload) for the selected coder is dynamic, enter a value from 0 to 120 (payload types of 'well-known' coders cannot be modified).
6. From the 'Silence Suppression' drop-down list, enable or disable the silence suppression option for the selected coder.
7. Repeat steps 2 through 6 for the next optional coders.
8. Click **Submit**.
9. To save the changes to flash memory, see 'Saving Configuration' on page 532.

The table below lists the supported coders:

**Supported Coders**

| Coder Name                      | Packetization Time (msec)                      | Rate (kbps)  | Payload Type                      | Silence Suppression                                                                   |
|---------------------------------|------------------------------------------------|--------------|-----------------------------------|---------------------------------------------------------------------------------------|
| G.711 A-law<br>[g711Alaw64k]    | 10, 20 (default), 30, 40, 50, 60, 80, 100, 120 | 64           | 8                                 | <ul style="list-style-type: none"> <li>▪ [0] Disable</li> <li>▪ [1] Enable</li> </ul> |
| G.711 U-law<br>[g711Ulaw64k]    | 10, 20 (default), 30, 40, 50, 60, 80, 100, 120 | 64           | 0                                 | <ul style="list-style-type: none"> <li>▪ [0] Disable</li> <li>▪ [1] Enable</li> </ul> |
| G.711A-law_VBD<br>[g711AlawVbd] | 10, 20 (default), 30, 40, 50, 60, 80, 100, 120 | 64           | Dynamic (0-127)<br>Default is 180 | N/A                                                                                   |
| G.711U-law_VBD<br>[g711UlawVbd] | 10, 20 (default), 30, 40, 50, 60, 80, 100, 120 | 64           | Dynamic (0-127)<br>Default is 120 | N/A                                                                                   |
| G.722<br>[g722]                 | 20 (default), 40, 60, 80, 100, 120             | 64 (default) | 9                                 | N/A                                                                                   |

| Coder Name                 | Packetization Time (msec)                 | Rate (kbps)                                                                                                                                                                                                                                  | Payload Type                     | Silence Suppression                                                                                                         |

## 23.2 Configuring Coder Groups

The Coder Group Settings page allows you to define up to 10 groups of coders (termed *Coder Groups*). For each Coder Group, you can define up to 10 coders configured with packetization time (ptime), rate, payload type, and silence suppression. The first coder in the Coder Group table has the highest priority and is used by the device whenever possible. If the remote side cannot use the first coder, the device attempts to use the next coder, and so on.

Coder Groups can be used as follows:

- Assigned to Tel Profiles in the Tel Profiles table (see Configuring Tel Profiles on page 237). This is applicable only to the GW/IP-to-IP application.
- Assigned to IP Profiles in the IP Profiles table (see 'Configuring IP Profiles' on page 239). In this setup, they can be used as Extension coders and Allowed coders for the SBC application.

### Notes:

- A specific coder can be selected only once per Coder Group.
- For a list of supported coders, see 'Configuring Coders' on page 233.
- The Coder Group Settings table can also be configured using the table *ini* file parameter, CodersGroup or CLI command, configure voip > coders-and-profiles coders-group-<index>.

### ➤ To configure Coder Groups:

1. Open the Coder Group Settings page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** submenu > **Coders Group Settings**).

**Figure 23-2: Coder Group Settings Page**

| Coder Name | Packetization Time | Rate | Payload Type | Silence Suppression |
|------------|--------------------|------|--------------|---------------------|
| G.723.1    | 30                 | 5.3  | 4            | Disabled            |
|            |                    |      |              |                     |
|            |                    |      |              |                     |
|            |                    |      |              |                     |
|            |                    |      |              |                     |

2. From the 'Coder Group ID' drop-down list, select a Coder Group ID.
3. From the 'Coder Name' drop-down list, select the first coder for the Coder Group.
4. From the 'Packetization Time' drop-down list, select the packetization time (in msec) for the coder. The packetization time determines how many coder payloads are combined into a single RTP packet.
5. From the 'Rate' drop-down list, select the bit rate (in kbps) for the coder you selected.
6. In the 'Payload Type' field, if the payload type (i.e., format of the RTP payload) for the coder you selected is dynamic, enter a value from 0 to 120 (payload types of common coders cannot be modified).

7. From the 'Silence Suppression' drop-down list, enable or disable the silence suppression option for the coder you selected.
8. Repeat steps 3 through 7 for the next coders (optional).
9. Repeat steps 2 through 8 for the next coder group (optional).
10. Click **Submit** to apply your changes.

## 23.3 Configuring Tel Profile

The Tel Profile Settings table allows you to define up to nine configuration profiles for Tel calls. These profiles are termed *Tel Profiles*. The Tel Profile Settings table contains a list of parameters, which can also be configured globally for all calls using their corresponding "global" parameters. The only difference between the Tel Profile parameters and the global parameters regarding description may be their default values.

Tel Profiles provide high-level adaptation when the device interworks between different equipment and protocols (at both the Tel and IP sides), each of which may require different handling by the device. Once configured, Tel Profiles can be assigned to specific channels (trunks). Therefore, Tel Profiles enable you to assign special configuration settings for device handling of specific calls. For example, if specific channels require the use of the G.711 coder, you can configure a Tel Profile with this coder and assign it to these channels. Tel Profiles are assigned to channels in the Trunk Group Table (see Configuring the Trunk Group Table on page 289).

The procedure below describes how to configure Tel Profiles using the Web interface.

**Note:** Tel Profiles can also be configured using the table *ini* file parameter, TelProfile (see 'Configuration Parameters Reference' on page 655) or CLI command, configure voip/coders-and-profiles tel-profile.

➤ **To configure Tel Profiles:**

1. Open the Tel Profile Settings page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** submenu > **Tel Profile Settings**).

|                                            |                     |
|--------------------------------------------|---------------------|
| Profile ID                                 | 1                   |
| Profile Name                               | mike                |
| <b>Profile Parameters</b>                  |                     |
| Profile Preference                         | 1                   |
| Fax Signaling Method                       | No Fax              |
| Dynamic Jitter Buffer Minimum Delay [msec] | 10                  |
| Dynamic Jitter Buffer Optimization Factor  | 10                  |
| RTP IP DiffServ                            | 46                  |
| Signaling DiffServ                         | 40                  |
| Voice Volume (-32 to 31 dB)                | 0                   |
| DTMF Volume (-31 to 0 dB)                  | -11                 |
| Input Gain (-32 to 31 dB)                  | 0                   |
| Enable Digit Delivery                      | Disable             |
| Enable Polarity Reversal                   | Enable              |
| Enable Current Disconnect                  | Disable             |
| MWI Analog Lamp                            | Disable             |
| MWI Display                                | Disable             |
| Dial Plan Index                            | -1                  |
| Echo Canceler                              | Enable              |
| Flash Hook Period                          | 700                 |
| Enable Early Media                         | Disable             |
| Progress Indicator to IP                   | Not Configured      |
| Enable DID Wink                            | Disable             |
| Dialing Mode                               | Two Stages          |
| Enable Voice Mail Delay                    | Enable              |
| Disconnect Call on Detection of Busy Tone  | Enable              |
| Time For Reorder Tone [sec]                | 255                 |
| Enable 911 PSAP                            | Disable             |
| Enable AGC                                 | Disable             |
| EC NLP Mode                                | Adaptive NLP        |
| Swap Tel To IP Phone Numbers               | Disable             |
| <b>Coder Group</b>                         |                     |
| Coder Group                                | Default Coder Group |

2. From the 'Profile ID' drop-down list, select the Tel Profile index.
3. In the 'Profile Name' field, enter an arbitrary name that enables you to easily identify the Tel Profile.
4. From the 'Profile Preference' drop-down list, select the priority of the Tel Profile, where **1** is the lowest priority and **20** the highest. If both IP and Tel profiles apply to the same call, the coders and other common parameters (noted by an asterisk in the description of the parameter TelProfile) of the preferred Profile are applied to that call. If the Preference of the Tel and IP Profiles is identical, the Tel Profile parameters are applied.  
**Note:** If the coder lists of both IP and Tel Profiles apply to the same call, only the coders common to both are used. The order of the coders is determined by the

preference.

5. Configure the parameters as required. For a description of each parameter, refer to the corresponding "global" parameter.
6. Click **Submit** to apply your changes.

## 23.4 Configuring IP Profiles

The IP Profile Settings table allows you to define up to nine *IP Profiles*. An IP Profile is a set of special call configuration behaviors relating to signaling (e.g., SIP message terminations such as REFER) and media (e.g., coder used) applied to specific IP calls (inbound and/or outbound). Therefore, IP Profiles provide high-level adaptation when the device interworks between different IP entities (for Tel and IP sides), each of which may require different handling by the device. For example, if a specific IP entity uses the G.711 coder only, you can configure an IP Profile with G.711 for this IP entity.

Many of the parameters in the IP Profile Settings table have a corresponding "global" parameter. If an IP Profile is not associated with specific calls, the settings of the global parameters are applied to these calls.

IP Profiles can be assigned to the following configuration elements:

- IP Groups - see Configuring IP Groups on page [204](#)
- Outbound IP routing rules (for Gateway / IP-to-IP application) - see Configuring Outbound IP Routing Table on page [321](#)
- Inbound IP routing rules (for Gateway / IP-to-IP application) - see Configuring Inbound IP Routing Table on page [330](#)

The device selects the IP Profile as follows:

- If different IP Profiles (not default) are assigned to the same specific calls in all these tables, the device uses the IP Profile that has the highest preference level (as set in the 'Profile Preference' field). If they have the same preference level, the device uses the IP Profile assigned in the IP Group table.
- If different IP Profiles are assigned to these tables and one table is set to the default IP Profile, the device uses the IP Profile that is not the default.

### Notes:

- IP Profiles can also be implemented when using a Proxy server (when the AlwaysUseRouteTable parameter is set to 1).
- RxDTMFOption configures the received DTMF negotiation method: [-1] not configured, use the global parameter; [0] don't declare RFC 2833; [1] declare RFC 2833 payload type is SDP.
- You can also configure IP Profiles using the table ini file parameter, IPProfile (see Configuration Parameters Reference on page [655](#)) or the CLI command, configure voip > coders-and-profiles ip-profile.

➤ **To configure IP Profiles:**

1. Open the IP Profile Settings page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** submenu > **IP Profile Settings**).

|              |   |
|--------------|---|
| Profile ID   | 1 |
| Profile Name |   |

|                                               |           |
|-----------------------------------------------|-----------|
| <b>Common Parameters</b>                      |           |
| RTP IP DiffServ                               | 46        |
| Signaling DiffServ                            | 40        |
| Disconnect on Broken Connection               | Yes       |
| Media IP Version Preference                   | Only IPv4 |
| Dynamic Jitter Buffer Minimum Delay [msec](*) | 10        |
| Dynamic Jitter Buffer Optimization Factor(*)  | 10        |
| RTP Redundancy Depth(*)                       | 0         |
| Echo Canceled(*)                              | Enable    |
| Input Gain (-32 to 31 dB)(*)                  | 0         |

| Web: Number of Calls Limit<br>[IpProfile_CallLimit]                                    | <p>Defines the maximum number of concurrent calls (incoming and outgoing). If the number of concurrent calls reaches this limit, the device rejects any new incoming and outgoing calls belonging to this IP Profile.</p> <p>This parameter can also be set to the following:</p> <ul style="list-style-type: none"> <li>▪ [-1] = (Default) No limitation on calls.</li> <li>▪ [0] = Calls are rejected.</li> </ul> <p><b>Note:</b> For IP-to-IP calls, you can configure the device to route calls to an alternative IP Group when this maximum number of concurrent calls is reached. To do so, you need to add an alternative routing rule in the Outbound IP Routing table that reroutes the call to an alternative IP Group. You also need to add a rule to the Reason for Alternative Routing table to initiate an alternative rule for Tel-to-IP calls using cause 805.</p> |

| Web: Extension Coders Group ID<br><b>[IpProfile_SBCExtensionCodersGroupID]</b> | <p>Defines the Coders Group ID used for Extended (additional) coders added to the outgoing leg for this profile. This is used when transcoding is required between two IP entities (i.e., the SDP answer from one doesn't include any coder included in the offer previously sent by the other). Therefore, to allow IP entities to communicate with each other regardless of their capabilities, an Extended coders table with at least one coder that is supported by each IP entity needs to be assigned to each IP Group. Therefore, each offer destined to specific IP Groups includes this coder.</p> <p><b>Note:</b> To configure Coders Groups, see Configuring Coders Groups.</p> |
| Web: Allowed Coders Group ID<br><b>[IpProfile_SBCAllowedCodersGroupID]</b>     | <p>Associates a Coders Group ID for defining the coders that can be used for this IP entity.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>For a description of the Allowed Coders feature, see Restricting Coders.</li> <li>To configure Allowed Coders Groups, see Configuring Allowed Coders Groups.</li> </ul>                                                                                                                                                                                                                                                                                                                                                       |

# Part V

## Gateway and IP-to-IP Application

## 24 IP-to-IP Routing Overview

This section describes configuration of the Gateway and IP-to-IP applications. The Gateway application refers to IP-to-Tel (PSTN) call routing and vice versa. The IP-to-IP application refers to call routing of calls received from the IP and forwarded to an IP destination. For a description of the IP-to-IP application, see IP-to-IP Routing Application on page 253.

### Notes:

- In some areas of the Web interface, the term "GW" and "IP2IP" application refers to the Gateway and IP-to-IP applications, respectively.
- The terms *IP-to-Tel* and *Tel-to-IP* refer to the direction of the call relative to the device. IP-to-Tel refers to calls received from the IP network and destined to the PSTN/PBX (i.e., telephone connected directly or indirectly to the device); Tel-to-IP refers to calls received from telephones connected directly to the device's FXS ports or from the PSTN/PBX, and destined for the IP network.
- FXO (Foreign Exchange Office) is the interface replacing the analog telephone and connects to a Public Switched Telephone Network (PSTN) line from the Central Office (CO) or to a Private Branch Exchange (PBX). The FXO is designed to receive line voltage and ringing current, supplied from the CO or the PBX (just like an analog telephone). An FXO VoIP device interfaces between the CO/PBX line and the Internet.
- FXS (Foreign Exchange Station) is the interface replacing the Exchange (i.e., the CO or the PBX) and connects to analog telephones, dial-up modems, and fax machines. The FXS is designed to supply line voltage and ringing current to these telephone devices. An FXS VoIP device interfaces between the analog telephone devices and the Internet.

The device's IP-to-IP application supports IP-to-IP VoIP call routing (or SIP Trunking). The IP-to-IP call routing application enables enterprises to seamlessly connect their IP-based PBX (IP-PBX) to SIP trunks, typically provided by Internet Telephony Service Providers (ITSP). The device enables the enterprise to communicate with the PSTN network (local and overseas) through the ITSP, which interfaces directly with the PSTN. Therefore, the IP-to-IP application enables enterprises to replace the bundles of physical PSTN wires with SIP trunks provided by ITSPs and use VoIP to communicate within and outside the enterprise network using its standard Internet connection. At the same time, the device can also provide an interface with the traditional PSTN network, enabling PSTN fallback in case of IP connection failure with the ITSPs.

The device also supports multiple SIP Trunking. This can be useful in scenarios where if a connection to one ITSP fails, the call can immediately be transferred to another ITSP. In addition, by allowing multiple SIP trunks where each trunk is designated a specific ITSP, the device can route calls to an ITSP based on call destination (e.g., country code).

In addition to providing VoIP communication within the enterprise's LAN, the device enables the enterprise to communicate outside of the corporate LAN using SIP Trunking. This includes remote (roaming) IP-PBX users, for example, employees using their laptops to communicate with one another from anywhere in the world such as at airports.

The IP-to-IP application can be implemented by enterprises in the following example scenarios:

- VoIP between an enterprise's headquarters and remote branch offices
- VoIP between an enterprise and the PSTN through an ITSP

The IP-to-IP call routing capability is feature-rich, allowing interoperability with different ITSPs:

- Easy and smooth integration with multiple ITSP SIP trunks.
- Supports SIP registration and authentication with ITSP servers (on behalf of the enterprise's IP telephony system) even if the enterprise's IP telephony system does not support registration and authentication.
- Supports SIP-over-UDP, SIP-over-TCP, and SIP-over-TLS transport protocols, one of which is generally required by the ITSP.
- Provides alternative routing to different destinations (to another ITSP or the PSTN) when the connection with an ITSP network is down.
- Provides fallback to the legacy PSTN telephone network upon Internet connection failure.
- Provides Transcoding from G.711 to G.729 coder with the ITSP for bandwidth reduction.
- Supports SRTP, providing voice traffic security toward the ITSP.
- IP-to-IP routing can be used in combination with the regular Gateway application. For example, an incoming IP call can be sent to an E1/T1 span or it can be forwarded to an IP destination.

Therefore, the device provides the ideal interface between the enterprise IP-PBX and the ITSP SIP trunk.

The device's IP-to-IP application handles and terminates SIP methods and responses at each leg independently:

- Initiating-dialog INVITE: terminated at one leg and initiated on the other leg, 180\182\183\200\4xx uses the same logic and same limitations, in some cases the result may be a different response code.
- OPTIONS: terminated at each leg independently.
- INFO: only specific INFO's (such as DTMF) are handled; other types are omitted.
- UPDATE: terminated at each leg independently and may cause only changes in the RTP flow - Hold\Retrieve are the only exceptions that traverse the two legs.
- Re-INVITE: terminated at each leg independently and may cause only changes in the RTP flow - Hold\Retrieve are the only exceptions that traverse the two legs.
- PRACK: terminated at each leg independently.
- REFER (within a dialog): terminated at each leg independently.
- 3xx Responses: terminated at each leg independently.
- 401\407 responses to initial INVITE: in case the back-to-back session is associated with an Account, the responses is terminated at the receiving leg; in other cases, the responses are passed transparently.
- REGISTER: handled only in cases associated with a User-type IP Group - Contact, To, From specific parameters are omitted.

## 24.1 Theory of Operation

The device's IP-to-IP SIP session is performed by implementing Back-to-Back User Agent (B2BUA). The device acts as a user agent for both ends (*legs*) of the SIP call (from call establishment to termination). The session negotiation is performed independently for each call leg, using global parameters such as coders or using IP Profiles associated with each call leg to assign different configuration behaviors for these two IP-to-IP call legs.

For the maximum number of supported IP-to-IP sessions, see DSP Templates on page 893.

The device also supports NAT traversal for SIP clients behind NAT, where the device is defined with a global IP address.

The figure below provides a simplified illustration of the device's handling of IP-to-IP call routing:

**Figure 24-1: Basic Schema of the Device's IP-to-IP Call Handling**

The basic IP-to-IP call handling process can be summarized as follows:

1. Incoming IP calls are identified as belonging to a specific logical entity in the network referred to as a *Source IP Group*, according to Inbound IP Routing rules.
2. The Source IP Group is sent to a specific IP Group referred to as a *Destination IP Group*; the IP destination address being as configured by the *Proxy Set* associated with the Destination IP Group.
3. Number manipulation can be done on inbound and outbound legs.

The following subsections discuss the main terms associated with the IP-to-IP call routing application.

### 24.1.1 Proxy Sets

A Proxy Set is a group of Proxy servers (for Proxy load balancing and redundancy) defined by IP address or fully qualified domain name (FQDN). The Proxy Set is assigned to Server-type IP Groups only, representing the address of the IP Group to where the device sends the INVITE message (i.e., the **destination** of the call). Typically, for IP-to-IP call routing, two Proxy Sets are defined for call destination – one for each leg (i.e., one for each IP Group) of the call (i.e., both directions).

### 24.1.2 IP Groups

An IP Group represents a logical SIP entity in the device's network environment such as an ITSP SIP trunk, Proxy/Registrar server, IP-PBX, or remote IP-PBX users. The address of the IP Group is typically defined by its associated Proxy Set.

The opposite legs of the call are each presented by an IP Group; one being a *Serving* IP Group the other a *Served* IP Group. The Serving IP Group denotes the IP Group that provides service (e.g., ITSP) to the Served IP Group (e.g., IP-PBX). This is the IP Group to where the device sends INVITE messages received from the Served IP Group as well as REGISTER messages for registering on behalf of the Served IP Group.

IP Group can be a *Server* or *User* type. For Server-type IP Groups (e.g., ITSP or IP-PBX), the destination address (defined by the Proxy Set) is known. In contrast, User-type IP Groups represents groups of users whose location is dynamically obtained by the device when REGISTER requests and responses traverse (or are terminated) by the device. Generally, these are remote IP-PBX users (e.g., IP phones and soft phones).

For registrations of User-type IP Groups, the device updates its internal database with the AOR and Contacts of the users (see the figure below) Digest authentication using SIP

401/407 responses, if needed, is done by the Serving IP Group (e.g., IP-PBX). The device forwards these responses directly to the remote SIP users. For a call to a registered remote user, the device searches its dynamic database using the Request URI for an entry that matches a registered AOR or Contact. Once an entry is found, the IP destination is obtained and a SIP request is then sent to the user.

**Figure 24-2: IP-to-IP Routing/Registration/Authentication of Remote IP-PBX Users (Example)**

The device also supports the IP-to-IP call routing Survivability mode feature (see the figure below) for User-type IP Groups. The device stores in its database REGISTER messages sent by the clients of the User-type IP Group. If communication with the Serving IP Group (e.g., IP-PBX) fails, the User-type IP Group enters into Survivability mode in which the device uses its database for routing calls between the clients of the User-type IP Group. The RTP packets between the clients traverse through the device. When the Serving IP Group is available again, the device returns to normal mode, sending INVITE and REGISTER messages to the Serving IP Group.

**Figure 24-3: IP-to-IP Routing for IP-PBX Remote Users in Survivability Mode (Example)**

### 24.1.3 Inbound and Outbound IP Routing Rules

The device's IP-to-IP call routing is performed using the following two routing rule stages:

1. **Inbound IP Routing Mapping Rule:** Identifies the received call as an IP-to-IP call based on various characteristics such as the call's source IP address, and assigns it to an IP Group.
2. **Outbound IP Routing Mapping Rule:** Determines the destination (i.e., IP address) to where the incoming call associated with a specific source IP Group is finally routed. The destination address is typically denoted by another IP Group (destination IP Group) and therefore, the call is sent to the IP address that is defined by the Proxy Set associated with this IP Group. If the destination is a User-type IP Group, the device searches for a match between the request-URI of the received INVITE to an AOR registration record in the device's database. If a match is found, the INVITE is sent to the IP address of the registered contact.

### 24.1.4 Accounts

Accounts are used by the device to register to a Serving IP Group (e.g., an ITSP) on behalf of a Served IP Group (e.g., IP-PBX). This is necessary for ITSPs that require registration to provide services. Accounts are also used for defining user name and password for digest authentication (with or without registration) if required by the ITSP. Multiple Accounts per Served IP Group can be configured for registration to more than one Serving IP Group (e.g., an IP-PBX that requires registering to multiple ITSP's).

**Figure 24-4: Registration with Multiple ITSP's on Behalf of IP-PBX**

## 24.2 IP-to-IP Routing Configuration Example

This section provides step-by-step procedures for configuring IP-to-IP call routing. These procedures are based on the setup example described below. In this example, the device serves as the communication interface between the enterprise's IP-PBX (located on the LAN) and the following network entities:

- ITSP SIP trunks (located on the WAN)
- Remote IP-PBX users (located on the WAN)
- Local PSTN network

Calls from the Enterprise are routed according to destination.

This example assumes the following:

- The device has the public IP address 212.25.125.136 and is connected to the enterprise's firewall/NAT demilitarized zone (DMZ) network, providing the interface

between the IP-PBX, and two ITSP's and the local PSTN.

- The enterprise has an IP-PBX located behind a Firewall/NAT:
  - IP-PBX IP address: 10.15.4.211
  - Transport protocol: UDP
  - Voice coder: G.711
  - IP-PBX users: 4-digit length extension number and served by two ITSPs.
  - The enterprise also includes remote IP-PBX users that communicate with the IP-PBX via the device. All dialed calls from the IP-PBX consisting of four digits starting with digit "4" are routed to the remote IP-PBX users.
- Using SIP trunks, the IP-PBX connects (via the device) to two different ITSP's:
  - **ITSP-A:**
    - ◆ Implements Proxy servers with fully qualified domain names (FQDN): "Proxy1.ITSP-A" and "Proxy2.ITSP-B", using TLS.
    - ◆ Allocates a range of PSTN numbers beginning with +1919, which is assigned to a range of IP-PBX users.
    - ◆ Voice coder: G.723.
  - **ITSP-B:**
    - ◆ Implements Proxy servers with IP addresses 216.182.224.202 and 216.182.225.202, using TCP.
    - ◆ Allocates a range of PSTN numbers beginning with 0200, which is assigned to a range of IP-PBX users.
    - ◆ Voice coder: G.723.
- Registration and authentication is required by both ITSP's, which is performed by the device on behalf of the IP-PBX. The SIP REGISTER messages use different URI's (host name and contact user) in the From, To, and Contact headers per ITSP as well as username and password authentication.
- Outgoing calls from IP-PBX users are routed according to destination:
  - If the calls are dialed with the prefix "+81", they are routed to ITSP-A (Region A).
  - If the calls are dialed with the prefix "9", they are routed to the local PSTN network.
  - For all other destinations, the calls are routed to ITSP-B.
- The device is also connected to the PSTN through a traditional T1 ISDN trunk for local incoming and outgoing calls. Calls dialed from the enterprise's IP-PBX with prefix '9' are sent to the local PSTN. In addition, in case of Internet interruption and loss of connection with the ITSP trunks, all calls are rerouted to the PSTN.

The figure below provides an illustration of this example scenario:

**Figure 24-5: SIP Trunking Setup Scenario Example**

The steps for configuring the device according to the scenario above can be summarized as follows:

- Enable the IP-to-IP feature (see 'Step 1: Enable the IP-to-IP Capabilities' on page 260).
- Configure the number of media channels (see 'Step 2: Configure the Number of Media Channels' on page 260).
- Configure a Trunk Group for interfacing with the local PSTN (see 'Step 3: Define a Trunk Group for the Local PSTN' on page 260).
- Configure Proxy Sets (see 'Step 4: Configure the Proxy Sets' on page 261).
- Configure IP Groups (see 'Step 5: Configure the IP Groups' on page 263).
- Configure Registration Accounts (see 'Step 6: Configure the Account Table' on page 264).
- Configure IP Profiles (see 'Step 7: Configure IP Profiles for Voice Coders' on page 265).
- Configure inbound IP routing rules (see 'Step 8: Configure Inbound IP Routing' on page 266).
- Configure outbound IP routing rules (see 'Step 9: Configure Outbound IP Routing' on page 268).
- Configure destination phone number manipulation (see 'Step 10: Configure Destination Phone Number Manipulation' on page 270).

## 24.2.1 Step 1: Enable the IP-to-IP Capabilities

This step describes how to enable the device's IP-to-IP application.

➤ **To enable IP-to-IP capabilities:**

1. Open the Applications Enabling page (**Configuration** tab > **VoIP** menu > **Applications Enabling** submenu > **Applications Enabling**).
2. From the 'IP to IP Application' drop-down list, select **Enable**.
3. Click **Submit**.
4. Save the setting to flash memory ("burn") with a device reset.

**Note:** For the IP-to-IP Application feature, the device must also be installed with the appropriate Software License Key.

## 24.2.2 Step 2: Configure the Number of Media Channels

The number of media channels represents the number of digital signaling processors (DSP) channels that the device allocates to IP-to-IP calls. The remaining DSP channels can be used for PSTN calls. Two IP media channels are used per IP-to-IP call.

➤ **To configure the number of media channels:**

1. Open the IP Media Settings page (**Configuration** tab > **VoIP** menu > **IP Media** > **IP Media Settings**).

**Figure 24-6: Defining Required Media Channels**

2. In the 'Number of Media Channels' field, enter the required number of media channels (in the example above, "120" to enable up to 60 IP-to-IP calls).
3. Click **Submit**.
4. Save the settings to flash memory ("burn") with a device reset (see 'Saving Configuration' on page 532).

## 24.2.3 Step 3: Define a Trunk Group for the Local PSTN

For incoming and outgoing local PSTN calls with the IP-PBX, you need to define the Trunk Group ID (#1) for the T1 ISDN trunk connecting the device to the local PSTN. This Trunk Group is also used for alternative routing to the PSTN if connectivity with the ITSP fails.

➤ **To configure the Trunk Group for local PSTN:**

1. Open the Trunk Group Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Trunk Group** > **Trunk Group**).
2. Configure Trunk Group ID #1 (as shown in the figure below):
  - From the 'From Trunk' and 'To Trunk' drop-down lists, select **1** to indicate Trunk 1 for this Trunk Group.
  - In the 'Channels' field, enter the Trunk channels or ports assigned to the Trunk Group (e.g. 1-31 for E1 and 1-24 for T1).

- In the 'Phone Number' field, enter any phone number (logical) for this Trunk (e.g. 1000).
- In the 'Trunk Group ID' field, enter "1" as the ID for this Trunk Group.

|                             |  |         |  |
|-----------------------------|--|---------|--|
| Add Phone Context As Prefix |  | Disable |  |
| Trunk Group Index           |  | 1-12    |  |

| Group Index | Module       | From Trunk | To Trunk | Channels | Phone Number | Trunk Group ID | Tel Profile ID |
|-------------|--------------|------------|----------|----------|--------------|----------------|----------------|
| 1           | Module 1 PRI | 1          | 1        | 1-31     | 1000         | 1              |                |
| 2           |              |            |          |          |              |                |                |

3. Configure the Trunk in the Trunk Settings page (**Configuration** tab > **VoIP** menu > **PSTN > Trunk Settings**).

## 24.2.4 Step 4: Configure the Proxy Sets

The Proxy Sets represent the actual destination (IP address or FQDN) to which the call is routed. These Proxy Sets are later assigned to IP Groups (see 'Step 5: Configure the IP Groups' on page 263).

This step describes how to configure the following Proxy Sets:

- Proxy Set ID #1 with two FQDN's for ITSP-A
- Proxy Set ID #2 with two IP addresses for ITSP-B
- Proxy Set ID #3 with an IP address for the IP-PBX

### ➤ To configure the Proxy Sets:

1. Open the Proxy Sets Table page (**Configuration** tab > **VoIP** menu > **Control Network > Proxy Sets Table**).
2. Configure Proxy Set ID #1 for ITSP-A:
  - a. From the 'Proxy Set ID' drop-down list, select **1**.
  - b. In the 'Proxy Address' column, enter the FQDN of ITSP-A SIP trunk Proxy servers (e.g., "Proxy1.ITSP-A" and "Proxy2. ITSP-A").
  - c. From the 'Transport Type' drop-down list corresponding to the Proxy addresses entered above, select **TLS**.

- d. In the 'Enable Proxy Keep Alive' drop-down list, select **Using Options**, and then in the 'Proxy Load Balancing Method' drop-down list, select **Round Robin**.

**Figure 24-7: Proxy Set ID #1 for ITSP-A**

Proxy Set ID: 1

|   | Proxy Address | Transport Type |
|---|---------------|----------------|
| 1 | Proxy1.ITSP-A | TLS            |
| 2 | Proxy2.ITSP-A | TLS            |
| 3 |               |                |
| 4 |               |                |
| 5 |               |                |

Enable Proxy Keep Alive: Using Options  
 Proxy Keep Alive Time: 60  
 Proxy Load Balancing Method: Round Robin  
 Is Proxy Hot Swap: No  
 Proxy Redundancy Mode: (-1) - Not Configured  
 SRD Index: 0

3. Configure Proxy Set ID #2 for ITSP-B:
  - a. From the 'Proxy Set ID' drop-down list, select 2.
  - b. In the 'Proxy Address' column, enter the IP addresses of the ITSP-B SIP trunk (e.g., "216.182.224.202" and "216.182.225.202").
  - c. From the 'Transport Type' drop-down list corresponding to the IP address entered above, select **UDP**.
  - d. In the 'Enable Proxy Keep Alive' drop-down list, select "Using Options", and then in the 'Proxy Load Balancing Method' drop-down list, select **Round Robin**.

**Figure 24-8: Proxy Set ID #2 for ITSP-B**

Proxy Set ID: 2

|   | Proxy Address   | Transport Type |
|---|-----------------|----------------|
| 1 | 216.182.224.202 | UDP            |
| 2 | 216.182.225.202 | UDP            |
| 3 |                 |                |
| 4 |                 |                |
| 5 |                 |                |

Enable Proxy Keep Alive: Using Options  
 Proxy Keep Alive Time: 60  
 Proxy Load Balancing Method: Round Robin  
 Is Proxy Hot Swap: No  
 Proxy Redundancy Mode: (-1) - Not Configured  
 SRD Index: 0

4. Configure Proxy Set ID #3 for the IP-PBX:
  - a. From the 'Proxy Set ID' drop-down list, select 3.
  - b. In the 'Proxy Address' column, enter the IP address of the IP-PBX (e.g., "10.15.4.211").

- c. From the 'Transport Type' drop-down list corresponding to the IP address entered above, select **UDP**".
- d. In the 'Enable Proxy Keep Alive' drop-down list, select **Using Options**. This is used in Survivability mode for remote IP-PBX users.

**Figure 24-9: Proxy Set ID #3 for the IP-PBX**

The screenshot shows the configuration for Proxy Set ID #3. The 'Proxy Set ID' dropdown is set to 3 (callout 4a). Below it is a table with 5 rows for Proxy Address and Transport Type (callout 4b). The first row has the address 10.15.4.211 and Transport Type UDP (callout 4c). Below the table is a section for Proxy Keep Alive settings (callout 4d). The 'Enable Proxy Keep Alive' dropdown is set to 'Using Options'. Other settings include Proxy Keep Alive Time: 60, Proxy Load Balancing Method: Disable, Is Proxy Hot Swap: No, Proxy Redundancy Mode: (-1) - Not Configured, and SRD Index: 0.

| Proxy Address | Transport Type |
|---------------|----------------|
| 1 10.15.4.211 | UDP            |
| 2             |                |
| 3             |                |
| 4             |                |
| 5             |                |

|                             |                       |
|-----------------------------|-----------------------|
| Enable Proxy Keep Alive     | Using Options         |
| Proxy Keep Alive Time       | 60                    |
| Proxy Load Balancing Method | Disable               |
| Is Proxy Hot Swap           | No                    |
| Proxy Redundancy Mode       | (-1) - Not Configured |
| SRD Index                   | 0                     |

## 24.2.5 Step 5: Configure the IP Groups

This step describes how to create the IP Groups for the following entities in the network:

- ITSP-A SIP trunk
- ITSP-B SIP trunk
- IP-PBX server
- IP-PBX remote users

These IP Groups are later used by the device for routing calls.

### ➤ To configure the IP Groups:

1. Open the IP Group Table page (**Configuration** tab > **VoIP** menu > **Control Network** > **IP Group Table**).
2. Define IP Group #1 for ITSP-A:
  - a. From the 'Type' drop-down list, select **Server**.
  - b. In the 'Description' field, type an arbitrary name for the IP Group (e.g., ITSP A).
  - c. From the 'Proxy Set ID' drop-down lists, select **1** (represents the IP addresses, configured in , for communicating with this IP Group).
  - d. In the 'SIP Group Name' field, enter the host name sent in the SIP Request From\To headers for this IP Group, as required by ITSP-A (e.g., RegionA).
  - e. Contact User = name that is sent in the SIP Request's Contact header for this IP Group (e.g., ITSP-A).
3. Define IP Group #2 for ITSP-B:
  - a. From the 'Type' drop-down list, select **Server**.
  - b. In the 'Description' field, type an arbitrary name for the IP Group (e.g., ITSP B).
  - c. From the 'Proxy Set ID' drop-down lists, select **2** (represents the IP addresses, configured in , for communicating with this IP Group).

- d. In the 'SIP Group Name' field, enter the host name sent in SIP Request From\To headers for this IP Group, as required by ITSP-B (e.g., RegionB).
- e. Contact User = name that is sent in the SIP Request Contact header for this IP Group (e.g., ITSP-B).
4. Define IP Group #3 for the IP-PBX:
  - a. From the 'Type' drop-down list, select **Server**.
  - b. In the 'Description' field, type an arbitrary name for the IP Group (e.g., IP-PBX).
  - c. From the 'Proxy Set ID' drop-down lists, select **3** (represents the IP address, configured in , for communicating with this IP Group).
  - d. In the 'SIP Group Name' field, enter the host name that is sent in SIP Request From\To headers for this IP Group (e.g., IPPBX).
  - e. Contact User = name that is sent in the SIP Request Contact header for this IP Group (e.g., PBXUSER).
5. Define IP Group #4 for the remote IP-PBX users:
  - a. From the 'Type' drop-down list, select **User**.
  - b. In the 'Description' field, type an arbitrary name for the IP Group (e.g., IP-PBX).
  - c. In the 'SIP Group Name' field, enter the host name that is used internal in the device's database for this IP Group (e.g., RemoteIPPBXusers).
  - d. From the 'Serving IP Group ID' drop-down list, select **3** (i.e. the IP Group for the IP-PBX).

**Note:** No Serving IP Groups are defined for ITSP-A and ITSP-B. Instead, the Outbound IP Routing table (see 'Step 9: Configure Outbound IP Routing' on page 268) is used to configure outbound IP call routing for calls originating from these ITSP IP Groups.

## 24.2.6 Step 6: Configure the Account Table

The Account table is used by the device to register to an ITSP on behalf of the IP-PBX. As described previously, the ITSP requires registration and authentication to provide service. For the example, the Served IP Group is the IP-PBX (IP Group ID #3) and the Serving IP Groups are the two ITSPs (IP Groups #1 and #2).

### ➤ To configure the Account table:

1. Open the Account Table page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Account Table**).

Figure 24-10: Defining Accounts for Registration

| Index | Served Trunk Group | Served IP Group | Serving IP Group | Username | Password |
|-------|--------------------|-----------------|------------------|----------|----------|
| 1     | -1                 | 3               | 1                | itsp_a   | *        |
| 2     | -1                 | 3               | 2                | itsp_b   | *        |

| Host Name | Register | Contact User | Application Type |
|-----------|----------|--------------|------------------|
| regiona   | Yes      | ITSP-A       | GW/VP2IP         |
| regionb   | Yes      | ITSP-B       | GW/VP2IP         |

2. Configure Account ID #1 for IP-PBX authentication and registration with ITSP-A:
  - In the 'Served IP Group' field, enter "3" to indicate that authentication is performed on behalf of IP Group #3 (i.e., the IP-PBX).

- In the 'Serving IP Group' field, enter "1" to indicate that registration/authentication is with IP Group #1 (i.e., ITSP-A).
  - In the 'Username', enter the SIP username for authentication supplied by ITSP-A (e.g., itsp\_a).
  - In the 'Password' field, enter the SIP password for authentication supplied by ITSP-A (e.g., 12345).
  - In the 'Register' field, enter "1" to enable registration with ITSP-A.
3. Configure Account ID #2 for IP-PBX registration) with ITSP-B Registrar server:
- In the 'Served IP Group' field, enter "3" to indicate that registration is performed on behalf of IP Group #3 (i.e., the IP-PBX).
  - In the 'Serving IP Group' field, enter "2" to indicate that registration is with IP Group #3 (e.g., ITSP-B).
  - In the 'Username', enter the SIP username for the registration/authentication supplied by ITSP-B (e.g., itsp\_b).
  - In the 'Password' field, enter the SIP password for registration/authentication supplied by ITSP-B (e.g., 11111).
  - In the 'Register' field, enter "1" to enable registration with ITSP-B.

### 24.2.7 Step 7: Configure IP Profiles for Voice Coders

Since different voice coders are used by the IP-PBX (G.711) and the ITSPs (G.723), you need to define two IP Profiles:

- Profile ID #1 - configured with G.711 for the IP-PBX
- Profile ID #2 - configured with G.723 for the ITSPs

These profiles are later used in the Inbound IP Routing table and Outbound IP Routing table.

➤ **To configure IP Profiles for voice coders:**

1. Open the **Coder Group Settings** page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** > **Coders Group Settings**)
2. Configure Coder Group ID #1 for the IP-PBX (as shown in the figure below):
  - a. From the 'Coder Group ID' drop-down list, select **1**.
  - b. From the 'Coder Name' drop-down list, select **G.711A-law**.
  - c. Click **Submit**.

**Figure 24-11: Defining Coder Group ID 1**

2a →

Coder Group ID: 1

| Coder Name      | Packetization Time | Rate | Payload Type | Silence Suppression |
|-----------------|--------------------|------|--------------|---------------------|
| 2b → G.711A-law | 20                 | 64   | 8            | Disabled            |
|                 |                    |      |              |                     |

3. Configure Coder Group ID #2 for the ITSP's (as shown in the figure below):
  - a. From the 'Coder Group ID' drop-down list, select **2**.
  - b. From the 'Coder Name' drop-down list, select **G.723.1**.

- c. Click **Submit**.

**Figure 24-12: Defining Coder Group ID 2**

| Coder Name | Packetization Time | Rate | Payload Type | Silence Suppression |
|------------|--------------------|------|--------------|---------------------|
| G.723.1    | 30                 | 5.3  | 4            | Disabled            |
|            |                    |      |              |                     |

4. Open the IP Profile Settings page (**Configuration** tab > **VoIP** menu > **Coders and Profiles** > **IP Profile Settings**).
5. Configure Profile ID #1 for the IP-PBX (as shown below):
  - a. From the 'Profile ID' drop-down list, select **1**.
  - b. From the 'Coder Group' drop-down list, select **Coder Group 1**.
  - c. Click **Submit**.

**Figure 24-13: Defining IP Profile ID 1**

| Profile ID | Profile Name |
|------------|--------------|
| 1          | IP-PBX       |

| Common Parameters               |     |
|---------------------------------|-----|
| RTP IP DiffServ                 | 46  |
| Signaling DiffServ              | 40  |
| Disconnect on Broken Connection | Yes |

|                          |               |
|--------------------------|---------------|
| Coder Group              | Coder Group 1 |
| Remote RTP Base UDP Port | 0             |
| First Tx DTMF Option     | Not Supported |
| Second Tx DTMF Option    | Not Supported |
| Declare RFC 2833 in SDP  | Yes           |
| Add IE In SETUP          |               |
| Enable Hold              | Enable        |

6. Configure Profile ID #2 for the ITSP's:
  - a. From the 'Profile ID' drop-down list, select **2**.
  - b. From the 'Coder Group' drop-down list, select **Coder Group 2**.
  - c. Click **Submit**.

## 24.2.8 Step 8: Configure Inbound IP Routing

This step defines how to configure the device for routing inbound (i.e., received) IP-to-IP calls. The table in which this is configured uses the IP Groups that you defined in 'Step 5: Configure the IP Groups' on page 263.

➤ **To configure inbound IP routing:**

1. Open the Inbound IP Routing Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Routing** submenu > **IP to Trunk Group Routing**).

**Figure 24-14: Defining Inbound IP Routing Rules**

| <div> <div>Routing Index</div> <div>1-12</div> <div>IP To Tel Routing Mode</div> <div>Route calls before manipulation</div> </div> |                   |                    |                    |                     |                   |                |               |                   |
|------------------------------------------------------------------------------------------------------------------------------------|-------------------|--------------------|--------------------|---------------------|-------------------|----------------|---------------|-------------------|
|                                                                                                                                    | Dest. Host Prefix | Source Host Prefix | Dest. Phone Prefix | Source Phone Prefix | Source IP Address | Trunk Group ID | IP Profile ID | Source IPGroup ID |
| ②                                                                                                                                  | 1                 |                    | 9                  | *                   | *                 | 1              | 0             |                   |
| ③                                                                                                                                  | 2                 |                    | *                  | *                   | 10.15.4.211       | -1             | 1             | 3                 |
| ④                                                                                                                                  | 3                 |                    | +1919              | *                   | *                 | -1             | 2             | 1                 |
| ⑤                                                                                                                                  | 4                 |                    | 0200               | *                   | *                 | -1             | 2             | 2                 |
| ⑥                                                                                                                                  | 5                 | pbxremote          | *                  | *                   | *                 | -1             | 0             | 4                 |
| ⑦                                                                                                                                  | 6                 |                    | *                  | *                   | 10.15.4.211       | 1              | 0             | -1                |

2. **Index #1:** routes calls with prefix 9 (i.e., local calls) dialed from IP-PBX users to the local PSTN:
  - 'Dest Phone Prefix': enter "9" for the dialing prefix for local calls.
  - 'Trunk Group ID': enter "1" to indicate that these calls are routed to the Trunk (belonging to Trunk Group #1) connected between the device and the local PSTN network.
3. **Index #2:** identifies IP calls received from the IP-PBX as IP-to-IP calls and assigns them to the IP Group ID configured for the IP-PBX:
  - 'Dest Phone Prefix': enter the asterisk (\*) symbol to indicate all destinations.
  - 'Source IP Address': enter the IP address of the IP-PBX (i.e., 10.15.4.211).
  - 'Trunk Group ID': enter "-1" to indicate that these calls are IP-to-IP calls.
  - 'IP Profile ID': enter "1" to assign these calls to Profile ID #1 to use G.711.
  - 'Source IP Group ID': enter "3" to assign these calls to the IP Group pertaining to the IP-PBX.
4. **Index #3:** identifies IP calls received from ITSP-A as IP-to-IP calls and assigns them to the IP Group ID configured for ITSP-A:
  - 'Dest Phone Prefix': ITSP-A assigns the Enterprise a range of numbers that start with +1919. Enter this prefix to indicate calls received from this ITSP.
  - 'Trunk Group ID': enter "-1" to indicate that these calls are IP-to-IP calls.
  - 'IP Profile ID': enter "2" to assign these calls to Profile ID #2 to use G.723.
  - 'Source IP Group ID': enter "1" to assign these calls to IP Group pertaining to ITSP-A.
5. **Index #4:** identifies IP calls received from ITSP-B as IP-to-IP calls and assigns them to the IP Group ID configured for ITSP-B:
  - 'Dest Phone Prefix': ITSP-B assigns the Enterprise a range of numbers that start with 0200. Enter this prefix to indicate calls coming from this ITSP.
  - 'Trunk Group ID': enter "-1" to indicate that these calls are IP-to-IP calls.
  - 'IP Profile ID': enter "2" to assign these calls to Profile ID #2 to use G.723.
  - 'Source IP Group ID': enter "2" to assign these calls to IP Group pertaining to ITSP-B.

6. **Index #5:** identifies all IP calls received from IP-PBX remote users:
  - 'Source Host Prefix': enter "PBXuser". This is the host name that appears in the From header of the Request URI received from remote IP-PBX users.
  - 'Trunk Group ID': enter "-1" to indicate that these calls are IP-to-IP calls.
  - 'Source IP Group ID': enter "4" to assign these calls to the IP Group pertaining to the remote IP-PBX users.
7. **Index #6:** is used for alternative routing. This configuration identifies all IP calls received from the IP-PBX and which can't reach the ITSP's servers (e.g. loss of connection with ITSP's) and routes them to the local PSTN network:
  - 'Dest Phone Prefix': enter the asterisk (\*) symbol to indicate all destinations.
  - 'Source IP Address': enter the IP address of the IP-PBX (i.e., 10.15.4.211).
  - 'Trunk Group ID': enter "1" to route these calls to the Trunk Group ID configured for the Trunk connected to the device and interfacing with the local PSTN.
  - 'Source IP Group ID': enter "-1" to indicate that these calls are not assigned to any source IP Group.

## 24.2.9 Step 9: Configure Outbound IP Routing

This step defines how to configure the device for routing outbound (i.e., sent) IP-to-IP calls. In our example scenario, calls from both ITSP's must be routed to the IP-PBX, while outgoing calls from IP-PBX users must be routed according to destination. If the calls are destined to the Japanese market, then they are routed to ITSP-B; for all other destinations, the calls are routed to ITSP-A. This configuration uses the IP Groups defined in 'Step 5: Configure the IP Groups' on page 263 and IP Profiles defined in 'Step 7: Configure IP Profiles for Voice Coders' on page 265.

### ➤ To configure outbound IP routing rules:

1. Open the Outbound IP Routing Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Routing** > **Tel to IP Routing**).
2. Configure **Index #1** to route IP calls received from ITSP-A to the IP-PBX:
  - 'Source IP Group ID': select **1** to indicate received (inbound) calls identified as belonging to the IP Group configured for ITSP-A.
  - 'Dest Phone Prefix' and 'Source Phone Prefix': enter the asterisk (\*) symbol to indicate all destinations and callers respectively.
  - 'Dest IP Group ID': select **3** to indicate the destination IP Group to where these calls are sent, i.e., to the IP-PBX.
  - 'IP Profile ID': enter "2" to indicate the IP Profile configured for G.723.
3. Configure **Index #2** to route IP calls received from ITSP-B to the IP-PBX:
  - 'Source IP Group ID': select **2** to indicate received (inbound) calls identified as belonging to the IP Group configured for ITSP-B.
  - 'Dest Phone Prefix' and 'Source Phone Prefix': enter the asterisk (\*) symbol to indicate all destinations and callers respectively.
  - 'Dest IP Group ID': select **3** to indicate the destination IP Group to where these calls are sent, i.e., to the IP-PBX.
  - 'IP Profile ID': enter "2" to indicate the IP Profile configured for G.723.
4. Configure **Index #3** to route calls received from the local PSTN network to the IP-PBX:
  - 'Source Trunk Group ID': enter "1" to indicate calls received on the trunk connecting the device to the local PSTN network.
  - 'Dest IP Group ID': select **3** to indicate the destination IP Group to where the calls must be sent, i.e., to the IP-PBX.

5. Configure **Index #4** to route IP calls received from the IP-PBX to ITSP-A:
  - 'Source IP Group ID': select **3** to indicate received (inbound) calls identified as belonging to the IP Group configured for the IP-PBX.
  - 'Dest Phone Prefix': enter "+81" to indicate calls to Japan (i.e., with prefix +81).
  - 'Source Phone Prefix': enter the asterisk (\*) symbol to indicate all sources.
  - 'Dest IP Group ID': select **1** to indicate the destination IP Group to where the calls must be sent, i.e., to ITSP-A.
  - 'IP Profile ID': enter "1" to indicate the IP Profile configured for G.711.
6. Configure **Index #5** to route IP calls received from the IP-PBX to ITSP-B:
  - 'Source IP Group ID': select **3** to indicate received (inbound) calls identified as belonging to the IP Group configured for the IP-PBX.
  - 'Dest Phone Prefix' and 'Source Phone Prefix': enter the asterisk (\*) symbol to indicate all destinations (besides Japan) and all sources respectively.
  - 'Dest IP Group ID': select **2** to indicate the destination IP Group to where the calls must be sent, i.e., to ITSP-A.
  - 'IP Profile ID': enter "1" to indicate the IP Profile configured for G.711.
7. Configure **Index #6** to route dialed calls (four digits starting with digit 4) from IP-PBX to remote IP-PBX users. The device searches its database for the remote users registered number, and then sends an INVITE to the remote user's IP address (listed in the database):
  - 'Source IP Group ID': select **3** to indicate received (inbound) calls identified as belonging to the IP Group configured for the IP-PBX.
  - 'Dest Phone Prefix': enter the "4xxx#" to indicate all calls dialed from IP-PBX that include four digits and start with the digit 4.
  - 'Dest IP Group ID': select **4** to indicate the destination IP Group to where the calls must be sent, i.e., to remote IP-PBX users.
  - 'IP Profile ID': enter "1" to indicate the IP Profile configured for G.711.

## 24.2.10 Step 10: Configure Destination Phone Number Manipulation

This step defines how to manipulate the destination phone number. The IP-PBX users in our example scenario use a 4-digit extension number. The incoming calls from the ITSP's have different prefixes and different lengths. This manipulation leaves only the four digits of the user's destination number coming from the ITSP's.

➤ **To configure destination phone number manipulation rules:**

1. Open the Destination Phone Number Manipulation Table for IP -> Tel calls page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Manipulations** > **Dest Number Tel->IP**).
2. Configure Index #1 to manipulate destination number of IP calls received from ITSP-A. The phone number of calls received with prefix +1919 (i.e., from ITSP-A) are removed except for the last four digits:
  - 'Destination Prefix': enter the prefix "+1919".
  - 'Source Prefix': enter the asterisk (\*) symbol to indicate all sources.
  - 'Number of Digits to Leave': enter "4" to leave only the last four digits.
3. Configure Index #2 to manipulate destination number of IP calls received from ITSP-B. The phone number of calls received with prefix 0200 (i.e., from ITSP-B) are removed except for the last four digits:
  - 'Destination Prefix': enter the prefix "0200".
  - 'Source Prefix': enter the asterisk (\*) symbol to indicate all sources.
  - 'Number of Digits to Leave': enter "4" to leave only the last four digits.

## 25 Digital PSTN

This section describes the configuration of the public switched telephone network (PSTN) related parameters.

### 25.1 Configuring Trunk Settings

The Trunk Settings page allows you to configure the device's trunks. This includes selecting the PSTN protocol and configuring related parameters. This page also provides the following features:

- **Taking a Trunk Out of Service:** Some parameters can be configured when the trunk is in service, while others require you to take the trunk out of service. This is done by

clicking the **Stop**  button. Once you have "stopped" a trunk, all current calls are dropped and no new calls can be made on the trunk.

- **Deactivating a Trunk:** You can deactivate a trunk for maintenance. This is done by

clicking the **Deactivate**  button. Deactivation temporarily disconnects (logically) the trunk from the PSTN network. Upon trunk deactivation, the device generates an AIS alarm on the trunk to the far-end. As a result, an RAI alarm signal may be received by the device. A subsequent trunk activation, done by clicking the

**Activate**  button, reconnects the trunk to the PSTN network and clears the AIS alarm. Trunk deactivation is typically used for maintenance such as checking the trunk's physical integrity.

- **Creating a Loopback Line:** You can create (and remove) remote loopback for DS1 lines. This is done by clicking the **Create Loopback**  button. To remove the loopback, click the **Remove Loopback**  button.

For a description of the trunk parameters, see 'PSTN Parameters' on page [793](#).

**Notes:**

- During trunk deactivation, trunk configuration cannot be performed.
- A stopped trunk cannot also be activated and a trunk cannot be deactivated if it has been stopped.

➤ **To configure the trunks:**

1. Open the Trunk Settings page (**Configuration** tab > **VoIP** menu > **PSTN** submenu > **Trunk Settings**).

On the top of the page, a bar with Trunk number icons displays the status of each trunk, according to the following color codes:

- **Grey:** Disabled
  - **Green:** Active
  - **Yellow:** RAI alarm (also appears when you deactivate a Trunk by clicking the **Deactivate** button)
  - **Red:** LOS/LOF alarm
  - **Blue:** AIS alarm
  - **Orange:** D-channel alarm (ISDN only)
2. Select the trunk that you want to configure by clicking the desired Trunk number icon. The bar initially displays the first eight trunk number icons (i.e., trunks 1 through 8). To scroll through the trunk number icons (i.e., view the next/last or previous/first group of eight trunks), see the figure below:

**Figure 25-1: Trunk Scroll Bar (Used Only as an Example)**

**Note:** If the Trunk scroll bar displays all available trunks, the scroll bar buttons are unavailable.

After you have selected a trunk, the following is displayed:

- The read-only 'Module ID' field displays the module number to which the trunk belongs.
- The read-only 'Trunk ID' field displays the selected trunk number.
- The read-only 'Trunk Configuration State' displays the state of the trunk ('Active' or 'Inactive').
- The displayed parameters pertain to the selected trunk only.

3. Click the **Stop Trunk**  button (located at the bottom of the page) to take the trunk out of service so that you can configure the currently grayed out (unavailable) parameters. (Skip this step if you want to configure parameters that are available when the trunk is active). The stopped trunk is indicated by the following:

- The 'Trunk Configuration State' field displays 'Inactive'.
- The **Stop Trunk** button is replaced by the **Apply Trunk Settings**  button.

When all trunks are stopped, the **Apply to All Trunks**  button also appears.

- All the parameters are available and can be modified.
4. Configure the trunk parameters as required.
  5. Click the **Apply Trunk Settings** button to apply the changes to the selected trunk (or click **Apply to All Trunks** to apply the changes to all trunks); the **Stop Trunk** button replaces **Apply Trunk Settings** and the 'Trunk Configuration State' displays 'Active'.
  6. To save the changes to flash memory, see 'Saving Configuration' on page 532.
  7. To reset the device, see 'Resetting the Device' on page 529.

**Notes:**

- If the 'Protocol Type' field displays 'NONE' (i.e., no protocol type is selected) and no other trunks have been configured, after selecting a PRI protocol type, you must reset the device.
- The displayed parameters depend on the protocol selected.
- All PRI trunks of the device must be of the same line type (i.e., E1 or T1). However, different variants of the same line type can be configured on different trunks, for example, E1 Euro ISDN and E1 CAS (subject to the constraints in the device's Release Notes).
- BRI trunks can operate with E1 or T1 trunks.
- If the protocol type is CAS, you can assign or modify a dial plan (in the 'Dial Plan' field) and perform this without stopping the trunk.
- If the trunk can't be stopped because it provides the device's clock (assuming the device is synchronized with the E1/T1 clock), assign a different E1/T1 trunk to provide the device's clock or enable 'TDM Bus PSTN Auto Clock' in the TDM Bus Settings page (see 'TDM and Timing' on page 274).
- To delete a previously configured trunk, set the parameter 'Protocol Type' to 'None'.

## 25.2 TDM and Timing

This section describes the configuration of the TDM and clock timing parameters.

### 25.2.1 Configuring TDM Bus Settings

The TDM page allows you to configure the device's Time-Division Multiplexing (TDM) bus settings. For a description of these parameters, see 'PSTN Parameters' on page 793.

➤ To configure the TDM Bus settings:

1. Open the TDM page (**Configuration** tab > **VoIP** menu > TDM > TDM Bus Settings).

Figure 25-2: TDM Page

| TDM Bus Settings                  |          |
|-----------------------------------|----------|
| PCM Law Select                    | MuLaw    |
| TDM Bus Clock Source              | Internal |
| TDM Bus PSTN Auto FallBack Clock  | Disable  |
| TDM Bus PSTN Auto Clock Reverting | Disable  |
| Idle PCM Pattern                  | 255      |
| Idle ABCD Pattern                 | 0x0F     |
| TDM Bus Local Reference           | 1        |
| TDM Bus Type                      | Framers  |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. Save the changes to flash memory, see 'Saving Configuration' on page 532.

### 25.2.2 Clock Settings

In a traditional TDM service network such as PSTN, both ends of the TDM connection must be synchronized. If synchronization is not achieved, voice frames are either dropped (to prevent a buffer overflow condition) or inserted (to prevent an underflow condition). In both cases, connection quality and reliability is affected.

- PSTN line clock (see 'Recovering Clock from PSTN Line' on page 274)
- Internal clock (see 'Configuring Internal Clock as Clock Source' on page 275)

**Note:** When the device is used in a 'non-span' configuration, the internal device clock must be used (as explained above).

#### 25.2.2.1 Recovering Clock from PSTN Line Interface

This section provides a brief description for configuring synchronization based on recovering clock from the PSTN line (Trunk) interface. For a full description of the clock parameters, see 'PSTN Parameters' on page 793.

➤ **To configure synchronization based on clock from PSTN line:**

1. In the TDM Bus Settings page, do the following:
  - a. Set the 'TDM Bus Clock Source' parameter (TDMBusClockSource) to **Network** to recover the clock from the line interface.
  - b. Select the trunk from which the clock is derived, using the 'TDM Bus Local Reference' parameter (TDMBusLocalReference).

**Note:** The E1/T1 trunk should recover the clock from the remote side (see below description of the 'Clock Master' parameter). The BRI trunk should be configured as an ISDN user-side.

- c. Enable automatic switchover to the next available "slave" trunk if the device detects that the local-reference trunk is no longer capable of supplying the clock to the system:
    1. Set the 'TDM Bus PSTN Auto FallBack Clock' parameter (TDMBusPSTNAutoClockEnable) to **Enable**.
    2. Enable the device to switch back to a previous trunk that returns to service if it has higher switchover priority, using the 'TDM Bus PSTN Auto Clock Reverting' parameter (TDMBusPSTNAutoClockRevertingEnable).
    3. In the Trunk Settings page, configure the priority level of the trunk for taking over as a local-reference trunk, using the 'Auto Clock Trunk Priority' parameter (AutoClockTrunkPriority). A value of 100 means that it never uses the trunk as local reference.
2. **For E1/T1 trunks only:** Set the PSTN trunk to recover/derive clock from/to the remote side of the PSTN trunk (i.e. clock slave or clock master): In the Trunk Settings page, set the 'Clock Master' parameter (ClockMaster) to one of the following:
  - **Recovered** - to recover clock (i.e. slave)
  - **Generated** - to transmit clock (i.e. master)

### 25.2.2.2 Configuring Internal Clock as Clock Source

This section describes how to configure the device to use its internal clock source. The internal clock source is a stratum 4E-compliant clock source. When the device has no line interfaces, the device should be configured in this mode.

➤ **To configure internal clock as clock source:**

1. Set the clock source to be from the device's internal oscillator. In the TDM Bus Settings page, set the 'TDM Bus Clock Source' parameter (TDMBusClockSource) to **Internal**.
2. For E1/T1 trunks only, set the line to drive the clock on all trunks: In the Trunk Settings page, set the 'Clock Master' parameter (ClockMaster) to **Generated** (for all trunks).

## 25.3 Configuring CAS State Machines

The CAS State Machine page allows you to modify various timers and other basic parameters to define the initialization of the CAS state machine without changing the state machine itself (no compilation is required). The change doesn't affect the state machine itself, but rather the configuration.

The CAS table used can be chosen in two ways (using the parameter CasChannelIndex):

- Single CAS table per trunk
- Different CAS table per group of B-channels in a trunk

**Note:** The CAS state machine can only be configured using the Web-based management tool.

➤ **To modify the CAS state machine parameters:**

1. Open the CAS State Machine page (**Configuration** tab > **VoIP** menu > **PSTN** submenu > **CAS State Machines**).

**Figure 25-3: CAS State Machine Page**

| CAS Table Name       | Generate Digit On Time | Generate Inter Digit Time | DTMF Max Detection Time | DTMF Min Detection Time | Max Incoming Address Digits | Max Incoming ANI Digits |
|----------------------|------------------------|---------------------------|-------------------------|-------------------------|-----------------------------|-------------------------|
| E_M_FGDWinkTable.dat | -1                     | -1                        | -1                      | -1                      | -1                          | -1                      |
| E_M_FGDWinkTable.dat | -1                     | -1                        | -1                      | -1                      | -1                          | -1                      |
| E_M_FGDWinkTable.dat | -1                     | -1                        | -1                      | -1                      | -1                          | -1                      |

2. Ensure that the trunk is inactive. The trunk number displayed in the 'Related Trunks' field must be green. If it is red, indicating that the trunk is active, click the trunk number to open the Trunk Settings page (see 'Configuring Trunk Settings' on page 271), select the required Trunk number icon, and then click **Stop Trunk**.
3. In the CAS State Machine page, modify the required parameters according to the table below.
4. Once you have completed the configuration, activate the trunk if required in the Trunk Settings page, by clicking the trunk number in the 'Related Trunks' field, and in the Trunk Settings page, select the required Trunk number icon, and then click **Apply Trunk Settings**.
5. Click **Submit**, and then reset the device (see 'Resetting the Device' on page 529).

**Notes:**

- Don't modify the default values unless you fully understand the implications of the changes and know the default values. Every change affects the configuration of the state machine parameters and the call process related to the trunk you are using with this state machine.
- You can modify CAS state machine parameters only if the following conditions are met:
  - 1) Trunks are inactive (stopped), i.e., the 'Related Trunks' field displays the trunk number in green.
  - 2) State machine is not in use or is in reset, or when it is not related to any trunk. If it is related to a trunk, you must delete the trunk or deactivate (*Stop*) the trunk.
- Field values displaying '-1' indicate CAS default values. In other words, CAS state machine values are used.
- The modification of the CAS state machine occurs at the CAS application initialization only for non-default values (-1).
- For more information on the CAS Protocol table, refer to the *CAS Protocol Table Configuration Note*.

## CAS State Machine Parameters Description

| Parameter                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Generate Digit On Time<br><b>[CasStateMachineGenerateDigitOnTime]</b>                | Generates digit on-time (in msec).<br>The value must be a positive value. The default is -1 (use value from CAS state machine).                                                                                                                                                                                                                                              |
| Generate Inter Digit Time<br><b>[CasStateMachineGenerateInterDigitTime]</b>          | Generates digit off-time (in msec).<br>The value must be a positive value. The default is -1 (use value from CAS state machine).                                                                                                                                                                                                                                             |
| DTMF Max Detection Time<br><b>[CasStateMachineDTMFMaxOnDetectionTime]</b>            | Detects digit maximum on time (according to DSP detection information event) in msec units.<br>The value must be a positive value. The default is -1 (use value from CAS state machine).                                                                                                                                                                                     |
| DTMF Min Detection Time<br><b>[CasStateMachineDTMFMinOnDetectionTime]</b>            | Detects digit minimum on time (according to DSP detection information event) in msec units. The digit time length must be longer than this value to receive a detection. Any number may be used, but the value must be less than CasStateMachineDTMFMaxOnDetectionTime.<br>The value must be a positive value. The default is -1 (use value from CAS state machine).         |
| MAX Incoming Address Digits<br><b>[CasStateMachineMaxNumOfIncomingAddressDigits]</b> | Defines the limitation for the maximum address digits that need to be collected. After reaching this number of digits, the collection of address digits is stopped.<br>The value must be an integer. The default is -1 (use value from CAS state machine).                                                                                                                   |
| MAX Incoming ANI Digits<br><b>[CasStateMachineMaxNumOfIncomingANIDigits]</b>         | Defines the limitation for the maximum ANI digits that need to be collected. After reaching this number of digits, the collection of ANI digits is stopped.<br>The value must be an integer. The default is -1 (use value from CAS state machine).                                                                                                                           |
| Collect ANI<br><b>[CasStateMachineCollectANI]</b>                                    | In some cases, when the state machine handles the ANI collection (not related to MFCR2), you can control the state machine to collect ANI or discard ANI. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No = Don't collect ANI.</li> <li>▪ <b>[1]</b> Yes = Collect ANI.</li> <li>▪ <b>[-1]</b> Default = Default value - use value from CAS state machine.</li> </ul> |
| Digit Signaling System<br><b>[CasStateMachineDigitSignalingSystem]</b>               | Defines which Signaling System to use in both directions (detection\generation). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> DTMF = Uses DTMF signaling.</li> <li>▪ <b>[1]</b> MF = Uses MF signaling (default).</li> <li>▪ <b>[-1]</b> Default = Default value - use value from CAS state machine.</li> </ul>                                                       |

## 25.4 Configuring Digital Gateway Parameters

The Digital Gateway Parameters page allows you to configure miscellaneous digital parameters. For a description of these parameters, see 'Configuration Parameters Reference' on page 655.

➤ **To configure the digital gateway parameters:**

1. Open the Digital Gateway Parameters page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Digital Gateway** submenu > **Digital Gateway Parameters**).

**Figure 25-4: Digital Gateway Parameters Page**

|                                                |                |  |
|------------------------------------------------|----------------|--|
| B-channel Negotiation                          | Exclusive      |  |
| Swap Redirect and Called Numbers               | No             |  |
| MFC R2 Category                                | 1              |  |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 25.5 Tunneling Applications

This section discusses the device's support for VoIP tunneling applications.

### 25.5.1 TDM Tunneling

The device's TDM Tunneling feature allows you to tunnel groups of digital trunk spans or timeslots (B-channels) over the IP network. TDM Tunneling utilizes the device's internal routing (without Proxy control) capabilities to receive voice and data streams from TDM (E1/T1/J1) spans or individual timeslots, convert them into packets, and then transmit them over the IP network (using point-to-point or point-to-multipoint device distributions). A device opposite it (or several devices when point-to-multipoint distribution is used) converts the IP packets back into TDM traffic. Each timeslot can be targeted to any other timeslot within a trunk in the opposite device.

When TDM Tunneling is enabled (the parameter `EnableTDMoverIP` is set to '1') on the originating device, the originating device automatically initiates SIP calls from all enabled B-channels belonging to the E1/T1/J1 spans that are configured with the protocol type 'Transparent' (for ISDN trunks) or 'Raw CAS' (for CAS trunks). The called number of each call is the internal phone number of the B-channel from where the call originates. The Inbound IP Routing Table is used to define the destination IP address of the terminating device. The terminating device automatically answers these calls if its E1/T1 protocol type is set to 'Transparent' (`ProtocolType` = 5) or 'Raw CAS' (`ProtocolType` = 3 for T1 and 9 for E1) and the parameter `ChannelSelectMode` is set to 0 (By Phone Number).

**Note:** It's possible to configure both devices to also operate in symmetric mode. To do so, set `EnableTDMoverIP` to 1 and configure the Outbound IP Routing Table in both devices. In this mode, each device (after it's reset) initiates calls to the second device. The first call for each B-channel is answered by the second device.

The device continuously monitors the established connections. If for some reason, one or more calls are released, the device automatically re-establishes these 'broken' connections. When a failure in a physical trunk or in the IP network occurs, the device re-establishes the tunneling connections when the network is restored.

**Note:** It's recommended to use the keep-alive mechanism for each connection, by activating the 'session expires' timeout and using Re-INVITE messages.

The device supports the configuration (`TDMoIPInitiateInviteTime` and `TDMoIPInviteRetryTime` parameters) of the following timers for the TDM-over-IP tunneling application:

- Time between successive INVITEs sent from the same E1/T1 trunk.
- Time between call release and the new INVITE that is sent on the same channel. The call can be released if the device receives a 4xx or 5xx response.

By utilizing the 'Profiles' mechanism (see 'Coders and Profiles' on page 233), you can configure the TDM Tunneling feature to choose different settings based on a timeslot or groups of timeslots. For example, you can use low-bit-rate vocoders to transport voice and 'Transparent' coder to transport data (e.g., for D-channel). You can also use Profiles to assign ToS (for DiffServ) per source - a timeslot carrying data or signaling is assigned a higher priority value than a timeslot carrying voice.

For tunneling of E1/T1 CAS trunks, set the protocol type to 'Raw CAS' (ProtocolType = 3 / 9) and enable RFC 2833 CAS relay mode ('CAS Transport Type' parameter is set to 'CAS RFC2833 Relay').

**Note:** For TDM over IP, the parameter CallerIDTransportType must be set to '0' (disabled), i.e., transparent.

Below is an example of *ini* files for two devices implementing TDM Tunneling for four E1 spans. Note that in this example both devices are dedicated to TDM tunneling.

### 25.5.1.1 DSP Pattern Detector

For TDM tunneling applications, you can use the DSP pattern detector feature to initiate the echo canceller at call start. The device can be configured to support detection of a specific one-byte idle data pattern transmitted over digital E1/T1 timeslots. The device can be configured to detect up to four different one-byte data patterns. When the defined idle data pattern is detected, the channel resets its echo canceller.

➤ **To configure DSP pattern detector:**

1. In the IPMedia Settings page (**Configuration** tab > **VoIP** menu > **Media** > **IPMedia Settings**), do the following:
  - a. Set the 'IPMedia Detectors' parameter (EnabledDSPIPMDetectors) to **Enable**.
  - b. Set the 'Enable Pattern Detector' parameter (EnablePatternDetector) to **Enable**.
2. Configure the number (e.g., 5) of consecutive patterns to trigger the pattern detection event, using the ini file parameter, PDThreshold.
3. Configure the patterns that can be detected by the Pattern Detector, using the ini file parameter, PDPattern. For example:
 

```
PDPattern = 84, 85, 212, 213 ; for idle patterns 54, 55, D4 and D5
```

## 25.5.2 QSIG Tunneling

The device supports QSIG tunneling over SIP, according to IETF Internet-Draft draft-elwell-sipping-qsig-tunnel-03 ("Tunnelling of QSIG over SIP") and ECMA-355/ISO/IEC 22535. This is applicable to all ISDN variants. QSIG tunneling can be applied to all calls or to specific calls using IP Profiles.

QSIG tunneling sends all QSIG messages as raw data in corresponding SIP messages using a dedicated message body. This is used, for example, to enable two QSIG subscribers connected to the same or different QSIG PBX to communicate with each other over an IP network. Tunneling is supported in both directions (Tel-to-IP and IP-to-Tel).

The term tunneling means that messages are transferred 'as is' to the remote side without being converted (QSIG > SIP > QSIG). The advantage of tunneling over QSIG-to-SIP interworking is that by using interworking, QSIG functionality can only be partially achieved. When tunneling is used, all QSIG capabilities are supported and the tunneling medium (the SIP network) does not need to process these messages.

QSIG messages are transferred in SIP messages in a separate Multipurpose Internet Mail Extensions (MIME) body. Therefore, if a message contains more than one body (e.g., SDP and QSIG), multipart MIME must be used. The Content-Type of the QSIG tunneled message is 'application/QSIG'. The device also adds a Content-Disposition header in the following format:

```
Content-Disposition: signal; handling=required.
```

QSIG tunneling is done as follows:

- **Call setup (originating device):** The QSIG Setup request is encapsulated in the SIP INVITE message without being altered. After the SIP INVITE request is sent, the device does not encapsulate the subsequent QSIG message until a SIP 200 OK response is received. If the originating device receives a 4xx, 5xx, or 6xx response, it disconnects the QSIG call with a 'no route to destination' cause.
- **Call setup (terminating device):** After the terminating device receives a SIP INVITE request with a 'Content-Type: application/QSIG', it sends the encapsulated QSIG Setup message to the Tel side and sends a 200 OK response (no 1xx response is

sent) to IP. The 200 OK response includes an encapsulated QSIG Call Proceeding message (without waiting for a Call Proceeding message from the Tel side). If tunneling is disabled and the incoming INVITE includes a QSIG body, a 415 response is sent.

- **Mid-call communication:** After the SIP connection is established, all QSIG messages are encapsulated in SIP INFO messages.
- **Call tear-down:** The SIP connection is terminated once the QSIG call is complete. The Release Complete message is encapsulated in the SIP BYE message that terminates the session.

➤ **To enable QSIG tunneling:**

1. In the Digital Gateway Parameters page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Digital Gateway** > **Digital Gateway Parameters**), set the 'Enable QSIG Tunneling' parameter (EnableQSIGTunneling) to **Enable** on the originating and terminating devices.
2. Configure the QSIGTunnelingMode parameter for defining the format of encapsulated QSIG message data in the SIP message MIME body (0 for ASCII presentation; 1 for binary encoding).
3. Set the ISDNDuplicateQ931BuffMode parameter to 128 to duplicate all messages.
4. Set the ISDNInCallsBehavior parameter to 4096.
5. Set the ISDNRxOverlap parameter to 0 for tunneling of QSIG overlap-dialed digits (see below for description).

The configuration of the ISDNInCallsBehavior and ISDNRxOverlap parameters allows tunneling of QSIG overlap-dialed digits (Tel to IP). In this configuration, the device **delays** the sending of the QSIG Setup Ack message upon receipt of the QSIG Setup message. Instead, the device sends the Setup Ack message to QSIG only when it receives the SIP INFO message with Setup Ack encapsulated in its MIME body. The PBX sends QSIG Information messages (to complete the Called Party Number) only after it receives the Setup Ack. The device relays these Information messages encapsulated in SIP INFO messages to the remote party.

## 25.6 ISDN Non-Facility Associated Signaling (NFAS)

In regular T1 ISDN trunks, a single 64 kbps channel carries signaling for the other 23 B-channels of that particular T1 trunk. This channel is called the D-channel and usually resides on timeslot # 24. ISDN Non-Facility Associated Signaling (NFAS) enables the use of a single D-channel to control multiple PRI interfaces.

With NFAS it is possible to define a group of T1 trunks, called an *NFAS group*, in which a single D-channel carries ISDN signaling messages for the entire group. The NFAS group's B-channels are used to carry traffic such as voice or data. The NFAS mechanism also enables definition of a backup D-channel on a different T1 trunk, to be used if the primary D-channel fails.

The device supports up to 12 NFAS groups. Each group can comprise up to 10 T1 trunks and each group must contain different T1 trunks. Each T1 trunk is called an 'NFAS member'. The T1 trunk whose D-channel is used for signaling is called the 'Primary NFAS Trunk'. The T1 trunk whose D-channel is used for backup signaling is called the 'Backup NFAS Trunk'. The primary and backup trunks each carry 23 B-channels while all other NFAS trunks each carry 24 B-channels.

The NFAS group is identified by an NFAS GroupID number (possible values are 1 to 12). To assign a number of T1 trunks to the same NFAS group, use the NFASGroupNumber\_x = groupID (where x is the physical trunk ID (0 to the maximum number of trunks) or the Web interface (see 'Configuring Trunk Settings' on page 271).

The parameter 'DchConfig\_x = Trunk\_type' defines the type of NFAS trunk. Trunk\_type is set to 0 for the primary trunk, to 1 for the backup trunk, and to 2 for an ordinary NFAS

trunk. 'x' denotes the physical trunk ID (0 to the maximum number of trunks). You can also use the Web interface (see 'Configuring Trunk Settings' on page 271).

For example, to assign the first four T1 trunks to NFAS group #1, in which trunk #0 is the primary trunk and trunk #1 is the backup trunk, use the following configuration:

```
NFASGroupNumber_0 = 1
NFASGroupNumber_1 = 1
NFASGroupNumber_2 = 1
NFASGroupNumber_3 = 1
DchConfig_0 = 0 ;Primary T1 trunk
DchConfig_1 = 1 ;Backup T1 trunk
DchConfig_2 = 2 ;24 B-channel NFAS trunk
DchConfig_3 = 2 ;24 B-channel NFAS trunk
```

The NFAS parameters are described in 'PSTN Parameters' on page 793.

## 25.6.1 NFAS Interface ID

Several ISDN switches require an additional configuration parameter per T1 trunk that is called 'Interface Identifier'. In NFAS T1 trunks, the Interface Identifier is sent explicitly in Q.931 Setup / Channel Identification IE for all NFAS trunks, except for the B-channels of the Primary trunk (see note below).

The Interface ID can be defined per member (T1 trunk) of the NFAS group, and must be coordinated with the configuration of the Switch. The default value of the Interface ID is identical to the number of the physical T1 trunk (0 for the first trunk, 1 for the second T1 trunk, and so on, up to the maximum number of trunks).

To define an explicit Interface ID for a T1 trunk (that is different from the default), use the following parameters:

- ISDNIBehavior\_x = 512 (x = 0 to the maximum number of trunks identifying the device's physical trunk)
- ISDNNFASInterfaceID\_x = ID (x = 0 to 255)

### Notes:

- Usually the Interface Identifier is included in the Q.931 Setup/Channel Identification IE only on T1 trunks that doesn't contain the D-channel. Calls initiated on B-channels of the Primary T1 trunk, by default, don't contain the Interface Identifier. Setting the parameter ISDNIBehavior\_x to 2048' forces the inclusion of the Channel Identifier parameter also for the Primary trunk.
- The parameter ISDNNFASInterfaceID\_x = ID can define the 'Interface ID' for any Primary T1 trunk, even if the T1 trunk is not a part of an NFAS group. However, to include the Interface Identifier in Q.931 Setup/Channel Identification IE configure ISDNIBehavior\_x = 2048 in the *ini* file.

## 25.6.2 Working with DMS-100 Switches

The DMS-100 switch requires the following NFAS Interface ID definitions:

- InterfaceID #0 for the Primary trunk
- InterfaceID #1 for the Backup trunk
- InterfaceID #2 for a 24 B-channel T1 trunk
- InterfaceID #3 for a 24 B-channel T1 trunk, and so on for subsequent T1 trunks

For example, if four T1 trunks on a device are configured as a single NFAS group with Primary and Backup T1 trunks that is used with a DMS-100 switch, the following parameters should be used:

```
NFASGroupNumber_0 = 1
NFASGroupNumber_1 = 1
NFASGroupNumber_2 = 1
NFASGroupNumber_3 = 1
DchConfig_0 = 0 ;Primary T1 trunk
DchConfig_1 = 1 ;Backup T1 trunk
DchConfig_2 = 2 ;B-Channel NFAS trunk
DchConfig_3 = 2 ;B-channel NFAS trunk
```

If there is no NFAS Backup trunk, the following configuration should be used:

```
ISDNNFASInterfaceID_0 = 0
ISDNNFASInterfaceID_1 = 2
ISDNNFASInterfaceID_2 = 3
ISDNNFASInterfaceID_3 = 4
ISDNIBehavior = 512 ;This parameter should be added because of
;ISDNNFASInterfaceID configuration above
NFASGroupNumber_0 = 1
NFASGroupNumber_1 = 1
NFASGroupNumber_2 = 1
NFASGroupNumber_3 = 1
DchConfig_0 = 0 ;Primary T1 trunk
DchConfig_1 = 2 ;B-Channel NFAS trunk
DchConfig_2 = 2 ;B-Channel NFAS trunk
DchConfig_3 = 2 ;B-channel NFAS trunk
```

### 25.6.3 Creating an NFAS-Related Trunk Configuration

The procedures for creating and deleting an NFAS group must be performed in the correct order, as described below.

➤ **To create an NFAS Group:**

1. If there's a backup ('secondary') trunk for this group, it must be configured first.
2. Configure the primary trunk before configuring any NFAS ('slave') trunk.
3. Configure NFAS ('slave') trunks.

➤ **To stop / delete an NFAS Group:**

1. Stop or delete (by setting ProtocolType to 0, i.e., 'None') all NFAS ('slave') trunks.
2. Stop or delete (by setting ProtocolType to 0, i.e., 'None') the backup trunk if a backup trunk exists.
3. Stop or delete (by setting ProtocolType to 0, i.e., 'None') the primary trunk.

**Notes:**

- All trunks in the group must be configured with the same values for trunk parameters TerminationSide, ProtocolType, FramingMethod, and LineCode.
- After stopping or deleting the backup trunk, delete the group and then reconfigure it.

## 25.6.4 Performing Manual D-Channel Switchover in NFAS Group

If an NFAS group is configured with two D-channels (Primary and Backup), you can do a manual switchover between these D-channels.

➤ **To manually switchover from active to standby D-channel:**

1. Open the NFAS Group & D-Channel Status page (**Status & Diagnostics** tab > **VoIP Status** menu > **NFAS Group & D-Channel Status**).
2. Select the required NFAS group, and then click the **Switch Activity** button.

### Notes:

- The **Switch Activity** button is unavailable (i.e, grayed out) if a switchover cannot be done due to, for example, alarms or unsuitable states.
- This feature is applicable only to T1 ISDN protocols supporting NFAS, and only if the NFAS group is configured with two D-channels.

## 25.7 ISDN Overlap Dialing

Overlap dialing is a dialing scheme used by several ISDN variants to send and/or receive called number digits one after the other (or several at a time). This is in contrast to en-bloc dialing in which a complete number is sent in one message. ISDN overlap dialing is applicable to PRI and BRI.

The device supports the following ISDN overlap dialing methods:

- Collects ISDN called party number digits and then sends the SIP INVITE to the IP side with the complete destination number (see 'Collecting ISDN Digits and Sending Complete Number in SIP' on page 286)
- Interworks ISDN overlap dialing with SIP, according to RFC 3578 (see 'Interworking ISDN Overlap Dialing with SIP According to RFC 3578' on page 287)

### 25.7.1 Collecting ISDN Digits and Sending Complete Number in SIP

The device can support an overlap dialing mode whereby the device collects the called party number digits from ISDN Q.931 Information messages or DTMF signals, and then sends a SIP INVITE message to the IP side containing the complete destination number.

ISDN overlap dialing for incoming ISDN calls can be configured for the entire device or per E1/T1 trunk. This is configured using the global, `ISDNRxOverlap` parameter or the `ISDNRxOverlap_x` parameter (where x denotes the trunk number), respectively.

By default (see the `ISDNINCallsBehavior` parameter), the device plays a dial tone to the ISDN user side when it receives an empty called number from the ISDN. In this scenario, the device includes the Progress Indicator in the SetupAck ISDN message that it sends to the ISDN side.

The device can also mute in-band DTMF detection until it receives the complete destination number from the ISDN. This is configured using the `MuteDTMFInOverlap` parameter. The Information digits can be sent in-band in the voice stream, or out-of-band using Q.931 Information messages. If Q.931 Information messages are used, the DTMF in-band detector must be disabled. Note that when at least one digit is received in the ISDN Setup message, the device stops playing a dial tone.

The device stops collecting digits (from the ISDN) upon the following scenarios:

- The device receives a Sending Complete IE in the ISDN Setup or Information messages, indicating no more digits.
- The timeout between received digits expires (configured by the `TimeBetweenDigits`

parameter).

- The maximum number of received digits has been reached (configured by the MaxDigits parameter).
- A match is found with the defined digit map (configured by the DigitMapping parameter).

Relevant parameters (described in 'PSTN Parameters' on page 793):

- ISDNRxOverlap\_x = 1 (can be configured per trunk)
- TimeBetweenDigits
- MaxDigits
- MuteDTMFInOverlap
- DigitMapping

For configuring ISDN overlap dialing using the Web interface, see 'Configuring Trunk Settings' on page 271.

## 25.7.2 Interworking ISDN Overlap Dialing with SIP According to RFC 3578

The device supports the interworking of ISDN overlap dialing to SIP and vice versa, according to RFC 3578.

- **Interworking ISDN overlap dialing to SIP (Tel to IP):** The device sends collected digits each time it receives them (initially from the ISDN Setup message and then from subsequent Q.931 Information messages) to the IP side, using subsequent SIP INVITE messages. You can also define the minimum number of overlap digits to collect before sending the first SIP message (INVITE) for routing the call, using the MinOverlapDigitsForRouting parameter.
- **Interworking SIP to ISDN overlap dialing (IP to Tel):** For each received SIP INVITE pertaining to the same dialog session, the device sends an ISDN Setup message (and subsequent Q.931 Information messages) with the collected digits to the Tel side. For all subsequent INVITEs received, the device sends a SIP 484 "Address Incomplete" response to the IP in order to maintain the current dialog session and to receive additional digits from subsequent INVITEs.

Relevant parameters (described in 'PSTN Parameters' on page 793):

- ISDNRxOverlap = 2
- ISDNTxOverlap
- ISDNOutCallsBehavior = 2
- MinOverlapDigitsForRouting
- TimeBetweenDigits
- MaxDigits
- DigitMapping
- MuteDTMFInOverlap

For configuring ISDN overlap dialing using the Web interface, see 'Configuring Trunk Settings' on page 271.

## 25.8 Redirect Number and Calling Name (Display)

The following tables define the device's redirect number and calling name (Display) support for various ISDN variants according to NT (Network Termination) / TE (Termination Equipment) interface direction:

**Calling Name (Display)**

| NT/TE Interface | DMS-100 | NI-2 | 4/5ESS | Euro ISDN | QSIG |
|-----------------|---------|------|--------|-----------|------|
| NT-to-TE        | Yes     | Yes  | Yes    | Yes       | Yes  |
| TE-to-NT        | Yes     | Yes  | Yes    | No        | Yes  |

**Redirect Number**

| NT/TE Interface | DMS-100 | NI-2 | 4/5ESS | Euro ISDN | QSIG |
|-----------------|---------|------|--------|-----------|------|
| NT-to-TE        | Yes     | Yes  | Yes    | Yes       | Yes  |
| TE-to-NT        | Yes     | Yes  | Yes    | Yes*      | Yes  |

\* When using ETSI DivertingLegInformation2 in a Facility IE (not Redirecting Number IE).

## 26 Trunk Group

This section describes the configuration of the device's channels, which entails assigning them numbers and Trunk Group IDs.

### 26.1 Configuring Trunk Group Table

The Trunk Group Table page allows you to define up to 120 Trunk Groups. A Trunk Group is a logical group of physical trunks and channels that are assigned a Trunk Group ID. The Trunk Group can include multiple trunks and ranges of channels.

To enable and activate the channels of the device, Trunk Groups need to be defined and with telephone numbers. Channels that are not defined in this table are disabled. The Trunk Groups are later used for routing IP-to-Tel and Tel-to-IP calls.

#### Notes:

- After you have configured a Trunk Group, you must configure the Inbound IP Routing Table rules (see 'Configuring Inbound IP Routing Table' on page 330) to route incoming IP calls to the Trunk Group. If you do not configure this, calls cannot be established.
- To select the method on how incoming calls are routed to channels within a Trunk Group, see 'Configuring Hunt Group Settings' on page 291.
- The Trunk Group Table can also be configured using the table ini file parameter, TrunkGroup\_x to (see 'Number Manipulation Parameters' on page 855) or CLI command, configure voip> gw hunt-or-trunk-group trunk-group.

#### ➤ To configure the Trunk Group Table:

1. Open the Trunk Group Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Trunk Group** > **Trunk Group**).

|                             |  |         |  |  |  |  |  |
|-----------------------------|--|---------|--|--|--|--|--|
| Add Phone Context As Prefix |  | Disable |  |  |  |  |  |
| Trunk Group Index           |  | 1-12    |  |  |  |  |  |

| Group Index | Module       | From Trunk | To Trunk | Channels | Phone Number | Trunk Group ID | Tel Profile ID |
|-------------|--------------|------------|----------|----------|--------------|----------------|----------------|
| 1           | Module 1 PRI | 1          | 1        | 1-30     | 6000         | 1              | 1              |
| 2           | Module 1 PRI | 2          | 2        | 1-30     | 7000         | 2              | 1              |
| 3           | Module 2 FXS |            |          | 1-4      | 101          | 3              | 2              |
| 4           |              |            |          |          |              |                |                |

2. Configure the Trunk Group as required. For a description of the parameters, see the table below.
3. Click **Submit** to apply your changes.
4. To save the changes to the flash memory, see 'Saving Configuration' on page 532.
5. To register the Trunk Groups, click the **Register** button. To unregister the Trunk Groups, click **Unregister**. The registration method for each Trunk Group is according to the 'Registration Mode' parameter in the Trunk Group Settings page (see 'Configuring Hunt Group Settings' on page 291).

### Trunk Group Table Parameters

| Parameter                                                                                                          | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|--------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Module<br>CLI: module<br>[TrunkGroup_Module]                                                                       | Defines the module (i.e., FXS, FXO, PRI, or BRI) for which you want to define the Trunk Group.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| From Trunk<br>CLI: first-trunk-id<br>[TrunkGroup_FirstTrunkId]                                                     | Defines the starting physical Trunk number in the Trunk Group. The number of listed Trunks depends on the device's hardware configuration.<br><b>Note:</b> This parameter is applicable only to PRI and BRI modules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| To Trunk<br>CLI: last-trunk-id<br>[TrunkGroup_LastTrunkId]                                                         | Defines the ending physical Trunk number in the Trunk Group. The number of listed Trunks depends on the device's hardware configuration.<br><b>Note:</b> This parameter is applicable only to PRI and BRI modules.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Channels<br>CLI: first-b-channel<br>[TrunkGroup_FirstBChannel]<br>CLI: last-b-channel<br>[TrunkGroup_LastBChannel] | Defines the device's channels/ports (analog module) or Trunk B-channels (digital module). To enable channels, enter the channel numbers. You can enter a range of channels by using the syntax <i>n-m</i> , where <i>n</i> represents the lower channel number and <i>m</i> the higher channel number. For example, "1-4" specifies channels 1 through 4.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>The number of defined channels must not exceed the maximum number of the Trunk's B-channels.</li> <li>To represent all the Trunk's B-channels, enter a single asterisk (*).</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Phone Number<br>CLI: first-phone-number<br>[TrunkGroup_FirstPhoneNumber]                                           | Defines the telephone number(s) of the channels.<br>The valid value can be up to 50 characters.<br>For a range of channels, enter only the first telephone number. Subsequent channels are assigned the next consecutive telephone number. For example, if you enter 400 for channels 1 to 4, then channel 1 is assigned phone number 400, channel 2 is assigned phone number 401, and so on.<br>These numbers are also used for channel allocation for IP-to-Tel calls if the Trunk Group's 'Channel Select Mode' parameter is set to <b>By Dest Phone Number</b> .<br><b>Notes:</b> <ul style="list-style-type: none"> <li>If this field includes alphabetical characters and the phone number is defined for a range of channels (e.g., 1-4), then the phone number must end with a number (e.g., 'user1').</li> <li>This field is optional for BRI/PRI interfaces. The logical numbers defined in this field are used when an incoming PSTN/PBX call doesn't contain the calling number or called number (the latter being determined by the ReplaceEmptyDstWithPortNumber parameter). These numbers are used to replace them.</li> </ul> |
| Trunk Group ID<br>CLI: trunk-group-id<br>[TrunkGroup_TrunkGroupNum]                                                | Defines the Trunk Group ID for the specified channels. The same Trunk Group ID can be assigned to more than one group of channels. If an IP-to-Tel call is assigned to a Trunk Group, the IP call is routed to the channel(s) pertaining to that Trunk Group ID.<br>The valid value can be 0 to 119.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Tel Profile ID<br>CLI: tel-profile-id<br>[TrunkGroup_ProfileId]                                                    | Assigns a Tel Profile ID to the Trunk Group.<br><b>Note:</b> For configuring Tel Profiles, see 'Configuring Tel Profiles' on page 237.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## 26.2 Configuring Hunt Group Settings

The Hunt Group Settings allows you to configure the following per Trunk Group:

- Channel select method by which IP-to-Tel calls are assigned to the Trunk Group's channels.
- Registration method for registering Trunk Groups to selected Serving IP Group IDs.

### Notes:

- For configuring Trunk Groups, see Configuring Trunk Group Table on page 289.
- The Hunt Group Settings table can also be configured using the table ini file parameter, TrunkGroupSettings (see 'Number Manipulation Parameters' on page 855) or CLI command, configure voip/gw hunt-or-trunk-group trunk-group-setting.

### ➤ To configure the Hunt Group Settings table:

1. Open the Hunt Group Settings page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Trunk Group** > **Hunt Group Settings**).

| Trunk Group ID | Channel Select Mode | Registration Mode | Serving IP Group ID | Gateway Name | Contact User | MWI Interrogation Type |
|----------------|---------------------|-------------------|---------------------|--------------|--------------|------------------------|
| 1              |                     |                   |                     |              |              | Not Configured         |
| 2              |                     |                   |                     |              |              | Not Configured         |
| 3              |                     |                   |                     |              |              | Not Configured         |
| 4              |                     |                   |                     |              |              | Not Configured         |
| 5              |                     |                   |                     |              |              | Not Configured         |
| 6              |                     |                   |                     |              |              | Not Configured         |
| 7              |                     |                   |                     |              |              | Not Configured         |
| 8              |                     |                   |                     |              |              | Not Configured         |
| 9              |                     |                   |                     |              |              | Not Configured         |
| 10             |                     |                   |                     |              |              | Not Configured         |

2. From the 'Index' drop-down list, select the range of entries that you want to edit.
3. Configure the Trunk Group as required. For a description of the parameters, see the table below.
4. Click **Submit** to apply your changes.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

### Hunt Group Settings Parameters Description

| Parameter                                                                  | Description                                            |
|----------------------------------------------------------------------------|--------------------------------------------------------|
| Trunk Group ID<br>CLI: trunk-group-id<br>[TrunkGroupSettings_TrunkGroupId] | Defines the Trunk Group ID that you want to configure. |

| Parameter                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Channel Select Mode<br>CLI: channel-select-mode<br><b>[TrunkGroupSettings_ChannelSelectMode]</b> | <p>Defines the method by which IP-to-Tel calls are assigned to the channels of the Trunk Group.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> By Dest Phone Number = The channel is selected according to the called (destination) number. If the number is not located, the call is released. If the channel is unavailable (e.g., busy), the call is put on call waiting (if call waiting is enabled and no other call is on call waiting); otherwise, the call is released.</li> <li>▪ <b>[1]</b> Cyclic Ascending = The next available channel in the Trunk Group, in ascending cyclic order is selected. After the device reaches the highest channel number in the Trunk Group, it selects the lowest channel number in the Trunk Group, and then starts ascending again.</li> <li>▪ <b>[2]</b> Ascending = The lowest available channel in the Trunk Group is selected, and if unavailable, the next higher channel is selected.</li> <li>▪ <b>[3]</b> Cyclic Descending = The next available channel in descending cyclic order is selected. The next lower channel number in the Trunk Group is always selected. When the device reaches the lowest channel number in the Trunk Group, it selects the highest channel number in the Trunk Group, and then starts descending again.</li> <li>▪ <b>[4]</b> Descending = The highest available channel in the Trunk Group is selected, and if unavailable, the next lower channel is selected.</li> <li>▪ <b>[5]</b> Dest Number + Cyclic Ascending = The channel is selected according to the called number. If the called number isn't found, the next available channel in ascending cyclic order is selected.<br/><b>Note:</b> If the called number is located, but the port associated with the number is busy, the call is released.</li> <li>▪ <b>[6]</b> By Source Phone Number = The channel is selected according to the calling number.</li> <li>▪ <b>[7]</b> Trunk Cyclic Ascending = The channel from the first channel of the next trunk (adjacent to the trunk from which the previous channel was selected) is selected. This option is applicable only to digital interfaces.</li> <li>▪ <b>[8]</b> Trunk &amp; Channel Cyclic Ascending = The device implements the Trunk Cyclic Ascending and Cyclic Ascending methods to select the channel. This method selects the next physical trunk in the Trunk Group, and then selects the B-channel of this trunk according to the Cyclic Ascending method (i.e., selects the channel after the last allocated channel). This option is applicable only to digital interfaces.<br/>For example, if the Trunk Group includes two physical trunks, 0 and 1: <ul style="list-style-type: none"> <li>✓ For the first incoming call, the first channel of Trunk 0 is selected.</li> <li>✓ For the second incoming call, the first channel of Trunk 1 is selected.</li> <li>✓ For the third incoming call, the second channel of Trunk 0 is selected.</li> </ul> </li> <li>▪ <b>[9]</b> Ring to Hunt Group = The device allocates IP-to-Tel calls to all the FXS ports (channels) in the Hunt Group. When a call is received for the Hunt Group, all telephones connected to the FXS ports belonging to the Hunt Group start ringing. The call is eventually received by whichever telephone first answers the call (after which the other phones stop ringing). This option is</li> </ul> |

| Parameter                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

By default, no name is configured.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ If this parameter is not configured, the Trunk Group decimal number is used in the SIP 'tgrp' parameter.</li> <li>▪ This feature is enabled by any of the following parameters: <ul style="list-style-type: none"> <li>✓ UseSIPtgrp</li> <li>✓ UseBroadsoftDTG</li> </ul> </li> <li>▪ Currently, this parameter can only be configured using the ini file.</li> </ul>                                                                                                                                                                                                                            |
| MWI Interrogation Type<br>CLI: mwi-interrogation-type<br><b>[TrunkGroupSettings_MWIInterrogationType]</b> | <p>Defines MWI QSIG-to-IP interworking for interrogating MWI supplementary services:</p> <ul style="list-style-type: none"> <li>▪ <b>[255]</b> Not Configured</li> <li>▪ <b>[0]</b> None = Disables the feature.</li> <li>▪ <b>[1]</b> Use Activate Only = MWI Interrogation messages are not sent and only "passively" responds to MWI Activate requests from the PBX.</li> <li>▪ <b>[2]</b> Result Not Used = MWI Interrogation messages are sent, but the result is not used. Instead, the device waits for MWI Activate requests from the PBX.</li> <li>▪ <b>[3]</b> Use Result = MWI Interrogation messages are sent, its results are used, and the MWI Activate requests are used. MWI Activate requests are interworked to SIP NOTIFY MWI messages. The SIP NOTIFY messages are sent to the IP Group defined by the NotificationIPGroupID parameter.</li> </ul> <p><b>Note:</b> This parameter appears in the table only if the VoiceMailInterface parameter is set to 3 (QSIG). Configuring Voice Mail on page <a href="#">389</a>.</p> |

## Reader's Notes

## 27 Manipulation

This section describes the configuration of various manipulation processes.

### 27.1 Configuring General Settings

The General Settings page allows you to configure general manipulation parameters. For a description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page 655.

➤ **To configure the general manipulation parameters:**

1. Open the General Settings page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** submenu > **General Settings**).

**Figure 27-1: General Settings Page**

|                               |                |   |
|-------------------------------|----------------|---|
| Set TEL-to-IP Redirect Reason | Not Configured | ▼ |
| Set IP-to-TEL Redirect Reason | Not Configured | ▼ |
| Redirect number SI to TEL     | Not Configured | ▼ |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.

### 27.2 Configuring Source/Destination Number Manipulation Rules

You can configure rules for manipulating destination and/or source telephone numbers for IP-to-Tel and Tel-to-IP calls. The following number manipulation tables are used for this:

■ **Tel-to-IP calls:**

- Destination Phone Number Manipulation Table for Tel > IP Calls table (up to 120 entries)
- Source Phone Number Manipulation Table for Tel > IP Calls table (up to 120 entries)

■ **IP-to-Tel calls:**

- Destination Phone Number Manipulation Table for IP > Tel Calls table (up to 120 entries)
- Source Phone Number Manipulation Table for IP > Tel Calls table (up to 120 entries)

The number manipulation tables provide two configuration areas:

- Matching characteristics (*Rule*) of incoming call, for example, prefix of destination number.
- Manipulation operation (*Action*), for example, remove user-defined number of digits from the left of the number.

If the incoming call matches the characteristics of a rule, then its manipulation action is applied.

The device searches a matching manipulation rule starting from the first entry (i.e., top of the table). In other words, a rule at the top of the table takes precedence over a rule defined lower down in the table. Therefore, define more specific rules above more generic rules. For example, if you enter 551 in Index 1 and 55 in Index 2, the device applies rule 1 to numbers that start with 551 and applies rule 2 to numbers that start with 550, 552, 553,

and so on until 559. However, if you enter 55 in Index 1 and 551 in Index 2, the device applies rule 1 to all numbers that start with 55, including numbers that start with 551.

You can perform a second "round" (additional) of destination (NumberMapIP2Tel parameter) and source (SourceNumberMapIP2Tel parameter) number manipulations for IP-to-Tel calls on an already manipulated number. The initial and additional number manipulation rules are both configured in these tables. The additional manipulation is performed on the initially manipulated number. Therefore, for complex number manipulation schemes, you only need to configure relatively few manipulation rules in these tables (that would otherwise require many rules). This feature is enabled using the following parameters:

- PerformAdditionalIP2TELSrcManipulation for source number manipulation
- PerformAdditionalIP2TELDestinationManipulation for destination number manipulation

Telephone number manipulation can be useful, for example, for the following:

- Stripping or adding dialing plan digits from or to the number, respectively. For example, a user may need to first dial 9 before dialing the phone number to indicate an external line. This number 9 can then be removed by number manipulation before the call is setup.
- Allowing or blocking Caller ID information according to destination or source prefixes. For more information on Caller ID, see [Configuring Caller Display Information](#) on page 398.
- For digital modules only: Assigning Numbering Plan Indicator (NPI) and Type of Numbering (TON) to IP-to-Tel calls. The device can use a single global setting for NPI/TON classification or it can use the setting in the manipulation tables on a call-by-call basis.

#### Notes:

- Number manipulation can occur before or after a routing decision is made. For example, you can route a call to a specific Trunk Group according to its original number, and then you can remove or add a prefix to that number before it is routed. To determine when number manipulation is performed, configure the 'IP to Tel Routing Mode' parameter (RouteModeIP2Tel) described in 'Configuring Inbound IP Routing Table' on page 330, and 'Tel to IP Routing Mode' parameter (RouteModeTel2IP) described in 'Configuring Outbound IP Routing Table' on page 321.
- The device manipulates the number in the following order: 1) strips digits from the left of the number, 2) strips digits from the right of the number, 3) retains the defined number of digits, 4) adds the defined prefix, and then 5) adds the defined suffix.
- The source/destination number manipulation tables can also be configured using the ini file and CLI:
  - 1) **Destination Phone Number Manipulation Table for IP > Tel Calls table:** NumberMapIP2Tel (ini); configure voip/gw manipulations dst-number-map-ip2tel (CLI)
  - 2) **Destination Phone Number Manipulation Table for Tel > IP Calls table:** NumberMapTel2IP (ini); configure voip/gw manipulations dst-number-map-tel2ip (CLI)
  - 3) **Source Phone Number Manipulation Table for IP > Tel Calls table:** SourceNumberMapIP2Tel (ini); configure voip/gw manipulations src-number-map-ip2tel (CLI)
  - 4) **Source Phone Number Manipulation Table for Tel > IP Calls table:** SourceNumberMapTel2IP (ini); configure voip/gw manipulations src-number-map-tel2ip (CLI)

➤ **To configure number manipulation rules:**

1. Open the required Number Manipulation page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** submenu > **Dest Number IP->Tel**, **Dest Number Tel->IP**, **Source Number IP->Tel**, or **Source Number Tel->IP**); the relevant Manipulation table page is displayed.
2. Click the **Add** button; the following dialog box appears:

**Figure 27-2: Number Manipulation Table - Add Dialog Box**

| Rule                    | Action |
|-------------------------|--------|
| Index                   | 0      |
| Destination Prefix      | *      |
| Source Prefix           | *      |
| Source IP Address       | *      |
| Source Host Prefix      | *      |
| Destination Host Prefix | *      |

Submit Cancel

3. Click the **Rule** tab, and then configure the matching characteristics. For a description of the parameters, see the table below.
4. Click the **Action** tab, and then configure the manipulation operation. For a description of the parameters, see the table below.
5. Click **Submit** to apply your changes.
6. To save the changes to flash memory, see 'Saving Configuration' on page 532.

The table below shows configuration examples of Tel-to-IP source phone number manipulation rules, where:

- **Rule 1:** When the destination number has the prefix 03 (e.g., 035000), source number prefix 201 (e.g., 20155), and from source IP Group ID 2, the source number is changed to, for example, 97120155.
- **Rule 2:** When the source number has prefix 1001 (e.g., 1001876), it is changed to 587623.
- **Rule 3:** When the source number has prefix 123451001 (e.g., 1234510012001), it is changed to 20018.
- **Rule 4:** When the source number has prefix from 30 to 40 and a digit (e.g., 3122), it is changed to 2312.
- **Rule 5:** When the destination number has the prefix 6, 7, or 8 (e.g., 85262146), source number prefix 2001, it is changed to 3146.

| Parameter          | Rule 1 | Rule 2 | Rule 3 | Rule 4 | Rule 5  |
|--------------------|--------|--------|--------|--------|---------|
| Source IP Group    | 2      | 0      | -      | -      | -       |
| Destination Prefix | 03     |        | *      | *      | [6,7,8] |

| Parameter                  | Rule 1  | Rule 2     | Rule 3     | Rule 4   | Rule 5 |
|----------------------------|---------|------------|------------|----------|--------|
| Source Prefix              | 201     | 1001       | 123451001# | [30-40]x | 2001   |
| Stripped Digits from Left  | -       | 4          | -          | -        | 5      |

| Number of Digits to Leave  | -       | -          | 4          | -        | -      |
| Presentation               | Allowed | Restricted | -          | -        | -      |

### Number Manipulation Parameters Description

| Parameter                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics (Rule)</b>                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Web: Destination Prefix<br>EMS: Prefix<br>CLI: dst-prefix<br><b>[DestinationPrefix]</b> | Defines the destination (called) telephone number prefix and/or suffix. You can use special notations for denoting the prefix. For example, <b>[100-199](100,101,105)</b> denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can also use the \$ sign to denote calls without a called number. For a description of available notations, see 'Dialing Plan Notation for Routing and Manipulation Tables' on page 653.                                                                                                                                                                                                     |
| Web/EMS: Source Prefix<br>CLI: src-prefix<br><b>[SourcePrefix]</b>                      | Defines the source (calling) telephone number prefix and/or suffix. You can use special notations for denoting the prefix. For example, <b>[100-199](100,101,105)</b> denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can also use the \$ sign to denote calls without a calling number. For a description of available notations, see 'Dialing Plan Notation for Routing and Manipulation Tables' on page 653.                                                                                                                                                                                                        |
| Web/EMS: Source IP Address<br>CLI: src-ip-address<br><b>[SourceAddress]</b>             | Defines the source IP address of the caller. This is obtained from the Contact header in the INVITE message.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>This parameter is applicable only to the number manipulation tables for IP-to-Tel calls.</li> <li>The source IP address can include the 'x' wildcard to represent single digits. For example: 10.8.8.xx represents all IP addresses between 10.8.8.10 to 10.8.8.99.</li> <li>The source IP address can include the asterisk (*) wildcard to represent any number between 0 and 255. For example, 10.8.8.* represents all IP addresses between 10.8.8.0 and 10.8.8.255.</li> </ul> |
| Web: Source Host Prefix<br>CLI: src-host-prefix<br><b>[SrcHost]</b>                     | Defines the URI host name prefix of the incoming SIP INVITE message in the From header.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>This parameter is applicable only to the number manipulation tables for IP-to-Tel calls.</li> <li>The asterisk (*) wildcard can be used to denote any prefix.</li> <li>If the P-Asserted-Identity header is present in the incoming INVITE</li> </ul>                                                                                                                                                                                                                                                  |

| Parameter                                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                                                                                         | message, then the value of this parameter is compared to the P-Asserted-Identity URI host name (instead of the From header).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|           | the From header in the INVITE message includes the following:<br>From: 'anonymous' <sip: anonymous@anonymous.invalid> and<br>'privacy: id' header. |

## 27.3 Manipulating Number Prefix

The device supports a notation for adding a prefix where part of the prefix is first extracted from a user-defined location in the original destination or source number. This notation is entered in the 'Prefix to Add' field in the Number Manipulation tables (see 'Configuring Source/Destination Number Manipulation' on page 297):  $x[n,l]y...$

where,

- $x$  = any number of characters/digits to add at the beginning of the number (i.e. first digits in the prefix).
- $[n,l]$  = defines the location in the original destination or source number where the digits  $y$  are added:
  - $n$  = location (number of digits counted from the left of the number) of a specific string in the original destination or source number.
  - $l$  = number of digits that this string includes.
- $y$  = prefix to add at the specified location.

For example, assume that you want to manipulate an incoming IP call with destination number +5492028888888 (area code 202 and phone number 8888888) to the number 0202158888888. To perform such a manipulation, the following configuration is required in the Number Manipulation table:

1. The following notation is used in the 'Prefix to Add' field:  
 $0[5,3]15$   
where,
  - 0 is the number to add at the beginning of the original destination number.
  - $[5,3]$  denotes a string that is located after (and including) the fifth character (i.e., the first '2' in the example) of the original destination number, and its length being three digits (i.e., the area code 202, in the example).
  - 15 is the number to add immediately after the string denoted by  $[5,3]$  - in other words, 15 is added after (i.e. to the right of) the digits 202.
2. The first seven digits from the left are removed from the original number, by entering "7" in the 'Stripped Digits From Left' field.

### Example of Configured Rule for Manipulating Prefix using Special Notation

| Parameter                 | Rule 1         |
|---------------------------|----------------|
| Destination Prefix        | +5492028888888 |
| Source Prefix             | *              |
| Source IP Address         | *              |
| Stripped Digits from Left | 7              |
| Prefix to Add             | $0[5,3]15$     |

In this configuration example, the following manipulation process occurs:

1. The prefix is calculated as 020215.
2. The first seven digits from the left are removed from the original number, thereby changing the number to 8888888.
3. The prefix that was previously calculated is then added.

## 27.4 SIP Calling Name Manipulations

The Calling Name Manipulations Tel2IP and Calling Name Manipulations IP2Tel tables allow you to configure up to 120 manipulation rules for manipulating the calling name (i.e., caller ID) in SIP messages. This can include modifying or removing the calling name. SIP calling name manipulation is applicable to Tel-to-IP and IP-to-Tel calls.

For example, assume that an incoming SIP INVITE message includes the following header:

```
P-Asserted-Identity: "company:john" sip:6666@78.97.79.104
```

Using the Calling Name Manipulations IP2Tel table, the text "company" can be changed to "worker" in the outgoing INVITE, as shown below:

```
P-Asserted-Identity: "worker:john" sip:996666@10.13.83.10
```

The calling name manipulation tables provide two configuration areas:

- Matching characteristics (*Rule*) of incoming call, for example, prefix of destination number.
- Manipulation operation (*Action*), for example, remove user-defined number of digits from the left of the calling name.

If the incoming call matches the characteristics of a rule, then its manipulation action is applied.

### Notes:

- For configuring the Calling Name Manipulation Table for Tel > IP Calls table for retrieving calling name (display name) from an Active Directory using LDAP queries, see 'Querying the AD for Calling Name' on page 188.
- The Calling Name Manipulations Tel2IP table can also be configured using the table *ini* file parameter, CallingNameMapTel2Ip or CLI command, configure voip/gw manipulations calling-name-map-tel2ip.
- The Calling Name Manipulations IP2Tel table can also be configured using the table *ini* file parameter, CallingNameMapIp2Tel or CLI command, configure voip/gw manipulations calling-name-map-ip2tel.

➤ **To configure calling name manipulation rules:**

1. Open the required Calling Name Manipulations page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** > **Calling Name IP->Tel** or **Calling Name Tel->IP**).
2. Click the **Add** button; the following dialog box appears:

**Figure 27-3: Calling Name Manipulation IP2Tel - Rule Tab**

3. Click the **Rule** tab, and then configure the matching characteristics. For a description of the parameters, see the table below.
4. Click the **Action** tab, and then configure the manipulation operation. For a description of the parameters, see the table below.
5. Click the **Submit** button to save your changes.

**Calling Name Manipulation Parameters Description**

| Parameter                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics (Rule)</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Web: Destination Prefix<br>CLI: dst-prefix           | Defines the destination (called) telephone number prefix and/or suffix. You can use special notations for denoting the prefix. For example, <b>[100-199](100,101,105)</b> denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can also use the \$ sign to denote calls without a called number. For a description of available notations, see 'Dialing Plan Notation for Routing and Manipulation Tables' on page 653. |
| Web/EMS: Source Prefix<br>CLI: src-prefix            | Defines the source (calling) telephone number prefix and/or suffix. You can use special notations for denoting the prefix. For example, <b>[100-199](100,101,105)</b> denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can also use the \$ sign to denote calls without a calling number. For a description of available notations, see 'Dialing Plan Notation for Routing and Manipulation Tables' on page 653.    |
| Web: Calling Name Prefix<br>CLI: calling-name-prefix | Defines the caller name (i.e., caller ID) prefix. You can use special notations for denoting the prefix. For example, to denote any prefix, use the asterisk (*) symbol or to denote calls without a calling name, use the \$ sign. For a description of available notations, see 'Dialing Plan Notation for Routing and Manipulation Tables' on page 653.                                                                                         |

| Parameter                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Operation (Action)</b>                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Web: Stripped Digits From Left<br>EMS: Number Of Stripped Digits<br>CLI: remove-from-left   | Defines the number of characters to remove from the left of the calling name. For example, if you enter 3 and the calling name is "company:john", the new calling name is "pany:john".                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Web: Stripped Digits From Right<br>EMS: Number Of Stripped Digits<br>CLI: remove-from-right | Defines the number of characters to remove from the right of the calling name. For example, if you enter 3 and the calling name is "company:name", the new name is "company:n".                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                                                             | Description                                                                                                                                                                            |
|-----------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Web/EMS: Number of Digits to Leave<br>CLI: num-of-digits-to-leave     | Defines the number of characters that you want to keep from the right of the calling name. For example, if you enter 4 and the calling name is "company:name", the new name is "name". |
| Web: Prefix to Add<br>EMS: Prefix/Suffix To Add<br>CLI: prefix-to-add | Defines the number or string to add at the front of the calling name. For example, if you enter ITSP and the calling name is "company:name", the new name is ITSPcompany:john".        |
| Web: Suffix to Add<br>EMS: Prefix/Suffix To Add<br>CLI: suffix-to-add | Defines the number or string to add at the end of the calling name. For example, if you enter 00 and calling name is "company:name", the new name is "company:name00".                 |

## 27.5 Configuring Redirect Number IP to Tel

You can configure rules for manipulating the redirect number received in the incoming message:

- IP-to-Tel redirect number manipulation: You can manipulate the value of the received SIP Diversion, Resource-Priority, or History-Info headers, which is then added to the Redirecting Number Information Element (IE) in the ISDN Setup message sent to the Tel side. This also includes the reason for the call redirection. This is configured in the Redirect Number IP > Tel table.
- Tel-to-IP redirect number manipulation: You can manipulate the prefix of the redirect number, received from the Tel side, in the outgoing SIP Diversion, Resource-Priority, or History-Info headers sent to the IP side. This is configured in the Redirect Number Tel > IP table.

The redirect number manipulation tables provide two configuration areas:

- Matching characteristics (*Rule*) of incoming call, for example, prefix of redirect number.
- Manipulation operation (*Action*), for example, remove user-defined number of digits from the left of the redirect number.

If the incoming call matches the characteristics of a rule, then its manipulation action is applied.

### Notes:

- If the device copies the received destination number to the outgoing SIP redirect number (enabled by the CopyDest2RedirectNumber parameter), then no redirect number Tel-to-IP manipulation is done.
- The manipulation rules are done in the following order: Stripped Digits From Left, Stripped Digits From Right, Number of Digits to Leave, Prefix to Add, and then Suffix to Add.
- The Redirect Prefix parameter is used before it is manipulated.
- The redirect number manipulation tables can also be configured using the ini file and CLI:
  - Redirect Number IP to Tel table: RedirectNumberMapIp2Tel (ini); configure voip/gw manipulations redirect-number-map-ip2tel (CLI)
  - Redirect Number Tel to IP table: RedirectNumberMapTel2Ip (ini); configure voip/gw manipulations redirect-number-map-tel2ip (CLI)

➤ **To configure redirect number manipulation rules:**

1. Open the required redirect number manipulation table (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** > **Redirect Number Tel > IP** or **Redirect Number IP > Tel**).
2. Click the **Add** button; the following dialog box appears (e.g., **Redirect Number Tel > IP** table):

**Figure 27-4: Redirect Number Manipulation (e.g., Tel to IP)**

3. Click the **Rule** tab, and then configure the matching characteristics. For a description of the parameters, see the table below.
4. Click the **Action** tab, and then configure the manipulation operation. For a description of the parameters, see the table below.
5. Click **Submit** to apply your settings.

**Redirect Number Manipulation Parameters Description**

| Parameter                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics (Rule)</b>                                            |                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Web/EMS: Redirect Prefix<br>CLI: redirect-prefix<br><b>[RedirectPrefix]</b>       | Defines the redirect telephone number prefix. To denote any number, use the wildcard asterisk (*) symbol.                                                                                                                                                                                                                                                                                                          |
| Web/EMS: Destination Prefix<br>CLI: dst-prefix<br><b>[DestinationPrefix]</b>      | Defines the destination (called) telephone number prefix. To denote any number, use the wildcard asterisk (*) symbol.<br>For manipulating the diverting and redirected numbers for call diversion, you can use the strings "DN" and "RN" to denote the destination prefix of these numbers. For more information, see <a href="#">Manipulating Redirected and Diverted Numbers for Call Diversion</a> on page 310. |
| Web: Source Trunk Group ID<br>CLI: src-trunk-group-id<br><b>[SrcTrunkGroupID]</b> | Defines the Trunk Group from where the Tel call is received. To denote any Trunk Group, leave this field empty.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>▪ This parameter is applicable only to the Redirect Number Tel &gt; IP table.</li> <li>▪ The value -1 indicates that this field is ignored in the rule.</li> <li>▪ For IP-to-IP call routing, this parameter is not relevant.</li> </ul>   |
| Source IP Group ID<br>CLI: src-ip-group-id<br><b>[SrcIPGroupID]</b>               | Defines the IP Group from where the IP call originated. Typically, the IP Group of an incoming INVITE is determined or classified by the Inbound IP Routing Table. If not used (i.e., any IP Group), leave the field empty.<br><b>Notes:</b>                                                                                                                                                                       |

| Parameter                                                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## 27.6 Manipulating Redirected and Diverted Numbers for Call Diversion

You can configure manipulation rules to manipulate the Diverted-to and Diverting numbers received in the incoming Call Redirection Facility message for call diversion, which is interworked to outgoing SIP 302 responses. This feature is applicable to the Euro ISDN and QSIG variants, and to IP-to-Tel calls.

The incoming redirection Facility message includes, among other parameters, the Diverted-to number and Diverting number. The Diverted-to number (i.e., new destination) is mapped to the user part in the Contact header of the SIP 302 response. The Diverting number is mapped to the user part in the Diversion header of the SIP 302 response.

These two numbers can be manipulated by entering the following special strings in the 'Destination Prefix' field of the Redirect Number Tel -> IP manipulation table:

- "RN" - used in the rule to manipulate the Redirected number (i.e., originally called number or Diverting number).
- "DN" - used in the rule to manipulate the Diverted-to number (i.e., the new called number or destination). This manipulation is done on the user part in the Contact header of the SIP 302 response.

For example, assume the following required manipulation:

- Manipulate Redirected number 6001 (originally called number) to 6005
- Manipulate Diverted-to number 8002 (the new called number or destination) to 8005

The configuration in the Redirect Number Tel -> IP manipulation table is as follows:

**Redirect Number Configuration Example**

| Parameter                  | Rule 1 | Rule 2 |
|----------------------------|--------|--------|
| Destination Prefix         | RN     | DN     |
| Redirect Prefix            | 6      | 8      |
| Stripped Digits From Right | 1      | 1      |
| Suffix to Add              | 5      | 5      |
| Number of Digits to Leave  | 5      | -      |

After the above manipulation is done, the device sends the following outgoing SIP 302 response:

```
SIP/2.0 302 Moved Temporarily
Via: SIP/2.0/TLS 10.33.45.68;branch=z9hG4bKac54132643;alias
From: "MP118 1" <sip:8001@10.33.45.68>;tag=1c54119560
To: <sip:6001@10.33.45.69;user=phone>;tag=1c664560944
Call-ID: 541189832710201115142@10.33.45.68
CSeq: 1 INVITE
Contact: <sip:8005@10.33.45.68;user=phone>
Supported: em,timer,replaces,path,early-session,resource-priority
Allow:
REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK,REFER,INFO,SUB
SCRIBE,UPDATE
Diversion: <tel:6005>;reason=unknown;counter=1
Server: Audiocodes-Sip-Gateway-IPmedia 260_UN/v.6.20A.043.001
Reason: SIP ;cause=302 ;text="302 Moved Temporarily"
Content-Length: 0
```

## 27.7 Mapping NPI/TON to SIP Phone-Context

The Phone-Context table page allows you to map Numbering Plan Indication (NPI) and Type of Number (TON) to the SIP 'phone-context' parameter. The 'phone-context' parameter appears in the standard SIP headers where a phone number is used (i.e., Request-URI, To, From, and Diversion). When a call is received from the ISDN/Tel side, the NPI and TON are compared against the table and the matching 'phone-context' value is used in the outgoing SIP INVITE message. The same mapping occurs when an INVITE with a 'phone-context' parameter is received.

For example, for a Tel-to-IP call with NPI/TON set as E164 National (values 1/2), the device sends the following SIP INVITE URI:

```
sip:12365432;phone-context= na.e.164.nt.com
```

This is configured for entry 3 in the figure below. In the opposite direction (IP-to-Tel call), if the incoming INVITE contains this 'phone-context' (e.g. "phone-context= na.e.164.nt.com"), the NPI/TON of the called number in the outgoing Setup message is changed to E164 National.

➤ **To configure NPI/TON to SIP phone-context rules:**

1. Open the Phone Context Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** > **Phone Context**).

**Figure 27-5: Phone Context Table Page**

|                             |  |        |
|-----------------------------|--|--------|
| Add Phone Context As Prefix |  | Enable |
| Phone Context Index         |  | 1-10   |

|   | NPI          | TON              | Phone Context    |
|---|--------------|------------------|------------------|
| 1 | Unknown      | Unknown          | unknown.com      |
| 2 | Private      | Level 2 Regional | host.com         |
| 3 | E.164 Public | National         | na.e164.host.com |
| 4 |              |                  |                  |

2. Configure the parameters as required. For a description of the parameters, see the table below.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**Notes:**

- You can configure multiple rows with the same NPI/TON or same SIP 'phone-context'. In such a configuration, a Tel-to-IP call uses the first matching rule in the table.
- The Phone Context table can also be configured using the table ini file parameter, PhoneContext (see 'Number Manipulation Parameters' on page 855) or CLI command, configure voip > gw manipulations phone-context-table.

**Phone-Context Parameters Description**

| Parameter                                                                                                                                        | Description                                                                                                                                                                                                                                                                                   |

## 27.8 Configuring Release Cause Mapping

The Release Cause Mapping table allows you to map up to 12 different ISDN ITU-T Q.850 cause codes, which indicate reasons for ISDN call failure, to SIP response codes, and vice versa. This allows you to override the default release cause mappings between ISDN and SIP, as described in 'Fixed Mapping of ISDN Release Reason to SIP Response' on page 316 and 'Fixed Mapping of SIP Response to ISDN Release Reason' on page 314.

### Notes:

- For Tel-to-IP calls, you can also map the less commonly used SIP responses to a single default ISDN Release Cause, using the DefaultCauseMapISDN2IP parameter. This parameter defines a default ISDN Cause that is always used except when the following Release Causes are received: Normal Call Clearing (16), User Busy (17), No User Responding (18) or No Answer from User (19).
- The release cause mapping tables can also be configured using the ini file and CLI:
  - 1) Release Cause Mapping from ISDN to SIP table:  
CauseMapISDN2SIP (ini) or CLI command, configure voip > gw manipulations cause-map-isdn2sip.
  - 2) Release Cause Mapping from SIP to ISDN  
table:CauseMapSIP2ISDN (ini) or CLI command, configure voip > gw manipulations cause-map-sip2isdn.

➤ **To configure Release Cause mapping:**

1. Open the Release Cause Mapping page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** > **Release Cause Mapping**).

**Figure 27-6: Release Cause Mapping Page**

## 27.8.1 Fixed Mapping of SIP Response to ISDN Release Reason

The following table describes the mapping of SIP response to ISDN release reason.

**Mapping of SIP Response to ISDN Release Reason**

| SIP Response | Description          | ISDN Release Reason | Description                    |
|--------------|----------------------|---------------------|--------------------------------|
| 400*         | Bad request          | 31                  | Normal, unspecified            |
| 401          | Unauthorized         | 21                  | Call rejected                  |
| 402          | Payment required     | 21                  | Call rejected                  |
| 403          | Forbidden            | 21                  | Call rejected                  |
| 404          | Not found            | 1                   | Unallocated number             |
| 405          | Method not allowed   | 63                  | Service/option unavailable     |
| 406          | Not acceptable       | 79                  | Service/option not implemented |
| 407          | Proxy authentication | 21                  | Call rejected                  |

| SIP Response | Description                        | ISDN Release Reason | Description                    |
|--------------|------------------------------------|---------------------|--------------------------------|
|              | required                           |                     |                                |
| 408          | Request timeout                    | 102                 | Recovery on timer expiry       |
| 409          | Conflict                           | 41                  | Temporary failure              |
| 410          | Gone                               | 22                  | Number changed w/o diagnostic  |
| 411          | Length required                    | 127                 | Interworking                   |
| 413          | Request entity too long            | 127                 | Interworking                   |
| 414          | Request URI too long               | 127                 | Interworking                   |
| 415          | Unsupported media type             | 79                  | Service/option not implemented |
| 420          | Bad extension                      | 127                 | Interworking                   |
| 480          | Temporarily unavailable            | 18                  | No user responding             |
| 481*         | Call leg/transaction doesn't exist | 127                 | Interworking                   |
| 482*         | Loop detected                      | 127                 | Interworking                   |
| 483          | Too many hops                      | 127                 | Interworking                   |
| 484          | Address incomplete                 | 28                  | Invalid number format          |
| 485          | Ambiguous                          | 1                   | Unallocated number             |
| 486          | Busy here                          | 17                  | User busy                      |
| 488          | Not acceptable here                | 31                  | Normal, unspecified            |
| 500          | Server internal error              | 41                  | Temporary failure              |
| 501          | Not implemented                    | 38                  | Network out of order           |
| 502          | Bad gateway                        | 38                  | Network out of order           |
| 503          | Service unavailable                | 41                  | Temporary failure              |
| 504          | Server timeout                     | 102                 | Recovery on timer expiry       |
| 505*         | Version not supported              | 127                 | Interworking                   |
| 600          | Busy everywhere                    | 17                  | User busy                      |
| 603          | Decline                            | 21                  | Call rejected                  |
| 604          | Does not exist anywhere            | 1                   | Unallocated number             |
| 606*         | Not acceptable                     | 38                  | Network out of order           |

\* Messages and responses were created because the 'ISUP to SIP Mapping' draft does not specify their cause code mapping.

## 27.8.2 Fixed Mapping of ISDN Release Reason to SIP Response

The following table describes the mapping of ISDN release reason to SIP response.

**Mapping of ISDN Release Reason to SIP Response**

| ISDN Release Reason | Description                                                | SIP Response | Description             |
|---------------------|------------------------------------------------------------|--------------|-------------------------|
| 1                   | Unallocated number                                         | 404          | Not found               |
| 2                   | No route to network                                        | 404          | Not found               |
| 3                   | No route to destination                                    | 404          | Not found               |
| 6                   | Channel unacceptable                                       | 406*         | Not acceptable          |
| 7                   | Call awarded and being delivered in an established channel | 500          | Server internal error   |
| 16                  | Normal call clearing                                       | -*           | BYE                     |
| 17                  | User busy                                                  | 486          | Busy here               |
| 18                  | No user responding                                         | 408          | Request timeout         |
| 19                  | No answer from the user                                    | 480          | Temporarily unavailable |
| 21                  | Call rejected                                              | 403          | Forbidden               |
| 22                  | Number changed w/o diagnostic                              | 410          | Gone                    |
| 26                  | Non-selected user clearing                                 | 404          | Not found               |

| 98                  | Message not compatible with call state or message type non-existent or not implemented | 409*         | Conflict                  |
| 99                  | Information element non-existent or not implemented                                    | 480*         | Not found                 |
| 100                 | Invalid information elements contents                                                  | 501*         | Not implemented           |
| 101                 | Message not compatible with call state                                                 | 503*         | Service unavailable       |
| 102                 | Recovery of timer expiry                                                               | 408          | Request timeout           |
| 111                 | Protocol error                                                                         | 500          | Server internal error     |
| 127                 | Interworking unspecified                                                               | 500          | Server internal error     |

\* Messages and responses were created because the 'ISUP to SIP Mapping' draft doesn't specify their cause code mapping.

### 27.8.3 Reason Header

The device supports the SIP Reason header according to RFC 3326. The Reason header conveys information describing the disconnection cause of a call:

- **Sending Reason header:** If a call is disconnected from the Tel side (ISDN), the Reason header is set to the received Q.850 cause in the appropriate message (BYE/CANCEL/final failure response) and sent to the SIP side. If the call is disconnected because of a SIP reason, the Reason header is set to the appropriate SIP response.
- **Receiving Reason header:** If a call is disconnected from the IP side and the SIP message includes the Reason header, it is sent to the Tel side according to the following logic:
  - If the Reason header includes a Q.850 cause, it is sent as is.
  - If the Reason header includes a SIP response:
    - ◆ If the message is a final response, the response status code is translated to Q.850 format and passed to ISDN.
    - ◆ If the message isn't a final response, it is translated to a Q.850 cause.
  - When the Reason header is received twice (i.e., SIP Reason and Q.850), the Q.850 takes precedence over the SIP reason and is sent to the Tel side.

### 27.8.4 Mapping PSTN Release Cause to SIP Response

The device's FXO interface interoperates between the SIP network and the PSTN/PBX. This interoperability includes the mapping of PSTN/PBX Call Progress tones to SIP 4xx or 5xx responses for IP-to-Tel calls. The converse is also true - for Tel-to-IP calls, the SIP 4xx or 5xx responses are mapped to tones played to the PSTN/PBX.

When establishing an IP-to-Tel call, the following rules are applied:

- If the remote party (PSTN/PBX) is busy and the FXO device detects a busy tone, it sends a SIP 486 Busy response to IP. If it detects a reorder tone, it sends a SIP 404 Not Found (no route to destination) to IP. In both cases the call is released. Note that if the 'Disconnect Call on Busy Tone Detection' parameter is set to **Disable**, the FXO device ignores the detection of busy and reorder tones and does not release the call.
- For all other FXS/FXO release types such as:
  - no free channels in the Trunk Group,
  - an appropriate call routing rule to a Trunk Group doesn't exist, or
  - the phone number isn't found

then the device sends a SIP response to the IP according to the 'Default Release Cause' parameter. This parameter defines Q.931 release causes. Its default is **3**, which is mapped to the SIP 404 response. By changing its value to **34**, the SIP 503 response is sent. Other causes can be used as well.

## 27.9 Numbering Plans and Type of Number

The IP-to-Tel destination or source number manipulation tables allow you to classify numbers by their Numbering Plan Indication (NPI) and Type of Number (TON). The device supports all NPI/TON classifications used in the ETSI ISDN variant, as shown in the table below:

**NPI/TON Values for ETSI ISDN Variant**

| NPI              | TON                          | Description                                                                                                                                                                                                            |
|------------------|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Unknown [0]      | Unknown [0]                  | A valid classification, but one that has no information about the numbering plan.                                                                                                                                      |
| E.164 Public [1] | Unknown [0]                  | A public number in E.164 format, but no information on what kind of E.164 number.                                                                                                                                      |
|                  | International [1]            | A public number in complete international E.164 format, e.g., 16135551234.                                                                                                                                             |
|                  | National [2]                 | A public number in complete national E.164 format, e.g., 6135551234.                                                                                                                                                   |
|                  | Network Specific [3]         | The type of number "network specific number" is used to indicate administration / service number specific to the serving network, e.g., used to access an operator.                                                    |
|                  | Subscriber [4]               | A public number in complete E.164 format representing a local subscriber, e.g., 5551234.                                                                                                                               |
|                  | Abbreviated [6]              | The support of this code is network dependent. The number provided in this information element presents a shorthand representation of the complete number in the specified numbering plan as supported by the network. |
| Private [9]      | Unknown [0]                  | A private number, but with no further information about the numbering plan.                                                                                                                                            |
|                  | Level 2 Regional [1]         |                                                                                                                                                                                                                        |
|                  | Level 1 Regional [2]         | A private number with a location, e.g., 3932200.                                                                                                                                                                       |
|                  | PISN Specific [3]            |                                                                                                                                                                                                                        |
|                  | Level 0 Regional (local) [4] | A private local extension number, e.g., 2200.                                                                                                                                                                          |

For NI-2 and DMS-100 ISDN variants, the valid combinations of TON and NPI for calling and called numbers include (Plan/Type):

- 0/0 - Unknown/Unknown
- 1/1 - International number in ISDN/Telephony numbering plan
- 1/2 - National number in ISDN/Telephony numbering plan

## 28 Routing

This section describes the configuration of call routing rules.

### 28.1 Configuring General Routing Parameters

The Routing General Parameters page allows you to configure general routing parameters. For a description of these parameters, see 'Configuration Parameters Reference' on page 655.

➤ **To configure general routing parameters:**

1. Open the Routing General Parameters page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Routing** submenu > **General Parameters**).

| General Parameters                                    |                                 |
|-------------------------------------------------------|---------------------------------|
| Add Hunt Group ID as Prefix                           | No                              |
| Add Trunk ID as Prefix                                | No                              |
| Replace Empty Destination with B-channel Phone Number | No                              |
| Add NPI and TON to Called Number                      | No                              |
| Add NPI and TON to Calling Number                     | No                              |
| IP to Tel Remove Routing Table Prefix                 | No                              |
| Source IP Address Input                               | SIP Contact Header              |
| Enable Alt Routing Tel to IP                          | Disable                         |
| Alt Routing Tel to IP Mode                            | Both                            |
| Alt Routing Tel to IP Connectivity Method             | ICMP Ping                       |
| Alt Routing Tel to IP Keep Alive Time                 | 60                              |
| Alternative Routing Tone Duration [ms]                | 0                               |
| Source Manipulation Mode                              | FROM & PAI (after manipulation) |
| Max Allowed Packet Loss for Alt Routing [%]           | 20                              |
| Max Allowed Delay for Alt Routing [msec]              | 250                             |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.

### 28.2 Configuring Outbound IP Routing Table

The Outbound IP Routing Table page allows you to configure up to 180 Tel-to-IP or outbound IP call routing rules. The device uses these rules to route calls from the Tel or IP to a user-defined IP destination.

The Outbound IP Routing Table table provides two configuration areas:

- **Matching Characteristics:** Characteristics of the incoming call. If the call characteristics match a table entry, the routing rule is used to route the call to the specified destination. One or more characteristics can be defined for the rule:
  - Source IP Group (to which the call belongs)
  - Source and destination Request-URI host name prefix
  - Source Trunk Group (from where the call is received)
  - Source (calling) and destination (called) telephone number prefix and suffix
  - Source and destination Request-URI host name prefix

- **Destination:** If the call matches the configured characteristics, the device routes the call to an IP destination. If no characteristics match is found in the table, the call is rejected. The destination can be any of the following:
  - IP address in dotted-decimal notation.
  - Fully Qualified Domain Name (FQDN).
  - E.164 Telephone Number Mapping (ENUM service).
  - Lightweight Directory Access Protocol (LDAP). For a description, see 'Routing Based on LDAP Active Directory Queries' on page 179.
  - IP Group, where the call is routed to the IP address configured for the Proxy Set or SRD associated with the IP Group (configured in 'Configuring IP Groups' on page 204). If the device is configured with multiple SRDs, you can also indicate (in the table's 'Dest. SRD' field) the destination SRD for routing to one of the following destination types - IP address, FQDN, ENUM, or LDAP. If the SRD is not specified, then the default SRD (0) is used. In scenarios where routing is to an IP Group, the destination SRD is obtained from the SRD associated with the IP Group (in the IP Group table). The specified destination SRD determines the:
    - ◆ Destination SIP interface (SIP port and control IP interface) - important when using multiple SIP control VLANs
    - ◆ Media Realm (port and IP interface for media / RTP voice)
    - ◆ Other SRD-related interfaces and features on which the call is routed

Since each call must have a destination IP Group (even in cases where the destination type is not to an IP Group), in cases when the IP Group is not specified, the SRD's default IP Group is used, which is the first configured IP Group that belongs to the SRD.

**Figure 28-1: Locating SRD**

**Notes:** When using a proxy server, you do not need to configure this table, unless you require one of the following:

- Fallback (alternative) routing if communication is lost with the proxy server.
- IP security, whereby the device routes only received calls whose source IP addresses are defined in this table. IP security is enabled using the SecureCallsFromIP parameter.
- Filter Calls to IP feature: the device checks this table before a call is routed to the proxy server. However, if the number is not allowed, i.e., the number does not exist in the table or a Call Restriction (see below) routing rule is applied, the call is released.
- Obtain different SIP URI host names (per called number).
- Assign IP Profiles to calls.
- For this table to take precedence over a proxy for routing calls, you need to set the parameter PreferRouteTable to 1. The device checks the 'Destination IP Address' field in this table for a match with the outgoing call; a proxy is used only if a match is not found.

In addition to basic outbound IP routing, this table supports the following features:

- **Least Cost Routing (LCR):** If the LCR feature is enabled, the device searches the routing table for matching routing rules and then selects the one with the lowest call cost. The call cost of the routing rule is done by assigning it a Cost Group. For configuring Cost Groups, see 'Least Cost Routing' on page 189. If two routing rules have identical costs, then the rule appearing higher up in the table (i.e., first-matched rule) is used. If a selected route is unavailable, the device uses the next least-cost routing rule. However, even if a matched rule is not assigned a Cost Group, the device can select it as the preferred route over other matched routing rules with Cost Groups, according to the settings of the LCR parameter, LCRDefaultCost (see 'Enabling LCR and Configuring Default LCR' on page 191).
- **Call Forking:** If the Tel-to-IP Call Forking feature is enabled, the device can send a Tel call to multiple IP destinations. An incoming Tel call with multiple matched routing rules (e.g., all with the same source prefix numbers) can be sent (forked) to multiple IP destinations if the rules are defined with a Forking Group in the table. The call is established with the first IP destination that answers the call.
- **Call Restriction:** Rejects calls whose matching routing rule is configured with the destination IP address of 0.0.0.0.
- **Always Use Routing Table:** Even if a proxy server is used, the SIP Request-URI host name in the outgoing INVITE message is obtained from this table. Using this feature, you can assign a different SIP URI host name for different called and/or calling numbers. This feature is enabled using the AlwaysUseRouteTable parameter.
- **IP Profiles:** IP Profiles can be assigned to destination addresses (also when a proxy is used).
- **Alternative Routing (when a proxy isn't used):** An alternative IP destination can be configured for a specific call. To associate an alternative IP address to a called telephone number prefix, assign it with an additional entry with a different IP address, or use an FQDN that resolves into two IP addresses. For more information on alternative routing, see 'Alternative Routing for Tel-to-IP Calls' on page 334.

**Notes:**

- Outbound IP routing can be performed before or after number manipulation. This is configured using the RouteModeTel2IP parameter, as described below.
- The Outbound IP Routing Table can also be configured using the table *ini* file parameter, Prefix or CLI command, configure voip > gw routing tel2ip-routing.

➤ **To configure Tel-to-IP or outbound IP routing rules:**

1. Open the Outbound IP Routing Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Routing > Tel to IP Routing**).

**Figure 28-2: Outbound IP Routing Page**

|   | Src. IP Group ID | Src. Host Prefix | Dest Host Prefix | Src. Trunk Group ID | Dest. Phone Prefix | Source Phone Prefix | -> | Dest. IP Address |
|---|------------------|------------------|------------------|---------------------|--------------------|---------------------|----|------------------|
| 1 | -1               |                  |                  |                     |                    |                     |    |                  |
| 2 | -1               |                  |                  |                     |                    |                     |    |                  |
| 3 | -1               |                  |                  |                     |                    |                     |    |                  |
| 4 | -1               |                  |                  |                     |                    |                     |    |                  |
| 5 | -1               |                  |                  |                     |                    |                     |    |                  |

2. From the 'Routing Index' drop-down list, select the range of entries that you want to add.
3. Configure the routing rule as required. For a description of the parameters, see the table below.
4. Click **Submit** to apply your changes.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

The table below shows configuration examples of Tel-to-IP or outbound IP routing rules, where:

- **Rule 1 and Rule 2 (Least Cost Routing rule):** For both rules, the called (destination) phone number prefix is 10, the caller's (source) phone number prefix is 100, and the call is assigned IP Profile ID 1. However, Rule 1 is assigned a cheaper Cost Group than Rule 2, and therefore, the call is sent to the destination IP address (10.33.45.63) associated with Rule 1.
- **Rule 3 (IP Group destination rule):** For all callers (\*), if the called phone number prefix is 20, the call is sent to IP Group 1 (whose destination is the IP address configured for its associated Proxy Set ID).
- **Rule 4 (domain name destination rule):** If the called phone number prefix is 5, 7, 8, or 9 and the caller belongs to Trunk Group ID 1, the call is sent to domain.com.
- **Rule 5 (block rule):** For all callers (\*), if the called phone number prefix is 00, the call is rejected (discarded).
- **Rule 6 (IP-to-IP rule):** If an incoming IP call from Source IP Group 2 with domain.com as source host prefix in its SIP Request-URI, the IP call is sent to IP address 10.33.45.65.
- **Rule 7, Rule 8, and Rule 9 (Forking Group rule):** For all callers (\*), if the called phone number prefix is 100, the call is sent to Rule 7 and 9 (belonging to Forking Group "1"). If their destinations are unavailable and alternative routing is enabled, the call is sent to Rule 8 (Forking Group "2").

Example of Tel-to-IP Source Phone Number Manipulation Rules

| Parameter           | Rule 1      | Rule 2      | Rule 3 | Rule 4     | Rule 5  | Rule 6      | Rule 7      | Rule 8      | Rule 9     |
|---------------------|-------------|-------------|--------|------------|---------|-------------|-------------|-------------|------------|
| Src. IP Group ID    | -           | -           | -      | -          | -       | 2           | -           | -           | -          |
| Src. Trunk Group ID | *           | 0           | 1      | -          | -       | -           | -           | -           | -          |
| Src. Host Prefix    | -           | -           | -      | -          | -       | domain.com  | -           | -           | -          |
| Src. Trunk Group ID | -           | -           | *      | 1          | -       | -           | *           | *           | *          |
| Dest. Phone Prefix  | 10          | 10          | 20     | [5,7-9]    | 00      | *           | 100         | 100         | 100        |
| Source Phone Prefix | 100         | 100         | *      | *          | *       | *           | *           | *           | *          |
| Dest. IP Address    | 10.33.45.63 | 10.33.45.50 | -      | domain.com | 0.0.0.0 | 10.33.45.65 | 10.33.45.68 | 10.33.45.67 | domain.com |
| Dest IP Group ID    | -           | -           | 1      | -          | -       | -           | -           | -           | -          |
| IP Profile ID       | 1           | 1           | -      | -          | -       | -           | -           | -           | -          |
| Cost Group ID       | Week end    | Weekend_B   | -      | -          | -       | -           | -           | -           | -          |
| Forking Group       |             |             | -      | -          | -       | -           | 1           | 2           | 1          |

Tel-to-IP / Outbound IP Routing Table Parameters

| Parameter                                                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Web/EMS: Source Phone Prefix<br>CLI: src-phone-prefix<br><b>[PREFIX_SourcePrefix]</b>       | <p>Defines the prefix and/or suffix of the calling (source) telephone number. You can use special notations for denoting the prefix. For example, <b>[100-199](100,101,105)</b> denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. To denote any prefix, use the asterisk (*) symbol or to denote calls without a calling number, use the \$ sign. For a description of available notations, see 'Dialing Plan Notation for Routing and Manipulation Tables' on page 653.</p> <p>The number can include up to 50 digits.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Web: Dest. IP Address<br>EMS: Address<br>CLI: dst-ip-address<br><b>[PREFIX_DestAddress]</b> | <p>Defines the IP address (in dotted-decimal notation or FQDN) to where the call is sent. If an FQDN is used (e.g., domain.com), DNS resolution is done according to the DNSQueryType parameter.</p> <p>For ENUM-based routing, enter the string value "ENUM". The device sends an ENUM query containing the destination phone number to an external DNS server, configured in the Multiple Interface table. The ENUM reply includes a SIP URI which is used as the Request-URI in the subsequent outgoing INVITE and for routing (if a proxy is not used). To configure the type of ENUM service (e.g., e164.arpa), use the EnumService parameter.</p> <p>For LDAP-based routing, enter the string value "LDAP" for denoting the IP address of the LDAP server. For more information, see Routing Based on LDAP Active Directory Queries on page 179.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ This field and any value assigned to it is ignored if you have configured a destination IP Group for this routing rule (in the 'Dest IP Group ID' field).</li> <li>▪ To reject calls, enter the IP address 0.0.0.0. For example, if you want to prohibit international calls, then in the 'Dest Phone Prefix' field, enter 00 and in the 'Dest IP Address' field, enter 0.0.0.0.</li> <li>▪ For routing calls between phones connected to the device (i.e., local routing), enter the device's IP address.</li> <li>▪ When the device's IP address is unknown (e.g., when DHCP is used), enter IP address 127.0.0.1.</li> <li>▪ When using domain names, enter the DNS server's IP address or alternatively, configure these names in the Internal DNS table (see 'Configuring the Internal DNS Table' on page 120).</li> <li>▪ The IP address can include the following wildcards: <ul style="list-style-type: none"> <li>✓ "x": represents single digits. For example, 10.8.8.xx denotes all addresses between 10.8.8.10 and 10.8.8.99.</li> <li>✓ "*": represents any number between 0 and 255. For example, 10.8.8.* denotes all addresses between 10.8.8.0 and 10.8.8.255.</li> </ul> </li> </ul> |
| Web: Port<br>EMS: Destination Port<br>CLI: dst-port<br><b>[PREFIX_DestPort]</b>             | Defines the destination port to where you want to route the call.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Cost Group ID<br>CLI: cost-group-id<br>[PREFIX_CostGroup]    | Assigns a Cost Group with the routing rule for determining the cost of the call. To configure Cost Groups, see 'Configuring Cost Groups' on page 193.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Forking Group<br>CLI: forking-group<br>[PREFIX_ForkingGroup] | <p>Defines a forking group ID for the routing rule. This enables forking of incoming Tel calls to two or more IP destinations. The device sends simultaneous INVITE messages and handles multiple SIP dialogs until one of the calls is answered. When a call is answered, the other calls are dropped.</p> <p>If all matched routing rules belong to the same Forking Group number, the device sends an INVITE to all the destinations belonging to this group and according to the following logic:</p> <ul style="list-style-type: none"> <li>▪ If matched routing rules belong to different Forking Groups, the device sends the call to the Forking Group of the first matched routing rule. If the call cannot be established with any of the destinations associated with this Forking Group and alternative routing is enabled, the device forks the call to the Forking Group of the next matched routing rules as long as the Forking Group is defined with a <b>higher</b> number than the previous Forking Group. For example:</li> <li>▪ Table index entries 1 and 2 are defined with Forking Group "1", and index entries 3 and 4 with Forking Group "2": The device first sends the call according to index entries 1 and 2, and if unavailable and alternative routing is enabled, sends the call according to index entries 3 and 4.</li> <li>▪ Table index entry 1 is defined with Forking Group "2", and index entries 2, 3, and 4 with Forking Group "1": The device sends the call according to index entry 1 only and ignores the other index entries even if the destination is unavailable and alternative routing is enabled. This is because the subsequent index entries are defined with a Forking Group number that is lower than that of index entry 1.</li> <li>▪ Table index entry 1 is defined with Forking Group "1", index entry 2 with Forking Group "2", and index entries 3 and 4 with Forking Group "1": The device first sends the call according to index entries 1, 3, and 4 (all belonging to Forking Group "1"), and if the destination is unavailable and alternative routing is enabled, the device sends the call according to index entry 2.</li> <li>▪ Table index entry 1 is defined with Forking Group "1", index entry 2 with Forking Group "3", index entry 3 with Forking Group "2", and index entry 4 with Forking Group "1": The device first sends the call according to index entries 1 and 4 (all belonging to Forking Group "1"), and if the destination is unavailable and alternative routing is enabled, the device sends the call according to index entry 2 (Forking Group "3"). Even if index entry 2 is unavailable and alternative routing is enabled, the device ignores index entry 3 because it belongs to a Forking Group that is lower than index entry 2.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>▪ To enable Tel-to-IP call forking, set the 'Tel2IP Call Forking Mode' (<i>Tel2IPCallForkingMode</i>) parameter to <b>Enable</b>.</li> <li>▪ You can implement Forking Groups when the destination is an LDAP server or a domain name using DNS. In such scenarios, the INVITE is sent to all the queried LDAP or resolved IP addresses respectively. You can also use LDAP routing rules with standard routing rules for Forking Groups.</li> <li>▪ When the UseDifferentRTPportAfterHold parameter is enabled, every</li> </ul> |

| Parameter | Description                                                                                                                 |
|-----------|-----------------------------------------------------------------------------------------------------------------------------|
|           | forked call is sent with a different RTP port. Thus, ensure that the device has available RTP ports for these forked calls. |

## 28.3 Configuring Inbound IP Routing Table

The Inbound IP Routing Table page allows you to configure up to 24 inbound call routing rules:

- For IP-to-IP routing: The table is used to identify an incoming call as an IP-to-IP call and subsequently, to assign the call to an IP Group, referred to as a source IP Group. These IP-to-IP calls can later be routed to an outbound destination IP Group (see [Configuring Outbound IP Routing Table](#) on page 321).
- For IP-to-Tel routing: This table is used to route incoming IP calls to Trunk Groups. The specific channel pertaining to the Trunk Group to which the call is routed is determined according to the Trunk Group's channel selection mode. The channel selection mode can be defined per Trunk Group (see 'Configuring Hunt Group Settings' on page 291) or for all Trunk Groups using the global parameter ChannelSelectMode.

The Inbound IP Routing Table provides two configuration areas:

- Matching characteristics of incoming IP call, for example, prefix of destination number.
- Operation (destination), for example, sends to a specific Trunk Group.

If the incoming call matches the characteristics of a rule, then the call is sent to the destination configured for that rule.

The device also supports alternative routing if the Trunk Group is unavailable:

- If a call release reason is received for a specific IP-to-Tel call and this reason is configured for alternative IP-to-Tel routing, then the device re-routes the call to an alternative Trunk Group. The alternative route is configured in this table as an additional row (below the main routing rule) with the same call characteristics, but with a destination to a different Trunk Group. For more information on IP-to-Tel alternative routing, see 'Alternative Routing to Trunk upon Q.931 Call Release Cause Code' on page 338.
- The device can re-route (i.e., call redirection) IP-to-Tel calls to an alternative IP destination using SIP 3xx responses. For more information, see 'Alternative Routing to IP Destinations upon Busy Trunk' on page 340.

The device automatically re-routes an IP-to-Tel call to a different physical FXO port or physical trunk if the initially destined FXO port or physical trunk within the same Trunk Group is detected as out of service (e.g., physically disconnected). When the physical FXO port or physical trunk is disconnected, the device sends the SNMP trap, GWAPP\_TRAP\_BUSYOUT\_LINK notifying of the out-of-service state for the specific FXO line or trunk number. When the FXO port or physical trunk is physically reconnected, this trap is sent notifying of the back-to-service state.

**Note:** You can also configure the Inbound IP Routing Table using the table ini file parameter, PSTNPrefix (see 'Number Manipulation Parameters' on page 855) or CLI command, configure voip > gw routing ip2tel-routing.

➤ **To configure IP-to-Tel or inbound IP routing rules:**

1. Open the Inbound IP Routing Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Routing** > **IP to Trunk Group Routing**).

**Figure 28-3: Inbound IP Routing Table**

| <div> <div>Routing Index</div> <div>1-12</div> </div> <div> <div>IP To Tel Routing Mode</div> <div>Route calls before manipulation</div> </div> |                   |                    |                    |                     |                   |                |               |                   |

|                                                                                                                                                 | Dest. Host Prefix | Source Host Prefix | Dest. Phone Prefix | Source Phone Prefix | Source IP Address | Trunk Group ID | IP Profile ID | Source IPGroup ID |
| 1                                                                                                                                               |                   |                    | 1x                 | *                   |                   | 1              | 2             | -1                |
| 2                                                                                                                                               |                   |                    | [501-502]          | 101                 |                   | 2              | 1             |                   |
| 3                                                                                                                                               |                   | domain.com         | *                  | *                   |                   | 3              |               |                   |
| 4                                                                                                                                               |                   |                    | *                  | *                   | 10.13.64.5        | -1             |               | 4                 |

The previous figure displays the following configured routing rules:

- **Rule 1:** If the incoming IP call destination phone prefix is between 10 and 19, the call is assigned settings configured for IP Profile ID 2 and routed to Trunk Group ID 1.
  - **Rule 2:** If the incoming IP call destination phone prefix is between 501 and 502 and source phone prefix is 101, the call is assigned settings configured for IP Profile ID 1 and routed to Trunk Group ID 2.
  - **Rule 3:** If the incoming IP call has a From URI host prefix as domain.com, the call is routed to Trunk Group ID 3.
  - **Rule 4:** If the incoming IP call has IP address 10.13.64.5 in the INVITE's Contact header, the call is identified as an IP-to-IP call and assigned to Source IP Group 4. This call is routed according to the outbound IP routing rules for this Source IP Group configured in the Outbound IP Routing Table.
2. Configure the routing rule, as required. For a description of the parameters, see the table below.
  3. Click **Submit** to apply your changes.

**IP-to-Tel or Inbound IP Routing Table Description**

## 28.4 IP Destinations Connectivity Feature

The device can be configured to check the integrity of the connectivity to IP destinations of Tel-to-IP routing rules in the Outbound IP Routing table. The IP Connectivity feature can be used for the Alternative Routing feature, whereby the device attempts to re-route calls from unavailable Tel-to-IP routing destinations to available ones (see 'Alternative Routing Based on IP Connectivity' on page 334).

The device supports the following methods for checking the connectivity of IP destinations:

- **Network Connectivity:** The device checks the network connectivity of the IP destination configured by the 'Alt Routing Tel to IP Connectivity Method' parameter:
  - **SIP OPTIONS:** The device sends "keep-alive" SIP OPTIONS messages to the IP destination. If the device receives a SIP 200 OK in response, it considers the destination as available. If the destination does not respond to the OPTIONS message, then it is considered unavailable. You can configure the time interval for sending these OPTIONS messages, using the 'Alt Routing Tel to IP Keep Alive Time' parameter.

These parameters are configured in the Routing General Parameters page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Routing** > **General Parameters**), as shown below:

**Figure 28-4: IP Connectivity Method in Routing General Parameters Page**

|                                           |             |
|-------------------------------------------|-------------|
| Alt Routing Tel to IP Connectivity Method | SIP OPTIONS |
| Alt Routing Tel to IP Keep Alive Time     | 60          |

- **Quality of Service (QoS):** You can enable the device to check the QoS of IP destinations. The device measures the QoS according to RTCP statistics of previously established calls with the IP destination. The RTCP includes packet delay (in milliseconds) and packet loss (in percentage). If these measured statistics exceed a user-defined threshold, the destination is considered unavailable. Note that if call statistics is not received within two minutes, the QoS data is reset. These thresholds are configured using the following parameters:
  - 'Max Allowed Packet Loss for Alt Routing' (IPConnQoSMaxAllowedPL): defines the threshold value for packet loss after which the IP destination is considered unavailable.
  - 'Max Allowed Delay for Alt Routing' (IPConnQoSMaxAllowedDelay): defines the threshold value for packet delay after which the IP destination is considered unavailable

These parameters are configured in the Routing General Parameters page, as shown below:

**Figure 28-5: IP QoS Thresholds in Routing General Parameters Page**

|                                             |     |
|---------------------------------------------|-----|
| Max Allowed Packet Loss for Alt Routing [%] | 20  |
| Max Allowed Delay for Alt Routing [msec]    | 250 |

- **DNS Resolution:** When a host name (FQDN) is used (instead of an IP address) for the IP destination, it is resolved into an IP address by a DNS server. The device checks network connectivity and QoS of the resolved IP address. If the DNS host name is unresolved, the device considers the connectivity of the IP destination as unavailable.

You can view the connectivity status of IP destinations in the following Web interface pages:

- **Outbound IP Routing Table:** The connectivity status of the IP destination per routing rule is displayed in the 'Status' column. For more information, see 'Configuring Outbound IP Routing Table' on page [321](#).
- **IP Connectivity:** This page displays a more informative connectivity status of the IP destinations used in Tel-to-IP routing rules in the Outbound IP Routing table. For viewing this page, see 'Viewing IP Connectivity' on page [598](#).

## 28.5 Alternative Routing for Tel-to-IP Calls

The device supports various alternative Tel-to-IP call routing methods, as described in this section.

### 28.5.1 Alternative Routing Based on IP Connectivity

You can configure the device to do alternative Tel-to-IP call routing based on IP connectivity. When the connectivity state of an IP destination is unavailable, the device attempts to re-route the Tel-to-IP call to an alternative IP destination. It does this by searching for the next call matching rule (e.g., phone number prefix) in the Outbound IP Routing table.

**Notes:**

- Alternative routing based on IP connectivity is applicable only when a proxy server is not used.
- As the device searches the Outbound IP Routing table for a matching rule starting from the top, you must configure the main routing rule above the alternative routing rules.
- You can configure up to two alternative routing rules.
- For configuring Tel-to-IP routing rules in the Outbound IP Routing table, see 'Configuring Outbound IP Routing Table' on page 321.

The device searches for an alternative IP destination when any of the following connectivity states are detected with the IP destination of the initial Tel-to-IP routing rule:

- No response received from SIP OPTIONS messages. This depends on the chosen method for checking IP connectivity.
- Poor QoS according to the configured thresholds for packet loss and delay.
- Unresolved DNS, if the configured IP destination is a domain name (or FQDN). If the domain name is resolved into two IP addresses, the timeout for INVITE re-transmissions can be configured using the HotSwapRtx parameter. For example, if you set this parameter to 3, the device attempts up to three times to route the call to the first IP address and if unsuccessful, it attempts up to three times to re-route it to the second resolved IP address.

The connectivity status of the IP destination is displayed in the 'Status' column of the Outbound IP Routing table per routing rule. If it displays a status other than "ok", then the device considers the IP destination as unavailable and attempts to re-route the call to an alternative destination. For more information on the IP connectivity methods and on viewing IP connectivity status, see 'IP Destinations Connectivity Feature' on page 333.

The table below shows an example of alternative routing where the device uses an available alternative routing rule in the Outbound IP Routing table to re-route the initial Tel-to-IP call.

**Alternative Routing based on IP Connectivity Example**

|                             | Destination Phone Prefix | IP Destination | IP Connectivity Status | Rule Used? |
|-----------------------------|--------------------------|----------------|------------------------|------------|
| <b>Main Route</b>           | 40                       | 10.33.45.68    | "No Connectivity"      | No         |
| <b>Alternative Route #1</b> | 40                       | 10.33.45.70    | "QoS Low"              | No         |
| <b>Alternative Route #2</b> | 40                       | 10.33.45.72    | "ok"                   | Yes        |

The steps for configuring alternative Tel-to-IP routing based on IP connectivity are summarized below.

➤ **To configure alternative Tel-to-IP routing based on IP connectivity:**

1. In the Outbound IP Routing table, add alternative Tel-to-IP routing rules for specific calls.
2. In the Routing General Parameters page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Routing** > **General Parameters**), do the following:
  - a. Enable alternative routing based on IP connectivity, by setting the 'Enable Alt Routing Tel to IP AltRouting' (Tel2IPEnable) parameter to **Enable**.

- b. Configure the IP connectivity reason for triggering alternative routing, by setting the 'Alt Routing Tel to IP Mode' parameter (AltRoutingTel2IPMode) to one of the following:
  - ◆ SIP OPTIONS failure
  - ◆ Poor QoS
  - ◆ SIP OPTIONS failure, poor QoS, or unresolved DNS
- c. The device plays a tone to the Tel endpoint (for analog interfaces) whenever an alternative route is used. This tone is played for a user-defined time configured by the 'Alternative Routing Tone Duration' parameter.

## 28.5.2 Alternative Routing Based on SIP Responses

You can configure the device to do alternative routing based on the received SIP response. If the SIP response code reflects an error (i.e., 4xx, 5xx, or 6xx) and you have configured this specific response code as a trigger for alternative routing, then the device attempts to re-route the call to an alternative destination.

You can configure up to five SIP response codes for triggering alternative routing. This is done in the Reasons for Alternative Routing table, explained in this section.

Typically, the device performs alternative routing when there is no response at all to an INVITE message after a user-defined number of INVITE re-transmissions, configured using the SIPMaxRtx parameter. In such a scenario, the device issues itself the SIP response code 408 "Request Timeout". If this response code is defined in the Reasons for Alternative Routing table, then alternative routing is done.

**Note:** The device also plays a tone to the endpoint whenever an alternative route is used. This tone is played for a user-defined time, configured by the AltRoutingToneDuration parameter.

Depending on configuration, the alternative routing is done using one of the following configuration entities:

- **Outbound IP Routing Rules:** You can configure up to two alternative routing rules in the table. If the initial, main routing rule destination is unavailable, the device searches the table (starting from the top) for the next call matching rule (e.g., destination phone number), and if available attempts to re-route the call to the IP destination configured for this alternative routing rule. The table below shows an example of alternative routing where the device uses the first available alternative routing rule to re-route the initial, unsuccessful Tel-to-IP call destination.

**Alternative Routing based on SIP Response Code Example**

|                      | Destination Phone Prefix | IP Destination | SIP Response        | Rule Used? |
|----------------------|--------------------------|----------------|---------------------|------------|
| Main Route           | 40                       | 10.33.45.68    | 408 Request Timeout | No         |
| Alternative Route #1 | 40                       | 10.33.45.70    | 486 Busy Here       | No         |
| Alternative Route #2 | 40                       | 10.33.45.72    | 200 OK              | Yes        |

- **Proxy Sets:** Proxy Sets are used for Server-type IP Groups (e.g., an IP PBX) and define the actual IP destination (IP address or FQDN) of the server. As you can define up to five IP destinations per Proxy Set, the device supports proxy redundancy, which works together with the alternative routing feature. If the destination of a routing rule in

the Outbound IP Routing table is an IP Group, the device routes the call to the IP destination configured for the Proxy Set associated with the IP Group. If the first IP destination of the Proxy Set is unavailable, the device attempts to re-route the call to the next proxy destination, and so on until an available IP destination is located. To enable the Proxy Redundancy feature, set the IsProxyHotSwap parameter to 1 (per Proxy Set) and set the EnableProxyKeepAlive to 1.

When the Proxy Redundancy feature is enabled, the device continually monitors the connection with the proxies by using keep-alive messages (SIP OPTIONS). The device sends these messages every user-defined interval (ProxyKeepAliveTime parameter). Any response from the proxy, either success (200 OK) or failure (4xx response) is considered as if the proxy is communicating. If there is no response from the first (primary) proxy after a user-defined number of re-transmissions (re-INVITEs) configured using the HotSwapRtx parameter, the device attempts to communicate (using the same INVITE) with the next configured (redundant) proxy in the list, and so on until an available redundant proxy is located. The device's behavior can then be one of the following, depending on the ProxyRedundancyMode parameter setting:

- The device continues operating with the redundant proxy (now active) until the next failure occurs, after which it switches to the next redundant proxy. This is referred to as *Parking* mode.
- The device always attempts to operate with the primary proxy. In other words, it switches back to the primary proxy whenever it's available again. This is referred to as *Homing* mode.

If none of the proxy servers respond, the device goes over the list again.

The steps for configuring alternative Tel-to-IP routing based on SIP response codes are summarized below.

➤ **To configure alternative Tel-to-IP routing based on SIP response codes:**

1. Enable alternative routing based on SIP responses, by setting the 'Redundant Routing Mode' parameter to one of the following:
  - **Routing Table** for using the Outbound IP Routing table for alternative routing.
  - **Proxy** for using the Proxy Set redundancy feature for alternative routing.
2. If you are using the Outbound IP Routing table, configure alternative routing rules with identical call matching characteristics, but with different IP destinations. If you are using the Proxy Set, configure redundant proxies.
3. Define SIP response codes (call failure reasons) that invoke alternative Tel-to-IP routing:
  - a. Open the Reasons for Alternative Routing page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Routing** submenu > **Alternative Routing Reasons**).

**Figure 28-6: Tel to IP Reasons - Reasons for Alternative Routing Page**

| Reason 4          | ▼ |
| Reason 5          | ▼ |

- b. Under the 'Tel to IP Reasons' group, select up to five different SIP response codes (call failure reasons) that invoke alternative Tel-to-IP routing.
- c. Click **Submit**.

### 28.5.3 PSTN Fallback

The PSTN Fallback feature enables the device to re-route a Tel-to-IP call to the legacy PSTN using one of its trunks if the IP destination is unavailable. For example, if poor voice quality is detected over the IP network, the device attempts to re-route the call to the PSTN.

The steps for configuring alternative Tel-to-IP routing to the legacy PSTN are summarized below.

➤ **To configure alternative Tel-to-IP routing to the legacy PSTN:**

1. Configure an alternative routing rule in the Outbound IP Routing table with the same call matching characteristics (e.g., phone number destination), but where the destination is the IP address of the device itself.
2. Configure an IP-to-Tel routing rule in the Inbound IP Routing table to route calls received from the device (i.e., its IP address) to a specific Trunk Group connected to the PSTN. This configuration is necessary as the re-routed call is now considered an IP-to-Tel call. For configuring IP-to-Tel routing rules, see 'Configuring the Inbound IP Routing Table' on page 330.

**Note:** The PSTN Fallback feature is applicable only to digital interfaces (e.g., E1 / T1 trunks).

## 28.6 Alternative Routing for IP-to-Tel Calls

The device supports alternative IP-to-Tel call routing, as described in this section.

### 28.6.1 Alternative Routing to Trunk upon Q.931 Call Release Cause Code

You can configure the device to do alternative IP-to-Tel call routing based on the received ISDN Q.931 cause code. If an IP-to-Tel call is rejected or disconnected on the Tel side as a result of a specific ISDN Q.931 release cause code that is listed in the Reasons for Alternative Routing table, the device searches for an alternative IP-to-Tel routing rule in the Inbound IP Routing table and sends it to the alternative Trunk Group. For example, you can enable alternative IP-to-Tel routing for scenarios where the initial Tel destination is busy and a Q.931 Cause Code No. 17 is received (or for other call releases that issue the default Cause Code No. 3).

You can also configure a default release cause code that the device issues itself upon the following scenarios:

- The device initiates a call release whose cause is unknown.
- No free channels (i.e., busy) in the Trunk Group.
- No appropriate routing rule located in the Inbound IP Routing table to the Trunk Group.
- Phone number is not found in the Inbound IP Routing table.

By default, it is set to Cause Code No. 3 (No Route to Destination). This default cause code can be changed using the 'Default Release Cause' parameter located in the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**). To enable alternative routing based on Q.931 cause code, you need to define this cause code in the Reasons for Alternative Routing table.

➤ **To configure alternative Trunk Group routing based on Q.931 cause codes:**

1. In the Proxy & Registration page, set the 'Redundant Routing Mode' parameter to **Routing Table** so that the device uses the Inbound IP Routing table for alternative routing.
2. In the Inbound IP Routing table, configure alternative routing rules with the same call matching characteristics, but with different Trunk Group destinations.
3. Configure up to five Q.931 cause codes that invoke alternative IP-to-Tel routing:
  - a. Open the Reasons for Alternative Routing page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Routing** > **Alternative Routing Reasons**).

**Figure 28-7: IP to Tel Reasons - Reasons for Alternative Routing Page**

| IP to Tel Reasons |      |
|-------------------|------|
| Reason 1          | 3 ▼  |
| Reason 2          | 17 ▼ |
| Reason 3          | ▼    |
| Reason 4          | ▼    |
| Reason 5          | ▼    |

- b. Under the 'IP to Tel Reasons' group, select the desired Q.931 cause codes.
- c. Click **Submit** to apply your changes.

**Notes:**

- You can configure up to two alternative routing rules in the Inbound IP Routing table.
- If a Trunk is disconnected or not synchronized, the device issues itself the internal Cause Code No. 27. This cause code is mapped (by default) to SIP 502.
- The default release cause is described in the Q.931 notation and is translated to corresponding SIP 40x or 50x values (e.g., Cause Code No. 3 to SIP 404, and Cause Code No. 34 to SIP 503).
- For analog interfaces: For information on mapping PSTN release causes to SIP responses, see PSTN Release Cause to SIP Response Mapping on page 318.
- For mapping SIP-to-Q.931 and Q.931-to-SIP release causes, see Configuring Release Cause Mapping on page 313.
- For configuring IP-to-Tel routing rules in the Inbound IP Routing table, see 'Configuring Inbound IP Routing Table' on page 330.
- The Reasons for Alternative Routing IP to Tel table can also be configured using the table ini file parameter, AltRouteCauseIP2Tel or CLI command, configure voip/gw routing alt-route-cause-ip2tel.

## 28.6.2 Alternative Routing to an IP Destination upon a Busy Trunk

You can configure the device to forward (i.e., call redirection) IP-to-Tel calls to an alternative IP destination using SIP 3xx responses. This can be done upon the following scenarios:

- For digital interfaces: Trunk Group has no free channels (i.e., “busy”).
- For analog interfaces: Unavailable FXS / FXO Trunk Group. This feature can be used, for example, to forward the call to another FXS / FXO device.

This feature is configured per Trunk Group and is configured in the Forward on Busy Trunk Destination table, as described in this section.

The alternative destination can be defined as a host name or as a SIP Request-URI user name and host part (i.e., user@host). For example, the below configuration forwards IP-to-Tel calls to destination user “112” at host IP address 10.13.4.12, port 5060, using transport protocol TCP, if Trunk Group ID 2 is unavailable:

```
ForwardOnBusyTrunkDest 1 = 2, 112@10.13.4.12:5060;transport=tcp;
```

When configured with user@host, the original destination number is replaced by the user part.

The device forwards calls using this table only if no alternative IP-to-Tel routing rule has been configured in the Inbound IP Routing table or alternative routing fails and one of the following reasons included in the SIP Diversion header of 3xx messages exists:

- For digital interfaces: “out-of-service” - all trunks are unavailable/disconnected
- “unavailable”:
  - For digital interfaces: All trunks are busy or unavailable
  - For analog interfaces: All FXS / FXO lines pertaining to a Trunk Group are busy or unavailable

**Note:** You can also configure the Forward on Busy Trunk Destination table using the table ini file parameter, ForwardOnBusyTrunkDest or CLI command, configure voip/gw routing fwd-on-busy-trk-dst.

### ➤ To configure Forward on Busy Trunk Destination rules:

1. Open the Forward on Busy Trunk Destination page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Routing** > **Forward on Busy Trunk**).

**Figure 28-8: Forward on Busy Trunk Destination Page**

| Index                   | Trunk Group ID                 | Forward Destination                     |
|-------------------------|--------------------------------|-----------------------------------------|
| 0 <input type="radio"/> | <input type="text" value="1"/> | <input type="text" value="10.13.5.67"/> |

The figure above displays a configuration that forwards IP-to-Tel calls destined for Trunk Group ID 1 to destination IP address 10.13.5.67 if the conditions mentioned earlier exist.

2. Configure the table as required, and then click **Submit** to apply your changes.
3. Save the changes to the device's flash memory with a device reset (see 'Saving Configuration' on page 532).

**Forward on Busy Trunk Destination Description Parameters**

| Parameter                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Trunk Group ID<br>CLI: trunk-group-id<br><b>[ForwardOnBusyTrunk<br/>Dest_TrunkGroupId]</b>              | Defines the Trunk Group ID to which the IP call is destined to.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Forward Destination<br>CLI: forward-dst<br><b>[ForwardOnBusyTrunk<br/>Dest_ForwardDestinati<br/>on]</b> | <p>Defines the alternative IP destination for the call used if the Trunk Group is busy or unavailable.</p> <p>The valid value can be an IP address in dotted-decimal notation, an FQDN, or a SIP Request-URI user name and host part (i.e., user@host). The following syntax can also be used: host:port;transport=xxx (i.e., IP address, port and transport type).</p> <p><b>Note:</b> When configured with a user@host, the original destination number is replaced by the user part.</p> |

## Reader's Notes

## 29 Configuring DTMF and Dialing

The DTMF & Dialing page is used to configure parameters associated with dual-tone multi-frequency (DTMF) and dialing. For a description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page 655.

➤ **To configure the DTMF and dialing parameters:**

1. Open the DTMF & Dialing page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **DTMF & Supplementary** submenu > **DTMF & Dialing**).

|                                  |                                            |
|----------------------------------|--------------------------------------------|
| Max Digits In Phone Num          | <input type="text" value="30"/>            |
| Inter Digit Timeout [sec]        | <input type="text" value="4"/>             |
| Declare RFC 2833 in SDP          | <input type="text" value="Yes"/>           |
| 1st Tx DTMF Option               | <input type="text" value="RFC 2833"/>      |
| 2nd Tx DTMF Option               | <input type="text"/>                       |
| RFC 2833 Payload Type            | <input type="text" value="96"/>            |
| Hook-Flash Option                | <input type="text" value="Not Supported"/> |
| Digit Mapping Rules              | <input type="text"/>                       |
| Dial Plan Index                  | <input type="text" value="-1"/>            |
| Dial Tone Duration [sec]         | <input type="text" value="16"/>            |
| Hotline Dial Tone Duration [sec] | <input type="text" value="16"/>            |
| Enable Special Digits            | <input type="text" value="Disable"/>       |
| Dial Plan Index                  | <input type="text" value="-1"/>            |
| Min Routing Overlap Digits       | <input type="text" value="1"/>             |
| ISDN Overlap IP to Tel Dialing   | <input type="text" value="Disable"/>       |
| Default Destination Number       | <input type="text" value="1000"/>          |
| Special Digit Representation     | <input type="text" value="Special"/>       |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 29.1 Dialing Plan Features

This section describes various dialing plan features supported by the device.

### 29.1.1 Digit Mapping

Digit map pattern rules are used for Tel-to-IP ISDN overlap dialing (by setting the ISDNRxOverlap parameter to 1) to reduce the dialing period (for digital interface). For more information on digit maps for ISDN overlapping, see ISDN Overlap Dialing on page 286. The device collects digits until a match is found in the user-defined digit pattern (e.g., for closed numbering schemes). The device stops collecting digits and starts sending the digits (collected number) when any one of the following scenarios occur:

- Maximum number of digits is received. You can define (using the MaxDigits parameter) the maximum number of collected destination number digits that can be received (i.e., dialed) from the Tel side by the device. When the number of collected digits reaches the maximum (or a digit map pattern is matched), the device uses these digits for the called destination number.
- Inter-digit timeout expires (e.g., for open numbering schemes). This is defined using the TimeBetweenDigits parameter. This is the time that the device waits between each received digit. When this inter-digit timeout expires, the device uses the collected digits to dial the called destination number.
- The phone's pound (#) key is pressed.
- Digit string (i.e., dialed number) matches one of the patterns defined in the digit map.

Digit map (pattern) rules are defined using the DigitMapping parameter. The digit map pattern can contain up to 52 options (rules), each separated by a vertical bar ("|"). The maximum length of the entire digit pattern is 152 characters. The available notations are described in the table below:

**Digit Map Pattern Notations**

| Notation | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| [n-m]    | Range of numbers (not letters).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| .        | (single dot) Repeat digits until next notation (e.g., T).                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| x        | Any single digit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| T        | Dial timeout (configured by the TimeBetweenDigits parameter).                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| S        | Short timer (configured by the TimeBetweenDigits parameter; default is two seconds) that can be used when a specific rule is defined after a more general rule. For example, if the digit map is 99 998, then the digit collection is terminated after the first two 9 digits are received. Therefore, the second rule of 998 can never be matched. But when the digit map is 99s 998, then after dialing the first two 9 digits, the device waits another two seconds within which the caller can enter the digit 8. |

Below is an example of a digit map pattern containing eight rules:

```
DigitMapping = 11xS|00[1-7]xxx|8xxxxxxx|xxxxxxx|*xx|91xxxxxxxxxx|9011x|xx.T
```

In the example, the rule "00[1-7]xxx" denotes dialed numbers that begin with 00, and then any digit from 1 through 7, followed by three digits (of any number). Once the device receives these digits, it does not wait for additional digits, but starts sending the collected digits (dialed number) immediately.

**Notes:**

- If you want the device to accept/dial any number, ensure that the digit map contains the rule "xx.T"; otherwise, dialed numbers not defined in the digit map are rejected.
- If you are using an external Dial Plan file for dialing plans (see 'Dialing Plans for Digit Collection' on page 542), the device first attempts to locate a matching digit pattern in the Dial Plan file, and if not found, then attempts to locate a matching digit pattern in the Digit Map (configured by the DigitMapping parameter).
- It may be useful to configure both Dial Plan file and Digit Maps. For example, the Digit Map can be used for complex digit patterns (which are not supported by the Dial Plan) and the Dial Plan can be used for long lists of relatively simple digit patterns. In addition, as timeout between digits is not supported by the Dial Plan, the Digit Map can be used to define digit patterns (MaxDigits parameter) that are shorter than those defined in the Dial Plan, or left at default. For example, "xx.T" Digit Map instructs the device to use the Dial Plan and if no matching digit pattern, it waits for two more digits and then after a timeout (TimeBetweenDigits parameter), it sends the collected digits. Therefore, this ensures that calls are not rejected as a result of their digit pattern not been completed in the Dial Plan.

### **29.1.2 External Dial Plan File**

The device can be loaded with a Dial Plan file with user-defined dialing plans. For more information, see 'Dial Plan File' on page [541](#).

## 30 Configuring Supplementary Services

This section describes SIP supplementary services that can enhance your telephone service.

**Notes:**

- All call participants must support the specific supplementary service that is used.
- When working with certain application servers (such as BroadSoft's BroadWorks) in client server mode (the application server controls all supplementary services and keypad features by itself), the device's supplementary services must be disabled.

The Supplementary Services page is used to configure many of the discussed supplementary services parameters. For a description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page [655](#).

➤ **To configure supplementary services parameters:**

1. Open the Supplementary Services page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **DTMF & Supplementary** submenu > **Supplementary Services**).

|                                       |                   |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes, or click the **Subscribe to MWI** or **Unsubscribe to MWI** buttons to save your changes and to subscribe / unsubscribe to the MWI server.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 30.1 Call Hold and Retrieve

Initiating Call Hold and Retrieve:

- Active calls can be put on-hold by pressing the phone's hook-flash button.
- The party that initiates the hold is called the *holding* party; the other party is called the *held* party.
- After a successful Hold, the holding party hears a dial tone (HELD\_TONE defined in the device's Call Progress Tones file).
- Call retrieve can be performed only by the holding party while the call is held and active.
- The holding party performs the retrieve by pressing the telephone's hook-flash button.
- After a successful retrieve, the voice is connected again.
- Hold is performed by sending a Re-INVITE message with IP address 0.0.0.0 or a=sendonly in the SDP according to the parameter HoldFormat.
- The hold and retrieve functionalities are implemented by re-INVITE messages. The IP address 0.0.0.0 as the connection IP address or the string 'a=inactive' in the received re-INVITE SDP cause the device to enter Hold state and to play the held tone (configured in the device) to the PBX/PSTN. If the string 'a=sendonly' is received in the SDP message, the device stops sending RTP packets, but continues to listen to the incoming RTP packets. Usually, the remote party plays, in this scenario, Music on Hold (MOH) and the device forwards the MOH to the held party.

Receiving Hold/Retrieve:

- When an active call receives a re-INVITE message with either the IP address 0.0.0.0 or the 'inactive' string in SDP, the device stops sending RTP and plays a local held tone.
- When an active call receives a re-INVITE message with the 'sendonly' string in SDP, the device stops sending RTP and listens to the remote party. In this mode, it is expected that on-hold music (or any other hold tone) is played (over IP) by the remote party.

You can also configure the device to keep a call on-hold for a user-defined time after which the call is disconnected, using the HeldTimeout parameter.

The device also supports "double call hold" for FXS interfaces where the called party, which has been placed on-hold by the calling party, can then place the calling party on hold as well and make a call to another destination. The flowchart below provides an example of this type of call hold:

**Figure 30-1: Double Hold SIP Call Flow**

The flowchart above describes the following "double" call-hold scenario:

1. A calls B and establishes a voice path.
2. A places B on hold; A hears a dial tone and B hears a held tone.
3. A calls C and establishes a voice path.
4. B places A on hold; B hears a dial tone.

5. B calls D and establishes a voice path.
6. A ends call with C; A hears a held tone.
7. B ends call with D.
8. B retrieves call with A.

**Notes:**

- If a party that is placed on hold (e.g., B in the above example) is called by another party (e.g., D), then the on-hold party receives a call waiting tone instead of the held tone.
- While in a Double Hold state, placing the phone on-hook disconnects both calls (i.e. call transfer is not performed).
- You can enable the device to handle incoming re-INVITE messages with "a=sendonly" in the SDP, in the same way as if "a=inactive" is received in the SDP. This is configured using the SIPHoldBehavior parameter. When enabled, the device plays a held tone to the Tel phone and responds with a 200 OK containing "a=recvonly" in the SDP.

## 30.2 Call Pickup

The device supports the Call Pick-Up feature, whereby the FXS user can answer someone else's telephone call by pressing a user-defined sequence of phone keys. When the user dials the user-defined digits (e.g., #77), the incoming call from the other phone is forwarded to the FXS user's phone. This feature is configured using the parameter KeyCallPickup.

**Note:** The Call Pick-Up feature is supported only for FXS endpoints pertaining to the same Trunk Group ID.

## 30.3 BRI Suspend and Resume

The device supports call suspend and resume services initiated by ISDN BRI phones connected to the device. During an ongoing call, the BRI phone user can suspend the call by typically pressing the phone's "P" button or a sequence of keys (depending on the phone), and then on-hooking the handset. To resume the call, the phone user typically presses the same keys or button again and then off-hooks the phone. During the suspended state, the device plays a howler tone to the remote party. This service is also supported when instead of pressing the call park button(s), the phone cable is disconnected (suspending the call) and then reconnected again (resuming the call).

If the phone user does not resume the call within a user-defined interval (configured using the HeldTimeout parameter), the device releases the call.

**Note:** Only one call can be suspended per trunk. If another suspend request is received from a BRI phone while there is already a suspended call (even if done by another BRI phone connected to the same trunk), the device rejects this suspend request.

## 30.4 Consultation Feature

The device's Consultation feature allows you to place one number on hold and make a second call to another party.

- After holding a call (by pressing hook-flash), the holding party hears a dial tone and can then initiate a new call, which is called a Consultation call.
- While hearing a dial tone, or when dialing to the new destination (before dialing is complete), the user can retrieve the held call by pressing hook-flash.
- The held call can't be retrieved while ringback tone is heard.
- After the Consultation call is connected, the user can toggle between the held and active call by pressing the hook-flash key.

**Note:** The Consultation feature is applicable only to FXS interfaces.

## 30.5 Call Transfer

This section describes the device's support for call transfer types.

### 30.5.1 Consultation Call Transfer

The device supports Consultation Call Transfer using the SIP REFER message and Replaces header. The common method to perform a consultation transfer is described in the following example, which assumes three call parties:

- Party A = transferring
  - Party B = transferred
  - Party C = transferred to
1. A Calls B.
  2. B answers.
  3. A presses the hook-flash button and places B on-hold (party B hears a hold tone).
  4. A dials C.
  5. After A completes dialing C, A can perform the transfer by on-hooking the A phone.
  6. After the transfer is complete, B and C parties are engaged in a call.

The transfer can be initiated at any of the following stages of the call between A and C:

- Just after completing dialing C phone number - transfer from setup
- While hearing ringback – transfer from alert
- While speaking to C - transfer from active

**Note:** For FXS interfaces, the device can also handle call transfers using SIP INVITE and re-INVITE messages, instead of REFER messages. This is useful when communicating with SIP UAs that do not support the receipt of REFER messages. This feature is applicable to FXS interfaces. To enable this support, use the EnableCallTransferUsingReinvites parameter.

The device also supports attended (consultation) call transfer for BRI phones (user side) connected to the device and using the Euro ISDN protocol. BRI call transfer is according to

ETSI TS 183 036, Section G.2 (Explicit Communication Transfer – ECT). Call transfer is enabled using the EnableTransfer and EnableHoldtoISDN parameters.

The Explicit Call Transfer (ECT, according to ETS-300-367, 368, 369) supplementary service is supported for BRI and PRI trunks. This service provides the served user who has two calls to ask the network to connect these two calls together and release its connection to both parties. The two calls can be incoming or outgoing calls. This service is similar to NI2 Two B-Channel Transfer (TBCT) Supplementary Service. The main difference is that in ECT one of the calls must be in HELD state. The ECT standard defines two methods - Implicit and Explicit. In implicit method, the two calls must be on the same trunk. BRI uses the implicit mechanism, and PRI the explicit mechanism.

### 30.5.2 Consultation Transfer for QSIG Path Replacement

The device can interwork consultation call transfer requests for ISDN QSIG-to-IP calls. When the device receives a request for a consultation call transfer from the PBX, the device sends a SIP REFER message with a Replaces header to the SIP UA to transfer it to another SIP UA. Once the two SIP UA parties are successfully connected, the device requests the PBX to disconnect the ISDN call, thereby freeing resources on the PBX.

For example, assume legacy PBX user "A" has two established calls connected through the device – one with remote SIP UA "B" and the other with SIP UA "C". In this scenario, user "A" initiates a consultation call transfer to connect "B" with "C". The device receives the consultation call transfer request from the PBX and then connects "B" with "C", by sending "B" a REFER message with a Replaces header (i.e., replace caller "A" with "C"). Upon receipt of a SIP NOTIFY 200 message in response to the REFER, the device sends a Q.931 Disconnect messages to the PBX, notifying the PBX that it can disconnect the ISDN calls (of user "A").

This feature is enabled by the QSIGPathReplacementMode parameter.

### 30.5.3 Blind Call Transfer

Blind call transfer is done (using SIP REFER messages) after a call is established between call parties A and B, and party A decides to immediately transfer the call to C without first speaking to C. The result of the transfer is a call between B and C (similar to consultation transfer, but skipping the consultation stage).

You can also use the ManipulateIP2PSTNReferTo parameter to manipulate the destination number according to the number received in the SIP Refer-To header. This is applicable to all types of blind transfers to the PSTN (e.g., TBCT, ECT, RLT, QSIG, FXO, and CAS). During blind transfer, the device initiates a new call to the PSTN and the destination number of this call can be manipulated if this parameter is enabled. The following is an example of such a blind transfer:

1. IP phone "A" calls PSTN phone "B", and the call is established.
2. "A" performs a blind transfer to PSTN phone "C". It does this as follows:
  - a. "A" sends a SIP REFER message (with the phone number of "C" in the Refer-To header) to the device.
  - b. The device sends a Q.931 Setup message to "C". This feature enables manipulating the called party number in this outgoing Setup message.

The manipulation is done as follows:

1. If you configure a value for the xferPrefix parameter, then this value (string) is added as a prefix to the number in the Refer-To header.
2. This called party number is then manipulated using the IP-to-Tel Destination Phone Number Manipulation table.

3. The source number of the transferred call is taken from the original call, according to its initial direction:
  - Tel-to-IP call: source number of the original call.
  - IP-to-Tel call: destination number of the original call.
  - If the UseReferredByForCallingNumber parameter is set to 1, the source number is taken from the SIP Referred-By header if included in the received SIP REFER message.

This source number can also be used as the value for the 'Source Prefix' field in the IP-to-Tel Destination Phone Number Manipulation table. The local IP address is used as the value for the 'Source IP Address' field.

**Note:** Manipulation using the ManipulateIP2PSTNReferTo parameter does not affect IP-to-Trunk Group routing rules.

## 30.6 Call Forward

For digital interfaces: The device supports Call Deflection (ETS-300-207-1) for Euro ISDN and QSIG (ETSI TS 102 393) for Network and User sides, which provides IP-ISDN interworking of call forwarding (call diversion) when the device receives a SIP 302 response.

Call forward performed by the SIP side: Upon receipt of a Facility message with Call Rerouting IE from the PSTN, the device initiates a SIP transfer process by sending a SIP 302 (including the Call Rerouting destination number) to the IP in response to the remote SIP entity's INVITE message. The device then responds with a Disconnect message to the PSTN side.

Call forward performed by the PSTN side: When the device sends the INVITE message to the remote SIP entity and receives a SIP 302 response, the device sends a Facility message with the same IE mentioned above to the PSTN, and waits for the PSTN side to disconnect the call. This is configured using the CallReroutingMode.

For analog interfaces: The following methods of call forwarding are supported:

- Immediate: incoming call is forwarded immediately and unconditionally.
- Busy: incoming call is forwarded if the endpoint is busy.
- No Reply: incoming call is forwarded if it isn't answered for a specified time.
- On Busy or No Reply: incoming call is forwarded if the port is busy or when calls are not answered after a specified time.
- Do Not Disturb: immediately reject incoming calls. Upon receiving a call for a Do Not Disturb, the 603 Decline SIP response code is sent.

Three forms of forwarding parties are available:

- Served party: party configured to forward the call (FXS device).
- Originating party: party that initiates the first call (FXS or FXO device).
- Diverted party: new destination of the forwarded call (FXS or FXO device).

The served party (FXS interface) can be configured through the Web interface (see Configuring Call Forward on page 399) or ini file to activate one of the call forward modes. These modes are configurable per endpoint.

**Notes:**

- When call forward is initiated, the device sends a SIP 302 response with a contact that contains the phone number from the forward table and its corresponding IP address from the routing table (or when a proxy is used, the proxy's IP address).
- For receiving call forward, the device handles SIP 3xx responses for redirecting calls with a new contact.

### 30.6.1 Call Forward Reminder Ring

The device supports the Call Forward Reminder Ring feature for FXS interfaces, whereby the device's FXS endpoint emits a short ring burst, only in **onhook** state, when a third-party Application Server (e.g., softswitch) forwards an incoming call to another destination. This is important in that it notifies (audibly) the FXS endpoint user that a call forwarding service is currently being performed.

**Figure 30-2: Call Forward Reminder with Application Server**

The device generates a Call Forward Reminder ring burst to the FXS endpoint each time it receives a SIP NOTIFY message with a “reminder ring” xml body. The NOTIFY request is sent from the Application Server to the device each time the Application Server forwards an incoming call. The service is cancelled when an UNSUBSCRIBE request is sent from the device, or when the Subscription time expires.

The reminder-ring tone can be defined by using the parameter `CallForwardRingToneID`, which points to a ring tone defined in the Call Progress Tone file.

The following parameters are used to configure this feature:

- `EnableNRTSubscription`
- `ASSubscribeIPGroupID`
- `NRTSubscribeRetryTime`
- `CallForwardRingToneID`

### 30.6.2 Call Forward Reminder (Off-Hook) Special Dial Tone

The device plays a special dial tone (stutter dial tone - Tone Type #15) to a specific FXS endpoint when the phone is off-hooked and when a third-party Application server (AS), e.g., a softswitch is used to forward calls intended for the endpoint, to another destination. This is useful in that it reminds the FXS user of this service. This feature does not involve device subscription (SIP SUBSCRIBE) to the AS.

Activation/deactivation of the service is notified by the server. An unsolicited SIP NOTIFY request is sent from the AS to the device when the Call Forward service is activated or de-activated. Depending on this NOTIFY request, the device plays either the standard dial tone or the special dial tone for Call Forward.

For playing the special dial tone, the received SIP NOTIFY message must contain the following headers:

- **From and To:** contain the same information, indicating the specific endpoint
- **Event:** ua-profile
- **Content-Type:** "application/simserv+xml"
- Message body is the XML body and contains the "dial-tone-pattern" set to "special-condition-tone" (<ss:dial-tone-pattern>special-condition-tone</ss:dial-tone-pattern>), which is the special tone indication.

To cancel the special dial tone and playing the regular dial tone, the received SIP NOTIFY message must contain the following headers:

- **From and To:** contain the same information, indicating the specific endpoint
- **Event:** ua-profile
- **Content-Type:** "application/simserv+xml"
- Message body is the XML body containing the "dial-tone-pattern" set to "standard-condition-tone" (<ss:dial-tone-pattern>standard-condition-tone</ss:dial-tone-pattern>), which is the regular dial tone indication.

Therefore, the special dial tone is valid until another SIP NOTIFY is received that instructs otherwise (as described above).

**Note:** if the MWI service is active, the MWI dial tone overrides this special Call Forward dial tone.

### 30.6.3 Call Forward Reminder Dial Tone (Off-Hook) upon Spanish SIP Alert-Info

The device plays a special dial tone to FXS phones in off-hook state that are activated with the call forwarding service. The special dial tone is used as a result of the device receiving a SIP NOTIFY message from a third-party softswitch providing the call forwarding service with the following SIP Alert-Info header:

```
Alert-Info: <http://127.0.0.1/Tono-Espec-Invitacion>; lpi-aviso=Desvio-Inmediato
```

This special tone is a stutter dial tone (Tone Type = 15), as defined in the CPT file.

The FXS phone user, connected to the device, activates the call forwarding service by dialing a special number (e.g., \*21\*xxxx) and as a result, the device sends a regular SIP INVITE message to the softswitch. The softswitch later notifies of the activation of the forwarding service by sending an unsolicited NOTIFY message with the Alert-Info header, as mentioned above.

When the call forwarding service is de-activated, for example, by dialing #21# and sending an INVITE with this number, the softswitch sends another SIP NOTIFY message with the following Alert-Info header:

```
Alert-Info: <http://127.0.0.1/ Tono-Normal-Invitacion>; Aviso = Desvió-Inmediato
```

From this point on, the device plays a normal dial tone to the FXS phone when it goes off-hook.

### 30.6.4 BRI Call Forwarding

The device supports call forwarding (CF) services initiated by ISDN Basic BRI phones connected to it. Upon receipt of an ISDN Facility message for call forward from the BRI phone, the device sends a SIP INVITE to the softswitch with a user-defined code in the SIP To header, representing the reason for the call forward.

The codes for the call forward can be defined using the following parameters:

- SuppServCodeCFU - Call Forward Unconditional
- SuppServCodeCFUDeact - Call Forward Unconditional Deactivation
- SuppServCodeCFB - Call Forward on Busy
- SuppServCodeCFBDeact - Call Forward on Busy Deactivation
- SuppServCodeCFNR - Call Forward on No Reply
- SuppServCodeCFNRDeact - Call Forward on No Reply Deactivation

**Note:** These codes must be defined according to the settings of the softswitch (i.e., the softswitch must recognize them).

Below is an example of an INVITE message sent by the device indicating an unconditional call forward ("\*72") to extension number 100. This code is defined using the SuppServCodeCFU parameter.

```
INVITE sip:*72100@10.33.8.53;user=phone SIP/2.0
Via: SIP/2.0/UDP 10.33.2.5:5060;branch=z9hG4bKWDSUKUHWFEXQSV0UVJGM
From: <sip:400@10.33.2.5;user=phone>;tag=DUOROSXS0YJJLNBFRTG
To: <sip:*72100@10.33.8.53;user=phone>
Call-ID: GMNOVQRRXUUCYCQSFAS@10.33.2.5
CSeq: 1 INVITE
Contact: <sip:400@10.33.2.5:5060>
Supported: em,100rel,timer,replaces
Allow:

SCRIBE
User-Agent: Sip Message Generator V1.0.0.5
User-to-User: 31323334;pd=4
Content-Type: application/sdp
Content-Length: 155
```

## 30.7 Call Waiting

The Call Waiting feature enables FXS devices to accept an additional (second) call on busy endpoints. If an incoming IP call is designated to a busy port, the called party hears a call waiting tone (several configurable short beeps) and (for Bellcore and ETSI Caller IDs) can view the Caller ID string of the incoming call. The calling party hears a call waiting ringback tone. The called party can accept the new call using hook-flash, and can toggle between the two calls.

➤ **To enable call waiting:**

1. Set the parameter EnableCallWaiting to 1.
2. Set the parameter EnableHold to 1.
3. Define the Call Waiting indication and call waiting ringback tones in the Call Progress Tones file. You can define up to four call waiting indication tones (refer to the

FirstCallWaitingToneID parameter).

4. To configure the call waiting indication tone cadence, modify the following parameters: NumberOfWaitingIndications, WaitingBeepDuration and TimeBetweenWaitingIndications.
5. To configure a delay interval before a Call Waiting Indication is played to the currently busy port, use the parameter TimeBeforeWaitingIndication. This enables the caller to hang up before disturbing the called party with Call Waiting Indications. Applicable only to FXS modules.

Both the calling and called sides are supported by FXS interfaces; FXO interfaces support only the calling side.

To indicate Call Waiting, the device sends a 182 Call Queued response. The device identifies Call Waiting when a 182 Call Queued response is received.

**Note:** The Call Waiting feature is applicable only to FXS/FXO interfaces.

## 30.8 Message Waiting Indication

The device supports Message Waiting Indication (MWI) according to IETF RFC 3842, including SUBSCRIBE to an MWI server.

For analog interfaces: The FXS device can accept an MWI NOTIFY message that indicates waiting messages or that the MWI is cleared. Users are informed of these messages by a stutter dial tone. The stutter and confirmation tones are defined in the CPT file. If the MWI display is configured, the number of waiting messages is also displayed. If the MWI lamp is configured, the phone's lamp (on a phone that is equipped with an MWI lamp) is lit. The device can subscribe to the MWI server per port (usually used on FXS) or per device (used on FXO).

### Notes:

- For more information on IP voice mail configuration, refer to the *IP Voice Mail CPE Configuration Guide*.
- For creating a CPT file using AudioCodes CPTWizard utility, refer to CPTWizard Utility User's Guide.

To configure MWI, use the following parameters:

- EnableMWI
- MWIServerIP, or MWISubscribeIPGroupID and ProxySet
- MWIAnalogLamp
- MWIDisplay
- StutterToneDuration
- EnableMWISubscription
- MWIExpirationTime
- SubscribeRetryTime
- SubscriptionMode
- CallerIDType (determines the standard for detection of MWI signals)
- ETSIVMWITypeOneStandard
- BellcoreVMWITypeOneStandard

- VoiceMailInterface
- EnableVMURI

The device supports the following MWI features for its digital PSTN interfaces:

- For BRI interfaces: This feature provides support for MWI on BRI phones connected to the device and using the Euro ISDN BRI variant. When this feature is activated and a voice mail message is recorded to the mail box of a BRI extension, the softswitch sends a notification to the device. In turn, the device notifies the BRI extension and a red light flashes on the BRI extension's phone. Once the voice message is retrieved, the MWI light on the BRI extension turns off. This feature is configured by setting the VoiceMailInterface parameter to 8 ("ETSI") and enabled by the EnableMWI parameter.
- Euro-ISDN MWI: The device supports Euro-ISDN MWI for IP-to-Tel calls. The device interworks SIP MWI NOTIFY messages to Euro-ISDN Facility information element (IE) MWI messages. This is supported by setting the VoiceMailInterface parameter to 8.
- QSIG MWI: The device also supports the interworking of QSIG MWI to IP (in addition to interworking of SIP MWI NOTIFY to QSIG Facility MWI messages). This provides interworking between an ISDN PBX with voicemail capabilities and a softswitch, which requires information on the number of messages waiting for a specific user. This support is configured using the TrunkGroupSettings\_MWIInterrogationType parameter (in the Trunk Group Settings table), which determines the device's handling of MWI Interrogation messages. The process for sending the MWI status upon request from a softswitch is as follows:
  1. The softswitch sends a SIP SUBSCRIBE message to the device.
  2. The device responds by sending an empty SIP NOTIFY to the softswitch, and then sending an ISDN Setup message with Facility IE containing an MWI Interrogation request to the PBX.
  3. The PBX responds by sending to the device an ISDN Connect message containing Facility IE with an MWI Interrogation result, which includes the number of voice messages waiting for the specific user.
  4. The device sends another SIP NOTIFY to the softswitch, containing this MWI information.
  5. The SIP NOTIFY messages are sent to the IP Group defined by the NotificationIPGroupID parameter.

In addition, when a change in the status occurs (e.g., a new voice message is waiting or the user has retrieved a message from the voice mail), the PBX initiates an ISDN Setup message with Facility IE containing an MWI Activate request, which includes the new number of voice messages waiting for the user. The device forwards this information to the softswitch by sending a SIP NOTIFY.

Depending on the PBX support, the MWIInterrogationType parameter can be configured to handle these MWI Interrogation messages in different ways. For example, some PBXs support only the MWI Activate request (and not MWI Interrogation request). Some support both these requests. Therefore, the device can be configured to disable this feature, or enable it with one of the following support:

- Responds to MWI Activate requests from the PBX by sending SIP NOTIFY MWI messages (i.e., does not send MWI Interrogation messages).
- Send MWI Interrogation message, but don't use its result. Instead, wait for MWI Activate requests from the PBX.
- Send MWI Interrogation message, use its result, and use the MWI Activate requests.

## 30.9 Caller ID

This section describes the device's Caller ID support.

**Note:** The Caller ID feature is applicable only to FXS/FXO interfaces.

### 30.9.1 Caller ID Detection / Generation on the Tel Side

By default, generation and detection of Caller ID to the Tel side is disabled. To enable Caller ID, set the parameter EnableCallerID to 1. When the Caller ID service is enabled:

- For FXS: the Caller ID signal is sent to the device's port
- For FXO: the Caller ID signal is detected

The configuration for Caller ID is described below:

- Use the parameter CallerIDType to define the Caller ID standard. Note that the Caller ID standard that is used on the PBX or phone must match the standard defined in the device.
- Select the Bellcore caller ID sub standard using the parameter BellcoreCallerIDTypeOneSubStandard
- Select the ETSI FSK caller ID sub standard using the parameter ETSICallerIDTypeOneSubStandard
- Enable or disable (per port) the caller ID generation (for FXS) and detection (for FXO) using the 'Generate / Detect Caller ID to Tel' table (EnableCallerID). If a port isn't configured, its caller ID generation / detection are determined according to the global parameter EnableCallerID.
- EnableCallerIDTypeTwo: disables / enables the generation of Caller ID type 2 when the phone is off-hooked (used for call waiting).
- RingsBeforeCallerID: sets the number of rings before the device starts detection of caller ID (FXO only). By default, the device detects the caller ID signal between the first and second rings.
- AnalogCallerIDTimingMode: determines the time period when a caller ID signal is generated (FXS only). By default, the caller ID is generated between the first two rings.
- PolarityReversalType: some Caller ID signals use reversal polarity and/or wink signals. In these scenarios, it is recommended to set PolarityReversalType to 1 (Hard) (FXS only).
- The Caller ID interworking can be changed using the parameters UseSourceNumberAsDisplayName and UseDisplayNameAsSourceNumber.

### 30.9.2 Debugging a Caller ID Detection on FXO

The procedure below describes debugging caller ID detection in FXO interfaces.

➤ **To debug a Caller ID detection on an FXO interface:**

1. Verify that the parameter EnableCallerID is set to 1.
2. Verify that the caller ID standard (and substandard) of the device matches the standard of the PBX (using the parameters CallerIDType, BellcoreCallerIDTypeOneSubStandard, and ETSICallerIDTypeOneSubStandard).

3. Define the number of rings before the device starts the detection of caller ID (using the parameter `RingsBeforeCallerID`).
4. Verify that the correct FXO coefficient type is selected (using the parameter `CountryCoefficients`), as the device is unable to recognize caller ID signals that are distorted.
5. Connect a phone to the analog line of the PBX (instead of to the device's FXO interface) and verify that it displays the caller ID.

If the above does not solve the problem, you need to record the caller ID signal (and send it to `AudioCodes`), as described below.

➤ **To record the caller ID signal using the debug recording mechanism:**

1. Access the FAE page (by appending "FAE" to the device's IP address in the Web browser's URL, for example, `http://10.13.4.13/FAE`).
2. Press the **Cmd Shell** link.
3. Enter the following commands:

```
dr
ait <IP address of PC to collect the debug traces sent from
the device>
AddChannelIdTrace ALL-WITH-PCM <port number, which starts from
0>
Start
```

4. Make a call to the FXO.
5. To stop the DR recording, at the CLI prompt, type **STOP**.

### 30.9.3 Caller ID on the IP Side

Caller ID is provided by the SIP From header containing the caller's name and "number", for example:

```
From: "John" <SIP:101@10.33.2.2>; tag=35dfsgasd45dg
```

If Caller ID is restricted (received from Tel or configured in the device), the From header is set to:

```
From: "anonymous" <anonymous@anonymous.invalid>; tag=35dfsgasd45dg
```

The P-Asserted (or P-Preferred) headers are used to present the originating party's caller ID even when the caller ID is restricted. These headers are used together with the Privacy header.

- If Caller ID is restricted:
  - The From header is set to "anonymous" <anonymous@anonymous.invalid>
  - The 'Privacy: id' header is included
  - The P-Asserted-Identity (or P-Preferred-Identity) header shows the caller ID
- If Caller ID is allowed:
  - The From header shows the caller ID
  - The 'Privacy: none' header is included
  - The P-Asserted-Identity (or P-Preferred-Identity) header shows the caller ID

The caller ID (and presentation) can also be displayed in the Calling Remote-Party-ID header.

The 'Caller Display Information' table (`CallerDisplayInfo`) is used for the following:

- **FXS interfaces** - to define the caller ID (per port) that is sent to IP.
- **FXO interfaces** - to define the caller ID (per port) that is sent to IP if caller ID isn't detected on the Tel side, or when `EnableCallerID = 0`.

- **FXS and FXO interfaces** - to determine the presentation of the caller ID (allowed or restricted).
- **To maintain backward compatibility** - when the strings 'Private' or 'Anonymous' are set in the Caller ID/Name field, the caller ID is restricted and the value in the Presentation field is ignored.

The value of the 'Presentation' field that is defined in the 'Caller Display Information' table can be overridden by configuring the 'Presentation' parameter in the 'Tel to IP Source Number Manipulation' table. Therefore, this table can be used to set the presentation for specific calls according to Source / Destination prefixes.

The caller ID can be restricted/allowed (per port) using keypad features KeyCLIR and KeyCLIRDeact (FXS only).

AssertedIdMode defines the header that is used (in the generated INVITE request) to deliver the caller ID (P-Asserted-Identity or P-Preferred-Identity). Use the parameter UseTelURIForAssertedID to determine the format of the URI in these headers (sip: or tel:).

The parameter EnableRPIheader enables Remote-Party-ID (RPI) headers for calling and called numbers for Tel-to-IP calls.

## 30.10 Three-Way Conferencing

The device supports three-way conference calls. These conference calls can also occur simultaneously. The device supports the following conference modes (configured by the parameter 3WayConferenceMode):

- **Conferencing managed by an external, AudioCodes Conference (media) server:**  
The Conference-initiating INVITE sent by the device uses the ConferenceID concatenated with a unique identifier as the Request-URI. This same Request-URI is set as the Refer-To header value in the REFER messages that are sent to the two remote parties. For this mode, the 3WayConferenceMode parameter is set to 0 (default.)
- **Conferencing managed by an external, third-party Conference (media) server:**  
The Conference-initiating INVITE sent by the device uses only the ConferenceID as the Request-URI. The Conference server sets the Contact header of the 200 OK response to the actual unique identifier (Conference URI) to be used by the participants. This Conference URI is included (by the device) in the Refer-To header value in the REFER messages sent by the device to the remote parties. The remote parties join the conference by sending INVITE messages to the Conference server using this conference URI. For this mode, the 3WayConferenceMode parameter is set to 1.
- **Local, on-board conferencing:** The conference is established on the device without the need for an external Conference server. This feature includes local mixing and transcoding of the 3-Way Call legs on the device, and even allowing multi-codec conference calls. The number of simultaneous, on-board conferences can be limited using the parameter MaxInBoardConferenceCalls. The device supports up to five simultaneous, on-board, three-way conference calls. For this mode, the 3WayConferenceMode parameter is set to 2.

**Notes:**

- Three-way conferencing using an external conference server is supported only by FXS interfaces.
- Instead of using the flash-hook button to establish a three-way conference call, you can dial a user-defined hook-flash code (e.g., "\*1"), configured by the HookFlashCode parameter.
- Three-way conferencing is applicable only to FXS and BRI interfaces. Three-way conferencing support for the BRI phones connected to the device complies with ETS 300 185.
- The device supports high definition, three-way conferencing using wideband codecs (e.g., G.722 and AMR-WB). This allows conference participants to experience wideband voice quality. Call conferences can also include narrowband and wideband participants.

The following example demonstrates three-way conferencing using the device's local, on-board conferencing feature. In this example, telephone "A" connected to the device establishes a three-way conference call with two remote IP phones, "B" and "C":

1. A establishes a regular call with B.
2. A places B on hold, by pressing the telephone's flash-hook button.
3. A hears a dial tone and then makes a call to C.
4. C answers the call.
5. A establishes a three-way conference call with B and C, by pressing the flash-hook button and digit 3.

To configure this local, on-board three-way conferencing:

1. Open the Supplementary Services page.
2. Set 'Enable 3-Way Conference' to **Enable** (Enable3WayConference = 1).
3. Set 'Three Way Conference Mode' to **On Board** (3WayConferenceMode = 2).
4. Set 'Flash Keys Sequence Style' to **Sequence 1** or **Sequence 2** (FlashKeysSequenceStyle = 1 or 2).

## 30.11 Emergency E911 Phone Number Services

This section describes the device's support for emergency phone number services. The device supports the North American emergency telephone number system known as Enhanced 911 (E911), according to the TR-TSY-000350 and Bellcore's GR-350-Jun2003 standards. The E911 emergency system automatically associates a physical address with the calling party's telephone number, and routes the call to the most appropriate (closest) Public Safety Answering Point (PSAP), allowing the PSAP to quickly dispatch emergency response (e.g., police) to the caller's location.

Typically, the dialed emergency number is routed to the appropriate PSAP by the telephone company's switch, known as a 911 Selective Router (or E911 tandem switch). If the PSAP receives calls from the telephone company on old-style digital trunks, they are specially formatted Multi-Frequency (MF) trunks that pass only the calling party's number (known as Automatic Number Identification - ANI). Once the PSAP receives the call, it searches for the physical address that is associated with the calling party's telephone number (in the Automatic Location Identification database - ALI).

### 30.11.1 FXS Device Emulating PSAP using DID Loop-Start Lines

The device's FXS interface can be configured to emulate PSAP (using DID loop start lines), according to the Telcordia GR-350-CORE specification.

**Figure 30-3: FXS Device Emulating PSAP using DID Loop-Start Lines**

The call flow of an E911 call to the PSAP is as follows:

1. The E911 tandem switch seizes the line.
2. The FXS device detects the line seize, and then generates a wink signal (nominal 250 msec). The wink can be delayed by configuring the parameter DelayBeforeDIDWink to 200 (for 200 msec or a higher value).
3. The switch detects the wink and then sends the MF Spill digits with ANI and (optional) Pseudo-ANI (P ANI).
4. The FXS device collects the MF digits, and then sends a SIP INVITE message to the PSAP with all collected MF digits in the SIP From header as one string.
5. The FXS device generates a mid-call wink signal (two subsequent polarity reversals) toward the E911 tandem switch upon either detection of an RFC 2833 "hookflash" telephony event, or if a SIP INFO message with a "hookflash" body is received from the PSAP (see the example below). The duration of this "flashhook" wink signal is configured using the parameter FlashHookPeriod (usually 500 msec). Usually the wink signal is followed by DTMF digits sent by PSAP to perform call transfer. Another way to perform the call transfer is to use SIP REFER messages, as described below.
6. The FXS device supports call transfer initiated by the PSAP. If it receives a SIP REFER message with the Refer-To URI host part containing an IP address that is equal to the device's IP address, the FXS device generates a 500-msec wink signal (double polarity reversals), and then (after a user-defined interval configured by the parameter WaitForDialTime), plays DTMF digits according to the transfer number received in the SIP Refer-To header URI userpart.
7. When the call is answered by the PSAP operator, the PSAP sends a SIP 200 OK to the FXS device, and the FXS device then generates a polarity reversal signal to the E911 switch.
8. After the call is disconnected by the PSAP, the PSAP sends a SIP BYE to the FXS device, and the FXS device reverses the polarity of the line toward the tandem switch.

The following parameters need to be configured:

- EnabledIDWink = 1
- EnableReversalPolarity = 1
- PolarityReversalType = 1
- FlashHookPeriod = 500 (for 500 msec "hookflash" mid-call Wink)
- WinkTime = 250 (for 250 msec signalling Wink generated by the FXS device after it detects the line seizure)
- EnableTransfer = 1 (for call transfer)
- LineTransferMode = 1 (for call transfer)
- WaitforDialTime = 1000 (for call transfer)
- SwapTEI2IPCalled&CallingNumbers = 1
- DTMFDetectorEnable = 0
- MFR1DetectorEnable = 1
- DelayBeforeIDWink = 200 (for 200 msec) - can be configured in the range from 0 (default) to 1000.

**Note:** Modification of the WinkTime and FlashHookPeriod parameters require a device reset.

The outgoing SIP INVITE message contains the following headers:

```
INVITE sip:Line@DomainName
From: <sip:*81977820#@sipgw>;tag=1c143
To: <sip:Line@DomainName>
```

Where:

- *Line* = as configured in the Endpoint Phone Number Table
- *SipGtw* = configured by the SIPGatewayName parameter
- *From* header/user part = calling party number as received from the MF spill

The ANI and the pseudo-ANI numbers are sent to the PSAP either in the From and/or P-AssertedID SIP header.

Typically, the MF spills are sent from the E911 tandem switch to the PSAP, as shown in the table below:

**Dialed MF Digits Sent to PSAP**

| Digits of Calling Number         | Dialed MF Digits                 |
|----------------------------------|----------------------------------|
| 8 digits "nnnnnnnn" (ANI)        | "KPnnnnnnnnST"                   |
| 12 digits "nnnnnnnnnnnn" (ANI)   | "KPnnnnnnnnnnnnSTP"              |
| 12 digits ANI and 10 digits PANI | "KPnnnnnnnnnnnnSTKPmmmmmmmmmmST" |
| two digits "nn"                  | "KPnnSTP"                        |

The MF KP, ST, and STP digits are mapped as follows:

- \* for KP
- # for ST
- B for STP

For example, if ANI and PANI are received, the SIP INVITE contains the following From header:

```
From: <sip:*nnnnnnnnnnnn#*mmmmmmmmmm#@10.2.3.4>;tag=1c14
```

**Note:** It is possible to remove the \* and # characters, using the device's number manipulation rules.

If the device receives the SIP INFO message below, it then generates a "hookflash" mid-call Wink signal:

```
INFO sip:4505656002@192.168.13.40:5060 SIP/2.0
Via: SIP/2.0/UDP 192.168.13.2:5060
From: port1vega1 <sip:06@192.168.13.2:5060>
To: <sip:4505656002@192.168.13.40:5060>;tag=132878796-1040067870294
Call-ID: 0010-0016-D69A7DA8-1@192.168.13.2
CSeq:2 INFO
Content-Type: application/broadsoft
Content-Length: 17
event flashhook
```

### 30.11.2 FXO Device Interworking SIP E911 Calls from Service Provider's IP Network to PSAP DID Lines

The device's FXO interface can interwork SIP emergency E911 calls from the Service Provider's IP network to the analog PSAP DID lines. The standards that define this interface include TR-TSY-000350 or Bellcore's GR-350-Jun2003. This protocol defines signaling between the E911 tandem switch (E911 Selective Router) and the PSAP, using analog loop-start lines. The FXO device can be implemented instead of an E911 switch, by connecting directly to the PSAP DID loop-start lines.

**Figure 30-4: FXO Device Interfacing between E911 Switch and PSAP**

When an IP phone subscriber dials 911, the device receives the SIP INVITE message and makes a call to the PSAP as follows:

1. The FXO device seizes the line.
2. PSAP sends a Wink signal (250 msec) to the device.
3. Upon receipt of the Wink signal, the device dials MF digits after a user-defined time (WaitForDialTime) containing the caller's ID (ANI) obtained from the SIP headers From or P-Asserted-Identity.
4. When the PSAP operator answers the call, the PSAP sends a polarity reversal to the device, and the device then sends a SIP 200 OK to the IP side.
5. After the PSAP operator disconnects the call, the PSAP reverses the polarity of the line, causing the device to send a SIP BYE to the IP side.
6. If, during active call state, the device receives a Wink signal (typically of 500 msec) from the PSAP, the device generates a SIP INFO message that includes a "hookflash" body, or sends RFC 2833 hookflash Telephony event (according to the HookFlashOption parameter).
7. Following the "hookflash" Wink signal, the PSAP sends DTMF digits. These digits are detected by the device and forwarded to the IP, using RFC 2833 telephony events (or inband, depending on the device's configuration). Typically, this Wink signal followed by the DTMF digits initiates a call transfer.

For supporting the E911 service, used the following configuration parameter settings:

- Enable911PSAP = 1 (also forces the EnableDIDWink and EnableReversalPolarity)
- HookFlashOption = 1 (generates the SIP INFO hookflash message) or 4 for RFC 2833 telephony event
- WinkTime = 700 (defines detection window of 50 to 750 msec for detection of both winks - 250 msec wink sent by the PSAP for starting the device's dialing; 500 msec wink during the call)
- IsTwoStageDial = 0
- EnableHold = 0
- EnableTransfer = 0
  - Use RFC 2833 DTMF relay:
    - ◆ RxDTMFOption = 3
    - ◆ TxDTMFOption = 4
    - ◆ RFC2833PayloadType = 101
- TimeToSampleAnalogLineVoltage = 100
- WaitForDialTime = 1000 (default is 1 sec)
- SetDefaultLinePolarityState = 0 (you need to verify that the RJ-11 two-wire cable is connected without crossing, Tip to Tip, Ring to Ring. Typically, the Tip line is positive compared to the Ring line.)

**Note:** If the two-wire cable is crossed, the SetDefaultLinePolarityState parameter must be set to 1.

The device expects to receive the ANI number in the From and/or P-Asserted-Identity SIP header. If the pseudo-ANI number exists, it should be sent as the display name in these headers.

Dialed Number by Device Depending on Calling Number

| Digits of Calling Number (ANI) | Digits of Displayed Number | Number Dialed MF Digits                                                                            |
|--------------------------------|----------------------------|----------------------------------------------------------------------------------------------------|
| 8<br>"nnnnnnnn"                | -                          | MF dialed "KPnnnnnnnnST"                                                                           |
| 12<br>"nnnnnnnnnnnn"           | None                       | "KPnnnnnnnnnnnnSTP"                                                                                |
| 12<br>"nnnnnnnnnnnn"           | 10<br>"mmmmmmmmmm" (pANI)  | "KPnnnnnnnnnnnnSTKPmmmmmmmmmmST"                                                                   |
| 2<br>"nn"                      | None                       | "KPnnSTP"                                                                                          |
| 1<br>"n"                       | -                          | MF dialed "KPnST"<br>For example:<br>"From: <sip:8>@xyz.com>" generates device MF spill of KP 8 ST |

Table notes:

- For all other cases, a SIP 484 response is sent.
- KP is for .
- ST is for #.
- STP is for B.

The MF duration of all digits, except for the KP digit is 60 msec. The MF duration of the KP digit is 120 msec. The gap duration is 60 msec between any two MF digits.

#### Notes:

- Manipulation rules can be configured for the calling (ANI) and called number (but not on the "display" string), for example, to strip 00 from the ANI "00INXXYYYY".
- The called number, received as userpart of the Request URI ("301" in the example below), can be used to route incoming SIP calls to FXO specific ports, using the TrunkGroup and PSTNPrefix parameters.
- When the PSAP party off-hooks and then immediately on-hooks (i.e., the device detects wink), the device releases the call sending SIP response "403 Forbidden" and the release reason 21 (i.e., call rejected) "Reason: Q.850 ;cause=21" is sent. Using the cause mapping parameter, it is possible to change the 403 to any other SIP reason, for example, to 603.
- Sometimes a wink signal sent immediately after the FXO device seizes the line is not detected. To overcome this problem, configure the parameter TimeToSampleAnalogLineVoltage to 100 (instead of 1000 msec, which is the default value). The wink is then detected only after this timeout + 50 msec (minimum 150 msec).

Below are two examples for a) INVITE messages and b) INFO messages generated by hook-flash.

- **Example A:** INVITE message with ANI = 333333444444 and pseudo-ANI = 0123456789:

```
INVITE sip:301@10.33.37.79;user=phone SIP/2.0
Via: SIP/2.0/UDP 10.33.37.78;branch=z9hG4bKac771627168
Max-Forwards: 70
```

```

### 30.11.3 Pre-empting Existing Calls for E911 IP-to-Tel Calls

If the device receives an E911 call from the IP network destined to the Tel, and there are unavailable channels (e.g., all busy), the device terminates one of the calls (arbitrary) and then sends the E911 call to that channel. The preemption is done only on a channel pertaining to the same Trunk Group for which the E911 call was initially destined and if the channel select mode (configured by the ChannelSelectMode parameter) is set to a value other than "By Dest Number" (0).

The preemption is done only if the incoming IP-to-Tel call is identified as an emergency call. The device identifies emergency calls by one of the following:

- The destination number of the IP call matches one of the numbers defined by the EmergencyNumbers parameter. For E911, you must defined this parameter with the value "911".
- The Priority header of the incoming SIP INVITE message contains the "emergency" value.

Emergency pre-emption of calls can be enabled for all calls, using the global parameter `CallPriorityMode`, or for specific calls using the Tel Profile parameter `CallPriorityMode`.

**Notes:**

- For Trunk Groups configured with call preemption, all must be configured to MLPP [1] or all configured to Emergency [2]. In other words, you cannot set some trunks to [1] and some to [2].
- The global parameter must be set to the same value as that of the Tel Profile parameter; otherwise, the Tel Profile parameter is not applied.
- If you configure call preemption using the global parameter and a new Tel Profile is subsequently added, the `TelProfile_CallPriorityMode` parameter automatically acquires the same setting as well.
- This feature is applicable to FXO, CAS, and ISDN interfaces.
- For FXO interfaces, the preemption is done only on existing IP-to-Tel calls. In other words, if all the current FXO channels are busy with calls that were answered by the FXO device (i.e., Tel-to-IP calls), new incoming emergency IP-to-Tel calls are rejected.

### 30.11.4 Enhanced 9-1-1 Support for Lync Server 2010

The Enhanced 9-1-1 (E9-1-1) service is becoming the mandatory emergency service required in many countries around the world. The E9-1-1 service, based on its predecessor 911, enables emergency operators to pinpoint the location (granular location) of callers who dial the 9-1-1 emergency telephone number.

Today, most enterprises implement an IP-based infrastructure providing a VoIP network with fixed and nomadic users, allowing connectivity anywhere with any device. This, together with an often deployed multi-line telephone system (MLTS) poses a challenge for E9-1-1 due to the difficulty in accurately locating the E9-1-1 caller.

This section describes the E9-1-1 solution provided by Microsoft Lync Server 2010 (hereafter referred to as *Lync Server 2010*), and the deployed AudioCodes ELIN Gateway which provides the ISDN (or CAMA) connectivity to the PSTN-based E9-1-1 emergency providers. This section also describes the configuration of AudioCodes ELIN Gateway for interoperating between the Lync Server 2010 environment and the E9-1-1 emergency provider.

#### 30.11.4.1 About E9-1-1 Services

E9-1-1 is a national emergency service for many countries, enabling E9-1-1 operators to automatically identify the geographical location and phone number of a 911 caller. In E9-1-1, the 911 caller is routed to the nearest E9-1-1 operator, termed *public safety answering point* (PSAP) based on the location of the caller. Automatic identification of the caller's location and phone number reduces the time spent on requesting this information from the 911 caller. Therefore, the E9-1-1 service enables the PSAP to quickly dispatch the relevant emergency services (for example, fire department or police) to the caller's location. Even if the call prematurely disconnects, the operator has sufficient information to call back the 911 caller.

The figure below illustrates the routing of an E9-1-1 call to the PSAP:

**Figure 30-5: Call Flow of E9-1-1 to PSTN-Based Emergency Services Provider**

1. The VoIP user dials 9-1-1.
2. The call is eventually sent to the PSTN through a PSTN Gateway.
3. The PSTN identifies the call is an emergency call and sends it to an E9-1-1 Selective Router in the Emergency Services provider's network.
4. The E9-1-1 Selective Router determines the geographical location of the caller by requesting this information from an Automatic Location Identification (ALI) database based on the phone number or Automatic Number Identifier (ANI) of the 911 caller. Exact location information is also supplied by the Master Street Address Guide (MSAG) database, which is a companion database to the ALI database. Phone companies and public safety agencies collaborate beforehand to create master maps that match phone numbers, addresses and cross streets to their corresponding PSAP. This MSAG is the official record of valid streets (with exact spelling), street number ranges, and other address elements with which the service providers are required to update their ALI databases.
5. The E9-1-1 Selective Router sends the call to the appropriate PSAP based on the retrieved location information from the ALI.
6. The PSAP operator dispatches the relevant emergency services to the E9-1-1 caller.

#### 30.11.4.2 Microsoft Lync Server 2010 and E9-1-1

Microsoft Lync Server 2010 enables Enterprise voice users to access its unified communications platform from virtually anywhere and through many different devices. This, together with a deployed MLTS, poses a challenge for E9-1-1 due to the difficulty in accurately locating the E9-1-1 caller. However, Lync Server 2010 offers an innovative solution to solving Enterprises E9-1-1 location problems.

##### 30.11.4.2.1 Gathering Location Information of Lync 2010 Clients for 911 Calls

When a Microsoft® Lync™ 2010 client (hereafter referred to as *Lync 2010 client*) is enabled for E9-1-1, the location data that is stored on the client is sent during an emergency call. This stored location information is acquired automatically from the

Microsoft Location Information Server (LIS). The LIS stores the location of each network element in the enterprise. Immediately after the Lync 2010 client registration process or when the operating system detects a network connection change, each Lync 2010 client submits a request to the LIS for a location. If the LIS is able to resolve a location address for the client request, it returns the address in a location response. Each client then caches this information. When the Lync 2010 client dials 9-1-1, this location information is then included as part of the emergency call and used by the Emergency Services provider to route the call to the correct PSAP.

The gathering of location information in the Lync Server 2010 network is illustrated in the figure below:

**Figure 30-6: Microsoft Lync Server 2010 Client Acquiring Location Information**

1. The Administrator provisions the LIS database with the location of each network element in the Enterprise. The location is a civic address, which can include contextual in-building and company information. In other words, it associates a specific network entity (for example, a WAP) with a physical location in the Enterprise (for example, Floor 2, Wing A, and the Enterprise's street address). For more information on populating the LIS database, see 'Adding ELINs to the Location Information Server' on page 373.
2. The Administrator validates addresses with the Emergency Services provider's MSAG—a companion database to the ALI database. This ensures that the civic address is valid as an official address (e.g., correct address spelling).
3. The Lync 2010 client initiates a location request to the LIS under the following circumstances:
  - Immediately after startup and registering the user with Lync Server 2010
  - Approximately every four hours after initial registration
  - Whenever a network connection change is detected (such as roaming to a new WAP)

The Lync 2010 client includes in its location request the following known network connectivity information:

- Always included:
  - ♦ IPv4 subnet
  - ♦ Media Access Control (MAC) address

- Depends on network connectivity:
  - ◆ Wireless access point (WAP) Basic Service Set Identifier (BSSID)
  - ◆ Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) chassis ID and port ID

For a Lync 2010 client that moves inside the corporate network such as a soft phone on a laptop that connects wirelessly to the corporate network, Lync Server 2010 can determine which subnet the phone belongs to or which WAP / SSID is currently serving the soft-client.

4. The LIS queries the published locations for a location and if a match is found, returns the location information to the client. The matching order is as follows:

- WAP BSSID
- LLDP switch / port
- LLDP switch
- Subnet
- MAC address

This logic ensures that for any client that is connected by a wireless connection, a match is first attempted based on the hardware address of its connected access point. The logic is for the match to be based on the most detailed location. The subnet generally provides the least detail. If no match is found in the LIS for WAP BSSID, LLDP switch / port, LLDP switch, or subnet, the LIS proxies the MAC address to an integrated Simple Network Management Protocol (SNMP) scanning application. Using SNMP may benefit some organizations for the following reasons:

- LLDP is not supported by Lync Server 2010 so this provides a mechanism for soft phones to acquire detailed location information.
- Installed Layer-2 switches may not support LLDP.

If there is no match and the LIS cannot determine the location, the user may be prompted to manually enter the location. For example, the client may be located in an undefined subnet, at home, in a coffee shop or anywhere else outside the network. When a user manually provides a location, the location is mapped based on the MAC address of the default gateway of the client's network and stored on the client. When the client returns to any previously stored location, the client is automatically set to that location. A user can also manually select any location stored in the local users table and manage existing entries.

#### 30.11.4.2.2 Adding ELINs to the Location Information Server

As mentioned in the previous section, the Administrator needs to populate the Location Information Server (LIS) database with a network wire map, which maps the Enterprise's network elements to civic addresses. Once done, it can automatically locate clients within a network. You can add addresses individually to the LIS or in a batch using a comma-separated value (CSV) file containing the column formats listed in the table below.

**Columns in the LIS Database**

| Network Element       | Columns                                                                                                                                                                                   |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Wireless access point | <BSSID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,...<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>  |
| Subnet                | <Subnet>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,...<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country> |
| Port                  | <ChassisID>,<PortIDSubType>,<PortID>,<Description>,<Location>,<Co                                                                                                                         |

| Network Element | Columns                                                                                                                                                                                      |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                 | mpanyName>,<HouseNumber>,<HouseNumberSuffix>,...<PreDirectional>,<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>                                         |
| <b>Switch</b>   | <ChassisID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,...<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country> |

For the ELIN number to be included in the SIP INVITE (XML-based PIDF-LO message) sent by the Mediation Server to the ELIN Gateway, the Administrator must add the ELIN number to the <CompanyName> column (shown in the table above in **bold** typeface). As the ELIN Gateway supports up to five ELINs per PIDF-LO, the <CompanyName> column can be populated with up to this number of ELINs, each separated by a semicolon. The digits of each ELIN can be separated by hyphens (xxx-xxx-xxx) or they can be adjacent (xxxxxxxxx).

When the ELIN Gateway receives the SIP INVITE, it extracts the ELINs from the NAM field in the PIDF-LO (e.g., <ca:NAM>1111-222-333; 1234567890 </ca:NAM>), which corresponds to the <CompanyName> column of the LIS.

If you do not populate the location database, and the Lync Server 2010 location policy, Location Required is set to **Yes** or **Disclaimer**, the user will be prompted to enter a location manually.

### 30.11.4.2.3 Passing Location Information to the PSTN Emergency Provider

When a Lync 2010 client, enabled for E9-1-1 emergency services, dials 9-1-1, the location data and callback information stored on the client is sent with the call through the Mediation Server to a PSTN-based Emergency Services provider. The Emergency Services provider then routes the call to the nearest and most appropriate PSAP based on the location information contained within the call.

Lync Server 2010 passes the location information of the Lync 2010 client in an IETF-standard format - Presence Information Data Format - Location Object (PIDF-LO)—in a SIP INVITE message. However, this content cannot be sent on the PSTN network using ISDN PRI due to protocol limitations. To overcome this, Enterprises using PSTN Gateways can divide their office space into Emergency Response Locations (ERLs) and assign a dedicated Emergency Location Identification Number (ELIN) to each ERL (or zone). When Lync Server 2010 sends a SIP INVITE message with the PIDF-LO to the PSTN Gateway, it can parse the content and translate the calling number to an appropriate ELIN. The PSTN Gateway then sends the call to the PSTN with the ELIN number as the calling number. This ELIN number is sent to the Emergency Services provider, which sends it on to the appropriate PSAP according to the ELIN address match in the ALI database lookup.

The ERL defines a specific location at a street address, for example, the floor number of the building at that address. The geographical size of an ERL is according to local or national regulations (for example, less than 7000 square feet per ERL). Typically, you would have an ERL for each floor of the building. The ELIN is used as the phone number for 911 callers within this ERL.

The figure below illustrates the use of ERLs and ELINs, with an E9-1-1 call from floor 2 at the branch office:

**Figure 30-7: Implementing ERLs and ELINs for E9-1-1 in Lync Server 2010**

The table below shows an example of designating ERLs to physical areas (floors) in a building and associating each ERL with a unique ELIN.

**Designating ERLs and Assigning to ELINs**

| ERL Number | Physical Area | IP Address    | ELIN         |
|------------|---------------|---------------|--------------|
| 1          | Floor 1       | 10.13.124.xxx | 503 972-4410 |
| 2          | Floor 2       | 10.15.xxx.xxx | 503 972-4411 |
| 3          | Floor 3       | 10.18.xxx.xxx | 503 972-4412 |

In the table above, a unique IP subnet is associated per ERL. This is useful if you implement different subnets between floors. Therefore, IP phones, for example, on a specific floor are in the same subnet and therefore, use the same ELIN when dialing 9-1-1.

### 30.11.4.3 AudioCodes ELIN Gateway for Lync Server 2010 E9-1-1 Calls to PSTN

The Microsoft Mediation Server sends the location information of the E9-1-1 caller in the XML-based PIDF-LO body contained in the SIP INVITE message. However, this content cannot be sent on the PSTN network using ISDN PRI due to protocol limitations. To solve this issue, Lync Server 2010 requires a PSTN Gateway (*ELIN Gateway*) to send the E9-1-1

call to the PSTN. When Lync Server 2010 sends the PIDF-LO to the PSTN Gateway, it parses the content and translates the calling number to an appropriate ELIN. This ensures that the call is routed to an appropriate PSAP, based on ELIN-address match lookup in the Emergency Services provider's ALI database.

The figure below illustrates an AudioCodes ELIN Gateway deployed in the Lync Server 2010 environment for handling E9-1-1 calls between the Enterprise and the PSTN.

**Figure 30-8: AudioCodes ELIN Gateway for E9-1-1 in Lync Server 2010 Environment**

#### 30.11.4.3.1 Detecting and Handling E9-1-1 Calls

The ELIN Gateway identifies E9-1-1 calls and translates their incoming E9-1-1 calling numbers into ELIN numbers, sent toward the PSAP. The ELIN Gateway handles the received E9-1-1 calls as follows:

1. The ELIN Gateway identifies E9-1-1 calls if the incoming SIP INVITE message contains a PIDF-LO XML message body. This is indicated in the SIP *Content-Type* header, as shown below:

```
Content-Type: application/pidf+xml
```

2. The ELIN Gateway extracts the ELIN number(s) from the "NAM" field in the XML message. The "NAM" field corresponds to the <CompanyName> column in the Location Information Server (LIS). The ELIN Gateway supports up to five ELIN numbers per XML message. The ELINs are separated by a semicolon. The digits of the ELIN number can be separated by hyphens (xxx-xxx-xxx) or they can be adjacent (xxxxxxxxx), as shown below:

```
<ca:NAM>1111-222-333; 1234567890 </ca:NAM>
```

3. The ELIN Gateway saves the *From* header value of the SIP INVITE message in its ELIN database table (**Call From** column). The ELIN table is used for PSAP callback, as discussed later in 'PSAP Callback to Lync 2010 Clients for Dropped E9-1-1 Calls' on page 378. The ELIN table also stores the following information:

- **ELIN:** ELIN number
- **Time:** Time at which the original E9-1-1 call was terminated with the PSAP
- **Count:** Number of E9-1-1 calls currently using this ELIN

An example of the ELIN database table is shown below:

| ELIN       | Time     | Count | Index | Call From  |
|------------|----------|-------|-------|------------|
| 4257275678 | 22:11:52 | 0     | 2     | 4258359333 |
| 4257275999 | 22:11:57 | 0     | 3     | 4258359444 |
| 4257275615 | 22:12:03 | 0     | 0     | 4258359555 |
| 4257275616 | 22:11:45 | 0     | 1     | 4258359777 |

The ELIN table stores this information for a user-defined period (see 'Configuring the E9-1-1 Callback Timeout' on page 380), starting from when the E9-1-1 call, established with the PSAP, terminates. After this time expires, the table entry with its ELIN is disregarded and no longer used (for PSAP callback). Therefore, table entries of only the most recently terminated E9-1-1 callers are considered in the ELIN table.

The maximum entries in the ELIN table depend on the AudioCodes ELIN Gateway deployed in the Lync Server 2010 environment:

- **Mediant 1000 Series and Mediant 2000:** 100 entries
- **Mediant 3000:** 300 entries

4. The ELIN Gateway uses the ELIN number as the E9-1-1 calling number and sends it in the ISDN Setup message (as an ANI / Calling Party Number) to the PSTN.

An example of a SIP INVITE message received from an E9-1-1 caller is shown below. The SIP *Content-Type* header indicating the PIDF-LO, and the NAM field listing the ELINs are shown in **bold** typeface.

#### 30.11.4.3.2 Pre-empting Existing Calls for E9-1-1 Calls

If the ELIN Gateway receives an E9-1-1 call from the IP network and there are unavailable channels (for example, all busy), the ELIN Gateway immediately terminates one of the non-E9-1-1 calls (arbitrary) and accepts the E9-1-1 call on the freed channel.

The preemption is done only on a channel pertaining to the same Trunk Group for which the E9-1-1 call was initially destined. For example, if an E9-1-1 call is destined for Trunk Group #2 and all the channels belonging to this group are busy, the ELIN Gateway terminates one of the calls in this group to free a channel for accepting the E9-1-1 call.

This feature is initiated only if the received SIP INVITE message contains a *Priority* header set to "emergency", as shown below:

```
PRIORITY: emergency
```

#### 30.11.4.3.3 PSAP Callback to Lync 2010 Clients for Dropped E9-1-1 Calls

As the E9-1-1 service automatically provides all the contact information of the E9-1-1 caller to the PSAP, the PSAP operator can call back the E9-1-1 caller. This is especially useful in cases where the caller disconnects prematurely. However, as the Enterprise sends ELINs to the PSAP for E9-1-1 calls, a callback can only reach the original E9-1-1 caller using the ELIN Gateway to translate the ELIN number back into the E9-1-1 caller's extension number.

In the ELIN table of the ELIN Gateway, the temporarily stored *From* header value of the SIP INVITE message originally received from the E9-1-1 caller is used for PSAP callback. When the PSAP makes a callback to the E9-1-1 caller, the ELIN Gateway translates the called number (i.e., ELIN) received from the PSAP to the corresponding E9-1-1 caller's extension number as matched in the ELIN table.

The handling of PSAP callbacks by the ELIN Gateway is as follows:

1. When the ELIN Gateway receives any call from the PSTN, it searches the ELIN table for an ELIN that corresponds to the received Called Party Number in the incoming PSTN call.
2. If a match is found in the ELIN table, it routes the call to the Mediation Server by sending a SIP INVITE, where the values of the *To* and *Request-URI* are taken from the value of the original *From* header that is stored in the ELIN table (in the **Call From** column).
3. The ELIN Gateway updates the Time in the ELIN table. (The Count is not affected).

The PSAP callback can be done only within a user-defined timeout (see 'Configuring the E9-1-1 Callback Timeout' on page 380) started from after the original E9-1-1 call established with the PSAP is terminated. After this time expires, the table entry with its ELIN is disregarded and no longer used (for PSAP callback). Therefore, table entries of only the most recently terminated

E9-1-1 callers are considered in the ELIN table. If the PSAP callback is done after this timeout expires, the ELIN Gateway is unable to route the call to the E9-1-1 caller and instead, either sends it as a regular call or most likely, rejects it if there are no matching routing rules. However, if another E9-1-1 caller has subsequently been processed with the same ELIN number, then the PSAP callback is routed to this new E9-1-1 caller.

In scenarios where the same ELIN number is being used by multiple E9-1-1 callers, upon receipt of a PSAP callback, the ELIN Gateway sends the call to the most recent E9-1-1 caller. For example, if the ELIN number "4257275678" is being used by three E9-1-1 callers, as shown in the table below, then when a PSAP callback is received, the ELIN Gateway sends it to the E9-1-1 caller with phone number "4258359555".

**Choosing Caller of ELIN**

| ELIN       | Time  | Call From         |
|------------|-------|-------------------|
| 4257275678 | 11:00 | 4258359333        |
| 4257275678 | 11:01 | 4258359444        |
| 4257275678 | 11:03 | <b>4258359555</b> |

#### 30.11.4.3.4 Selecting ELIN for Multiple Calls within Same ERL

The ELIN Gateway supports the receipt of up to five ELIN numbers in the XML message of each incoming SIP INVITE message. As discussed in the preceding sections, the ELIN Gateway sends the ELIN number as the E9-1-1 calling number to the PSTN-based emergency provider. If the XML message contains more than one ELIN number, the ELIN Gateway chooses the ELIN according to the following logic:

- If the first ELIN in the list is not being used by other active calls, it chooses this ELIN.
- If the first ELIN in the list is being used by another active call, the ELIN Gateway skips to the next ELIN in the list, and so on until it finds an ELIN that is not being used and sends this ELIN.
- If all the ELINs in the list are in use by active calls, the ELIN Gateway selects the ELIN number as follows:

1. The ELIN with the lowest count (i.e., lowest number of active calls currently using this ELIN).
2. If the count between ELINs is identical, the ELIN Gateway selects the ELIN with the greatest amount of time passed since the original E9-1-1 call using this ELIN was terminated with the PSAP. For example, if E9-1-1 caller using ELIN 4257275678 was terminated at **11:01** and E9-1-1 caller using ELIN 4257275670 was terminated at **11:03**, then the ELIN Gateway selects ELIN 4257275678.

In this scenario, multiple E9-1-1 calls will be sent with the same ELIN.

### 30.11.4.3.5 Location Based Emergency Routing

The device supports location-based emergency routing (E-911) in Lync Server 2010. This ensures that E-911 calls from remote branches are routed to emergency providers that are relevant to the geographical area in which the remote branch callers are physically located.

To support this, the device enables routing and SIP header / number manipulation of such emergency calls based on the geographical location of the caller. The device manipulates the received destination number (i.e., 911) from the remote branch callers, into a destination number of an emergency provider that is relevant to the geographical area in which the remote branch office is located.

### 30.11.4.4 Configuring AudioCodes ELIN Gateway

This section describes E9-1-1 configuration of the AudioCodes ELIN Gateway deployed in the Lync Server 2010 environment.

#### 30.11.4.4.1 Enabling the E9-1-1 Feature

By default, the E9-1-1 feature in the ELIN Gateway for Lync Server 2010 is disabled. To enable it, the following *ini* file parameter setting must be done:

```
E911Gateway = 1
```

#### 30.11.4.4.2 Configuring the E9-1-1 Callback Timeout

The PSAP can use the ELIN to call back the E9-1-1 caller within a user-defined time interval (in minutes) from when the initial call established with the PSAP has been terminated. By default, an ELIN can be used for PSAP callback within 30 minutes after the call is terminated. You can change this interval, by using the following *ini* file parameter:

```
E911CallbackTimeout = <time value> ; where <time value> can be any value from 0 through 60
```

#### 30.11.4.4.3 Configuring the SIP Release Cause Code for Failed E9-1-1 Calls

When a Lync 2010 client makes an emergency call, the call is routed through the Microsoft Mediation Server to the ELIN Gateway, which sends it on to the PSTN. In some scenarios, the call may not be established due to either the PSTN (for example, the destination is busy or not found) or ELIN Gateway (for example, lack of resources or an internal error). In such a scenario, the Mediation Server requires that the ELIN Gateway "reject" the call with the SIP release cause code 503 "Service Unavailable" instead of the designated release call. Such a release cause code enables the Mediation Server to issue a failover to another entity (for example, another ELIN Gateway), instead of retrying the call or returning the release call to the user.

To support this requirement, the ELIN Gateway can be configured to send the 503 "Service Unavailable" release cause code instead of SIP 4xx if an emergency call cannot be established. To enable this support, the following *ini* file parameter setting must be done:

**Note:** This can also be configured using the *ini* file parameter, EmergencySpecialReleaseCause.

➤ **To enable SIP response 503 upon failed E911:**

1. Open the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**).
2. From the 'Emergency Special Release Cause' drop-down list, select **Enable**.

#### 30.11.4.4.4 Configuring Location-Based Emergency Routing

The device identifies callers by their ELIN numbers contained in the PIDF-LO XML body of the received SIP INVITE message. To configure the manipulation rule for location-based emergency routing, the ELIN number is used as the source prefix in the Destination Phone Number Manipulation Table for Tel -> IP Calls table. To identify this source prefix as an E-911 ELIN number, the "ELIN" string is added in front of the source prefix number, for example, "ELIN1234567890". For example, assume an E-9-1-1 call is received for destination 911@company.com and the ELIN number is 1234567890; to create the new destination as 15509115000@company.com, the destination number is manipulated using the manipulation table by adding prefix 1550 and suffix 5000.

➤ **To configure location-based emergency routing:**

1. Enable location-based emergency routing, by loading an ini file to the device with the following parameter setting:  

```
E911Gateway = 2
```
2. In the Destination Phone Number Manipulation Table for Tel -> IP Calls table (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** > **Dest Number Tel->IP**), configure the following fields:
  - Under the **Rule** tab:
    - ◆ 'Source Prefix': ELIN<ELIN source number>
  - Under the **Action** tab:
    - ◆ Configure the manipulation action as required

#### 30.11.4.4.5 Viewing the ELIN Table

You can view the ELIN table of the ELIN Gateway. The method depends on the type of device:

- Using the following CLI command:

```
show voip gw e911
ELIN Time Count Index Call From

4257275678 22:11:52 0 2 4258359333
4257275999 22:11:57 0 3 4258359444
4257275615 22:12:03 0 0 4258359555
4257275616 22:11:45 0 1 4258359777
----- Current Time: 22:12:40
```

- Using Syslog, by invoking the following Web command shell:

```
SIP / Gateway / E911Dump
```

## 30.12 Multilevel Precedence and Preemption

The device supports Multilevel Precedence and Preemption (MLPP) service. MLPP is a call priority scheme, which does the following:

- Assigns a precedence level (priority level) to specific phone calls or messages.
- Allows higher priority calls (*precedence call*) and messages to preempt lower priority calls and messages (i.e., terminates existing lower priority calls) that are recognized within a user-defined domain (*MLPP domain ID*). The domain specifies the collection of devices and resources that are associated with an MLPP subscriber. When an MLPP subscriber that belongs to a particular domain places a precedence call to another MLPP subscriber that belongs to the same domain, MLPP service can preempt the existing call that the called MLPP subscriber is on for a higher-precedence call. MLPP service availability does not apply across different domains.

MLPP is typically used in the military where, for example, high-ranking personnel can preempt active calls during network stress scenarios such as a national emergency or degraded network situations.

MLPP can be enabled for all calls, using the global parameter, `CallPriorityMode`, or for specific calls using the Tel Profile parameter, `CallPriorityMode`.

### Notes:

- For Trunk Groups configured with call preemption, all must be configured to MLPP [1] or all configured to Emergency [2]. In other words, you cannot set some trunks to [1] and some to [2].
- The global parameter must be set to the same value as that of the Tel Profile parameter; otherwise, the Tel Profile parameter is not applied.
- If you configure call preemption using the global parameter and a new Tel Profile is subsequently added, the `TelProfile_CallPriorityMode` parameter automatically acquires the same setting as well.

The Resource Priority value in the Resource-Priority SIP header can be any one of those listed in the table below. A default MLPP call Precedence Level (configured by the `SIPDefaultCallPriority` parameter) is used if the incoming SIP INVITE or PRI Setup message contains an invalid priority or Precedence Level value respectively. For each MLPP call priority level, the Multiple Differentiated Services Code Points (DSCP) can be set to a value from 0 to 63.

**MLPP Call Priority Levels (Precedence) and DSCP Configuration Parameters**

| MLPP Precedence Level | Precedence Level in Resource-Priority SIP Header | DSCP Configuration Parameter |
|-----------------------|--------------------------------------------------|------------------------------|
| 0 (lowest)            | routine                                          | MLPPRoutineRTPDSCP           |
| 2                     | priority                                         | MLPPPriorityRTPDSCP          |
| 4                     | immediate                                        | MLPPImmediateRTPDSCP         |
| 6                     | flash                                            | MLPPFlashRTPDSCP             |
| 8                     | flash-override                                   | MLPPFlashOverRTPDSCP         |
| 9 (highest)           | flash-override-override                          | MLPPFlashOverOverRTPDSCP     |

The device automatically interworks the network identity digits (NI) in the ISDN Q.931 Precedence Information Element (IE) to the network domain subfield of the INVITE's Resource-Priority header, and vice versa. The SIP Resource-Priority header contains two fields, namespace and priority. The namespace is subdivided into two subfields, network-

domain and precedence-domain. Below is an example of a Resource-Priority header whose network-domain subfield is "uc", r-priority field is "priority" (2), and precedence-domain subfield is "000000":

Resource-Priority: uc-000000.2

The MLPP Q.931 Setup message contains the Precedence IE. The NI digits are presented by four nibbles found in octets 5 and 6. The device checks the NI digits according to the translation table of the Department of Defense (DoD) Unified Capabilities (UC) Requirements (UCR 2008, Changes 3) document, as shown below:

**NI Digits in ISDN Precedence**

| Level IE | Network Domain in SIP Resource-Priority Header |
|----------|------------------------------------------------|
| 0000     | uc                                             |
| 0001     | cuc                                            |
| 0002     | dod                                            |
| 0003     | nato                                           |

**Notes:**

- If the received ISDN message contains NI digits that are not listed in the translation table, the device sets the network-domain to "uc" in the outgoing SIP message.
- If the received SIP message contains a network-domain value that is not listed in the translation table, the device sets the NI digits to "0000" in the outgoing ISDN message.
- If the received ISDN message does not contain a Precedence IE, you can configure the namespace value - dsn (default), dod, drsn, uc, or cuc - in the SIP Resource-Priority header of the outgoing INVITE message. This is done using the MLPPDefaultNamespace parameter. You can also configure up to 32 user-defined namespaces, using the table ini file parameter, ResourcePriorityNetworkDomains. Once defined, you need to set the MLPPDefaultNamespace parameter value to the desired table row index.

By default, the device maps the received Resource-Priority field of the SIP Resource-Priority header to the outgoing ISDN PRI Precedence Level (priority level) field as follows:

- If the network-domain field in the Resource-Priority header is "uc", then the device sets the Precedence Level field in the ISDN PRI Precedence Level IE according to Table 5.3.2.12-4 (Mapping of RPH r-priority Field to PRI Precedence Level Value):

**Mapping of SIP Resource-Priority Header to PRI Precedence Level for MLPP**

| MLPP Precedence Level | PRI Precedence Level | SIP Resource-Priority Header Field |
|-----------------------|----------------------|------------------------------------|
| Routine               | 4                    | 0                                  |
| Priority              | 3                    | 2                                  |
| Immediate             | 2                    | 4                                  |
| Flash                 | 1                    | 6                                  |
| Flash Override        | 0                    | 8                                  |

- If the network-domain field in the Resource-Priority header is any value other than "uc", then the device sets the Precedence Level field to "0 1 0 0" (i.e., "routine").

This can be modified using the EnableIp2TelInterworkingtable field of the ini file parameter, ResourcePriorityNetworkDomains.

#### Notes:

- If required, you can exclude the "resource-priority" tag from the SIP Require header in INVITE messages for Tel-to-IP calls when MLPP priority call handling is used. This is configured using the RPRequired parameter.
- For a complete list of the MLPP parameters, see 'MLPP and Emergency Call Parameters' on page 783.

### 30.12.1 MLPP Preemption Events in SIP Reason Header

The device sends the SIP Reason header (as defined in RFC 4411) to indicate the reason and type of a preemption event. The device sends a SIP BYE or CANCEL request, or SIP 480, 486, 488 response (as appropriate) with a Reason header whose Reason-params can include one of the following preemption cause classes:

- Reason: preemption ;cause=1 ;text="UA Preemption"
- Reason: preemption ;cause=2 ;text="Reserved Resources Preempted"
- Reason: preemption ;cause=3 ;text="Generic Preemption"
- Reason: preemption ;cause=4 ;text="Non-IP Preemption"

This Reason cause code indicates that the session preemption has occurred in a non-IP portion of the infrastructure. The device sends this code in the following scenarios:

- The device performs a network preemption of a busy call (when a high priority call is received), the device sends a SIP BYE or CANCEL request with this Reason cause code.
- The device performs a preemption of a B-channel for a Tel-to-IP outbound call request from the softswitch for which it has not received an answer response (e.g., Connect), and the following sequence of events occurs:
  - a. The device sends a Q.931 DISCONNECT over the ISDN MLPP PRI to the partner switch to preempt the remote end instrument.
  - b. The device sends a 488 (Not Acceptable Here) response with this Reason cause code.

- Reason: preemption; cause=5; text="Network Preemption"

This Reason cause code indicates preempted events in the network. Within the Defense Switched Network (DSN) network, the following SIP request messages and response codes for specific call scenarios have been identified for signaling this preemption cause:

- SIP:BYE - If an active call is being preempted by another call
- CANCEL - If an outgoing call is being preempted by another call
- 480 (Temporarily Unavailable), 486 (User Busy), 488 (Not Acceptable Here) - Due to incoming calls being preempted by another call.

The device receives SIP requests with preemption reason cause=5 in the following cases:

- The softswitch performs a network preemption of an active call - the following sequence of events occurs:
  - a. The softswitch sends the device a SIP BYE request with this Reason cause code.

- b. The device initiates the release procedures for the B-channel associated with the call request and maps the preemption cause to PRI Cause = #8 'Preemption'. This value indicates that the call is being preempted. For PRI, it also indicates that the B-channel is not reserved for reuse.
  - c. The device sends a SIP 200 OK in response to the received BYE, before the SIP end instrument can proceed with the higher precedence call.
- The softswitch performs a network preemption of an outbound call request for the device that has not received a SIP 2xx response - the following sequence of events occur:
  - a. The softswitch sends the device a SIP 488 (Not Acceptable Here) response code with this Reason cause code. The device initiates the release procedures for the B-channel associated with the call request and maps the preemption cause to PRI Cause = #8 'Preemption'.
  - b. The device deactivates any user signaling (e.g., ringback tone) and when the call is terminated, it sends a SIP ACK message to the softswitch.

### 30.12.2 Precedence Ring Tone

You can assign a ring tone that is defined in the CPT file to be played when a precedence call is received from the IP side. This is configured by the `PrecedenceRingingType` parameter. You can configure the duration for which the device plays a preemption tone to the Tel and IP sides if a call is preempted, using the `PreemptionToneDuration` parameter.

Emergency Telecommunications Services (ETS) calls (e.g., E911) can be configured with a higher priority than any MLPP call (default), using the `E911MLPPBehavior` parameter.

### 30.13 Denial of Collect Calls

You can configure the device to reject (disconnect) incoming Tel-to-IP collect calls and to signal this denial to the PSTN. This capability is required, for example, in the Brazilian telecommunication system to deny collect calls. When this feature is enabled upon rejecting the incoming call, the device sends a sequence of signals to the PSTN. This consists of an off-hook, an on-hook after one second, and then an off-hook after two seconds. In other words, this is in effect, a double-answer sequence.

This feature can be enabled for all calls, using the EnableFXODoubleAnswer "global" parameter, or it can be enabled for specific calls, by enabling this feature in a Tel Profile.

### Notes:

- This feature is applicable only to FXO interfaces.
- If automatic dialing is also configured for an FXO port enabled with Denial of Collect Calls, the FXO line does not answer the incoming call (ringing) until a SIP 200 OK is received from the remote destination. When a 200 OK is received, a double answer is sent from the FXO line.
- Ensure that the PSTN side is configured to identify this double-answer signal.

## 30.14 Configuring ISDN Supplementary Services

The ISDN Supp Services Table page allows you to configure supplementary services for Integrated Services Digital Network (ISDN) Basic Rate Interface (BRI) phones connected to the device. This feature enables the device to route IP-to-Tel calls (including voice and fax) to specific BRI ports (channels).

This table allows you to define BRI phone extension numbers per BRI port pertaining to a specific BRI module. Therefore, this offers support for point-to-multipoint configuration of several phone numbers per BRI channel. Up to eight phone numbers can be defined per BRI trunk. For each BRI endpoint, the following optional configurations can also be defined:

- User ID and password - for registering the BRI endpoint to a third-party softswitch for authentication and/or billing. For viewing BRI registration status, see 'Viewing Endpoint Registration Status' on page 596.
- Caller ID name - for displaying the BRI endpoint's caller ID to a dialed destination, if enabled (i.e., "Presentation" is not restricted)
- Caller ID presentation or restriction
- Enable/disable sending caller ID to BRI endpoints

### Notes:

- To use this table for routing of IP-to-Tel calls to specific BRI channels, the Channel Select Mode in the Hunt Group Settings must be set to 'Select Trunk by ISDN Supplementary Services Table' (see 'Configuring Hunt Group Settings' on page 291).
- The ISDN Supp Services table can also be configured using the table ini file parameter, ISDNSuppServ or CLI command, configure voip > gw digitalgw isdn-supp-serv.
- To allow the end-user to hear a dial tone when picking up the BRI phone, it is recommended to set the Progress Indicator in the Setup Ack bit (0x10000=65536). Therefore, the recommended value is 0x10000 + 0x1000 = 65536 + 4096 = 69632 (i.e., set the ISDNInCallsBehavior parameter to 69632).

### ➤ To configure BRI supplementary services:

1. Open the ISDN Supp Services Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Digital Gateway** > **ISDN Supp Services**).

Figure 30-9: ISDN Supp Services Table Page

| Index                   | Phone Number | Module | Port | User ID |
|-------------------------|--------------|--------|------|---------|
| 1 <input type="radio"/> | 4112         | 1      | 3    | mike    |
| 2 <input type="radio"/> |              | 0      | 0    |         |

| User Password | Caller ID | Presentation Restricted | Caller ID Enabled |
|---------------|-----------|-------------------------|-------------------|
| *             | mike      | Allowed                 | Enabled           |
| *             |           | Not Configured          | Not Configured    |

2. Configure the parameters as described in the table below.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.
5. To register the BRI endpoints, click the **Register** button. To unregister the BRI endpoints, click **Unregister**. The registration method for each BRI endpoint is according to the setting of the 'Registration Mode' parameter in the Trunk Group Settings page.

ISDN Supp Services Table Parameters

| Parameter                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Phone Number<br>CLI: phone-number<br><b>[ISDNSuppServ_PhoneNumber]</b>                                    | Defines the telephone extension number for the BRI endpoint.                                                                                                                                                                                                                                                                                                                          |
| Module<br>CLI: module<br><b>[ISDNSuppServ_Module]</b>                                                     | Defines the BRI module number to which the BRI extension pertains.                                                                                                                                                                                                                                                                                                                    |
| Port<br>CLI: port<br><b>[ISDNSuppServ_Port]</b>                                                           | Defines the port number on the BRI module to which the BRI extension is connected.                                                                                                                                                                                                                                                                                                    |
| User ID<br>CLI: user-id<br><b>[ISDNSuppServ_UserId]</b>                                                   | Defines the User ID for registering the BRI endpoint to a third-party softswitch for authentication and/or billing.                                                                                                                                                                                                                                                                   |
| User Password<br>CLI: user-password<br><b>[ISDNSuppServ_UserPassword]</b>                                 | Defines the user password for registering the BRI endpoint to a third-party softswitch for authentication and/or billing.<br><b>Note:</b> For security, the password is displayed as an asterisk (*).                                                                                                                                                                                 |
| Caller ID Number<br>CLI: caller-id-number<br><b>[ISDNSuppServ_CallerID]</b>                               | Defines the caller ID name of the BRI extension (sent to the IP side). The valid value is a string of up to 18 characters.                                                                                                                                                                                                                                                            |
| Presentation Restricted<br>CLI: presentation-restricted<br><b>[ISDNSuppServ_IsPresentationRestricted]</b> | Determines whether the BRI extension sends its Caller ID information to the IP when a call is made. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Allowed = The device sends the string defined in the 'Caller ID' field when this BRI extension makes a Tel-to-IP call.</li> <li>▪ <b>[1]</b> Restricted = The string defined in the 'Caller ID' field is not sent.</li> </ul> |
| Caller ID Enabled<br>CLI: caller-id-enable<br><b>[ISDNSuppServ_IsCallerIDEnabled]</b>                     | Enables the receipt of Caller ID. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disabled = The device does not send Caller ID information to the BRI extension.</li> <li>▪ <b>[1]</b> Enabled = The device sends Caller ID information to the BRI extension</li> </ul>                                                                                                          |

## 30.15 Advice of Charge Services for Euro ISDN

Advice of charge (AOC) is a pre-billing function that tasks the rating engine with calculating the cost of using a service and relaying that information back to the customer thus, allowing users to obtain charging information for all calls during the call (AOC-D) or at the end of the call (AOC-E), or both.

The AOC-D and AOC-E messages are part of the Facility Information Element (IE) message:

- AOC-D message—ISDN Advice of Charge information sent during a call. The message is sent periodically to subscribers of AOC during-call services.
- AOC-E message—ISDN Advice of Charge information sent at the end of a call.

The device supports the sending of AoC messages for Tel-to-IP calls, providing billing applications with the number of charged units. This feature can typically be implemented in the hotel industry, where external calls made by guests can be billed accurately. In such a setup, the device is connected on one side to a PBX through an E1 line (Euro ISDN), and on the other side to a SIP trunk provided by an ITSP. When a call is made by a guest, the device first sends an AOC-D Facility message to the PBX indicating the connection charge unit, and then sends subsequent AOC-D messages every user-defined interval to indicate the charge unit during the call. When the call ends, the device sends an AOC-E Facility message to the PBX indicating the total number of charged units.

To configure AoC:

1. Ensure that the PSTN protocol for the E1 trunk line is Euro ISDN and set to network side.
2. Ensure that the date and time of the device is correct. For accuracy, it is recommended to use an NTP server to obtain the date and time.
3. Enable the AoC service, using the EnableAOC parameter.
4. Configure charge codes in the Charge Code table (ChargeCode) - see [Configuring Charge Codes](#) on page 393. Note that in the Charge Code table, the table fields are as follows:
  - 'End Time' - time at which this charge code ends
  - 'Pulse Interval' - time between every sent AOC-D Facility message
  - 'Pulses On Answer' - number of charging units in first generated AOC-D Facility message
5. Assign the charge code index to the desired routing rule in the Outbound IP Routing table (see '[Configuring Outbound IP Routing Table](#)' on page 321).

## 30.16 Configuring Voice Mail

The Voice Mail Settings page allows you to configure the voice mail parameters. For a description of these parameters, see 'Configuration Parameters Reference' on page 655.

### Notes:

- The Voice Mail Settings page is available only for FXO and CAS interfaces.
- For more information on configuring voice mail, refer to the *CPE Configuration Guide for Voice Mail User's Manual*.

### ➤ To configure the Voice Mail parameters:

1. Open the Voice Mail Settings page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Advanced Applications** > **Voice Mail Settings**).

|                                                    |                      |   |
|----------------------------------------------------|----------------------|---|
| Line Transfer Mode                                 | None                 | ▼ |
| Voice Mail Interface                               | NONE                 | ▼ |
| ▼ Digit Patterns                                   |                      |   |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## Reader's Notes

## 31 Analog Gateway

This section describes configuration of analog settings.

**Note:** The Analog Gateway submenu appears only if the device is installed with an FXS or FXO module.

### 31.1 Configuring Keypad Features

The Keypad Features page enables you to activate and deactivate the following features directly from the connected telephone's keypad:

- Call Forward
- Caller ID Restriction
- Hotline for automatic dialing
- Call Transfer
- Call Waiting
- Rejection of Anonymous Calls

**Notes:**

- The Keypad Features page is available only for FXS interfaces.
- The method used by the device to collect dialed numbers is identical to the method used during a regular call (i.e., max digits, interdigit timeout, digit map, etc.).
- The activation of each feature remains in effect until it is deactivated (i.e., not deactivated after a call).
- For a description of the keypad parameters, see 'Telephone Keypad Sequence Parameters' on page [839](#).

➤ **To configure the keypad features**

1. Open the Keypad Features page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Keypad Features**).

**Figure 31-1: Keypad Features Page**

|                         |                      |
|-------------------------|----------------------|
| ▼ Forward               |                      |
| Unconditional           | <input type="text"/> |
| No Answer               | <input type="text"/> |
| On Busy                 | <input type="text"/> |
| On Busy or No Answer    | <input type="text"/> |
| Do Not Disturb          | <input type="text"/> |
| Deactivate              | <input type="text"/> |
| ▼ Caller ID Restriction |                      |
| Activate                | <input type="text"/> |
| Deactivate              | <input type="text"/> |
| ▼ Hotline               |                      |
| Activate                | <input type="text"/> |
| Deactivate              | <input type="text"/> |
| ▼ Transfer              |                      |
| Blind                   | <input type="text"/> |
| ▼ Call Waiting          |                      |
| Activate                | <input type="text"/> |
| Deactivate              | <input type="text"/> |
| ▼ Reject Anonymous Call |                      |
| Activate                | <input type="text"/> |
| Deactivate              | <input type="text"/> |

2. Configure the keypad features as required.
3. Click **Submit** to apply your changes.

## 31.2 Configuring Metering Tones

The FXS interfaces can generate 12/16 KHz metering pulses toward the Tel side (e.g., for connection to a pay phone or private meter). Tariff pulse rate is determined according to the device's Charge Codes table. This capability enables users to define different tariffs according to the source/destination numbers and the time-of-day. The tariff rate includes the time interval between the generated pulses and the number of pulses generated on answer.

**Notes:**

- The Metering Tones page is available only for FXS interfaces.
- Charge Code rules can be assigned to routing rules in the Outbound IP Routing Table (see 'Configuring Outbound IP Routing Table' on page 321). When a new call is established, the Outbound IP Routing Table is searched for the destination IP address. Once a route is located, the Charge Code (configured for that route) is used to associate the route with an entry in the Charge Codes table.

➤ **To configure Metering tones:**

1. Open the Metering Tones page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Metering Tones**).

**Figure 31-2: Metering Tones Page**

|                         |         |
|-------------------------|---------|
| Generate Metering Tones | Disable |
| Metering Tone Type      | 16 KHz  |
| Charge Codes Table      |         |

2. Configure the Metering tones parameters as required. For a description of the parameters appearing on this page, see 'Configuration Parameters Reference' on page 655.
3. Click **Submit** to apply your changes.
4. To save the changes to the flash memory, see 'Saving Configuration' on page 532.

If you set the 'Generate Metering Tones' parameter to **Internal Table**, access the Charge Codes Table page by clicking the **Charge Codes Table** button. For more information on configuring the Charge Codes table, see 'Configuring Charge Codes' on page 393.

## 31.3 Configuring Charge Codes

The Charge Codes table is used to configure the metering tones (and their time interval) that the FXS interfaces generate to the Tel side. To associate a charge code to an outgoing Tel-to-IP call, use the Outbound IP Routing Table.

You can configure up to 25 different charge codes, where each table row represents a charge code. Each charge code can include up to four different time periods in a day (24 hours). The device selects the time period by comparing the device's current time to the end time of each time period of the selected Charge Code. The device generates the Number of Pulses on Answer once the call is connected and from that point on, it generates a pulse each Pulse Interval. If a call starts at a certain time period and crosses to the next, the information of the next time period is used.

**Notes:**

- The Charge Codes Table page is available only for FXS interfaces.
- The Charge Codes table can also be used to configure Advice of Charge (AoC) services for Euro ISDN trunks (see Advice of Charge Services for Euro ISDN on page 388).
- The Charge Codes table can also be configured using the table ini file parameter, ChargeCode or CLI command, configure voip > gw analoggw charge-code.

➤ **To configure the Charge Codes:**

1. Open the Charge Codes Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Analog Gateway** submenu > **Charge Codes**). Alternatively, you can access this page from the Metering Tones page (see 'Configuring Metering Tones' on page 392).

**Figure 31-3: Charge Codes Table Page**

| Table Index |               |                |                  |               |                |                  |               |                |                  |               |                |                  | 0-4 |
|-------------|---------------|----------------|------------------|---------------|----------------|------------------|---------------|----------------|------------------|---------------|----------------|------------------|-----|
| Index       | Time Period 1 |                |                  | Time Period 2 |                |                  | Time Period 3 |                |                  | Time Period 4 |                |                  |     |
|             | End Time      | Pulse Interval | Pulses On Answer | End Time      | Pulse Interval | Pulses On Answer | End Time      | Pulse Interval | Pulses On Answer | End Time      | Pulse Interval | Pulses On Answer |     |
| 0           | 07            | 30             | 1                | 14            | 20             | 2                | 20            | 15             | 1                | 00            | 60             | 1                |     |
| 1           | 05            | 60             | 1                | 14            | 20             | 1                | 00            | 60             | 1                |               |                |                  |     |
| 2           | 00            | 60             | 1                |               |                |                  |               |                |                  |               |                |                  |     |
| 3           |               |                |                  |               |                |                  |               |                |                  |               |                |                  |     |
| 4           |               |                |                  |               |                |                  |               |                |                  |               |                |                  |     |

2. Configured the charge codes, as required. For a description of the parameters, see the table below.
3. Click **Submit** to apply your changes.
4. To save the changes to the flash memory, see 'Saving Configuration' on page 532.

**Charge Codes Table Parameter Description**

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                           |
|-------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| End Time<br>CLI: end-time-<1-4><br>[ChargeCode_EndTime<1-4>]                        | Defines the end of the time period in a 24 hour format, <i>hh</i> . For example, "04" denotes 4 A.M.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The first time period always starts at midnight (00).</li> <li>▪ It is mandatory that the last time period of each rule end at midnight (00). This prevents undefined time frames in a day.</li> </ul> |
| Pulse Interval<br>CLI: pulse-interval-<1-4><br>[ChargeCode_PulseInterval<1-4>]      | Defines the time interval between pulses (in tenths of a second).                                                                                                                                                                                                                                                                                                     |
| Pulses On Answer<br>CLI: pulses-on-answer-<1-4><br>[ChargeCode_PulsesOnAnswer<1-4>] | Defines the number of pulses sent on answer.                                                                                                                                                                                                                                                                                                                          |

## 31.4 Configuring FXO Settings

The FXO Settings page allows you to configure the device's specific FXO parameters. For a description of these parameters, see 'Configuration Parameters Reference' on page 655.

**Note:** The FXO Settings page is available only for FXO interfaces.

➤ **To configure the FXO parameters:**

1. Open the FXO Settings page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **FXO Settings**).

**Figure 31-4: FXO Settings Page**

|                                              |            |   |
|----------------------------------------------|------------|---|
| Dialing Mode                                 | Two Stages | ▼ |
| Waiting for Dial Tone                        | No         | ▼ |
| Time to Wait before Dialing [msec]           | 1000       |   |
| Ring Detection Timeout [sec]                 | 8          |   |
| Reorder Tone Duration [sec]                  | 255        |   |
| Answer Supervision                           | No         | ▼ |
| Rings before Detecting Caller ID             | 1          | ▼ |
| Send Metering Message to IP                  | No         | ▼ |
| Disconnect Call on Busy Tone Detection (CAS) | Enable     | ▼ |
| Disconnect On Dial Tone                      | Disable    | ▼ |
| Guard Time Between Calls                     | 1          |   |
| FXO Double Answer                            | Disable    | ▼ |
| FXO AutoDial Play BusyTone                   | Disable    | ▼ |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 31.5 Configuring Authentication

The Authentication page [defines](#) a user name and password for authenticating each device port. Authentication is typically used for FXS interfaces, but can also be used for FXO interfaces.

**Notes:**

- For configuring whether authentication is done per port or for the entire device, use the parameter AuthenticationMode.
- If authentication is configured for the entire device, the configuration in this table is ignored.
- If the user name or password is not configured in this table, the port's phone number (configured in the Trunk Group Table) and global password (configured by the global parameter, Password) are used instead for authentication of the port.
- After you click **Submit**, the password is displayed as an asterisk (\*).
- The Authentication table can also be configured using the table ini file parameter, Authentication (see 'Configuration Parameters Reference' on page 655) or CLI command, configure voip > gw analoggw authentication.

- **To configure authentication credentials per port:**
- Set the parameter 'Registration Mode' (AuthenticationMode) to **Per Endpoint**. This can be configured in any of the following pages:
    - Proxy & Registration page (see 'Configuring Proxy and Registration Parameters' on page 222).
    - Trunk Group Settings page (see 'Configuring Hunt Group Settings' on page 291), where registration method is configured per Trunk Group.
  - Open the Authentication page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Authentication**).

**Figure 31-5: Authentication Page**

| Gateway Port        | User Name                          | Password                                   |
|---------------------|------------------------------------|--------------------------------------------|
| Module 1 Port 1 FXS | <input type="text" value="user1"/> | <input type="password" value="skkkskksk"/> |
| Module 1 Port 2 FXS | <input type="text" value="user2"/> | <input type="password" value="skkkskksk"/> |
| Module 2 Port 1 FXO | <input type="text"/>               | <input type="password"/>                   |
| Module 2 Port 2 FXO | <input type="text"/>               | <input type="password"/>                   |
| Module 2 Port 3 FXO | <input type="text"/>               | <input type="password"/>                   |
| Module 2 Port 4 FXO | <input type="text"/>               | <input type="password"/>                   |

- Configure port authentication credentials as required. For a description of the parameters, see the table below.
- Click **Submit** to apply your changes.

**Authentication Table Parameter Description**

| Parameter                                                  | Description                                                                                                                  |
|------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------|
| CLI: port<br>[Authentication_Port]                         | Defines the port to authenticate.<br><b>Note:</b> This parameter is not relevant to the Web interface.                       |
| CLI: port-type<br>[Authentication_Module]                  | Defines the module number on which the port is located.<br><b>Note:</b> This parameter is not relevant to the Web interface. |
| User Name<br>CLI: user-name<br>[Authentication_UserId]     | Defines the user name used for authenticating the port.                                                                      |
| Password<br>CLI: password<br>[Authentication_UserPassword] | Defines the password used for authenticating the port.                                                                       |

## 31.6 Configuring Automatic Dialing

The Automatic Dialing page allows you to define a telephone number that is automatically dialed when an FXS or FXO port goes off-hook. The dialing can be done immediately upon off-hook, or after a user-defined interval after off-hook referred to as *Hotline* dialing.

**Note:** The Automatic Dialing can also be configured using the table ini file parameter, TargetOfChannel or CLI command, configure voip > gw analoggw automatic-dialing.

➤ **To configure automatic dialing per port:**

1. Open the Automatic Dialing page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Analog Gateway** > **Automatic Dialing**).

| Gateway Port        | Destination Phone Number | Auto Dial Status | Hotline Dial Tone Duration [sec] |
|---------------------|--------------------------|------------------|----------------------------------|
| Module 3 Port 1 FXS | 911                      | Hotline ▼        | 15                               |
| Module 3 Port 2 FXS | 200                      | Enable ▼         | 0                                |
| Module 3 Port 3 FXS |                          | Enable ▼         | 0                                |
| Module 3 Port 4 FXS |                          | Enable ▼         | 0                                |

The first table entry in the figure above enables Hotline automatic dialing for an FXS port, whereby if the port is off-hooked for over 15 seconds, the device automatically dials 911.

2. Configure automatic dialing per port, as required. See the table below for parameter descriptions.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**Automatic Dialing Table Parameter Description**

| Parameter                                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gateway Port<br>[TargetOfChannel_Module]<br>CLI: port<br>[TargetOfChannel_Port] | Lists the FXS or FXO port (per module) for which you want to configure automatic dialing.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Destination Phone Number<br>CLI: /dst-number<br>[TargetOfChannel_Destination]   | Defines the destination telephone number to automatically dial.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Auto Dial Status<br>CLI: auto-dial-status<br>[TargetOfChannel_Type]             | <p>Enables automatic dialing.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable = Automatic dialing for the specific port is disabled.</li> <li>▪ <b>[1]</b> Enable = (Default) Automatic dialing is enabled and the phone number configured in the 'Destination Phone Number' field is automatically dialed if the following occurs: <ul style="list-style-type: none"> <li>✓ FXS interfaces: The phone is off-hooked</li> <li>✓ FXO interfaces: A ring signal (from a PBX/PSTN switch) is detected on the FXO line. The device initiates a call to the destination without seizing the FXO line. The line is seized only after the SIP call is answered.</li> </ul> </li> <li>▪ <b>[2]</b> Hotline = Automatic dialing is done after an interval configured by the 'Hotline Dial Tone Duration' parameter: <ul style="list-style-type: none"> <li>✓ FXS interfaces: When the phone is off-hooked and no digit is dialed within a user-defined time, the configured destination number is automatically dialed.</li> <li>✓ FXO interfaces: If a ring signal is detected, the device seizes the FXO line, plays a dial tone, and then waits for DTMF digits. If no digits are detected within a user-defined time, the configured destination number is automatically dialed by sending a SIP INVITE message with this number.</li> </ul> </li> </ul> |

| Parameter                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hotline Dial Tone Duration<br>CLI: hotline-dia-ltone-duration<br>[TargetOfChannel_HotLineToneDuration] | Defines the duration (in seconds) after which the destination phone number is automatically dialed. This is applicable only if the port has been configured for Hotline (i.e., 'Auto Dial Status' is set to <b>Hotline</b> ).<br>The valid value is 0 to 60. The default is 16.<br><b>Note:</b> You can configure this Hotline interval for all ports, using the global parameter, HotLineToneDuration. |

## 31.7 Configuring Caller Display Information

The Caller Display Information table allows you to define a caller identification string (Caller ID) for FXS and FXO ports and enable the device to send the Caller ID to the IP when a call is made. The called party can use this information for caller identification.

The device sends the configured caller ID in the outgoing INVITE message's From header. For information on Caller ID restriction according to destination/source prefixes, see 'Configuring Source/Destination Number Manipulation' on page 297.

### Notes:

- If an FXS port receives 'Private' or 'Anonymous' strings in the SIP From header, the calling name or number is not sent to the Caller ID display.
- If Caller ID is detected on an FXO line (EnableCallerID = 1), it is used instead of the Caller ID configured in this table.
- If you set the 'Caller ID/Name' parameter to the strings "Private" or "Anonymous", Caller ID is restricted and the settings of the 'Presentation' parameter is ignored.
- The Caller Display Information table can also be configured using the table ini file parameter, CallerDisplayInfo or CLI command, configure voip > gw analoggw caller-display-info.

### ➤ To configure Caller Display:

1. Open the Caller Display Information page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Caller Display Information**).

| Gateway Port        | Caller ID/Name | Presentation |
|---------------------|----------------|--------------|
| Module 1 Port 1 FXS | Private        | Restricted ▼ |
| Module 1 Port 2 FXS | Susan C.       | Restricted ▼ |
| Module 2 Port 1 FXO | Lee P.         | Allowed ▼    |
| Module 2 Port 2 FXO | Ronaldo        | Allowed ▼    |
| Module 2 Port 3 FXO |                | Allowed ▼    |
| Module 2 Port 4 FXO |                | Allowed ▼    |

2. Configure the table as required. For a description of the parameters, see the table below.
3. Click **Submit** to apply your changes.

Caller Display Parameter Description

| Parameter                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Gateway Port<br>CLI: port<br>[CallerDisplayInfo_Port]<br>[CallerDisplayInfo_Module] | Displays the port per module.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Caller ID/Name<br>CLI: display-string<br>[CallerDisplayInfo_DisplayString]          | Defines the Caller ID string.<br>The valid value is a string of up to 18 characters.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Presentation<br>CLI: presentation<br>[CallerDisplayInfo_IsCidRestricted]            | <p>Enables the sending of the caller ID string.</p> <ul style="list-style-type: none"> <li>[0] Allowed = The caller ID string is sent when a Tel-to-IP call is made.</li> <li>[1] Restricted = The caller ID string is not sent.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>This parameter is overridden by the 'Presentation' parameter in the Source Number Manipulation table (see 'Configuring Source/Destination Number Manipulation' on page 297).</li> <li>If this parameter is set to <b>Restricted</b>, the Caller ID is sent to the remote side using only the SIP P-Asserted-Identity and P-Preferred-Identity headers (AssertedIdMode).</li> </ul> |

## 31.8 Configuring Call Forward

The Call Forwarding table allows you to configure call forwarding per port for IP-to-Tel calls. This redirects the call (using SIP 302 response) initially destined to a specific device Tel port, to a different device port or to an IP destination.

### Notes:

- To enable call forwarding, set the 'Enable Call Forward' parameter to **Enable**. This is done in the Supplementary Services page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **DTMF and Supplementary** > **Supplementary Services**).
- The Call Forward table can also be configured using the table ini file parameter, FwdInfo or CLI command, configure voip > gw analoggw call-forward.

➤ **To configure Call Forward per port:**

1. Open the Call Forward Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Call Forward**).

| Gateway Port        | Forward Type  | Forward to Phone Number | Time for No Reply Forward |
|---------------------|---------------|-------------------------|---------------------------|
| Module 1 Port 1 FXS | On busy       | 201                     | 30                        |
| Module 1 Port 2 FXS | Unconditional | 202@10.2.1.1            | 30                        |
| Module 2 Port 1 FXO | No Answer     | 203                     | 30                        |
| Module 2 Port 2 FXO | Deactivate    |                         | 30                        |
| Module 2 Port 3 FXO | Deactivate    |                         | 30                        |
| Module 2 Port 4 FXO | Deactivate    |                         | 30                        |

2. Configure the table as required. For descriptions of the parameters, see the table below.
3. Click **Submit** to apply your changes.

### Call Forward Table Parameter Description

| Parameter                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Time for No Reply Forward<br>CLI: no-reply-time<br>[FwdInfo_NoReplyTime] | <p>If you have set the 'Forward Type' for this port to <b>No Answer</b>, then configure the number of seconds the device waits before forwarding the call to the specified phone number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## 31.9 Configuring Caller ID Permissions

The Caller ID Permissions table allows you to enable per port, Caller ID generation for FXS interfaces and Caller ID detection for FXO interfaces.

### Notes:

- If Caller ID permissions is not configured for a port in this table, its Caller ID generation / detection is determined according to the global parameter, 'Enable Call ID' in the Supplementary Services page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **DTMF and Supplementary** > **Supplementary Services**).
- The Caller ID Permissions table can also be configured using the table ini file parameter, EnableCallerID or the CLI command, configure voip > gw analoggw enable-caller-id.

### ➤ To configure Caller ID permissions per port:

1. Open the Caller ID Permissions page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Caller ID Permissions**).

| Gateway Port |        |     |  | Caller ID |
|--------------|--------|-----|--|-----------|
| Module 1     | Port 1 | FXS |  | Enable ▼  |
| Module 1     | Port 2 | FXS |  | Disable ▼ |
| Module 2     | Port 1 | FXO |  | ▼         |
| Module 2     | Port 2 | FXO |  | ▼         |
| Module 2     | Port 3 | FXO |  | ▼         |
| Module 2     | Port 4 | FXO |  | ▼         |

2. Configure the table as required. For a description of the parameter, see the table below.
3. Click **Submit** to apply your changes.

**Caller ID Permissions Table Parameter Description**

| Parameter                                                 | Description                                                                                                                                                         |
|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Caller ID<br>CLI: caller-id<br>[EnableCallerId_IsEnabled] | Enables Caller ID generation (FXS) or detection (FXO) per port. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable</li> <li>▪ <b>[1]</b> Enable</li> </ul> |

## 31.10 Configuring Call Waiting

The Call Waiting table allows you to enable or disable call waiting per FXS port.

### Notes:

- This page is applicable only to FXS interfaces.
- You can enable or disable call waiting for all the device's ports using the global parameter, 'Enable Call Waiting' in the Supplementary Services page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **DTMF and Supplementary** > **Supplementary Services**).
- The CPT file installed on the device must include a 'call waiting Ringback' tone (caller side) and a 'call waiting' tone (called side, FXS interfaces only).
- The EnableHold parameter must be enabled on both the calling and the called sides.
- For additional call waiting configuration, see the following parameters: FirstCallWaitingToneID (in the CPT file), TimeBeforeWaitingIndication, WaitingBeepDuration, TimeBetweenWaitingIndications, and NumberOfWaitingIndications.
- The Call Waiting table can also be configured using the table ini file parameter, CallWaitingPerPort or CLI command, configure voip > gw analoggw call-waiting.

### ➤ To enable call waiting per port:

1. Open the Call Waiting page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Call Waiting**).

| Gateway Port        | Call Waiting Configuration              |
|---------------------|-----------------------------------------|
| Module 1 Port 1 FXS | Enable <input type="button" value="v"/> |
| Module 1 Port 2 FXS | Enable <input type="button" value="v"/> |
| Module 2 Port 1 FXO | <input type="button" value="v"/>        |
| Module 2 Port 2 FXO | <input type="button" value="v"/>        |
| Module 2 Port 3 FXO | <input type="button" value="v"/>        |
| Module 2 Port 4 FXO | <input type="button" value="v"/>        |

2. Configure the table as required. For a description of the parameter, see the table below.
3. Click **Submit** to apply your changes.

### Call Waiting Table Parameter Description

| Parameter                                                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Call Waiting Configuration<br>CLI: enable-call-waiting<br>[CallWaitingPerPort_IsEnabled] | <p>Enables call waiting for the port.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Disable</li> <li>▪ <b>[1]</b> Enable = Enables call waiting for the port. When the device receives a call on a busy port, it responds with a SIP 182 response (not with a 486 busy). The device plays a call waiting indication signal. When the device detects a hook-flash from the FXS port, the device switches to the waiting call. The device that initiated the</li> </ul> |

| Parameter | Description                                                                                            |
|-----------|--------------------------------------------------------------------------------------------------------|
|           | waiting call plays a call waiting ringback tone to the calling party after a 182 response is received. |

## 31.11 Rejecting Anonymous Calls

You can configure the device to reject anonymous calls received from the IP and destined for a specific FXS port. This can be configured using the ini file parameter, `RejectAnonymousCallPerPort`. If configured, when an FXS interface receives an anonymous call, the device rejects the call and responds with a SIP 433 (Anonymity Disallowed) response. For a description of the parameter see 'Caller ID Parameters' on page 768.

## 31.12 Configuring FXS Distinctive Ringing and Call Waiting Tones per Source/Destination Number

You can configure a distinctive ringing tone and call waiting tone per calling (source) and/or called (destination) number (or prefix) for IP-to-Tel calls. This feature can be configured per FXS endpoint or for a range of FXS endpoints. Therefore, different tones can be played per FXS endpoint depending on the source and/or destination number of the received call. You can also configure multiple entries with different source and/or destination prefixes and tones for the same FXS port.

Typically, the played ring and/or call waiting tone is indicated in the SIP Alert-info header field of the received INVITE message. If this header is not present in the received INVITE, then this feature is used and the tone played is according to the settings in this table.

### Notes:

- This page is applicable only to FXS interfaces.
- The Tone Index table can also be configured using the table ini file parameter, `ToneIndex` or CLI command, `configure voip > gw analoggw tone-index`.

- **To configure distinctive ringing and call waiting per FXS port:**
- 1. Open the Tone Index Table page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Analog Gateway** > **Tone Index**).
- 2. Click the **Add** button; the following dialog box appears:

**Figure 31-6: Tone Index Table Page**

The figure above shows a configuration example for using distinctive ringing and call waiting tones of Index #9 ('Priority Index' 1) in the CPT file for FXS endpoints 1 to 4 when a call is received from a source number with prefix 2.

- 3. Configure the table as required. For a description of the parameters, see the table below.
- 4. Click **Submit** to apply your changes.

**Tone index Table Parameter Description**

| Parameter                                                              | Description                                                     |
|------------------------------------------------------------------------|-----------------------------------------------------------------|
| Index                                                                  | Defines the table index entry. Up to 50 entries can be defined. |
| FXS Port First<br>CLI: fxs-port-first<br>[ToneIndex_FXSPort_First]     | Defines the first port in the FXS port range.                   |
| FXS Port Last<br>CLI: fxs-port-last<br>[ToneIndex_FXSPort_Last]        | Defines the last port in the FXS port range.                    |
| Source Prefix<br>CLI: src-prefix<br>[ToneIndex_SourcePrefix]           | Defines the prefix of the calling number.                       |
| Destination Prefix<br>CLI: dst-prefix<br>[ToneIndex_DestinationPrefix] | Defines the prefix of the called number.                        |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Priority Index<br>CLI: priority<br>[ToneIndex_PriorityIndex] | Defines the index of the distinctive ringing and call waiting tones. The call waiting tone index equals to the Priority Index plus the value of the FirstCallWaitingToneID parameter. For example, if you want to use the call waiting tone in the CPT file at Index #9, you need to enter "1" as the Priority Index value and set the FirstCallWaitingToneID parameter to "8". The summation of these values is 9, i.e., index #9.<br><br>The default is 0. |

### 31.13 FXS/FXO Coefficient Types

The FXS Coefficient and FXO Coefficient types used by the device can be one of the following:

- US line type of 600 ohm AC impedance and 40 V RMS ringing voltage for REN = 2
- European standard (TBR21)

These Coefficient types are used to increase return loss and trans-hybrid loss performance for two telephony line type interfaces (US or European). This adaptation is performed by modifying the telephony interface characteristics. This means, for example, that changing impedance matching or hybrid balance doesn't require hardware modifications, so that a single device is able to meet requirements for different markets. The digital design of the filters and gain stages also ensures high reliability, no drifts (over temperature or time) and simple variations between different line types.

The FXS Coefficient types provide best termination and transmission quality adaptation for two FXS line type interfaces. This parameter affects the following AC and DC interface parameters:

- DC (battery) feed characteristics
- AC impedance matching
- Transmit gain
- Receive gain
- Hybrid balance
- Frequency response in transmit and receive direction
- Hook thresholds
- Ringing generation and detection parameters

➤ **To select the FXO and FXS Coefficient types:**

1. Open the Analog Settings page (**Configuration** tab > **VoIP** menu > **Media** > **Analog Settings**). This page includes the Coefficient type parameters, as shown below:

**Figure 31-7: FXS/FXO Coefficient Parameters in Analog Settings Page**

|                                                                                                          |     |
|----------------------------------------------------------------------------------------------------------|-----|
|  FXS Coefficient Type | USA |
|  FXO Coefficient Type | USA |

2. From the 'FXS Coefficient Type' drop-down list (FXSCountryCoefficients), select the required FXS Coefficient type.
3. From the 'FXO Coefficient Type' drop-down list (CountryCoefficients), select the required FXO Coefficient type.
4. Click **Submit**.
5. Save your settings to the flash memory ("burn") with a device reset.

## 31.14 FXO Operating Modes

This section provides a description of the device's FXO operating modes:

- For IP-to-Tel calls (see 'FXO Operations for IP-to-Tel Calls' on page 406)
- For Tel-to-IP calls (see 'FXO Operations for Tel-to-IP Calls' on page 408)
- Call termination on FXO devices (see 'Call Termination on FXO Devices' on page 410)

### 31.14.1 FXO Operations for IP-to-Tel Calls

The FXO device provides the following operating modes for IP-to-Tel calls:

- One-stage dialing (see 'One-Stage Dialing' on page 406)
  - Waiting for dial tone (see 'Two-Stage Dialing' on page 407)
  - Time to wait before dialing
  - Answer supervision
- Two-stage dialing (see 'Two-Stage Dialing' on page 407)
- Dialing time: DID wink (see 'DID Wink' on page 408)

#### 31.14.1.1 One-Stage Dialing

One-stage dialing is when the FXO device receives an IP-to-Tel call, off-hooks the PBX line connected to the telephone, and then immediately dials the destination telephone number. In other words, the IP caller doesn't dial the PSTN number upon hearing a dial tone.

One-stage dialing incorporates the following FXO functionality:

- **Waiting for Dial Tone:** Enables the device to dial the digits to the Tel side only after detecting a dial tone from the PBX line. The *ini* file parameter `IsWaitForDialTone` is used to configure this operation.

- **Time to Wait Before Dialing:** Defines the time (in msec) between seizing the FXO line and starting to dial the digits. The *ini* file parameter `WaitForDialTime` is used to configure this operation.

**Note:** The *ini* file parameter `IsWaitForDialTone` must be disabled for this mode.

- **Answer Supervision:** The Answer Supervision feature enables the FXO device to determine when a call is connected, by using one of the following methods:
  - **Polarity Reversal:** the device sends a 200 OK in response to an INVITE only when it detects a polarity reversal.
  - **Voice Detection:** the device sends a 200 OK in response to an INVITE only when it detects the start of speech (fax or modem answer tone) from the Tel side. Note that the IPM detectors must be enabled.

### 31.14.1.2 Two-Stage Dialing

Two-stage dialing is when the IP caller is required to dial twice. The caller initially dials to the FXO device and only after receiving a dial tone from the PBX (via the FXO device), dials the destination telephone number.

**Figure 31-8: Call Flow for Two-Stage Dialing**

Two-stage dialing implements the Dialing Time feature. Dialing Time allows you to define the time that each digit can be separately dialed. By default, the overall dialing time per digit is 200 msec. The longer the telephone number, the greater the dialing time.

The relevant parameters for configuring Dialing Time include the following:

- `DTMFDigitLength` (100 msec): time for generating DTMF tones to the PSTN (PBX) side
- `DTMFInterDigitInterval` (100 msec): time between generated DTMF digits to PSTN (PBX) side

### 31.14.1.3 DID Wink

The device's FXO ports support Direct Inward Dialing (DID). DID is a service offered by telephone companies that enables callers to dial directly to an extension on a PBX without the assistance of an operator or automated call attendant. This service makes use of DID trunks, which forward only the last three to five digits of a phone number to the PBX. If, for example, a company has a PBX with extensions 555-1000 to 555-1999, and a caller dials 555-1234, the local central office (CO) would forward, for example, only 234 to the PBX. The PBX would then ring extension 234.

DID wink enables the originating end to seize the line by going off-hook. It waits for acknowledgement from the other end before sending digits. This serves as an integrity check that identifies a malfunctioning trunk and allows the network to send a re-order tone to the calling party.

The "start dial" signal is a wink from the PBX to the FXO device. The FXO then sends the last four to five DTMF digits of the called number. The PBX uses these digits to complete the routing directly to an internal station (telephone or equivalent)

- DID Wink can be used for connection to EIA/TIA-464B DID Loop Start lines
- Both FXO (detection) and FXS (generation) are supported

### 31.14.2 FXO Operations for Tel-to-IP Calls

The FXO device provides the following FXO operating modes for Tel-to-IP calls:

- Automatic Dialing (see 'Automatic Dialing' on page 408)
- Collecting Digits Mode (see 'Collecting Digits Mode' on page 409)
- FXO Supplementary Services (see 'FXO Supplementary Services' on page 409)
  - Hold/Transfer Toward the Tel side
  - Hold/Transfer Toward the IP side
  - Blind Transfer to the Tel side

#### 31.14.2.1 Automatic Dialing

Automatic dialing is defined using the Web interface's Automatic Dialing (TargetOfChannel ini file parameter) page, described in see 'Configuring Automatic Dialing' on page 396.

The SIP call flow diagram below illustrates Automatic Dialing.

### 31.14.2.2 Collecting Digits Mode

When automatic dialing is not defined, the device collects the digits. The SIP call flow diagram below illustrates the Collecting Digits Mode.

Figure 31-9: Call Flow for Collecting Digits Mode

### 31.14.2.3 FXO Supplementary Services

The FXO supplementary services include the following:

- **Hold / Transfer toward the Tel side:** The *ini* file parameter *LineTransferMode* must be set to 0 (default). If the FXO receives a hook-flash from the IP side (using out-of-band or RFC 2833), the device sends the hook-flash to the Tel side by performing one of the following:

- Performing a hook flash (i.e., on-hook and off-hook)
- Sending a hook-flash code (defined by the *ini* file parameter *HookFlashCode*)

The PBX may generate a dial tone that is sent to the IP, and the IP side may dial digits of a new destination.

- **Blind Transfer to the Tel side:** A blind transfer is one in which the transferring phone connects the caller to a destination line before ringback begins. The *ini* file parameter *LineTransferMode* must be set to 1.

The blind transfer call process is as follows:

- FXO receives a REFER request from the IP side
- FXO sends a hook-flash to the PBX, dials the digits (that are received in the Refer-To header), and then drops the line (on-hook). Note that the time between flash to dial is according to the *WaitForDialTime* parameter.
- PBX performs the transfer internally

- **Hold / Transfer toward the IP side:** The FXO device doesn't initiate hold / transfer as a response to input from the Tel side. If the FXO receives a REFER request (with or without replaces), it generates a new INVITE according to the Refer-To header.

### 31.14.3 Call Termination on FXO Devices

This section describes the device's call termination capabilities for its FXO interfaces:

- Calls terminated by a PBX (see 'Call Termination by PBX' on page 410)
- Calls terminated before call establishment (see 'Call Termination before Call Establishment' on page 411)
- Ring detection timeout (see 'Ring Detection Timeout' on page 411)

#### 31.14.3.1 Calls Termination by PBX

The FXO device supports various methods for identifying when a call has been terminated by the PBX.

The PBX doesn't disconnect calls, but instead signals to the device that the call has been disconnected using one of the following methods:

- **Detection of polarity reversal/current disconnect:** The call is immediately disconnected after polarity reversal or current disconnect is detected on the Tel side (assuming the PBX/CO generates this signal). This is the recommended method.

Relevant parameters: EnableReversalPolarity, EnableCurrentDisconnect, CurrentDisconnectDuration, CurrentDisconnectDefaultThreshold, and TimeToSampleAnalogLineVoltage.

- **Detection of Reorder, Busy, Dial, and Special Information Tone (SIT) tones:** The call is immediately disconnected after a Reorder, Busy, Dial, or SIT tone is detected on the Tel side (assuming the PBX / CO generates this tone). This method requires the correct tone frequencies and cadence to be defined in the Call Progress Tones file. If these frequencies are unknown, define them in the CPT file. The tone produced by the PBX / CO must be recorded and its frequencies analyzed. Adding a reorder tone to the CPT file can be done using AudioCodes CPTWizard utility (refer to the *CPTWizard Utility User's Guide*). This method is slightly less reliable than the previous one. You can use the CPTWizard to analyze Call Progress Tones generated by any PBX or telephone network.

Relevant parameters: DisconnectOnBusyTone and DisconnectOnDialTone.

- **Detection of silence:** The call is disconnected after silence is detected on both call directions for a specific (configurable) amount of time. The call isn't disconnected immediately; therefore, this method should only be used as a backup option.

Relevant parameters: EnableSilenceDisconnect and FarEndDisconnectSilencePeriod.

- **Special DTMF code:** A digit pattern that when received from the Tel side, indicates to the device to disconnect the call.

Relevant *ini* file parameter: TelDisconnectCode.

- **Interruption of RTP stream:** Relevant parameters: BrokenConnectionEventTimeout and DisconnectOnBrokenConnection.

**Note:** This method operates correctly only if silence suppression is not used.

- **Protocol-based termination of the call from the IP side**

**Note:** The implemented disconnect method must be supported by the CO or PBX.

### 31.14.3.2 Call Termination before Call Establishment

The device supports the following call termination methods before a call is established:

- **Call termination upon receipt of SIP error response (in Automatic Dialing mode):**  
By default, when the FXO device operates in Automatic Dialing mode, there is no method to inform the PBX if a Tel-to-IP call has failed (SIP error response - 4xx, 5xx or 6xx - is received). The reason is that the FXO device does not seize the line until a SIP 200 OK response is received. Use the `FXOAutoDialPlayBusyTone` parameter to allow the device to play a busy / reorder tone to the PSTN line if a SIP error response is received. The FXO device seizes the line (off-hook) for the duration defined by the `TimeForReorderTone` parameter. After playing the tone, the line is released (on-hook).
- **Call termination after caller (PBX) on-hooks phone (Ring Detection Timeout feature):** This method operates in one of the following manners:
  - **Automatic Dialing is enabled:** if the remote IP party doesn't answer the call and the ringing signal (from the PBX) stops for a user-defined time (configured by the parameter `FXOBetweenRingTime`), the FXO device releases the IP call.
  - **No automatic dialing and Caller ID is enabled:** the device seizes the line after detection of the second ring signal (allowing detection of caller ID sent between the first and the second rings). If the second ring signal is not received within this timeout, the device doesn't initiate a call to IP.

### 31.14.3.3 Ring Detection Timeout

The operation of Ring Detection Timeout depends on the following:

- **Automatic dialing is disabled and Caller ID is enabled:** if the second ring signal is not received for a user-defined time (using the parameter `FXOBetweenRingTime`), the FXO device doesn't initiate a call to the IP.
- **Automatic dialing is enabled:** if the remote party doesn't answer the call and the ringing signal stops for a user-defined time (using the parameter `FXOBetweenRingTime`), the FXO device releases the IP call.

Ring Detection Timeout supports full ring cycle of ring on and ring off (from ring start to ring start).

## 31.15 Remote PBX Extension between FXO and FXS Devices

Remote PBX extension offers a company the capability of extending the "power" of its local PBX by allowing remote phones (remote offices) to connect to the company's PBX over the IP network (instead of via PSTN). This is as if the remote office is located in the head office (where the PBX is installed). PBX extensions are connected through FXO ports to the IP network, instead of being connected to individual telephone stations. At the remote office, FXS units connect analog phones to the same IP network. To produce full transparency, each FXO port is mapped to an FXS port (i.e., one-to-one mapping). This allows individual extensions to be extended to remote locations. To call a remote office worker, a PBX user or a PSTN caller simply dials the PBX extension that is mapped to the remote FXS port.

This section provides an example on how to implement a remote telephone extension through the IP network, using FXO and FXS interfaces. In this configuration, the FXO device routes calls received from the PBX to the 'Remote PBX Extension' connected to the FXS device. The routing is transparent as if the telephone connected to the FXS device is directly connected to the PBX.

The following is required:

- FXO interfaces with ports connected directly to the PBX lines (shown in the figure below)
- FXS interfaces for the 'remote PBX extension'
- Analog phones (POTS)
- PBX (one or more PBX loop start lines)
- LAN network

### 31.15.1 Dialing from Remote Extension (Phone at FXS)

The procedure below describes how to dial from the 'remote PBX extension' (i.e., phone connected to the FXS interface).

- **To make a call from the FXS interface:**
  1. Off-hook the phone and wait for the dial tone from the PBX. This is as if the phone is connected directly to the PBX. The FXS and FXO interfaces establish a voice path connection from the phone to the PBX immediately after the phone is off-hooked.
  2. Dial the destination number (e.g., phone number 201). The DTMF digits are sent over IP directly to the PBX. All the audible tones are generated from the PBX (such as ringback, busy, or fast busy tones). One-to-one mapping occurs between the FXS ports and PBX lines.
  3. The call disconnects when the phone connected to the FXS goes on-hook.

### 31.15.2 Dialing from PBX Line or PSTN

The procedure below describes how to dial from a PBX line (i.e., from a telephone directly connected to the PBX) or from the PSTN to the 'remote PBX extension' (i.e., telephone connected to the FXS interface).

- **To dial from a telephone directly connected to the PBX or from the PSTN:**
  - Dial the PBX subscriber number (e.g., phone number 101) in the same way as if the

user's phone was connected directly to the PBX. As soon as the PBX rings the FXO device, the ring signal is 'sent' to the phone connected to the FXS device. Once the phone connected to the FXS device is off-hooked, the FXO device seizes the PBX line and the voice path is established between the phone and PBX.

There is one-to-one mapping between PBX lines and FXS device ports. Each PBX line is routed to the same phone (connected to the FXS device). The call disconnects when the phone connected to the FXS device is on-hooked.

### 31.15.3 Message Waiting Indication for Remote Extensions

The device supports the relaying of Message Waiting Indications (MWI) for remote extensions (and voice mail applications). Instead of subscribing to an MWI server to receive notifications of pending messages, the FXO device receives subscriptions from the remote FXS device and notifies the appropriate extension when messages (and the number of messages) are pending.

The FXO device detects an MWI message from the Tel (PBX) side using any one of the following methods:

- 100 VDC (sent by the PBX to activate the phone's lamp)
- Stutter dial tone from the PBX
- MWI display signal (according to the parameter CallerIDType)

Upon detection of an MWI message, the FXO device sends a SIP NOTIFY message to the IP side. When receiving this NOTIFY message, the remote FXS device generates an MWI signal toward its Tel side.

### 31.15.4 Call Waiting for Remote Extensions

When the FXO device detects a Call Waiting indication (FSK data of the Caller Id - CallerIDType2) from the PBX, it sends a proprietary INFO message, which includes the caller identification to the FXS device. Once the FXS device receives this INFO message, it plays a call waiting tone and sends the caller ID to the relevant port for display. The remote extension connected to the FXS device can toggle between calls using the Hook Flash button.

### 31.15.5 FXS Gateway Configuration

The procedure below describes how to configure the FXS interface (at the 'remote PBX extension').

➤ **To configure the FXS interface:**

1. In the Trunk Group Table page (see , assign the phone numbers 100 to 104 to the device's endpoints.

**Figure 31-10: Assigning Phone Numbers to FXS Endpoints**

| Group Index | Module       | From Trunk | To Trunk | Channels | Phone Number | Trunk Group ID |
|-------------|--------------|------------|----------|----------|--------------|----------------|
| 1           | Module 3 FXS | 1          | 1        | 1-4      | 100          | 0              |

2. In the Automatic Dialing page (see 'Configuring Automatic Dialing' on page 396), enter the phone numbers of the FXO device in the 'Destination Phone Number' fields. When a phone connected to Port #1 off-hooks, the FXS device automatically dials the number '200'.

**Figure 31-11: Automatic Dialing for FXS Ports**

| Gateway Port        | Destination Phone Number | Auto Dial Status |
|---------------------|--------------------------|------------------|
| Module 3 Port 1 FXS | 200                      | Enable           |
| Module 3 Port 2 FXS | 201                      | Enable           |
| Module 3 Port 3 FXS | 202                      | Enable           |
| Module 3 Port 4 FXS | 203                      | Enable           |

3. In the Outbound IP Routing Table page (see 'Configuring Outbound IP Routing Table' on page 321), enter 20 for the destination phone prefix, and 10.1.10.2 for the IP address of the FXO device.

|   | Src. Host Prefix | Dest Host Prefix | Src. Trunk Group ID | Dest. Phone Prefix | Source Phone Prefix | Dest. IP Address |
|---|------------------|------------------|---------------------|--------------------|---------------------|------------------|
| 1 |                  |                  |                     | 20                 | *                   | 10.1.10.2        |

**Note:** For the transfer to function in remote PBX extensions, Hold must be disabled at the FXS device (i.e., Enable Hold = 0) and hook-flash must be transferred from the FXS to the FXO (HookFlashOption = 4).

### 31.15.6 FXO Gateway Configuration

The procedure below describes how to configure the FXO interface (to which the PBX is directly connected).

➤ **To configure the FXO interface:**

1. In the Trunk Group Table page (see , assign the phone numbers 200 to 204 to the device's FXO endpoints.

**Figure 31-12: Assigning Phone Numbers to FXO Ports**

| Group Index | Module         | From Trunk | To Trunk | Channels | Phone Number |
|-------------|----------------|------------|----------|----------|--------------|
| 1           | Module 3 FXO ▼ | ▼          | ▼        | 1-4      | 200          |

2. In the Automatic Dialing page, enter the phone numbers of the FXS device in the 'Destination Phone Number' fields. When a ringing signal is detected at Port #1, the FXO device automatically dials the number '100'.

**Figure 31-13: FXO Automatic Dialing Configuration**

| Gateway Port        | Destination Phone Number | Auto Dial Status |
|---------------------|--------------------------|------------------|
| Module 3 Port 1 FXO | 100                      | Enable ▼         |
| Module 3 Port 2 FXO | 101                      | Enable ▼         |
| Module 3 Port 3 FXO | 102                      | Enable ▼         |
| Module 3 Port 4 FXO | 103                      | Enable ▼         |

3. In the Outbound IP Routing Table page, enter 10 in the 'Destination Phone Prefix' field, and the IP address of the FXS device (10.1.10.3) in the field 'IP Address'.

**Figure 31-14: FXO Tel-to-IP Routing Configuration**

|   | Dest. Phone Prefix | Source Phone Prefix | -<br>> | Dest. IP Address |
|---|--------------------|---------------------|--------|------------------|
| 1 | 10                 | *                   |        | 10.1.10.3        |

4. In the FXO Settings page (see 'Configuring FXO Parameters' on page 394), set the parameter 'Dialing Mode' to **Two Stages** (IsTwoStageDial = 1).

## Reader's Notes

# Part VI

## Session Border Controller Application

## 32 SBC Overview

This section provides a detailed description of the device's SBC application.

**Notes:**

- For guidelines on how to deploy your E-SBC device based on network topology, refer to the *SBC Design Guide* document.
- For SBC functionality, the Software License Key installed on the device must include the SBC feature.

The SBC application supports the following main features:

- NAT traversal: The device supports NAT traversal, allowing, for example, communication with ITSPs with globally unique IP addresses, for LAN-to-WAN VoIP signaling (and bearer), using two independent legs. This also enables communication for "far-end" users located behind a NAT on the WAN. The device supports this by:
  - Continually registering far-end users in its dynamic database.
  - Maintaining remote NAT binding state by frequent registrations, thereby, off-loading far-end registrations from the LAN IP PBX.
  - Using Symmetric RTP (RFC 4961) to overcome bearer NAT traversal.
- VoIP firewall and security for signaling and media:
  - SIP signaling:
    - ◆ Deep and stateful inspection of all SIP signaling packets.
    - ◆ SIP dialog initiations may be rejected based on values of incoming SIP INVITE message and other Layer-3 characteristics.
    - ◆ Packets not belonging to an authorized SIP dialog are discarded.
  - RTP:
    - ◆ Opening pinholes (ports) in the device's firewall based on Offer-Answer SDP negotiations.
    - ◆ Deep packet inspection of all RTP packets.
    - ◆ Late rouge detection - if a SIP session was gracefully terminated and someone tries to "ride on it" with rouge traffic from the already terminated RTP and SIP context, the VoIP Firewall prevents this from occurring.
    - ◆ Disconnects call (after user-defined time) if RTP connection is broken.
    - ◆ Black/White lists for both Layer-3 firewall and SIP classification.
- Topology hiding: The device intrinsically supports topology hiding, limiting the amount of topology information displayed to external parties. For example, IP addresses of ITSPs' equipment (e.g. proxies, gateways, and application servers) can be hidden from outside parties. The device's topology hiding is provided by implementing back-to-back user agent (B2BUA) leg routing:
  - Strips all incoming SIP Via header fields and creates a new Via value for the outgoing message.
  - Each leg has its own Route/Record Route set.
  - Modifies SIP To, From, and Request-URI host names (must be configured using the Message Manipulations table).
  - Generates a new SIP Call-ID header value (different between legs).
  - Changes the SIP Contact header to the device's own address.
  - Layer-3 topology hiding by modifying source IP address in the SIP IP header.

- SIP normalization: The device supports SIP normalization, whereby the SBC application can overcome interoperability problems between SIP user agents. This is achieved by the following:
  - Manipulation of SIP URI user and host parts.
  - Connection to ITSP SIP trunks on behalf of an IP-PBX - the device can register and utilize user and password to authenticate for the IP-PBX.
- Survivability:
  - Routing calls to alternative routes such as the PSTN.
  - Routing calls between user agents in the local network using a dynamic database (built according to registrations of SIP user agents).
- Routing:
  - IP-to-IP routing translations of SIP, UDP, TCP, TLS (when extensive transcoding is not required).
  - Load balancing and redundancy of SIP servers.
  - Routing according to Request-URI\Specific IP address\Proxy\FQDN.
  - Alternative routing.
  - Routing between different Layer-3 networks (e.g., LAN and WAN).
- Load balancing\redundancy of SIP servers.
- ITSP accounts.
- SIP URI user and host name manipulations.
- Coder transcoding.

## 32.1 SIP Network Definitions

The device's SBC application can implement multiple SIP signaling and RTP (media) interfaces.

## 32.2 SIP Dialog Initiation Process

The device's SIP dialog initiation process concerns all incoming SIP dialog initiation requests. This includes SIP methods such as INVITE, SUBSCRIBE, OPTIONS, REFER, INFO, UNSOLICITED NOTIFY, MESSAGE, and REGISTER.

The SIP dialog initiation process consists of the following stages:

1. **Determining source and destination URL:** The SIP protocol has more than one URL in a dialog-establishing request that may represent the source and destination URLs. When handling an incoming request, the device uses specific SIP headers for obtaining the source and destination URLs. Once these URLs are determined, their user and host parts are used as input for the classification process, message manipulation, and call routing.
  - **All SIP requests (e.g., INVITE) except REGISTER dialogs:**
    - ◆ Source URL: The source URL is obtained from the SIP header according to the following logic:
      - ✓ The source URL is obtained from the From header.
      - ✓ If the From header contains the value 'Anonymous', the source URL is obtained from the P-Preferred-Identity header.
      - ✓ If the P-Preferred-Identity header does not exist, the source URL is obtained from the P-Asserted-Identity header.
    - ◆ Destination URL: The destination URL is obtained from the Request-URI.

- **REGISTER dialogs:**
  - ◆ Source URL: The source URL is obtained from the To header.
  - ◆ Destination URL: The destination URL is obtained from the Request-URI.

**Note:** You can determine the SIP header from where the device obtains the source URL in the incoming SIP request. This is done in the IP Group table using the 'Source URI Input' parameter.

2. **Classifying incoming SIP dialog-initiating requests to a source IP Group:** The classification identifies the incoming SIP dialog request as belonging to a specific IP Group (from where the SIP dialog request originated). For more information, see 'Configuring Classification Rules' on page 456.
3. **SBC IP-to-IP routing:** The device routes the call to a destination that can be configured to one of the following:
  - Registered user Contact listed in the device's database (only for User-type IP Groups).
  - IP Group - the destination is the address configured for the Proxy Set associated with the IP Group (allows redundancy/load balancing).
  - Specified destination address (can be based on IP address, host name, port, transport type, and/or SRD). Routing to a host name can be resolved using NAPTR/SRV/A-Record.
  - Request-URI of incoming SIP dialog initiating requests.
  - ENUM query.
  - Hunt Group - used for call survivability.
  - IP address (in dotted-decimal notation or FQDN - NAPTR/SRV/A-Record resolutions) according to a specified Dial Plan index listed in the loaded Dial Plan file.
  - LDAP server or LDAP query result.For more information, see 'Configuring SBC IP-to-IP Routing' on page 462.
4. **Manipulating SIP URI user part (source and destination) of inbound and/or outbound SIP dialog requests:** You can configure rules for manipulating the SIP URI user part (source and destination) on the inbound and/or outbound leg. For more information, see 'SBC Manipulations' on page 469.
5. **SIP message manipulations:** You can configure SIP message manipulation rules that can add, remove, and/or modify SIP headers and parameters. For more information, see 'Configuring SIP Message Manipulation' on page 224.

The flowchart below illustrates the SBC process:

**Figure 32-1: Routing Process**

## 32.3 User Registration and Internal Database

To allow registrations to traverse the SBC, the device must be configured with at least one User-type IP Group. These IP Groups represent a group of user agents that share the following characteristics:

- Perform registrations and share the same serving proxy/registrar
- Possess identical SIP and media behavior
- Reside on the same Layer-3 network and are associated with the same SRD

Typically, the device is configured as the user agent's outbound proxy and the device is configured (using the IP-to-IP Routing table) to route requests received from this IP Group to the serving proxy and vice versa. Survivability can be achieved using the alternative routing feature.

### 32.3.1 Initial Registration Request Processing

Registration requests have different processing policies than other SIP methods:

1. Determining source and destination URL's:
  - The source URL is obtained from the To header
  - The destination URL is obtained from the Request URI
2. Classification: The REGISTER classification process is the same as the general classification process (described in previous sections). The source IP Group must be of type User. If classification fails or the source IP Group is not of type User, the registration is rejected.
3. Routing: The REGISTER routing is performed using the IP-to-IP Routing table:
  - The destination type can be an IP Group, specific IP address, Request-URI, or ENUM query (can also use DNS queries).
  - If the destination is a User-type IP Group, then the registration is not be forwarded. Instead, the device accepts (replies with 200 OK response) or rejects (Reply with 4xx) the request according to the user group policy.
4. Internal registration database: If the source IP Group is of type User and registration succeeds (replied with 200 OK by the IP-PBX), then the device adds a record to its database that identified the specific contact of this specific user (AOR). This record is used later to route requests to this specific user (either in normal or in survivability modes).
5. Alternative Routing: Alternative routing can be configured in the IP-to-IP Routing table for REGISTER requests.
6. Inbound Manipulation: The SBC record in the device's database includes the Contact header. Every REGISTER request is added to the database before manipulation, allowing correct user identification in the SBC Classification process for the next received request.
7. Session Admission Control: Applies various limitations on incoming and outgoing REGISTER requests. For example, limiting REGISTER requests from a certain IP Group/SRD. Note that this limitation is only for concurrent register dialogs and not concurrent registrations in the internal database.
8. The device can retain the original value of the SIP Expires header received from the user or proxy, in the outgoing REGISTER message. This feature also applies when the device is in "survivability" state (i.e., REGISTER requests cannot be forwarded to the proxy and is terminated by the device). This is configured by the `SBCUserRegistrationTime`, `SBCProxyRegistrationTime`, and `SBCSurvivabilityRegistrationTime` parameters.
9. By default, the Contact of the outgoing REGISTER is populated with a unique Contact generated by the device and associated with this specific registration. Alternatively, the original user can be retained in the Contact and used in the outgoing REGISTER request (using the `SBCKeepContactUserinRegister` parameter).

### 32.3.2 Internal Database

The device manages a dynamic database that is updated according to registration requests that traverse the SBC. Each database entry represents a binding between an AOR and one or more contact. Database bindings are added upon successful registration

responses. For specific registrations, the AOR is obtained from the SIP To header and the contact is taken from the SIP Contact header.

Database bindings are removed in the following cases:

- Successful de-registration responses (REGISTER with Expires header that equals zero)
- Registration failure responses
- Timeout of the Expires header value (in scenarios where the user agent did not send a refresh registration request)

The database has the following limitations:

- Maximum of five contacts per AOR
- The same contact cannot belong to more than one AOR
- Contacts with identical URIs and different ports and transport types are not supported (same key is created)
- Multiple contacts in a single REGISTER is not supported
- One database is shared between all User-type IP Groups

### 32.3.3 Routing using Internal Database

Typically, routing using the database is applicable to all method types other than registrations. To route to a registered user (using the internal dynamic database), the following steps must be taken:

1. An IP-to-IP Routing rule with the desired input parameters (matching characteristics) and the destination type as IP Group (operation rule).
2. The destination IP Group must be of type User.
3. To find a match for these specific rules, the device attempts to locate a match between the incoming Request-URI and (according to the description order):
  - a. Unique contact - the Contact generated by the SBC and sent in the initial registration request to the serving proxy
  - b. Registered AOR - the AOR of the incoming REGISTER request
  - c. Registered contact - the Contact of the incoming REGISTER request

If registrations are destined to the database (using the above rules), the device does not attempt to find a database match, but instead replies with 200 OK (used for Survivability). Once a match is found, the request is routed either to the contact received in the initial registration or (if the device identifies that the user agent is behind a NAT) to the source IP address of the initial registration.

### 32.3.4 Registration Refreshes

Registration refreshes are incoming REGISTER requests that are associated with a specific registered user. The association is performed by searching the internal registration database. These refreshes are routed to the serving proxy only if the serving proxy Expires time is about to expire; otherwise, the device responds with a 200 OK without routing the REGISTER. Each such refreshes also refresh the internal timer time set on the device for this specific registration.

### 32.3.5 Notification of Expired User Registration to SIP Proxy / Registrar

The device automatically notifies SIP Proxy / Registrar servers of users registered in the device's database whose registration timeout has expired. When a user's registration timer expires, the device removes the user record from its Registration database and sends an unregister notification (REGISTER message with the Expires header set to 0) to the Proxy/Registrar.

This feature is enabled only if a REGISTER message is sent to an IP Group destination type, configured in the IP-to-IP Routing table.

### 32.3.6 Registration Restriction Control

The device provides flexibility in controlling user registration:

- **Limiting Number of Registrations per Source SRD and/or IP Group:** You can limit the number of users that can register with the device. This limitation can be applied per source IP Group and/or SRD. By default, no limitation exists for registered users. This is configured using the parameters SRD or IPGroup.
- **Blocking Incoming Calls from Unregistered Users:** You can block incoming calls (INVITE requests) from unregistered users (pertaining to User-type IP Groups). By default, calls from unregistered users are not blocked. This is configured using the parameter SRD. The flowchart below depicts the process for blocking unregistered users. When the call is rejected, the device sends a SIP 500 "Server Internal Error" response to the remote end.

Figure 32-2: Blocking Incoming Calls from Unregistered Users

## 32.4 SBC Media Handling

Media behavior includes anything related to the establishment, management and termination of media sessions within the SIP protocol. Media sessions are created using the SIP "offer"/"answer" mechanism. If successful, the result is a bi-directional media (RTP) flow (e.g. audio, fax, modem, DTMF). Each offer/answer may create more than one media session of different types (e.g. audio and fax). In a SIP dialog, multiple offer/answer transactions may occur, each may change the media sessions characteristics (e.g. IP

address, port, coders, media types, and RTP mode). The media capabilities exchanged in an offer/answer transaction include the following:

- Media types (Audio, Secure Audio, Video, Fax, Text...)
- IP addresses and ports of the media flow
- Media flow mode (send receive, receive only, send only, inactive)
- Media coders (coders and their characteristics used in each media flow)
- Other (standard or proprietary) media and session characteristics

Even though the device usually does not change the negotiated media capabilities (mainly performed by the remote user agents), it does examine the media exchange to control negotiated media types (if necessary) and to know how to open the RTP media channels (IP addresses, coder type, payload type etc.). The device forwards multiple video streams and text, as is.

The device interworks (normalization) the media (RTP-to-RTP, SRTP-to-RTP, and SRTP-to-SRTP) between its SBC legs. It "re-builds" specific fields in the RTP header when forwarding media packets. The main fields include the sequence number, SSRC, and timestamp.

The device is aware and sometimes active in the offer/answer process due to the following:

- NAT traversal: the device changes the SDP address to be its own address, thereby, resolving NAT problems.
- Firewall and security:
  - RTP pin holes - only RTP packets related to a successful offer/answer negotiation traverse the device: When the device initializes, there are no RTP pin holes opened, this means that each RTP/RTCP packets destined to the device are discarded. Once an offer/answer transaction ends successfully, an RTP pin hole is opened and RTP/RTCP flows between the two remote user agents. Once a pin hole is opened, the payload type and RTP header version is validated for each packet. RTP pin holes close if one of the associated SIP dialogs is closed (may also be due to broken connection).
  - Late rogue detection - once a dialog is disconnected, the related pin holes also disconnect.
  - Deep Packet inspection of the RTP that flows through the opened pin holes.
- Adding of media functionality to SIP user agents:
  - Transcoding (for a description on the transcoding modes, see 'Transcoding Modes' on page [431](#))
  - Broken connection

According to the above functionalities, the call can be configured to operate in one of the following modes:

- **Media Anchoring without Transcoding (Transparent):** RTP traverses the device with minimal RTP packet changes (no DSP resources needed). This is typically used to solve NAT, firewall, and security issues. In this mode, all the "audio" coders in the received offer are included in the SBC outgoing offer. The Coder Table configuration has no effect on the coders in the outgoing offer. For more information, see 'Media Anchoring without Transcoding (Transparent)' on page [427](#).
- **Media Anchoring with Transcoding:** RTP traverses the device and each leg uses a different coder or coder parameters (DSP resources are required). For more information, see 'Media Anchoring with Transcoding' on page [427](#).
- **No Media Anchoring:** The RTP packet flow does not traverse the device. Instead, the two SIP UA's establish a direct RTP/SRTP flow between one another (see 'No Media Anchoring' on page [429](#)).

### 32.4.1 Media Anchoring without Transcoding (Transparent)

To direct the RTP to flow through the device (for NAT traversal, firewall and security), all IP address fields in the SDP are modified:

- Origin: IP address, session and version id
- Session connection attribute ('c=' field)
- Media connection attribute ('c=' field)
- Media port number
- RTCP media attribute IP address and port

Each SBC leg allocates and uses the device's local ports (e.g., for RTP/RTCP/fax). The local ports are allocated from a Media Realm associated with each leg. The legs are associated with a Media Realm as follows: If the leg's IP Group is configured with a Media Realm, then this is the associated Media Realm; otherwise, the leg's SRD Media Realm is the associated one. The figure below illustrates an example of SDP handling for a call between a LAN IP Phone 10.2.2.6 and a remote IP Phone 212.179.1.13 on the WAN.

Figure 32-3: SDP Offer/Answer Example

### 32.4.2 Media Anchoring with Transcoding

The device performs transcoding when there are no common coders between the two user agents (i.e., the SDP answer from one user agent doesn't include any coder included in the offer previously sent by the other user agent). For transcoding, the device can be configured to add media capabilities to user agents pertaining to a specific IP Group, and then perform transcoding in cases where the selected coder in the answer SDP is not one that appears in the original offer. The capabilities that can be added are one or more of the device's supported coders and are configured by using the parameter `SBCExtensionCodersGroupID` (points to a coders list) in the IP Profile table (which is assigned to the IP Group). Therefore, to allow user agents of different IP Groups to communicate with each other (regardless of their capabilities), an extended coders table with at least one coder that is supported by each IP Groups' user agents needs to be

assigned to each IP Group. Therefore, each offer destined to specific IP Groups include this coder.

In the scenario depicted in the figure below, the IP phone on the LAN side initiates a call to the IP phone on the WAN. The initial SDP offer (from the LAN leg) includes codec G.711 as its supported codec. Since this is sent to a Destination IP Group that is configured with an extended coder list, on the WAN leg the device adds another supported codec G.729 to the SDP, which is now offered to the WAN IP phone. The WAN IP phone chooses the extended codec (G.729) in its SDP answer to the device's WAN leg. Since this codec was not included in the original incoming offer, the device performs transcoding (between G.729 and G.711) between its two legs, allowing the streaming of media to occur.

**Figure 32-4: Transcoding using Extended Coders (Example)**

For an SDP offer to provide an extended coder list to a remote user agent, the following prerequisites must be fulfilled:

- An extended coders list has been configured for the user agent's IP Group (i.e., Destination IP Group)
- The incoming offer contains at least one supported coder (otherwise, transcoding can't be performed)
- Both legs have available DSP's
- T.38 doesn't appear in the offer

If the above prerequisites are not met, the SDP offer is sent without the extended coders list. The coders from the extended list are added after the ones from the original offer (decreases transcoding probability). Coders common between the extended coders list and those in the original SDP offer are not added. Transcoding may be performed even in scenarios when the same coder has been chosen - this occurs if the coders use different coder parameters (e.g. rate and packetization time).

The device also supports early media, whereby the first offer\answer transaction is finalized and the media flow starts before the SIP call is connected (before the INVITE 200 OK response). The offer and answer options can be included in the following SIP messages:

- Offer in first INVITE, answer on 180, and no or same answer in the 200 OK
- Offer in first INVITE, answer on 180, and a different answer in the 200 OK (not standard)
- INVITE without SDP, offer in 180, and answer in PRACK

- PRACK and UPDATE transactions can also be used for initiating subsequent offer\answer transactions before the INVITE 200 OK response.
- In a SIP dialog life time, media characteristics after originally determined by the first offer\answer transaction can be changed by using subsequent offer\answer transactions. These transactions may be carried either in UPDATE or ReINVITE SIP transactions. The media handling is similar to the original offer/answer handling. If the offer is rejected by the remote party, then no media changes occur (e.g. INVITE without SDP, then 200 OK and ACK, offer\answer within an offer/answer, and Hold ReINVITE with IP address of 0.0.0.0 - IP address is unchanged).

### 32.4.3 No Media Anchoring

The No Media Anchoring or Anti-Tromboning feature enables the use of SBC signaling capabilities without handling the RTP/SRTP (media) flow between remote SIP user agents (UA). The RTP packet flow does not traverse the device and instead, the two SIP UAs establish a direct RTP/SRTP flow (i.e., direct call) between one another. Signaling continues to traverse the device with minimal intermediation and involvement to enable certain SBC abilities such as routing.

By default, media packets traverse the device. This is done in order to:

- Solve NAT problems
- Enforce media security policy
- Perform media transcoding between the two legs
- Media monitoring

However, since media packets traverse the SBC, media quality may degrade, for example, due to packet delay.

In some setups, specific calls do not require media anchoring, for example, when there is no need for NAT, security, or transcoding. This is typical for calls between users in the LAN:

- Internal LAN calls: When the SBC routes a call between two UAs within the same LAN, the SBC can forward the SDP directly between caller and callee, and direct the RTP to flow between the UAs without traversing the SBC.
- Internal LAN calls via WAN: In this setup, the SBC dynamically identifies that the call is between UAs located in the same network (i.e., LAN) and thereby, directs the RTP to flow between these UAs without traversing the SBC

In contrast to the regular SBC implementation, the No Media Anchoring feature:

- Does not perform any manipulation on SDP data (offer/answer transaction) such as ports, IP address, coders
- Opening voice channels and allocation of IP media ports are not required

The No Media Anchoring feature is typically implemented in the following scenarios:

- SBC device is located within the LAN.

- Calls between two SIP UA's in the same LAN and signals are sent to a SIP proxy server (or hosted IP PBX) located in the WAN.

**Figure 32-5: SBC SIP Signaling without RTP Media Flow**

The benefits of implementing the No Media Anchoring include the following:

- Saves network bandwidth
- Reduces CPU usage (no RTP/SRTP handling)
- Avoids interference in SDP negotiation and header manipulation on RTP/SRTP

The No Media Anchoring process is as follows:

1. Identifies a No Media Anchoring call - according to configuration and the call's properties (such as source, destination, IP Group, and SRD).
2. Handles the identified No Media Anchoring call.

The No Media Anchoring feature is enabled using the SBCDirectMedia parameter. You can also enable No Media Anchoring per SRD (using the IntraSRDMediaAnchoring parameter), whereby calls between two UA's that pertain to the same SRD (source and destination) are handled as No Media Anchoring (direct media) calls.

#### Notes:

- No Media Anchoring can be used when the SBC does not do NAT traversal (for media) where all the users are in the same domain.
- No Media Anchoring calls cannot operate simultaneously with the following SBC features:
  - Force transcoding
  - Extension Coders
  - Extension of RFC 2833/Out-of-band DTMF/In-band DTMF
  - Extension of SRTP/RTP
All restriction features (Allowed Coders, restrict SRTP/SRT, restrict RFC 2833) can operate simultaneously. Once No Media Anchoring is enabled, the features listed above are disabled.
- The Coder Restriction feature operates simultaneously with No Media Anchoring calls. Restricted coders are removed from the SDP offer message.
- When two UA's pertain to the same SRD, the parameter IntraSRDMediaAnchoring is set to 1, and one of the UA's is defined as a foreign user (example, "follow me service") located in the WAN, while the other UA is located in the LAN: calls between these two UA's can't be established until IntraSRDMediaAnchoring is set to 0, as the device doesn't interfere in the SIP signaling. In other words, parameters such as IP addresses are not manipulated for calls between LAN and WAN (although required).
- When the parameter SBCDirectMedia is disabled, No Media Anchoring calls between two UA's belonging to separate SRD's cannot be configured. No Media Anchoring calls between two UA's belonging to the same SRD is configurable only (in this case).

### 32.4.4 Transcoding Modes

The device supports the configuration of the voice transcoding mode (media negotiation) between the two SBC legs. The device can be configured to perform transcoding only when necessary. Typically, the SBC passes RTP packets transparently (RTP-to-RTP) between the two user agents. If the device is configured to always perform transcoding, then transcoding is performed on the outgoing SBC leg and the device's SBC application interworks the media by implementing PSTN transcoding (since both legs have different media capabilities).

In the SBC application, forced transcoding of voice in an SBC session allows the device to receive capabilities that are not negotiated between the SBC legs. For example, if on the SBC session you want to force Gain Control to use voice transcoding even though both sides of the session have negotiated without SBC intervention (for example, coder extension).

The transcoding mode can be configured using the parameters `TranscodingMode` and `IPProfile`.

**Note:** To implement transcoding, you must configure the number of required DSP channels for transcoding (for example, `MediaChannels = 120`). Each transcoding session uses two DSP resources.

### 32.4.5 Restricting Coders

The SBC Allowed Coders (coders restriction) feature determines the coders that can be used for a specific SBC leg. This provides greater control over bandwidth by enforcing the use of specific coders (*allowed coders groups*) while preventing the use of other coders. This is done by defining a group of allowed coders for the SBC leg, as described below:

1. Configure a Coders Group for allowed coders, using the `AllowedCodersGroup` parameter.
2. Select this Coders Group using the `SBCAllowedCodersGroupID` parameter of the IP Profile table.
3. Enable this feature by setting the `SBCAllowedCodersMode` parameter of the IP Profile table to **Restriction**.

Coders that are not listed (including unknown coders) in the Allowed Coders Group are removed from the SDP offer. Therefore, only coders common between the SDP offer and Allowed Coders Group are used. If the SDP offer does not list any of the Allowed Coders, the call is rejected, unless transcoding is configured (using Extension coders – see 'Coder Transcoding' on page 432).

**Notes:**

- For a list of supported coders, see 'Configuring Coders' on page [233](#).
- Allowed Coders Groups are applicable only to audio media.

The Allowed Coders process is as follows:

- a. The device receives an incoming SIP message with SDP (offer) and checks the offered coders.
- b. The source (first) leg may have Allowed Coders (i.e. list of coders that can be used - enforced).
- c. The device checks for common coders between the SDP offered coders and the Allowed Coders Group list.

For example, assume the following:

- The SDP coder offer includes the following coders: G.729, G.711, and G.723.
- The source (first) leg includes the following Allowed Coders: G.711 and G.729.

The device selects the common coders, i.e., G.711 and G.729 (with changed preferred coder priority - highest for G.711). In other words, it removes the coders that are not in the Allowed Coders list and the order of priority is first according to the Allowed Coders list.

## 32.4.6 Coder Transcoding

The device can add coders, referred to as *Extension coders* to the SDP offer in the outgoing leg.

For example, assume the following:

- The SDP coder offer includes the following coders: G.729, G.711, and G.723.
  - The incoming leg includes the following Allowed coders: G.711 and G.729.
1. The device selects the common coders, i.e., G.711 and G.729 (with changed preferred coder priority - highest for G.711). In other words, it removes the coders that are not in the Allowed coders list and the order of priority is first according to the Allowed coders list.
  2. Assuming that the outgoing leg also includes Allowed coders and/or Extension coders: The device performs the Allowed coders procedure (common coders) between the updated coder list and the outgoing leg's Allowed coders. The Extension coders procedure is performed before Allowed coders.
  3. Adding to the example, assume the following:
    - For the outgoing leg, the device selects the common coders G.711 and G.729 (explained in the example above).
    - Outgoing leg includes the Extended coder G.726.
    - Outgoing leg includes the following Allowed coders: G.723, G.726, and G.729.

As a result, the device selects the common coders, i.e., G.729 and G.726 (coder priority did not change Extension coder order).

If the Allowed coders policy on the SDP incoming leg returns an empty coders list, the device rejects the call (SIP 488 or ACK and BYE). If both Extension coders and Allowed coders policies on SDP (in this order) returns an empty coders list, the outgoing leg rejects the call (SIP 488, or ACK and BYE).

Below is an example, assuming that Allowed Coders list (ordered) includes G711A-law (PCMA), G729, and G711U-law (PCMU), and Extension Coder is G729.

1. SDP offer - original offer:

```
m=audio 6050 RTP/AVP 0 8 4 96
a=rtpmap:0 PCMU/8000
a=rtpmap:8 PCMA/8000
a=rtpmap:4 G723/8000
a=fmtp:4 annexa=no
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
a=ptime:20
a=sendrecv
```

2. SDP offer - after manipulation:

```
m=audio 6010 RTP/AVP 8 0 96 18
a=rtpmap:0 PCMU/8000
a=rtpmap:8 PCMA/8000
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
```

```
aptime:20
a=sendrecv
a=rtpmap:18 G729/8000
a=fmtp:18 annexb=no
```

In the SDP, the "m=audio 6010 RTP/AVP 8 0 96 18" line shows that the coder priority has changed - G.711A-law ("8") and then G.711U-law ("0") - and that the Extension coder G.729 ("18") has been added. The G.723 coder ("4") in the original offer was removed as it was not defined in the Allowed Coders list (i.e., a restricted coder).

➤ **To configure Extension coders:**

1. In the Coders Group table (see 'Configuring Coder Groups' on page 236), configure a Coders Group for extension coders.
2. In the IP Profile table, select this Coders Group in the 'Extension Coders Group ID' parameter.
3. In the IP Profile table, enable this feature by setting the 'Allowed Coders Mode' parameter to **Restriction** or **Restriction and Preference**.

### 32.4.7 Prioritizing Coder List in SDP Offer

In addition to restricting the use of coders with Allowed coders, the device can prioritize the coders listed in the SDP offer. This feature is referred to as *Coder Preference*. This is done on both SBC legs:

- **Incoming SDP offer:** The device arranges the coder list according to the order in the Allowed Coders Group table. The coders listed higher up in the table take preference over ones listed lower down in the table. This feature is enabled by setting the 'Allowed Coders Mode' parameter in the IP Profile table to **Preference** or **Restriction and Preference**. If set to **Preference**, in addition to the Allowed coders that are listed first in the SDP offer, the original coders received in the SDP are retained and listed after the Allowed coders. Thus, this mode does not necessarily restrict coder use to Allowed coders, but uses (prefers) the Allowed coders whenever possible.
- **Outgoing SDP offer:** If only Allowed coders are used, the coders are arranged in the SDP offer as described above. However, if Extension coders are also used, then the coder list is arranged according to the 'SBC Preferences Mode' parameter in the IP Profile table. This parameter can be configured to add the Extension coders after the Allowed coders (i.e., at the end of the list - default) according to their order in the Coders Group table, or arrange Allowed and Extension coders according to their position in the Coders Group table.

### 32.4.8 SRTP-RTP and SRTP-SRTP Transcoding

The device supports transcoding between SRTP and RTP. The device can also enforce specific SBC legs to use SRTP and/or RTP. The device's handling of SRTP/RTP is configured using the IP Profile parameter, SBCMediaSecurityBehaviour, which provides the following options:

- SBC passes the media as is, regardless of whether it's RTP or SRTP (default).
- SBC legs negotiate only SRTP media lines (m=); RTP media lines are removed from the incoming SDP offer\answer.
- SBC legs negotiate only RTP media lines; SRTP media lines are removed from the incoming offer\answer.
- Each SDP offer\answer is extended (if not already) to two media lines for RTP and SRTP.

If after SDP offer/answer negotiation, one SBC leg uses RTP while the other uses SRTP, then the device performs RTP-SRTP transcoding. To translate between RTP and SRTP, the following prerequisites must be met:

- At least one supported SDP "crypto" attribute.
- The EnableMediaSecurity parameter must be set to 1.

Channel resources are not required for transcoding between RTP and SRTP.

Transcoding where both legs are configured for SRTP is typically required to trans-encrypt and trans-decrypt. This is relevant when the MKI and Symmetric MKI parameters are enabled. In other words, both sides need to both encrypt and decrypt the outgoing and incoming SRTP packets, respectively. Channel resources are not required for transcoding between SRTP and SRTP.

### 32.4.9 Multiple RTP Media Streams per Call Session

The device's SBC application supports multiple RTP media streams per SBC call session. Up to five different media types can be included in a session:

- Audio (m=audio)
- Video (m=video)
- Text (m=text)
- Fax (m=image)

Therefore, the device can provide transcoding of various attributes in the SDP offer/answer (e.g., codec, port, and packetization time) per media type. If the device is unable to perform transcoding (for example, does not support the codec), it relays the SBC dialog transparently.

### 32.4.10 Interworking DTMF Methods

The device supports interworking between various DTMF methods such as RFC 2833, In-Band DTMF's, and SIP INFO (Cisco\Nortel\Korea). By default, the device allows the remote user agents to negotiate (in case of RFC 2833) and passes DTMF without intervention. However, if two user agents (UA) support different DTMF methods, the device can interwork these different DTMF methods at each leg.

This DTMF interworking feature is enabled using IP Profiles (*ini* file parameter IPProfile):

- SBCRFC2833Behavior - affects the RFC 2833 SDP offer/answer negotiation:
  - [0] (default): the device does not intervene in the RFC 2833 negotiation.
  - [1]: each outgoing offer/answer includes RFC 2833 in the offered SDP (the device adds RFC 2833 only if the incoming offer does not include RFC 2833).
  - [2]: the device removes RFC 2833 from the incoming offer.
- SBCAlternativeDTMFMethod – the device's first priority for DTMF method at each leg is RFC 2833. Therefore, if a specific leg negotiates RFC 2833 successfully, then the chosen DTMF method for this leg is RFC 2833. For legs where RFC 2833 is not negotiated successfully, the device uses this parameter to determine the DTMF method for the leg.
  - [0] (default): the device does not attempt to interwork any special DTMF method
  - [1]: In Band
  - [2]: INFO, Cisco
  - [3]: INFO, Nortel
  - [4]: INFO, Korea

The chosen DTMF method determines (for each leg) which DTMF method is used for sending DTMF's. If the device interworks between different DTMF methods and one of the

methods is In-band\RFC 2833, detection and generation of DTMF methods requires DSP allocation.

## 32.5 Fax Negotiation and Transcoding

The device can allow fax transmissions to traverse transparently without transcoding or it can handle the fax as follows:

- Allow interoperability between different fax machines, supporting fax transcoding if required.
- Restrict usage of specific fax coders to save bandwidth, enhance performance, or comply with supported coders. These coders include G.711 (A-Law or Mu-Law), VBD (G.711 A-Law or G.711 Mu-Law), and T38.

Fax configuration is done in the IP Profile and Coder Group Settings tables. The IP Profile table determines the supported fax coders and the negotiation method used between the incoming and outgoing fax legs, using the following fax-related parameters:

- SBCFaxBehavior: defines the offer negotiation method - pass fax transparently, negotiate fax according to fax settings in IP Profile, or enforce remote UA to first establish a voice channel before fax negotiation.
- SBCFaxCodersGroupID: defines the supported fax coders (from the Coders Group Settings table).
- SBCFaxOfferMode: determines the fax coders sent in the outgoing SDP offer.
- SBCFaxAnswerMode: determines the fax coders sent in the outgoing SDP answer.

**Note:** The voice-related coder configuration (Allowed and Extended coders) is independent of the fax-related coder configuration, with the exception of the G.711 coder. If the G.711 coder is restricted by the Allowed Coders Group table, it is not used for fax processing even if it is listed in the Coders Group Settings table for faxes. However, support for G.711 coders for voice is not dependent upon which fax coders are listed in the Coders Group Settings table.

## 32.6 Limiting SBC Call Duration

You can define a maximum allowed duration (in minutes) for SBC calls. If an established call reaches this user-defined limit, the device terminates the call. This feature ensures calls are properly terminated, allowing available resources for new calls. This feature is configured using the MaxCallDuration parameter.

## 32.7 SIP Authentication Server for SBC Users

The device can function as an authentication server for SIP SBC message requests, based on HTTP authentication DIGEST with MD5. Alternatively, such requests can be authenticated by an external, third-party server.

When functioning as an authentication server (set by the IP Group table parameter, AuthenticationMode), the device authenticates users belonging to a User-type IP Group. When the device receives an INVITE or REGISTER request from a client (e.g., SIP phone) for SIP message authorization, the device processes the authorization as follows:

1. The device verifies the type of incoming SIP method (e.g., INVITE) that must be challenged for authorization. This is configured using the IP Group table parameter, MethodList.

2. If the message is received without an Authorization header, the device "challenges" the client by sending a 401 or 407 SIP response. The client then resends the request with an Authorization header (containing the user name and password).
3. The device validates the SIP message according to the settings of the parameters, AuthNonceDuration, AuthChallengeMethod and AuthQOP.
  - If validation fails, the message is rejected and the device sends a 403 "Forbidden" response.
  - If validation succeeds, the device verifies identification of the SBC user. This is done by checking that the user name and password received from the user is the same username and password that appears in the device's database. The SBC users in the database are obtained from the User Information file. If the SIP SBC user is not successfully authenticated after three attempts, the device sends a 403 "Forbidden" response.
4. If the user is successfully identified, the SIP message request is processed.

## 32.8 Interworking SIP Signaling

The device supports interworking of SIP signaling messages to ensure interoperability between communicating SIP UAs or entities. This is critical in network environments where the UAs on opposing SBC legs have different SIP signaling support. For example, some UAs may support different versions of a SIP method while others may not even support a specific SIP method. The configuration method for assigning specific SIP message handling modes to UAs, includes configuring an IP Profile with the required interworking mode, and then assigning the IP Profile to the relevant IP Group.

This section describes some of the device's support for handling SIP methods to ensure interoperability.

### 32.8.1 Interworking SIP 3xx Redirect Responses

The device supports interworking of SIP 3xx redirect responses. By default, the device's handling of SIP 3xx responses is to send the Contact header unchanged. However, some SIP UAs may support different versions of the SIP 3xx standard while others may not even support SIP 3xx.

The handling of SIP 3xx can be configured for all calls, using the global parameter SBC3xxBehavior. For configuring different SIP 3xx handling options for different UAs (i.e., per IP Group), use the IP Profile table parameter, 'SBC Remote 3xx Behavior'.

#### 32.8.1.1 Resultant INVITE Traversing Device

The device can handle SIP 3xx responses so that the new INVITE message sent as a result of the 3xx traverses the device. The reasons for enforcing resultant INVITEs to traverse the device may vary:

- The user that receives the 3xx is unable to route to the 3xx contact (i.e., the user is on the LAN and the new contact is on the WAN). In such a scenario, the device enables the user to reach the WAN contact and overcome NAT problems.
- Enforce certain SBC policies (e.g., call admission control, header manipulation, and transcoding) on the resultant INVITE.

The device enforces this by modifying each Contact in the 3xx response as follows:

- Changes the host part to the device's IP address – this change causes the remote user agent to send the INVITE to the device.
- Adds a special prefix ("T~&R\_") to the Contact user part – to identify the new INVITE as a 3xx resultant INVITE.

The SBC handling for the 3xx resultant INVITE is as follows:

1. The incoming INVITE is identified as a 3xx resultant INVITE according to the special prefix.
2. The device automatically replaces the SBC host part (in the Request-URI) with the host from the 3xx Contact.
3. The prefix ("T~&R\_") remains in the user part for the classification, manipulation, and routing mechanisms.
4. The classification, manipulation, and routing processes are done exactly like any other INVITE handling. The special prefix can be used for specific routing rules for 3xx resultant INVITES.
5. The prefix is removed before the resultant INVITE is sent to the destination.

**Figure 32-6: SIP 3xx Response Handling**

The process of this feature is described using an example:

1. The device receives the Redirect server's SIP 3xx response (e.g., Contact: <sip:User@IPPBX:5060;transport=tcp;param=a>;q=0.5).
2. The device replaces the Contact header value with the special prefix and database key value as user part, and with the device's URL as host part (e.g., Contact: <sip:Prefix\_Key\_User@SBC:5070;transport=udp>;q=0.5).
3. The device sends this manipulated SIP 3xx response to the Far-End User (FEU).
4. The FEU sends a new request with the Request-URI set to the value of the received 3xx response's Contact header (e.g., RequestURI: sip:Prefix\_Key\_User@SBC:5070;transport=udp).
5. Upon receipt of the new request from the FEU, the device replaces the Request-URI with the new destination address (e.g., RequestURI: sip:Prefix\_User@IPPBX:5070;transport=tcp;param=a).
6. The device removes the user prefix from the Request-URI, and then sends this Request-URI to the new destination (e.g., RequestURI: sip:User@IPPBX:5070;transport=tcp;param=a).

### 32.8.1.2 Local Handling of SIP 3xx

The device can handle SIP 3xx responses on behalf of the dialog-initiating UA and retry the request (e.g., INVITE) using one or more alternative URIs included in the 3xx response. The new request includes SIP headers from the initial request such as Diversion, History-Info, P-Asserted-Id, and Priority. The source and destination URIs can be manipulated using the regular manipulation mechanism.

The device sends the new request to the alternative destination according to the IP-to-IP Routing table rules. (where the 'Call Trigger' field is set to **3xx**). It is also possible to specify the IP Group that sent the 3xx request as matching criteria for the re-routing rule in this table ('ReRoute IP Group ID' field).

## 32.8.2 Interworking SIP Diversion and History-Info Headers

This device can be configured to interwork between the SIP Diversion and History-Info headers. This is important, for example, to networks that support the Diversion header but not the History-Info header, or vice versa. Therefore, mapping between these headers is crucial for preserving the information in the SIP dialog regarding how and why (e.g., call redirection) the call arrived at a certain SIP UA.

This feature is configured in the IP Profile table (IPProfile parameter) using the following new parameters:

- SBCDiversionMode - defines the device's handling of the Diversion header
- SBCHistoryInfoMode - defines the device's handling of the History-Info header

The handling of the SIP Diversion and History-Info headers is described in the table below:

**Handling of SIP Diversion and History-Info Headers**

| Parameter Value                                            | SIP Header Present in Received SIP Message                 |                                                               |                                                           |
|------------------------------------------------------------|------------------------------------------------------------|---------------------------------------------------------------|-----------------------------------------------------------|
|                                                            | Diversion                                                  | History-Info                                                  | Diversion and History-Info                                |
| <b>HistoryInfoMode = Add<br/>DiversionMode = Remove</b>    | Diversion converted to History-Info.<br>Diversion removed. | Not present                                                   | Diversion removed.                                        |
| <b>HistoryInfoMode = Remove<br/>DiversionMode = Add</b>    | Not present.                                               | History-Info converted to Diversion.<br>History-Info removed. | History-Info added to Diversion.<br>History-Info removed. |
| <b>HistoryInfoMode = Disable<br/>DiversionMode = Add</b>   | Diversion converted to History-Info.                       | Not present.                                                  | Diversion added to History-Info.                          |
| <b>HistoryInfoMode = Disable<br/>DiversionMode = Add</b>   | Not present.                                               | History-Info converted to Diversion.                          | History-Info added to Diversion.                          |
| <b>HistoryInfoMode = Add<br/>DiversionMode = Add</b>       | Diversion converted to History-Info.                       | History-Info converted to Diversion.                          | Headers are synced and sent.                              |
| <b>HistoryInfoMode = Remove<br/>DiversionMode = Remove</b> | Diversion removed.                                         | History-Info removed.                                         | Both removed.                                             |

### 32.8.3 Interworking SIP REFER Messages

The device supports interworking of SIP REFER messages. SIP UAs may support different versions of the REFER standard while others may not even support REFER.

This feature supports the following:

- Attended, unattended, and semi-attended call transfers
- Sending INVITE, REFER-notifications, BYE, PRACK and Session Timer on behalf of peer PBXs
- Advanced routing rules for the new, initiated INVITE
- Forwarding early media after REFER while attempting to avoid transcoding (by sending session update)
- Interoperate with environments where different SIP UAs lack basic SIP functionality such as re-INVITE, UPDATE, PRACK, Delayed Offer, re-INVITE without SDP
- Session updates after connect to avoid transcoding

The handling of REFER can be configured for all calls, using the global parameter `SBCReferBehavior`. For configuring different REFER handling options for different UAs (i.e., IP Groups), use the IP Profile table parameter, 'SBC Remote Refer Behavior'.

- **Local handling of REFER:** This option is used for UAs that do not support REFER. Upon receipt of a REFER request, instead of forwarding it to the IP Group, the device handles it locally. It generates a new INVITE to the alternative destination according to the rules in the IP-to-IP Routing table (where the 'Call Trigger' field is set to **REFER**). It is also possible to specify the IP Group that sent the REFER request, as matching criteria for the re-routing rule in this table ('ReRoute IP Group ID' field).
- **Transparent handling:** The device forwards the REFER with the Refer-To header unchanged.
- **Re-routing through SBC:** The device changes the Refer-To header so that the re-routed INVITE is sent through the SBC application.
- **IP Group Name =** The device sets the host part in the REFER message to the name configured for the IP Group in the IP Group table.

### 32.8.4 Interworking SIP PRACK Messages

The device supports interworking of SIP Provisional Response ACKnowledgement (PRACK) messages (18x). While some UAs may not support PRACK (RFC 3262), others may require it. The device can be configured to resolve this interoperable issue and enable sessions between such endpoints. SIP PRACK handling is configured using the IP Profile parameter, 'SBC Prack Mode':

- **Optional:** PRACK is optional for these UAs. If required, the device performs the PRACK process on behalf of the destination UA.
- **Mandatory:** PRACK is required for these UAs. Calls from UAs that do not support PRACK are rejected. Calls destined to these UAs are also required to support PRACK.
- **Transparent (default):** The device does not intervene with the PRACK process and forwards the request as is.

## 32.8.5 Interworking SIP Session Timer

The device supports interworking of the SIP signaling keep-alive mechanism. The SIP standard provides a signaling keep-alive mechanism using re-INVITE and UPDATE messages. In certain setups, keep-alive may be required by some SIP UAs while for others it may not be supported. The device can resolve this mismatch by performing the keep-alive process on behalf of SIP UAs that do not support it.

For configuring the handling of session expires, use the IP Profile parameter, 'SBC Session Expires Mode'.

## 32.8.6 Interworking SIP Early Media

The device supports various interworking modes for SIP early media between SIP UAs (i.e., IP Groups):

- **Early Media Enabling:** The device supports the interworking of early media between SIP UAs that support early media and those that do not support receipt of early media. Early media can arrive in provisional responses to an INVITE request. The device forwards the request of early media for IP Groups that support this capability; otherwise, the device terminates it. Provisional responses whose SDP are suppressed are changed to a SIP 180 response. This feature is also supported for delayed offers. This is configured using the IP Profile parameter, 'SBC Remote Early Media Support'. The device refers to this parameter also for features that require early media such as playing ringback tone.
- **Early Media Response Type:** The device supports the interworking of different SIP provisional response types between UAs for forwarding the early media to the caller. This can support all early media response types (default), SIP 180 only, or SIP 183 only, and is configured by the IP Profile parameter, 'SBC Remote Early Media Response Type'.
- **Multiple 18x:** The device supports the interworking of different support for multiple 18x responses (including 180 Ringing, 181 Call is Being Forwarded, 182 Call Queued, and 183 Session Progress) that are forwarded to the caller. The UA can be configured as supporting only receipt of the first 18x response (i.e., the device forwards only this response to the caller), or receipt of multiple 18x responses (default). This is configured by the IP Profile parameter, 'SBC Remote Multiple 18x Support'.
- **Early Media RTP:** The device supports the interworking with remote clients that send 18x responses with early media and whose subsequent RTP is delayed, and with remote clients that do not support this and require RTP to immediately follow the 18x response. Some clients do not support 18x with early media, while others require 18x with early media (i.e., they cannot play ringback tone locally). These various interworking capabilities are configured by the IP Profile parameters, 'SBC Remote Early Media RTP', 'SBC Remote Supports RFC 3960', and 'SBC Remote Can Play Ringback'. See the flowcharts below for the device's handling of such scenarios:

Figure 32-7: SBC Early Media RTP 18x without SDP

Figure 32-8: Early Media RTP - SIP 18x with SDP

### 32.8.7 Interworking SIP re-INVITE Messages

The device supports interworking of SIP re-INVITE messages. This enables communication between endpoints that generate re-INVITE requests and those that do not support the receipt of re-INVITES. The device does not forward re-INVITE requests to IP Groups that do not support it. Instead, it sends a SIP response to the re-INVITE request, which can either be a success or a failure, depending on whether the device can bridge the media between the endpoints. The device can also handle re-INVITES with or without an SDP body, enabling communication between endpoints that do not support re-INVITE requests without SDP, and those that require SDP. The device generates an SDP offer and adds it to the incoming re-INVITE request if it does not contain an SDP and only then forwards it to the destination endpoint. This interworking support is configured by the IP Profile parameter, 'SBC Remote Reinvite Support'.

### 32.8.8 Interworking SIP UPDATE Messages

The device supports interworking of the SIP UPDATED message. This enables communication between UAs that generate UPDATE requests and those that do not support the receipt of UPDATE requests. The device does not forward UPDATE requests to IP Groups that do not support it. Instead, it sends a SIP response to the UPDATE request which can either be a success or a failure, depending on whether the device can bridge the media between the endpoints. The handling of UPDATE messages is configured by the IP Profile parameter 'SBC Remote Update Support'.

### 32.8.9 Interworking SIP re-INVITE to UPDATE

The device enables communication between endpoints (IP Groups) that do not support re-INVITE requests but support the UPDATE method, and vice versa. The device translates the re-INVITE request to the UPDATE request, and vice versa. Note that if a re-INVITE request arrives without SDP, the device generates the SDP and adds it to the outgoing UPDATE request. To enable this feature, each IP Group needs to be configured with its unique capabilities by associating it with a relevant IP Profile. For example, an IP Group that supports UPDATE requests but not re-INVITES would be configured as follows:

- SBCRemoteUpdateSupport = 2 (Supported)
- SBCRemoteReinviteSupport = 0 (Not Supported)

If a re-INVITE request needs to be forwarded to this IP Group, it is translated to an UPDATE request.

### 32.8.10 Interworking Delayed Offer

The device enables sessions between endpoints (IP Groups) that send INVITES without SDP (i.e., delayed media) and those that do not support the receipt of INVITES without SDP. The device creates an SDP and adds it to INVITES that arrive without SDP. This intervention in the SDP offer/answer process may require transcoding. Delayed offer is also supported when early media is present.

The interworking of delayed offer is configured using the IP Profile parameter 'SBC Remote Delayed Offer Support'.

**Note:** For this feature to function properly, a valid Extension Coders Group ID needs to be configured for IP Profiles that do not support delayed offer.

### 32.8.11 Interworking Call Hold

The device supports the interworking of call hold / retrieve requests between IP entities supporting different call hold capabilities:

- Interworking SDP call hold formats. This is configured by the IP Profile parameter, 'SBC Remote Hold Format'.
- Interworking the play of the held tone for IP entities that cannot play held tones locally. This is configured by the IP Profile parameter, 'SBC Play Held Tone'.
- Interworking generation of held tone where the device generates the tone to the held party instead of the call hold initiator. This is configured by the IP Profile parameter, 'SBC Reliable Held Tone Source'.

For configuring IP Profiles, see Configuring IP Profiles [239](#).

## 32.9 Call Survivability

This section describes various call survivability features supported by the SBC device.

### 32.9.1 Auto-Provisioning of Subscriber-Specific Information for BroadWorks Server for Survivability

This feature enables SBC user registration for interoperability with BroadSoft BroadWorks server to provide call survivability in case of connectivity failure with the BroadWorks server, for example, due to a WAN failure. This feature enables local users to dial a local extension (or any other configured alias) that identifies another local user, in survivability mode. This feature is enabled using the SBCExtensionsProvisioningMode parameter.

In normal operation, when subscribers (such as IP phones) register to the BroadWorks server through the device, the device includes the SIP Allow-Events header in the sent REGISTER message. In response, the BroadWorks server sends the device a SIP 200 OK containing an XML body with subscriber information such as extension number, phone number, and URIs (aliases). The device forwards the 200 OK to the subscriber (without the XML body).

**Figure 32-9: Interoperability with BroadWorks Registration Process**

The device saves the users in its registration database with their phone numbers and extensions, enabling future routing to these destinations during survivability mode. When in survivability mode, the device routes the call to the Contact associated with the dialed phone number or extension number in the registration database.

Below is an example of an XML body received from the BroadWorks server:

```
<?xml version="1.0" encoding="utf-8"?>
<BroadsoftDocument version="1.0" content="subscriberData">
 <phoneNumbers>
 <phoneNumber>2403645317</phoneNumber>
 <phoneNumber>4482541321</phoneNumber>
 </phoneNumbers>
 <aliases>
 <alias>sip:bob@broadsoft.com</alias>
 <alias>sip:rhughes@broadsoft.com</alias>
 </aliases>
</BroadsoftDocument>
```

```
</aliases>
<extensions>
 <extension>5317</extension>
 <extension>1321</extension>
</extensions>
</BroadSoftDocument>
```

### 32.9.2 BroadSoft's Shared Phone Line Call Appearance for SBC Survivability

The device can provide redundancy for BroadSoft's Shared Call Appearance feature. When the BroadSoft application server switch (AS) fails or does not respond, or when the network connection between the device and the BroadSoft AS is down, the device manages the Shared Call Appearance feature for the SIP clients.

This feature is supported by configuring a primary extension and associating it with secondary extensions (i.e., *shared lines*) so that incoming calls to the primary extension also ring at the secondary extensions. The call is established with the first extension to answer the call, and consequently, the ringing at the other extensions stop. For example, assume primary extension number 600 is shared with secondary extensions 601 and 602. In the case of an incoming call to 600, all three phone extensions ring simultaneously (using the device's call forking feature as described in 'SIP Forking Initiated by SIP Proxy Server' on page 448). Note that incoming calls specific to extensions 601 or 602 ring only at these specific extensions.

**Figure 32-10: Call Survivability for BroadSoft's Shared Line Appearance**

To configure this capability, you need to configure a shared-line, inbound manipulation rule for registration requests to change the destination number of the secondary extension numbers (e.g. 601 and 602) to the primary extension (e.g., 600). Call forking must also be enabled. The procedure below describes the main configuration required.

**Notes:**

- You can configure whether REGISTER messages from secondary lines are terminated on the device or forwarded transparently (as is), using the SBCSharedLineRegMode parameter.
- The device enables outgoing calls from all equipment that share the same line simultaneously (usually only one simultaneous call is allowed per a specific shared line).
- The LED indicator of a shared line may display the wrong current state.

➤ **To configure the Shared Line feature:**

1. In the IP Group table (see 'Configuring IP Groups' on page 204), add a Server-type IP Group for the BroadWorks server.
2. In the IP Group table, add a User-type IP Group for the IP phone users and set the 'Enable SBC Client Forking' parameter to **Yes** so that the device forks incoming calls to all contacts under the same AOR that are registered in the device's registration database.
3. In the IP-to-IP Routing table (see 'Configuring SBC IP-to-IP Routing' on page 462), add a rule for routing calls between the above configured IP Groups.
4. In the IP to IP Inbound Manipulation table (see 'Configuring IP-to-IP Inbound Manipulations' on page 472), add a manipulation rule for the secondary extensions (e.g., 601 and 602) so that they also register in the device's database under the primary extension contact (e.g., 600):
  - Set the 'Manipulation Purpose' field to **Shared Line**.
  - Set the 'Source IP Group' field to the IP Group ID that you created for the users (e.g., 2).
  - Set the 'Source Username Prefix' field to represent the secondary extensions (e.g., 601 and 602).
  - Set the 'Manipulated URI' field to **Source** to manipulate the source URI.
  - Set the 'Remove From Right' field to "1" to remove the last digit of the extensions (e.g., 601 is changed to 60).
  - Set the 'Suffix to Add' field to "0" to add 0 to the end of the manipulated number (e.g., 60 is changed to 600).

### 32.9.3 Call Survivability for Call Centers

The device supports call survivability for call centers. When a communication failure (e.g., in the network) occurs with the remote voice application server responsible for handling the call center application (such as IVR), the device routes the incoming calls received from the customer (i.e., from the TDM gateway) to the call center agents.

In normal operation, the device registers the agents in its users registration database. Calls received from the TDM gateway are forwarded by the device to the application server, which processes the calls and sends them to specific call center agents, through the device. Upon a failure with the application server, the device routes the calls from the TDM Gateway to the agents. The device routes the call to the first available user it finds. If the call is not answered by the user, the device routes it to the next available user. The SBC can handle a sequence of up to five users, after which the session is timed out and the call is dropped.

**Figure 32-11: Normal Operation in Call Center Application**

**Figure 32-12: Call Survivability for Call Center**

➤ **To configure call survivability for a call center application:**

1. In the IP Group table (see 'Configuring IP Groups' on page 204), add IP Groups for the following entities:
  - TDM Gateway (Server-type IP Group). This entity forwards the customer calls through the device to the Application server.
  - Application server (Server-type IP Group). This entity processes the call and sends the call through the device to the specific call center agent located on a different network (remote).
  - Call center agents (User-type IP Group). You can configure multiple IP Groups to represent different groups of call center agents, for example, agents and managers.
2. In the Classification table (see 'Configuring Classification Rules' on page 456), add rules to classify incoming calls that are received from the entities listed in Step 1, to IP Groups.
3. In the SBC IP-to-IP Routing table (see 'Configuring SBC IP-to-IP Routing' on page 462), add the following IP-to-IP routing rules:
  - For normal operation:
    - ◆ Routing from TDM Gateway to Application server.
    - ◆ Routing from Application server to call center agents.
  - For call survivability mode: Routing from TDM Gateway to call center agents. This configuration is unique due to the following settings:
    - ◆ The 'Source IP Group ID' field is set to the IP Group of the TDM Gateway.
    - ◆ The 'Destination Type' field is set to **Hunt Group**, which is specifically used for call center survivability.
    - ◆ The 'Destination IP Group ID' field is set to the IP Group of the call center agents.

The figure below displays a routing rule example, assuming IP Group "1" represents the TDM Gateway and IP Group "3" represents the call center agents:

**Figure 32-13: Routing Rule Example for Call Center Survivability**

|                                                        |              |
|--------------------------------------------------------|--------------|
| <b>Add Record</b> <span>✕</span>                       |              |
| Index                                                  | 3            |
| Source IPGroup ID                                      | 1            |

| <div> <span>Submit</span> <span>✕ Cancel</span> </div> |              |

### 32.9.4 Survivability Mode Display on Aastra IP Phones

If the SBC device is deployed in an Enterprise network with Aastra IP phones and connectivity with the WAN fails, the device provides call survivability by enabling communication between IP phone users within the LAN enterprise. In such a scenario, the device can be configured to notify the IP phones that it is currently operating in Survivability mode. When this occurs, the Aastra IP phones display the message, "StandAlone Mode" on their LCD screens. This feature is enabled by setting the `SBCEnableAASTRASurvivabilityNotice` parameter to 1.

When this feature is enabled and the SBC device is in Survivability mode, it responds to SIP REGISTER messages from the IP phones with a SIP 200 OK containing the following XML body:

```
Content-Type: application/xml
<?xml version="1.0" encoding="utf-8"?>
<LMIDocument version="1.0">
 <LocalModeStatus>
 <LocalModeActive>true</LocalModeActive>
 <LocalModeDisplay>StandAlone Mode</LocalModeDisplay>
 </LocalModeStatus>
</LMIDocument>
```

## 32.10 Call Forking

This section describes various Call Forking features supported by the device.

### 32.10.1 Initiating SIP Call Forking

The SBC device supports call forking of an incoming call to multiple SBC users (destinations). Call forking is supported by the device's capability of registering multiple SIP client user phone contacts (mobile and fixed-line extensions) under the same Address of Record (AOR) in its registration database. This feature can be implemented in the following example scenarios:

- An enterprise Help Desk, where incoming customer calls are simultaneously sent to multiple customer service agent extensions.
- An employee's phone devices, where the incoming call is simultaneously sent to multiple devices (e.g., to the employee's office phone and mobile SIP phone).
- An enterprise reception desk, where an incoming call is simultaneously sent to multiple receptionists.

The device supports various modes of call forking. For example, in Parallel call forking mode, the device sends the INVITE message simultaneously to all the users registered under the same AOR, resulting in the ringing of all extensions; the first extension to pick up the call receives the call, and all other extensions stop ringing. The Call Forking feature is configured by creating a User-type IP Group and configuring the IP Group table's parameter, 'SBC Client Forking Mode' (see Configuring IP Groups on page 255).

The device can also fork INVITE messages received for a Request-URI of a specific contact (user) registered in the database to all other users located under the same AOR as the specific contact. This is configured using the SBCSendInviteToAllContacts parameter.

### 32.10.2 SIP Forking Initiated by SIP Proxy Server

The device can handle SIP forking responses received from a proxy server in response to an INVITE forwarded by the device from a UA. In other words, received responses with a different SIP To header 'tag' parameter for the request forwarded by the device. This occurs in scenarios, for example, where a proxy server forks the INVITE request to several UAs, and therefore, the SBC device may receive several replies for a single request. Forked SIP responses may result in a single SDP offer with two or more SDP answers during call setup. The SBC handles this scenario by "hiding" the forked responses from the INVITE-initiating UA. This is achieved by marking the UA that responded first to the INVITE as the active UA, and only requests/responses from that UA are subsequently forwarded. All other requests/responses from other UAs are handled by the SBC (SDP offers from these users are answered with an 'inactive' media).

The SBC supports two forking modes, configured by the SBCForkingHandlingMode parameter:

- Latch On First - only the first received 18x response is forwarded to the INVITE initiating UA, and disregards any subsequently received 18x forking responses (with or without SDP).
- Sequential - all 18x responses are forwarded to the INVITE initiating UA, one at a time in a sequential manner. If 18x arrives with an offer only, only the first offer is forwarded to the INVITE initiating UA.

The SBC also supports media synchronization for call forking. If the active UA is the first one to send the final response (e.g., 200 OK), the call is established and all other final responses are acknowledged and a BYE is sent if needed. If another UA sends the first final response, then it is possible that the SDP answer that was forwarded to the INVITE-initiating UA is not relevant, and media synchronization is needed between the two UAs. Media synchronization is done by sending a re-INVITE request immediately after the call is established. The re-INVITE is sent without an offer to the INVITE-initiating UA. This causes

the UA to send an offer which is forwarded to the UA that confirmed the call. The media synchronization process is enabled by the EnableSBCMediaSync parameter.

## 32.11 Alternative Routing on Detection of Failed SIP Response

The device can detect failure of a sent SIP response (e.g., TCP timeout, and UDP ICMP). In such a scenario, the device re-sends the response to an alternative destination. This support is in addition to alternative routing if the device detects failed SIP requests.

For example, assume the device sends a SIP 200 OK in response to a received INVITE request. If the device does not receive a SIP ACK in response to this, it sends a new 200 OK to the next alternative destination. This new destination can be the next given IP address resolved from a DNS from the Contact or Record-Route header in the request related to the response.

## Reader's Notes

## 33 SBC Configuration

This section describes the configuration of the SBC application.

**Note:** For the SBC application, the following requirements must be met:

- The SBC application must be enabled (see 'Enabling Applications' on page 197).
- The 'SBC' Software License Key must be installed on the device (see 'Software License Key' on page 553).

### 33.1 Configuring General Settings

The General Settings page allows you to configure general SBC parameters. For a description of these parameters, see 'SBC Parameters' on page 869.

➤ **To configure general parameters:**

1. Open the General Settings page (**Configuration** tab > **VoIP** menu > **SBC** > **General Settings**).

**Figure 33-1: General Settings Page**

|                                      |                  |
|--------------------------------------|------------------|
| Transcoding Mode                     | Only If Required |
| SBC No Answer Timeout                | 600              |
| SBC GRUU Mode                        | AsProxy          |
| Minimum Session-Expires [sec]        | 90               |
| BroadWorks Survivability Feature     | Disable          |
| Bye Authentication                   | Disable          |
| SBC User Registration Time           | 0                |
| SBC Proxy Registration Time          | 0                |
| SBC Survivability Registration Time  | 0                |
| SBC Forking Handling Mode            | Latch On First   |
| Allow Unclassified Calls             | Reject           |
| SBC Session-Expires [sec]            | 180              |
| SBC Direct Media                     | Disable          |
| <b>Server Authentication</b>         |                  |
| Lifetime of the nonce in seconds     | 300              |
| Authentication Challenge Method      | 0                |
| Authentication Quality of Protection | 2                |

2. Configure the parameters as required.
3. Click **Submit** to apply your changes.
4. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 33.2 Configuring Admission Control

The Admission Control page allows you to define up to 100 rules for limiting the number of concurrent calls (SIP dialogs). These call limits can be applied per SRD, IP Group, SIP request type (e.g., INVITES), SIP dialog direction (e.g., inbound), and/or per user (identified by its registered contact). This is especially important for applications where VoIP and Data traffic contend on the WAN throughput, which may be limited by itself. For example, DSL WAN access interface is very limited in the uplink. Therefore, by controlling the number of calls allowed, bandwidth can be reserved for specific Data applications. This feature can be useful for implementing Service Level Agreements (SLA) policies.

The SIP dialog limits can be defined per SIP request type and direction. These relate to requests that initiate SIP dialogs and not the subsequent requests that can be of different type and direction. The SIP dialog-initiating request types can include SIP INVITES, REGISTER, and/or SUBSCRIBE, or it can be configured to include the total number of all dialogs.

This feature also provides support for SIP-dialog rate control, using the "token bucket" mechanism. The token bucket is a control mechanism that dictates the rate of SIP-dialog setups based on the presence of tokens in the bucket – a logical container that holds aggregate SIP dialogs to be accepted or transmitted. Tokens in the bucket are removed ("cached in") for the ability to setup a dialog. Therefore, a flow can setup dialogs up to its peak burst rate if there are adequate tokens in the bucket and if the burst threshold is configured appropriately:

- Every SIP dialog setup request must attempt to take a token from the bucket.
- If there are no tokens, the request is dropped.
- New tokens are added to the bucket at a user-defined rate (token rate).
- If the bucket contains the maximum number of tokens, tokens to be added at that moment are dropped.

Requests that reach the user-defined call limit (maximum concurrent calls and/or call rate) are sent to an alternative route, if configured in the IP-to-IP Routing table for the SRD or IP Group. If no alternative routing rule is located, the device rejects the SIP request with a SIP 486 "Busy Here" response.

### Notes:

- The enforcement of a configured limitation for the incoming leg is performed immediately after the Classification process. If the call/request is rejected at this stage, no routing is performed. The enforcement for the outgoing leg is performed within each alternative route iteration. This is accessed from two places: one during initial classification/routing, and another during alternative routing process.
- The Admission Control table can also be configured using the table *ini* file parameter, `SBCAdmissionControl` or CLI command, `configure voip > sbc sbc-admission-control`.

➤ **To configure Admission Control rules:**

1. Open the Admission Control page (**Configuration** tab > **VoIP** menu > **SBC** > **Admission Control**).
2. Click the **Add** button; the following dialog box appears:

**Figure 33-2: Admission Control Page - Add Record Dialog Box**

|                   |          |
|-------------------|----------|
| Index             | 0        |
| Limit Type        | IP Group |
| IP Group ID       | -1       |
| SRD ID            | -1       |
| Request Type      | All      |
| Request Direction | Both     |
| Limit             | -1       |
| Limit Per User    | -1       |
| Rate              | 0        |
| Max Burst         | 0        |

3. Configure the rule as required. For a description of the parameters, see the table below.
4. Click **Submit** to apply your changes.

**Admission Control Parameters**

| Parameter                                                              | Description                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Limit Type<br>CLI: limit-type<br>[SBCAdmissionControl_LimitType]       | Defines the entity to which the rule applies. <ul style="list-style-type: none"> <li>▪ [0] IP Group (default)</li> <li>▪ [1] SRD</li> </ul>                                                                                                                                                                                                         |
| IP Group ID<br>CLI: ip-group-id<br>[SBCAdmissionControl_IPGroupID]     | Defines the IP Group to which you want to apply the rule. To apply the rule to all IP Groups, set this parameter to -1 (default).<br><b>Note:</b> This parameter is applicable only if 'Limit Type' is set to <b>IP Group</b> .                                                                                                                     |
| SRD ID<br>CLI: srd-id<br>[SBCAdmissionControl_SRDID]                   | Defines the SRD to which you want to apply the rule. To apply the rule to all SRDs, set this parameter to -1 (default).<br><b>Note:</b> This parameter is applicable only if 'Limit Type' is set to <b>SRD</b> .                                                                                                                                    |
| Request Type<br>CLI: request-type<br>[SBCAdmissionControl_RequestType] | Defines the SIP dialog-initiating request type to which you want to apply the rule (not the subsequent requests that can be of different type and direction). <ul style="list-style-type: none"> <li>▪ [0] All = (Default) Includes the total number of all dialogs.</li> <li>▪ [1] INVITE</li> <li>▪ [2] SUBSCRIBE</li> <li>▪ [3] Other</li> </ul> |

| Parameter                                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Request Direction<br>CLI: request-direction<br><b>[SBCAdmissionControl<br/>_RequestDirection]</b> | Defines the direction of the SIP request to which the rule applies. <ul style="list-style-type: none"> <li><b>[0]</b> Both = (Default) Rule applies to inbound and outbound SIP dialogs.</li> <li><b>[1]</b> Inbound = Rule applies only to inbound SIP dialogs.</li> <li><b>[2]</b> Outbound = Rule applies only to outbound SIP dialogs.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Limit<br>CLI: limit<br><b>[SBCAdmissionControl<br/>_Limit]</b>                                    | Defines the maximum number of concurrent SIP dialogs per IP Group or SRD. You can also use the following special values: <ul style="list-style-type: none"> <li><b>[0]</b> 0 = Block all these dialogs.</li> <li><b>[-1]</b> -1 = (Default) No limit.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Limit Per User<br>CLI: limit-per-user<br><b>[SBCAdmissionControl<br/>_LimitPerUser]</b>           | Defines the maximum number of concurrent SIP dialogs per user belonging to the specified IP Group or SRD. You can also use the following special values: <ul style="list-style-type: none"> <li><b>[0]</b> 0 = Block all these dialogs.</li> <li><b>[-1]</b> -1 = (Default) No limit.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Rate<br>CLI: rate<br><b>[SBCAdmissionControl<br/>_Rate]</b>                                       | Defines the rate at which tokens are added to the token bucket per second (i.e., token rate). One token is added to the bucket every 1000 divided by the value of this parameter (in milliseconds).<br>The default is 0 (i.e., unlimited rate).<br><b>Note:</b> The token bucket feature is per IP Group, SRD, SIP request type, and SIP request direction.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Max Burst<br>CLI: max-burst<br><b>[SBCAdmissionControl<br/>_MaxBurst]</b>                         | Defines the maximum number of tokens (SIP dialogs) that the bucket can hold. The device only accepts a SIP dialog if a token exists in the bucket. Once the SIP dialog is accepted, a token is removed from the bucket. If a SIP dialog is received by the device and the token bucket is empty, then the device rejects the SIP dialog. Alternatively, if the bucket is full, for example, 100 tokens, and 101 SIP dialogs arrive (before another token is added to the bucket, i.e., faster than that defined in the Rate field), then the device accepts the first 100 SIP dialogs and rejects the last one.<br><br>Dropped requests are replied with the SIP 486 "Busy Here" response. Dropped requests are not counted in the bucket.<br><br>The default is 0 (i.e., unlimited SIP dialogs).<br><b>Note:</b> The token bucket feature is per IP Group, SRD, SIP request type, and SIP request direction. |

## 33.3 Configuring Allowed Coder Groups

The Allowed Coders Group page allows you to define up to five Allowed Coder Groups, each with up to 10 coders. Allowed Coder Groups determine the coders that can be used for a specific SBC leg. Therefore, the device can enforce the use of specific coders while preventing the use of other coders. Coders excluded from the Allowed Coders Group are removed from the SDP offer. Only common coders between SDP offered coders and coders configured in the Allowed Coder Groups are used. For more information, see 'Restricting Coders' on page [431](#).

The Allowed Coders Group table is also used to configure Extension coders. These are coders that are added to the SDP offer. For more information on Extension coders, see Coder Transcoding on page [432](#).

The order of appearance of coders in the Allowed Coder Group determines the coder priority (preference), whereby the first coder is given the highest priority. For more information, see 'Prioritizing Coder List in SDP Offer' on page [433](#).

**Notes:**

- Each coder can appear only once per Allowed Coder Group.
- Allowed Coder Groups are applicable only to audio media.
- Allowed Coder Groups can be assigned to IP Profiles (see 'Configuring IP Profiles' on page 239).
- The Allowed Coder Groups table can also be configured using the table ini file parameter, AllowedCodersGroup or CLI command, configure voip > sbc allowed-coders-group group0.

➤ **To configure Allowed Coder Groups:**

1. Open the Allowed Coders Group page (**Configuration** tab > **VoIP** menu > **SBC** > **Allowed Coders Group**).

**Figure 33-3: Allowed Coders Group Page**

2. From the 'Allowed Coders Group ID' drop-down list, select an ID for the Allowed Coder Group.
3. In the Coder Name table, select coders for the Allowed Coder Group.
4. Click **Submit** to apply your changes.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

## 33.4 Routing SBC

This section describes the configuration of the routing entities for the SBC application. These include the following:

- Classification rules - see 'Configuring the Classification Rules' on page 456
- Condition rules - see 'Configuring Condition Rules' on page 461
- IP-to-IP routing rules - see 'Configuring SBC IP-to-IP Routing' on page 462
- Alternative routing reasons - see 'Configuring Alternative Routing Reasons' on page 468

### 33.4.1 Configuring Classification Rules

The Classification table enables you to configure up to 100 Classification rules. Classification rules are used to classify incoming SIP dialog-initiating requests (e.g., INVITE messages) to source IP Groups from where the SIP dialog request originated. The identified IP Group is later used in the manipulation and routing processes.

Classification rules also enhance security by allowing you to create a SIP access list, whereby classified calls can be denied (i.e., blacklist) or allowed (i.e., whitelist).

The Classification table is used to classify incoming SIP dialog requests only if the other classification stages fail, as described below:

1. **Classification Stage 1 - Registered Users Database:** The device searches its registration database to check if the incoming SIP dialog arrived from a registered user:
  - Compares the SIP Contact header of the received SIP dialog to the Contact of the registered user.
  - Compares the URL in the SIP P-Asserted-Identity/From header to the registered address-of-record (AOR).

If this stage fails, the device proceeds to classification based on Proxy Set.

2. **Classification Stage 2 - Proxy Set:** If the database search fails, the device performs classification based on Proxy Set if the 'Classify By Proxy Set' parameter is enabled for the IP Group (see 'Configuring IP Groups' on page 204). If enabled, the device checks whether the INVITE's IP address (if host names, then according to the dynamically resolved IP address list) is defined for a Proxy Set ID (in the Proxy Set table). If a Proxy Set ID has such an IP address, the device classifies the INVITE to the IP Group that is associated with this Proxy Set. (The Proxy Set ID is assigned to the IP Group using the IP Group table's 'Proxy Set ID' parameter.)

**Note:** For security purposes, it is highly recommended to disable the Classify by Proxy Set feature so that the device can use the Classification table instead, for "strict" classification of incoming calls to IP Groups. In addition, in cases where multiple IP Groups are associated with the same Proxy Set ID, do **not** use the Classify by Proxy Set feature.

If this stage fails (or Classify by Proxy Set is disabled), the device proceeds to classification based on the Classification table.

3. **Classification Stage 3 - Classification Table:** If classification based on Proxy Set fails (or disabled), the device uses the Classification table to classify the SIP dialog to an IP Group. If it locates a classification rule whose characteristics (such as source IP address) match the incoming SIP dialog, then the SIP dialog is assigned to the associated IP Group. In addition, if the classification rule is defined as a whitelist, the SIP dialog is allowed and proceeds with the manipulation, routing and other SBC processes. If the classification rule is defined as a blacklist, the SIP dialog is denied.

If the classification process fails, the device rejects or allows the call, depending on the setting of the 'Unclassified Calls' parameter (on the General Settings page - **Configuration** tab > **VoIP** menu > **SBC** > **General Settings**). If this parameter is set to **Allow**, the incoming SIP dialog is assigned to an IP Group as follows:

1. The device checks on which SIP listening port (e.g., 5061) the incoming SIP dialog request arrived and the SIP Interface which is configured with this port (in the SIP Interface table).
2. The device checks the SRD that is associated with this SIP Interface (in the SIP Interface table) and then classifies the SIP dialog with the first IP Group that is associated with this SRD. For example, if IP Groups 3 and 4 use the same SRD, the device classifies the call to IP Group 3.

**Note:** If classification for a SIP request fails and the device is configured to reject unclassified calls, the device can send a specific SIP response code per SIP interface, configured by the 'Classification Failure Response Type' parameter in the SIP Interface table (see 'Configuring SIP Interface Table' on page 201).

The flowchart below illustrates the classification process:

**Figure 33-4: Classification Process (Identifying IP Group or Rejecting Call)**

**Notes:**

- Incoming REGISTER messages are saved in the device's registration database and sent to a destination only if they are associated with a source User-type IP Group.
- The Classification table can also be configured using the table ini file parameter, Classification or CLI command, configure voip > sbc routing classification.

The Classification table provides two configuration areas:

- Matching characteristics of incoming IP call, for example, source IP address.
- Operation - classifies call to an IP Group.

If the incoming call matches the characteristics of a rule, then the call is classified to the IP Group configured for that rule.

➤ **To configure classification rules:**

1. Open the Classification Table page (**Configuration** tab > **VoIP** menu > **SBC** > **Routing SBC** > **Classification Table**).
2. Click the **Add** button; the following appears:

**Figure 33-5: Classification Table Page**

| Add Record                                                                  |       |

The URI is typically located in the SIP From header. However, you can configure the SIP header from where the device obtains the source URI. This is done in the IP Group table, using the 'Source URI Input' parameter. For more information on how the device obtains this URI, see 'SIP Dialog Initiation Process' on page 420.<br>If this routing rule is not required, leave the field empty. The asterisk (*) symbol can be used to depict any source host prefix.<br><b>Note:</b> For REGISTER requests, the source URL is obtained from the To header.                                                                                                        |
| Destination Username Prefix<br>CLI: dst-user-name-prefix<br><b>[Classification_DestinationUsernamePrefix]</b> | Defines the prefix of the destination Request-URI user part of the incoming SIP dialog.<br><b>Note:</b> The prefix can be a single digit or a range of digits. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| Destination Host<br>CLI: dst-host<br><b>[Classification_DestinationHost]</b>                                  | Defines the prefix of the destination Request-URI host name of the incoming SIP dialog request. If this routing rule is not required, leave the field empty. The asterisk (*) symbol can be used to depict any destination host prefix.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Parameter                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Message Condition<br>CLI: message-condition<br><b>[Classification_MessageCondition]</b> | Assigns a Condition rule which can also be used to classify the incoming SIP dialog.<br><b>Note:</b> Condition rules are configured in the Condition Table (see 'Configuring Condition Rules' on page 461).                                                                                                                                                                                                                                                                            |
| <b>Operation Rule</b>                                                                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Source IP Group ID<br>CLI: src-ip-group-id<br><b>[Classification_SrcIPGroupID]</b>      | Defines an IP Group to which the incoming SIP dialog request is assigned if this SIP dialog matches the matching rule.<br>The default is -1 (i.e., no IP Group is assigned).<br><b>Notes:</b> <ul style="list-style-type: none"> <li>The IP Group must be associated with the selected SRD.</li> <li>The IP Group is used for SBC routing and manipulations.</li> <li>To define IP Groups, see 'Configuring IP Groups' on page 204.</li> </ul>                                         |
| Action Type<br>CLI: action-type<br><b>[Classification_ActionType]</b>                   | Defines a whitelist or blacklist for incoming SIP dialog requests that match the characteristics of the classification rule. <ul style="list-style-type: none"> <li><b>[0]</b> Deny = Blocks incoming SIP dialogs that match the characteristics of the Classification rule (blacklist).</li> <li><b>[1]</b> Allow = Allows incoming SIP dialogs that match the characteristics of the Classification rule (whitelist) and assigns it to the associated IP Group. (default)</li> </ul> |

### 33.4.1.1 Classification Based on URI of Selected Header Example

The following example describes how to configure classification of incoming calls to IP Groups, based on source URI in a specific SIP header.

This example assumes the following incoming INVITE message:

```
INVITE sip:8000@10.33.4.226 SIP/2.0
Via: SIP/2.0/UDP 10.33.4.226;branch=z9hG4bKVEBTDAHSUYRTEXEDEGJY
From: <sip:100@10.33.4.226>;tag=YSQQKXXREVDPTYPTNFMWG
To: <sip:8000@10.33.4.226>
Call-ID: FKPN0YRNKROIMEGBSSKS@10.33.4.226
CSeq: 1 INVITE
Contact: <sip:100@10.33.4.226>
Route: <sip:2000@10.10.10.10>,<sip:300@10.10.10.30>
Supported: em,100rel,timer,replaces
P-Called-Party-ID: <sip:1111@10.33.38.1>
User-Agent: Sip Message Generator V1.0.0.5
Content-Length: 0
```

1. In the Classification table, add the following classification rules:

| Index | Source Username Prefix | Destination Username Prefix | Destination Host | Source IP Group ID |
|-------|------------------------|-----------------------------|------------------|--------------------|
| 0     | 333                    | -                           | -                | 1                  |
| 1     | 1111                   | 2000                        | 10.10.10.10      | 2                  |

2. In the IP Group table, add the following IP Groups:

| Index | Source URI Input  | Destination URI Input |
|-------|-------------------|-----------------------|
| 1     | -                 | -                     |
| 2     | P-Called-Party-ID | Route                 |

In this example, a match exists only for Classification Rule #1. This is because the source (1111) and destination (2000) username prefixes match those in the INVITE's P-Called-Party-ID header (i.e., "<sip:1111@10.33.38.1>") and Route header (i.e., "<sip:2000@10.10.10.10>"), respectively. These SIP headers were determined in IP Group ID 2.

### 33.4.2 Configuring Condition Rules

Condition rules define special conditions for the incoming SIP messages. Condition rules are configured using the same syntax as that used for message conditions in the Message Manipulations table (see Configuring SIP Message Manipulation on page 224).

Condition rules are used if assigned to any of the following:

- Classification rules in the Classification table (see Configuring Classification Rules on page 456). This enables you to use SIP message conditions as an additional matching criteria for classifying incoming SIP dialogs to IP Groups, thereby increasing the strictness of the classification process.
- IP-to-IP routing rules in the IP-to-IP Routing table (see Configuring SBC IP-to-IP Routing on page 462): This enables you to use SIP message conditions as an additional matching criteria for selecting the routing rule.

You can define simple Condition rules, for example, "header.to.host contains company" or complex rules using the "AND" or "OR" Boolean operands. You can also use regular expressions (regex), for example:

- "body.sdp regex pcmu" can be used to enable routing based on the offered codec (G.711 Mu) in the incoming SDP message.
- "body.sdp regex (AVP[0-9][\s]\*s8[\s][\n])" can be used to enable routing based on payload type 8 in the incoming SDP message.

#### Notes:

- For a detailed description of the syntax for configuring SIP message manipulation rules, refer to *SIP Message Manipulations Quick Reference Guide*.
- The Condition table can also be configured using the table ini file parameter, ConditionTable or CLI command, configure voip > sbc routing condition-table.

➤ **To configure Condition rules:**

1. Open the Condition Table page (**Configuration** tab > **VoIP** menu > **SBC** > **Routing SBC** > **Condition Table**).
2. Click the **Add** button; the following dialog box appears:

**Figure 33-6: Condition Table Page - Add Record Dialog Box**

The dialog box titled "Add Record" contains three input fields: "Index" with the value "0", "Condition" with the value "param.ipg.src.type==user", and "Description" with the value "IP Group USER". At the bottom right are "Submit" and "Cancel" buttons.

3. Configure the rule as required. For a description of the parameters, see the table below.
4. Click **Submit**.

The figure below shows an example of the Condition table configured with the following rules:

- **Index 1:** Incoming SIP dialog that is classified as belonging to a User-type IP Group.
- **Index 2:** Incoming SIP dialog with a SIP Via header.
- **Index 3:** Incoming SIP dialog with 101 as the user part in the SIP From header.

**Figure 33-7: Condition Table Page**

| Index | Condition                   | Description                  |
|-------|-----------------------------|------------------------------|
| 0     | param.ipg.src.type==user    | IP Group USER                |
| 1     | header.via.exists           | Includes SIP Via header      |
| 2     | header.from.url.user=='101' | 101 user part of From header |

**Condition Table Parameters Description**

| Parameter                                                       | Description                                                                                                                                           |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| Condition<br>CLI: condition<br>[ConditionTable_Condition]       | Defines the Condition rule of the SIP message.<br>The valid value is a string.<br><b>Note:</b> User and host parts must be enclosed in single quotes. |
| Description<br>CLI: description<br>[ConditionTable_Description] | Defines a brief description of the Condition rule.                                                                                                    |

### 33.4.3 Configuring SBC IP-to-IP Routing

The IP-to-IP Routing table enables you to configure up to 200 SBC IP-to-IP routing rules. This table provides enhanced IP-to-IP call routing capabilities for routing received SIP dialog messages (e.g., INVITE) to a destination IP address. The SIP message is routed according to a routing rule whose configured input characteristics (e.g., Source IP Group) match the incoming SIP message. If the characteristics of an incoming call does not match the first rule, the call characteristics is then compared to those of the second rule, and so on until a matching rule is located. If no rule is matched, the call is rejected.

The call can be routed to one of the following IP destinations:

- Registered user Contact listed in the device's database (only for User-type IP Groups).
- IP Group - the destination is the address configured for the Proxy Set associated with the IP Group (allows redundancy/load balancing).
- Specified destination address (can be based on IP address, host name, port, transport type, and/or SRD). Routing to a host name can be resolved using NAPTR/SRV/A-Record.
- Request-URI of incoming SIP dialog initiating requests.
- ENUM query.
- Hunt Group - used for call survivability (see 'Call Survivability for Call Centers' on page 445).
- IP address (in dotted-decimal notation or FQDN - NAPTR/SRV/A-Record resolutions) according to a specified Dial Plan index listed in the loaded Dial Plan file.
- LDAP server or LDAP query result. For more information on LDAP-based routing, see 'Routing Based on LDAP Active Directory Queries' on page 179.

**Figure 33-8: IP-to-IP Routing Types**

For all destination types listed above except destination IP Group, the IP Group can optionally be itself, configured to provide the destination SRD and/or IP Profile. If neither destination SRD nor destination IP Group is defined, the destination SRD is the source SRD and the destination IP Group is its default IP Group.

The IP-to-IP Routing table also provides the following features:

- **Alternative routing or load balancing:** In addition to the alternative routing/load balancing provided by the Proxy Set associated with the destination IP Group, the table allows the configuration of alternative routes whereby if a route fails, the next adjacent (below) rule in the table that is configured as 'Alt Route Ignore/Consider Inputs' are used. The alternative routes rules can be set to enforce the input matching criteria or to ignore any matching criteria. Alternative routing occurs upon one of the following conditions:
  - A request sent by the device is responded with one of the following:
    - ◆ SIP response code (i.e., 4xx, 5xx, and 6xx SIP responses) configured in the SBC Alternative Routing Reasons table (see 'Configuring Alternative Routing

Reasons' on page 468).

- ◆ SIP 408 Timeout or no response (after timeout).
- The DNS resolution includes IP addresses that the device has yet to try (for the current call).

Messages are re-routed with the same SIP Call-ID and CSeq header fields (increased by 1).

- **Re-routing of SIP requests:** This table enables you to configure "re-routing" rules of requests (e.g., INVITEs) that the device sends upon receipt of SIP 3xx responses or REFER messages. These rules are configured for destinations that do not support receipt of 3xx or REFER and where the device handles the requests locally (instead of forwarding the 3xx or REFER to the destination).
- **Least cost routing (LCR):** If the LCR feature is enabled, the device searches the routing table for matching routing rules and then selects the one with the lowest call cost. The call cost of the routing rule is done by assigning it a Cost Group. For configuring Cost Groups, see 'Least Cost Routing' on page 189. If two routing rules have identical costs, then the rule appearing higher up in the table (i.e., first-matched rule) is used. If a selected route is unavailable, the device uses the next least-cost routing rule. However, even if a matched rule is not assigned a Cost Group, the device can select it as the preferred route over other matched routing rules with Cost Groups, according to the settings of the LCR parameter, LCRDefaultCost (see 'Enabling LCR and Configuring Default LCR' on page 191).

**Note:** The IP-to-IP Routing table can also be configured using the table ini file parameter, IP2IPRouting (see 'SBC Parameters' on page 869) or CLI command, configure voip > sbc routing ip2ip-routing.

➤ **To configure SBC IP-to-IP routing rules:**

1. Open the IP-to-IP Routing Table page (**Configuration** tab > **VoIP** menu > **SBC** submenu > **Routing SBC** submenu > **IP to IP Routing Table**).
2. Click the **Add** button; the following dialog box appears:

**Figure 33-9: IP-to-IP Routing Table - Add Record Dialog Box**

|                                                                             |           |
|-----------------------------------------------------------------------------|-----------|
| Add Record                                                                  |           |
| Index                                                                       | 0         |
| Source IP Group ID                                                          | -1        |
| Source Username Prefix                                                      | *         |
| Source Host                                                                 | *         |
| Destination Username Prefix                                                 | *         |
| Destination Host                                                            | *         |
| Request Type                                                                | All       |
| Message Condition                                                           | None      |
| ReRoute IP Group ID                                                         | -1        |
| Call Trigger                                                                | Any       |
| Destination Type                                                            | IP Group  |
| Destination IP Group ID                                                     | -1        |
| Destination SRD ID                                                          | None      |
| Destination Address                                                         |           |
| Destination Port                                                            | 0         |
| Destination Transport Type                                                  |           |
| Alternative Route Options                                                   | Route Row |
| Cost Group                                                                  | None      |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |           |

3. Configure the rule as required. For a description of the parameters, see the table below.
4. Click **Submit**.

#### IP-to-IP Routing Table Parameters Description

| Parameter                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics</b>                                                                      |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Source IP Group ID<br><b>[IP2IPRouting_SrcIPGroupID]</b><br>CLI: src-ip-group-id                     | Selects the IP Group from where the IP-to-IP call originated. Typically, the IP Group of an incoming SIP dialog is determined (or classified) using the 'Classification' table (see Configuring Classification Rules on page 456). If not used (i.e., any IP Group), simply leave the field empty. The default is -1.                                                                                                            |
| Source Username Prefix<br><b>[IP2IPRouting_SrcUsernamePrefix]</b><br>CLI: src-user-name-prefix       | Defines the prefix of the user part of the incoming SIP dialog's source URI (usually the From URI). You can use special notations for denoting the prefix. For example, to denote any prefix, use the asterisk (*) symbol; to denote calls without a user part in the URI, use the \$ sign. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653. The default is * (i.e., any prefix).  |
| Source Host<br><b>[IP2IPRouting_SrcHost]</b><br>CLI: src-host                                        | Defines the host part of the incoming SIP dialog's source URI (usually the From URI). If this rule is not required, leave the field empty. To denote any host name, use the asterisk (*) symbol (default).                                                                                                                                                                                                                       |
| Destination Username Prefix<br><b>[IP2IPRouting_DestUsernamePrefix]</b><br>CLI: dst-user-name-prefix | Defines the prefix of the incoming SIP dialog's destination URI (usually the Request URI) user part. You can use special notations for denoting the prefix. For example, to denote any prefix, use the asterisk (*) symbol; to denote calls without a user part in the URI, use the \$ sign. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653. The default is * (i.e., any prefix). |
| Destination Host<br><b>[IP2IPRouting_DestHost]</b><br>CLI: dst-host                                  | Defines the host part of the incoming SIP dialog's destination URI (usually the Request-URI). If this rule is not required, leave the field empty. The asterisk (*) symbol (default) can be used to denote any destination host.                                                                                                                                                                                                 |
| Request Type<br><b>[IP2IPRouting_RequestType]</b><br>CLI: request-type                               | Defines the SIP dialog request type of the incoming SIP dialog. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> All (default)</li> <li>▪ <b>[1]</b> INVITE</li> <li>▪ <b>[2]</b> REGISTER</li> <li>▪ <b>[3]</b> SUBSCRIBE</li> <li>▪ <b>[4]</b> INVITE and REGISTER</li> <li>▪ <b>[5]</b> INVITE and SUBSCRIBE</li> <li>▪ <b>[6]</b> OPTIONS</li> </ul>                                                                      |
| Message Condition<br><b>[IP2IPRouting_MessageCondition]</b><br>CLI: message-condition                | Selects a Message Condition rule. To configure Message Condition rules, see 'Configuring Condition Rules' on page 461.                                                                                                                                                                                                                                                                                                           |
| ReRoute IP Group ID<br><b>[IP2IPRouting_ReRouteIPGroupID]</b><br>CLI: re-route-ip-group-id           | Defines the IP Group that initiated (sent) the SIP redirect response (e.g., 3xx) or REFER message. This field is typically used for re-routing requests (e.g., INVITEs) when interworking is required for SIP 3xx redirect responses or REFER messages (for more information, see                                                                                                                                                |

| Parameter                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                                                              | 'Interworking SIP 3xx Redirect Responses' on page 436 and 'Interworking SIP REFER Messages' on page 439, respectively). This parameter functions together with the 'Call Trigger' field (see below). The default is -1 (i.e., not configured).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Call Trigger<br>[IP2IPRouting_Trigger]<br>CLI: trigger       | <p>Defines the reason (i.e., trigger) for re-routing the SIP request:</p> <ul style="list-style-type: none"> <li>[0] Any = (Default) This routing rule is used for all scenarios (re-routes and non-re-routes).</li> <li>[1] 3xx = Re-routes the request if it was triggered as a result of a SIP 3xx response.</li> <li>[2] REFER = Re-routes the INVITE if it was triggered as a result of a REFER request.</li> <li>[3] 3xx or REFER = Applies to options [1] and [2].</li> <li>[4] Initial only = This routing rule is used for regular requests that the device forwards to the destination. | CLI: dst-ip-group-id                                                  | <p>unnecessary to configure a destination IP address (in the 'Destination Address' field). However, if both parameters are configured, then the IP Group takes precedence.</p> <p>If the destination IP Group is of USER type, the device searches for a match between the Request-URI (of the received SIP dialog) to an AOR registration record in the device's database. The SIP dialog is then sent to the IP address of the registered contact.</p> <p>The default is -1.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>This parameter is only relevant if the parameter 'Destination Type' is set to 'IP Group'. However, regardless of the settings of the parameter 'Destination Type', the IP Group is still used - only for determining the IP Profile or outgoing SRD. If neither IP Group nor SRD are defined in this table, the destination SRD is determined according to the source SRD associated with the Source IP Group (configured in the IP Group table, see 'Configuring IP Groups' on page 204). If this table does not define an IP Group but only an SRD, then the first IP Group associated with this SRD (in the IP Group table) is used.</li> <li>If the selected destination IP Group ID is type SERVER, the request is routed according to the IP Group addresses.</li> <li>If the selected destination IP Group ID is type USER, the request is routed according to the IP Group specific database (i.e., only to registered users of the selected database).</li> <li>If the selected destination IP Group ID is ANY USER ([2]), the request is routed according to the general database (i.e., any matching registered user).</li> </ul> |
| Destination SRD ID<br>[IP2IPRouting_DestSRDID]<br>CLI: dst-srd-id     | <p>Defines the SRD ID. The default is None.</p> <p><b>Note:</b> The destination IP Group must belong to the destination SRD if both are configured in this table.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Destination Address<br>[IP2IPRouting_DestAddress]<br>CLI: dst-address | <p>Defines the destination to where the call is sent. This can be an IP address or a domain name (e.g., domain.com).</p> <p>If ENUM-based routing is used (i.e., the 'Destination Type' parameter is set to ENUM) this parameter defines the IP address or domain name (FQDN) of the ENUM service, for example, e164.arpa, e164.customer.net, or NRENum.net. The device sends the ENUM query containing the destination phone number to an external DNS server, configured in the Multiple Interface table. The ENUM reply includes a SIP URI (user@host) which is used as the destination Request-URI in this routing table.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>This parameter is applicable only if the 'Destination Type' parameter is set to Dest Address [1] or ENUM [3].</li> <li>When using domain names, enter a DNS server IP address or alternatively, define these names in the Internal DNS table (see Configuring the Internal SRV Table on page 122).</li> <li>To terminate SIP OPTIONS messages at the device (i.e., to handle them locally), set this parameter to "internal".</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Alternative Route Options<br><b>[IP2IPRouting_AltRouteOptions]</b><br>CLI: alt-route-options     | Determines whether this routing rule is the main routing rule or an alternative routing rule (to the rule defined directly above it in the table). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Route Row (default) = Main routing rule - the device first attempts to route the call to this route if the incoming SIP dialog's input characteristics matches this rule.</li> <li>▪ <b>[1]</b> Alt Route Ignore Inputs = If the call cannot be routed to the main route (Route Row), the call is routed to this alternative route regardless of the incoming SIP dialog's input characteristics.</li> <li>▪ <b>[2]</b> Alt Route Consider Inputs = If the call cannot be routed to the main route (Route Row), the call is routed to this alternative route only if the incoming SIP dialog matches this routing rule's input characteristics.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>▪ The alternative routing entry (<b>[1]</b> or <b>[2]</b>) must be defined in the next consecutive table entry index to the Route Row entry (i.e., directly below it). For example, if Index 4 is configured as a Route Row, Index 5 must be configured as the alternative route.</li> <li>▪ For IP-to-IP alternative routing, configure alternative routing reasons upon receipt of 4xx, 5xx, and 6xx SIP responses (see <a href="#">Configuring Alternative Routing Reasons</a> on page 468). However, if no response, ICMP, or a SIP 408 response is received, the device attempts to use the alternative route even if no entries are configured in the 'SBC Alternative Routing Reasons' table.</li> <li>▪ Multiple alternative route entries can be configured (e.g., Index 1 is the main route - Route Row - and indices 2 through 4 are configured as alternative routes).</li> </ul> |
| Cost Group<br><b>[IP2IPRouting_CostGroup]</b><br>CLI: cost-group                                 | Assigns a Cost Group to the routing rule for determining the cost of the call. To configure Cost Groups, see 'Configuring Cost Groups' on page 193.<br><br>By default, no Cost Group is assigned to the rule.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 33.4.4 Configuring Alternative Routing Reasons

The SBC Alternative Routing Reasons page allows you to define up to five different call release (termination) reasons for call releases. If a call is released as a result of one of these reasons provided in SIP 4xx, 5xx, and 6xx response codes, the device attempts to locate an alternative route for the call. The call release reason type can be configured, for example, when there is no response to an INVITE message (after INVITE re-transmissions), where the device issues an internal 408 'No Response' implicit release reason.

Release reasons can also be configured to indicate that a route for an SRD or IP Group has reached its call admission control limit (i.e., maximum concurrent calls and/or call rate), as set in the Admission Control table (see 'Configuring Admission Control' on page 452). In such a scenario, an alternative route configured in the IP-to-IP Routing table can be used.

Alternative routing rules are configured in the IP-to-IP Routing table where the 'Alternative Route Options' parameter is set to **Alt Route Ignore Inputs** or **Alt Route Consider Inputs**. For more information, see 'Configuring SBC IP-to-IP Routing' on page 462.

**Notes:**

- Alternative routing occurs even if this table is not configured upon scenarios where no response, ICMP, or a SIP 408 response is received.
- SIP requests pertaining to an SRD or IP Group that reach the call limit (maximum concurrent calls and/or call rate) as defined in the Call Admission table are sent to an alternative route if configured in the IP-to-IP Routing table for the SRD or IP Group. If no alternative routing rule is located, the device automatically rejects the SIP request with a SIP 486 "Busy Here" response.
- The SBC Alternative Routing Reasons table can also be configured using the table ini file parameter, SBCAlternativeRoutingReasons or CLI command, configure voip > sbc routing sbc-alt-routing-reasons.

➤ **To configure SIP reason codes for alternative IP routing:**

1. Open the SBC Alternative Routing Reasons page (**Configuration** tab > **VoIP** menu > **SBC > Routing SBC > Alternative Routing Reasons**).

**Figure 33-10: Alternative Routing Reasons Page**

| SBC Alternative Routing Reasons |     |
|---------------------------------|-----|
| Reason 1                        | 401 |
| Reason 2                        |     |
| Reason 3                        |     |
| Reason 4                        |     |
| Reason 5                        |     |

2. Configure different call failure reasons that invoke alternative routing.
3. Click **Submit** to apply your changes.

## 33.5 SBC Manipulations

This section describes the configuration of the manipulation rules for the SBC application.

**Note:** For additional manipulation features, see the following:

- 'Configuring SIP Message Policy Rules'.
- 'Configuring SIP Message Manipulation' on page 224.

The device supports SIP URI user part (source and destination) manipulations for inbound and outbound routing. These manipulations can be applied to a source IP group, source and destination host and user prefixes, and/or user-defined SIP request (e.g., INVITE, OPTIONS, SUBSCRIBE, and/or REGISTER). Since outbound manipulations are performed after routing, the outbound manipulation rule matching can also be done by destination IP Group. Manipulated destination user and host are performed on the following SIP headers: Request-URI, To, and Remote-Party-ID (if exists). Manipulated source user and host are performed on the following SIP headers: From, P-Asserted (if exists), P-Preferred (if exists), and Remote-Party-ID (if exists).

You can also restrict source user identity in outgoing SIP dialogs in the Outbound Manipulation table (using the column PrivacyRestrictionMode). The device identifies an incoming user as restricted if one of the following exists:

- From header user is 'anonymous'.
- P-Asserted-Identity and Privacy headers contain the value 'id'.

All restriction logic is done after the user number has been manipulated.

Host name (source and destination) manipulations are simply host name substitutions with the names defined for the source and destination IP Groups respectively (if any, in the IP Group table).

Below is an example of a call flow and consequent SIP URI manipulations:

■ **Incoming INVITE from LAN:**

```

INVITE sip:1000@10.2.2.3;user=phone;x=y;z=a SIP/2.0
Via: SIP/2.0/UDP 10.2.2.6;branch=z9hGLLLLan
From: <sip:7000@10.2.2.6;user=phone;x=y;z=a>;tag=0llan;parameter1=abe
To: <sip:1000@10.2.2.3;user=phone>
Call-ID: USELLLLAN@10.2.2.3
CSeq: 1 INVITE
Contact: <sip:7000@10.2.2.3>
Supported: em,100rel,timer,replaces
Allow: REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK
User-Agent: Sip Message Generator V1.0.0.5
Content-Type: application/sdp
Content-Length: 155

v=0
o=SMG 791285 795617 IN IP4 10.2.2.6
s=Phone-Call
c=IN IP4 10.2.2.6
t=0 0
m=audio 6000 RTP/AVP 8
a=rtpmap:8 pcma/8000
a=sendrecv
a=ptime:20

```

■ **Outgoing INVITE to WAN:**

```

INVITE sip: 9721000@ITSP;user=phone;x=y;z=a SIP/2.0
Via: SIP/2.0/UDP 212.179.1.12;branch=z9hGwwan
From:
<sip:97000@IP_PBX;user=phone;x=y;z=a>;tag=0Wan;parameter1=abe
To: <sip: 9721000@ ITSP;user=phone>
Call-ID: USEVWWAN@212.179.1.12
CSeq: 38 INVITE

```

```

Contact: <sip:7000@212.179.1.12>
Supported: em,100rel,timer,replaces
Allow:
REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK,REFER
User-Agent: Sip Message Generator V1.0.0.5
Content-Type: application/sdp
Content-Length: 155
v=0
o=SMG 5 9 IN IP4 212.179.1.11
s=Phone-Call

t=0 0
m=audio 8000 RTP/AVP 8
a=rtpmap:8 pcma/8000
a=sendrecv
a=ptime:20

```

The SIP message manipulations in the example above (contributing to typical topology hiding) are as follows:

- Inbound source SIP URI user name from "7000" to "97000":

```

From:<sip:7000@10.2.2.6;user=phone;x=y;z=a>;tag=0llan;parameter1=abe

```

to

```

From:
<sip:97000@IP_PBX;user=phone;x=y;z=a>;tag=0Wan;parameter1=abe

```

- Source IP Group name (i.e., SIP URI host name) from "10.2.2.6" to "IP\_PBX":

```

From:<sip:7000@10.2.2.6;user=phone;x=y;z=a>;tag=0llan;parameter1=abe

```

to

```

From:
<sip:97000@IP_PBX;user=phone;x=y;z=a>;tag=0Wan;parameter1=abe

```

- Inbound destination SIP URI user name from "1000" to "9721000":

```

INVITE sip:1000@10.2.2.3;user=phone;x=y;z=a SIP/2.0
To: <sip:1000@10.2.2.3;user=phone>

```

to

```

INVITE sip:9721000@ITSP;user=phone;x=y;z=a SIP/2.0
To: <sip:9721000@ITSP;user=phone>

```

- Destination IP Group name (SIP URI host name) from "10.2.2.3" to "ITSP":

```

INVITE sip:1000@10.2.2.3;user=phone;x=y;z=a SIP/2.0
To: <sip:1000@10.2.2.3;user=phone>

```

to

```

INVITE sip:9721000@ITSP;user=phone;x=y;z=a SIP/2.0
To: <sip:9721000@ITSP;user=phone>

```

### 33.5.1 Configuring IP-to-IP Inbound Manipulations

The IP to IP Inbound Manipulation table allows you to configure up to 100 manipulation rules for manipulating the source or destination SIP URI user part of inbound SIP dialog requests. You can apply these manipulations to different SIP dialog message types (e.g., INVITE or REGISTER) and SIP headers as follows:

- Manipulated destination URI user part are done on the following SIP headers: Request-URI, To, and Remote-Party-ID (if exists)
- Manipulated source URI user part are done on the following SIP headers: From, P-Asserted-Identity (if exists), P-Preferred-Identity (if exists), and Remote-Party-ID (if exists)

The IP to IP Inbound Manipulation table provides two configuration areas:

- Matching characteristics (*Rule*) of incoming call, for example, source host name.
- Manipulation operation (*Action*), for example, remove user-defined number of characters from the left of the SIP URI user part.

If the incoming call matches the characteristics of a rule, then its manipulation action is applied.

#### Notes:

- The IP Group table can be used to configure a host name that overwrites the received host name. This manipulation can be done for source or destination IP Groups (see 'Configuring IP Groups' on page 204).
- The IP to IP Inbound Manipulation table can also be configured using the table ini file parameter, IPInboundManipulation or CLI command, configure voip > sbc manipulations ip-inbound-manipulation.

#### ➤ To configure IP-to-IP inbound manipulation rules:

1. Open the IP to IP Inbound Manipulation page (**Configuration** tab > **VoIP** menu > **SBC** > **Manipulations SBC** > **IP to IP Inbound**).
2. Click the **Add** button; the following dialog box appears:

**Figure 33-12: IP to IP Inbound Manipulation Page - Add Dialog Box**

| Rule                                                                        | Action                              |
|-----------------------------------------------------------------------------|-------------------------------------|
| Index                                                                       | <input type="text" value="0"/>      |
| Additional Manipulation                                                     | <input type="text" value="No"/>     |
| Manipulation Purpose                                                        | <input type="text" value="Normal"/> |
| Source IP Group ID                                                          | <input type="text" value="-1"/>     |
| Source Username Prefix                                                      | <input type="text" value="*"/>      |
| Source Host                                                                 | <input type="text" value="*"/>      |
| Destination Username Prefix                                                 | <input type="text" value="*"/>      |
| Destination Host                                                            | <input type="text" value="*"/>      |
| Request Type                                                                | <input type="text" value="All"/>    |
| Manipulated URI                                                             | <input type="text" value="Source"/> |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |                                     |

3. Configure a rule as required. For a description of the parameters, see the table below.
4. Click **Submit**.

#### IP to IP Inbound Manipulation Parameters Description

| Parameter                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics (Rule)</b>                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Request Type<br>CLI: request-type<br><b>[IPInboundManipulation_RequestType]</b>               | Defines the SIP request type to which the manipulation rule is applied. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> All = (Default) All SIP messages.</li> <li>▪ <b>[1]</b> INVITE = All SIP messages except REGISTER and SUBSCRIBE.</li> <li>▪ <b>[2]</b> REGISTER = Only REGISTER messages.</li> <li>▪ <b>[3]</b> SUBSCRIBE = Only SUBSCRIBE messages.</li> <li>▪ <b>[4]</b> INVITE and REGISTER = All SIP messages except SUBSCRIBE.</li> <li>▪ <b>[5]</b> INVITE and SUBSCRIBE = All SIP messages except REGISTER.</li> </ul> |
| Manipulated URI<br>CLI: manipulated-uri<br><b>[IPInboundManipulation_ManipulatedURI]</b>      | Determines whether the source or destination SIP URI user part is manipulated. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Source = (Default) Manipulation is done on the source SIP URI user part.</li> <li>▪ <b>[1]</b> Destination = Manipulation is done on the destination SIP URI user part.</li> </ul>                                                                                                                                                                                                                     |
| <b>Operation Rule (Action)</b>                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Remove From Left<br>CLI: remove-from-left<br><b>[IPInboundManipulation_RemoveFromLeft]</b>    | Defines the number of digits to remove from the left of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "n".                                                                                                                                                                                                                                                                                                                                                                          |
| Remove From Right<br>CLI: remove-from-right<br><b>[IPInboundManipulation_RemoveFromRight]</b> | Defines the number of digits to remove from the right of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "j".<br><b>Note:</b> If both 'Remove From Right' and 'Leave From Right' parameters are configured, the 'Remove From Right' setting is applied first.                                                                                                                                                                                                                         |
| Leave From Right<br>CLI: leave-from-right<br><b>[IPInboundManipulation_LeaveFromRight]</b>    | Defines the number of characters that you want retained from the right of the user name.<br><b>Note:</b> If both 'Remove From Right' and 'Leave From Right' parameters are configured, the 'Remove From Right' setting is applied first.                                                                                                                                                                                                                                                                                                  |
| Prefix to Add<br>CLI: prefix-to-add<br><b>[IPInboundManipulation_Prefix2Add]</b>              | Defines the number or string that you want added to the front of the user name. For example, if you enter 'user' and the user name is "john", the new user name is "userjohn".                                                                                                                                                                                                                                                                                                                                                            |
| Suffix to Add<br>CLI: suffix-to-add<br><b>[IPInboundManipulation_Suffix2Add]</b>              | Defines the number or string that you want added to the end of the user name. For example, if you enter '01' and the user name is "john", the new user name is "john01".                                                                                                                                                                                                                                                                                                                                                                  |

## 33.5.2 Configuring IP-to-IP Outbound Manipulations

The IP to IP Outbound Manipulation page allows you to configure up to 100 manipulation rules for manipulating SIP URI user part (source and destination) of outbound SIP dialog requests. Manipulation rules in the table are located according to the source IP Group, and source and destination host and user prefixes and can be applied to a user-defined SIP request type (e.g., INVITE, OPTIONS, SUBSCRIBE, and /or REGISTER). However, since outbound manipulations are done only after routing, the outbound manipulation rule matching can also be done by destination IP Group.

- Manipulated destination URI user part are performed on the following SIP headers: Request URI, To, and Remote-Party-ID (if exists).

- Manipulated source URI user part are performed on the following SIP headers: From, P-Asserted (if exists), P-Preferred (if exists), and Remote-Party-ID (if exists).

The IP to IP Outbound Manipulation table provides two configuration areas:

- Matching characteristics (*Rule*) of incoming call, for example, source host name.
- Manipulation operation (*Action*), for example, remove user-defined number of characters from the left of the SIP URI user part.

If the incoming call matches the characteristics of a rule, then its manipulation action is applied.

**Notes:**

- Manipulated destination SIP URI user names are done on the following SIP headers: Request URI, To, and Remote-Party-ID (if exists).
- Manipulated source SIP URI user names are done on the following SIP headers: From, P-Asserted (if exists), P-Preferred (if exists), and Remote-Party-ID (if exists)
- SIP URI host name (source and destination) manipulations can also be configured in the IP Group table. These manipulations are simply host name substitutions with the names defined for the source and destination IP Groups respectively.
- The IP to IP Outbound Manipulation table can also be configured using the table ini file parameter, IPOutboundManipulation or CLI command, configure voip > sbc manipulations ip-outbound-manipulation.

➤ **To configure IP-to-IP outbound manipulation rules:**

1. Open the IP to IP Outbound Manipulation page (**Configuration** tab > **VoIP** menu > **SBC > Manipulations SBC > IP to IP Outbound**).
2. Click the **Add** button; the following dialog box appears:

**Figure 33-13: IP to IP Outbound Manipulation Page - Add Dialog Box**

| Rule                                                                        | Action |
|-----------------------------------------------------------------------------|--------|
| Index                                                                       | 0      |
| Additional Manipulation                                                     | No     |
| Source IP Group ID                                                          | -1     |
| Destination IP Group ID                                                     | -1     |
| Source Username Prefix                                                      | *      |
| Source Host                                                                 | *      |
| Destination Username Prefix                                                 | *      |
| Destination Host                                                            | *      |
| Request Type                                                                | All    |
| ReRoute IP Group ID                                                         | -1     |
| Call Trigger                                                                | Any    |
| Manipulated URI                                                             | Source |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |        |

3. Configure a rule as required. For a description of the parameters, see the table below.
4. Click **Submit**.

### IP to IP Outbound Manipulation Table Parameters Description

| Parameter                                                                                                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics (Rule)</b>                                                                                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Additional Manipulation<br>CLI: is-additional-manipulation<br><b>[IPOutboundManipulation_IsAdditionalManipulation]</b> | <p>Determines whether additional SIP URI user part manipulation is done for the table entry rule listed directly above it.</p> <ul style="list-style-type: none"> <li><b>[0]</b> No = (Default) Regular manipulation rule - not done in addition to the rule above it.</li> <li><b>[1]</b> Yes = If the previous table row entry rule matched the call, consider this row entry as a match as well and perform the manipulation specified by this rule.</li> </ul> <p><b>Note:</b> Additional manipulation can only be performed on a different SIP URI (either source or destination) to the rule configured in the row above (configured by the 'Manipulated URI' parameter).</p> |
| Source IP Group ID<br>CLI: src-ip-group-id<br><b>[IPOutboundManipulation_SrcIPGroupID]</b>                             | <p>Defines the IP Group from where the INVITE is received.</p> <p>For any Source IP Group, enter the value -1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Destination IP Group ID<br>CLI: dst-ip-group-id<br><b>[IPOutboundManipulation_DestIPGroupID]</b>                       | <p>Defines the IP Group to where the INVITE is to be sent.</p> <p>For any Destination IP Group, enter the value -1.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Source Username Prefix<br>CLI: src-user-name-prefix<br><b>[IPOutboundManipulation_SrcUsernamePrefix]</b>               | <p>Defines the prefix of the source SIP URI user name (usually in the From header).</p> <p>For any prefix, enter the asterisk "*" symbol (default).</p> <p><b>Note:</b> The prefix can be a single digit or a range of digits. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.</p>                                                                                                                                                                                                                                                                                                                                                   |
| Source Host<br>CLI: src-host<br><b>[IPOutboundManipulation_SrcHost]</b>                                                | <p>Defines the source SIP URI host name - full name (usually in the From header).</p> <p>For any host name, enter the asterisk "*" symbol (default).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Destination Username Prefix<br>CLI: dst-user-name-prefix<br><b>[IPOutboundManipulation_DestUsernamePrefix]</b>         | <p>Defines the prefix of the destination SIP URI user name (usually in the Request-URI).</p> <p>For any prefix, enter the asterisk "*" symbol (default).</p> <p><b>Note:</b> The prefix can be a single digit or a range of digits. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.</p>                                                                                                                                                                                                                                                                                                                                              |
| Destination Host<br>CLI: dst-host<br><b>[IPOutboundManipulation_DestHost]</b>                                          | <p>Defines the destination SIP URI host name - full name (usually in the Request URI).</p> <p>For any host name, enter the asterisk "*" symbol (default).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Request Type<br>CLI: request-type<br><b>[IPOutboundManipulation_RequestType]</b>                                       | <p>Defines the SIP request type to which the manipulation rule is applied.</p> <ul style="list-style-type: none"> <li><b>[0]</b> All = (Default) all SIP messages.</li> <li><b>[1]</b> INVITE = All SIP messages except REGISTER and SUBSCRIBE.</li> <li><b>[2]</b> REGISTER = Only SIP REGISTER messages.</li> <li><b>[3]</b> SUBSCRIBE = Only SIP SUBSCRIBE messages.</li> <li><b>[4]</b> INVITE and REGISTER = All SIP messages except SUBSCRIBE.</li> <li><b>[5]</b> INVITE and SUBSCRIBE = All SIP messages except REGISTER.</li> </ul>                                                                                                                                        |
| ReRoute IP Group ID                                                                                                    | Defines the IP Group that initiated (sent) the SIP redirect response (e.g.,                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| Parameter                                                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-----------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLI: re-route-ip-group-id<br><b>[IPOutboundManipulation_ReRouteIPGroupID]</b>                       | 3xx) or REFER message. This parameter is typically used for re-routing requests (e.g., INVITEs) when interworking is required for SIP 3xx redirect responses or REFER messages.<br>The default is -1 (i.e., not configured).<br><b>Notes:</b> <ul style="list-style-type: none"> <li>This parameter functions together with the 'Call Trigger' parameter (see below).</li> <li>For more information on interworking of SIP 3xx redirect responses or REFER messages, see 'Interworking SIP 3xx Redirect Responses' on page 436 and 'Interworking SIP REFER Messages' on page 439, respectively.</li> </ul>                                                                    |
| Call Trigger<br>CLI: trigger<br><b>[IPOutboundManipulation_Trigger]</b>                             | Defines the reason (i.e, trigger) for the re-routing of the SIP request: <ul style="list-style-type: none"> <li><b>[0]</b> Any = (Default) Re-routed for all scenarios (re-routes and non-re-routes).</li> <li><b>[1]</b> 3xx = Re-routed if it triggered as a result of a SIP 3xx response.</li> <li><b>[2]</b> REFER = Re-routed if it triggered as a result of a REFER request.</li> <li><b>[3]</b> 3xx or REFER = Applies to options <b>[1]</b> and <b>[2]</b>.</li> <li><b>[4]</b> Initial only = Regular requests that the device forwards to a destination. In other words, re-routing of requests triggered by the receipt of REFER or 3xx does not apply.</li> </ul> |
| Manipulated URI<br>CLI: manipulated-uri<br><b>[IPOutboundManipulation_IsAdditionalManipulation]</b> | Determines whether the source or destination SIP URI user part is manipulated. <ul style="list-style-type: none"> <li><b>[0]</b> Source = (Default) Manipulation is done on the source SIP URI user part.</li> <li><b>[1]</b> Destination = Manipulation is done on the destination SIP URI user part.</li> </ul>                                                                                                                                                                                                                                                                                                                                                             |
| <b>Operation Manipulation Rule (Action)</b>                                                         |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Remove From Left<br>CLI: remove-from-left<br><b>[IPOutboundManipulation_RemoveFromLeft]</b>         | Defines the number of digits to remove from the left of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "n".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Remove From Right<br>CLI: remove-from-right<br><b>[IPOutboundManipulation_RemoveFromRight]</b>      | Defines the number of digits to remove from the right of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "j".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Leave From Right<br>CLI: leave-from-right<br><b>[IPOutboundManipulation_LeaveFromRight]</b>         | Defines the number of characters that you want retained from the right of the user name.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Prefix to Add<br>CLI: prefix-to-add<br><b>[IPOutboundManipulation_Prefix2Add]</b>                   | Defines the number or string that you want added to the front of the user name. For example, if you enter 'user' and the user name is "john", the new user name is "userjohn".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Suffix to Add<br>CLI: suffix-to-add<br><b>[IPOutboundManipulation_Suffix2Add]</b>                   | Defines the number or string that you want added to the end of the user name. For example, if you enter '01' and the user name is "john", the new user name is "john01".                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Privacy Restriction Mode<br>CLI: privacy-restriction-                                               | Determines user privacy handling (i.e., restricting source user identity in outgoing SIP dialogs).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Parameter                                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

# Part VII

## Cloud Resilience Package Application

## 34 CRP Overview

The device's Cloud Resilience Package (CRP) application enhances cloud-based or hosted communications environments by ensuring survivability, high voice quality and security at enterprise branch offices and cloud service customer premises. CRP is designed to be deployed at customer sites and branches of:

- Cloud-based and hosted communications
- Cloud-based or hosted contact-center services
- Distributed PBX or unified communications deployments

The CRP application is based on the functionality of the SBC application, providing branch offices with call routing and survivability support similar to the SAS application. CRP is implemented in a network topology where the device is located at the branch office, routing calls between the branch users, and/or between the branch users and other users located elsewhere (at headquarters or other branch offices), through a hosted server (IP PBX) located at the Enterprise headquarters. The device maintains call continuity even if a failure occurs in communication with the hosted IP PBX. It does this by using its Call Survivability feature, enabling the branch users to call one another or make external calls through the device's PSTN gateway interface (if configured).

For cloud providers, CRP ensures uninterrupted communications in the event of lost connection with the cloud providers' control systems. For distributed enterprises and contact centers, CRP is an essential solution for enterprises deploying geographically distributed communications solutions or distributed call centers with many branch offices. CRP ensures the delivery of internal and external calls even when the connection with the centralized control servers is lost.

**Table 2: Key Features**

| Survivability                                                                                                                                                                        | Quality of Experience/Service                                                                                                                                                                                    | Security                                                                                                                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>■ PSTN fallback*</li> <li>■ WAN redundancy</li> <li>■ Local mode</li> <li>■ High availability*</li> <li>■ Emergency calling (E911)</li> </ul> | <ul style="list-style-type: none"> <li>■ QoE monitoring</li> <li>■ Call Admission Control</li> <li>■ SLA fulfillment</li> <li>■ SIP mediation</li> <li>■ Media transcoding</li> <li>■ Test call agent</li> </ul> | <ul style="list-style-type: none"> <li>■ Layer 3 to 7 protection</li> <li>■ Media encryption</li> <li>■ Call control encryption</li> <li>■ NAT traversal</li> <li>■ Topology hiding</li> </ul> |

One of the main advantages of CRP is that it enables quick-and-easy configuration. This is accomplished by its pre-configured routing entities, whereby only minimal configuration is required such as for IP addresses to get the device up and running and deployed in the network.

## Reader's Notes

## 35 CRP Configuration

This section describes configuration specific to the CRP application. As CRP has similar functionality to the SBC application, for configuration common to the SBC, which is not covered in this section, see the following SBC sections:

- Configuring General Settings (see Configuring General Settings on page 451)
- Configuring Admission Control (see Configuring Admission Control on page 452)
- Configuring Allowed Coder Groups (see Configuring Allowed Coder Groups on page 454)
- Configuring Classification Rules (see Configuring Classification Rules on page 456)
- Configuring Condition Rules (see Configuring Condition Rules on page 461)
- Configuring SBC IP-to-IP Routing (see Configuring SBC IP-to-IP Routing on page 462)
- Configuring Alternative Routing Reasons (see Configuring Alternative Routing Reasons on page 468)
- Configuring IP-to-IP Inbound Manipulations (see Configuring IP-to-IP Inbound Manipulations on page 472)
- Configuring IP-to-IP Outbound Manipulations (see Configuring IP-to-IP Outbound Manipulations on page 474)

**Note:** The main difference in the common configuration between the CRP and SBC applications is the navigation menu paths to opening these Web configuration pages. Wherever "SBC" appears in the menu path, for the CRP application it appears as "CRP".

### 35.1 Enabling the CRP Application

The procedure below describes how to enable the CRP application.

**Note:** For CRP support, the device must be installed with the relevant Software License Key. This License Key must also be defined with the required number of call sessions.

➤ **To enable the CRP application:**

1. Open the Applications Enabling page (**Configuration** tab > **VoIP** menu > **Applications Enabling** > **Applications Enabling**).
2. From the 'Enable CRP Application' drop-down list, select **Enable**.
3. Save (burn) the changes to the device's flash memory with a device reset (see Saving Configuration on 532).

## 35.2 Configuring Call Survivability Mode

The CRP can be configured to operate in one of the following call survivability modes:

- **Normal (Default):** The CRP interworks between the branch users and the IP PBX located at headquarters. The CRP forwards all requests (such as for registration) from the branch users to the IP PBX, and routes the calls based on the IP-to-IP routing rules. If communication with the IP PBX fails (i.e., Emergency mode), it routes the calls between the branch users themselves. If this fails, it routes the calls to the PSTN (if employed).

**Figure 14: CRP in Normal & Auto Answer to Registrations Modes**

- **Auto Answer to Registrations:** This mode is the same as the Normal mode, except that the CRP registers the branch users in its registration database instead of forwarding them to the IP PBX.

**Note:** SIP REGISTER and OPTIONS requests are terminated at the CRP.

- **Always Emergency:** The CRP routes the calls between the branch users themselves as if connectivity failure has occurred with the IP PBX. The CRP also registers the branch users in its registration database.

Figure 15: CRP in Always Emergency Mode

➤ **To configure the Call Survivability mode:**

1. Open the General Settings page (**Configuration** tab > **VoIP** menu > **CRP** > **General Settings**).
2. From the 'CRP Survivability Mode' drop-down list, select the required mode.
3. Click **Submit**.

### 35.3 Pre-Configured IP Groups

The IP Group table for CRP is pre-configured with the following IP Groups:

Table 3: Pre-configured IP Groups in the IP Group Table

| Index | Type   | Description |
|-------|--------|-------------|
| 1     | User   | Users       |
| 2     | Server | Proxy       |
| 3     | Server | Gateway     |

These IP Groups represent the following IP entities:

- **"Users" IP Group:** LAN users (e.g., IP phones) at the branch office
- **"Server" IP Group:** server (e.g., hosted IP PBX at headquarters)
- **"Gateway" IP Group:** interface with the PSTN

These IP Groups are used in the IP-to-IP Routing rules to indicate the source and destination of the call (see "Pre-Configured IP-to-IP Routing Rules" on page 486).

**Notes:**

- These IP Groups cannot be deleted and additional IP Groups cannot be configured. The IP Groups can be edited, except for the fields listed above, which are read-only.
- For accessing the IP Group table and for a description of its parameters, see Configuring IP Groups on page 204.

## 35.4 Pre-Configured IP-to-IP Routing Rules

The IP-to-IP Routing table is pre-configured with IP-to-IP routing rules. These rules depend on the configured Call Survivability mode, as described in "Configuring Call Survivability Mode" on page 484.

### Notes:

- The IP-to-IP Routing table is read-only.
- For accessing the IP-to-IP Routing table and for a description of its parameters, see Configuring SBC IP-to-IP Routing on page 462.

**Table 4: Pre-Configured Rules in IP-to-IP Routing Table**

| Mode                         | Index | Source IP Group ID | Request Type | Destination Type | Destination IP Group ID | Destination Address | Alternative Route Options |
|------------------------------|-------|--------------------|--------------|------------------|-------------------------|---------------------|---------------------------|
| Normal                       | 1     | *                  | OPTIONS      | Dest Address     | -                       | Internal            | Route Row                 |
|                              | 3     | 1                  | All          | IP Group         | 2                       | -                   | Route Row                 |
|                              | 4     | 1                  | All          | IP Group         | 1                       | -                   | Alternative               |
|                              | 5     | 1                  | All          | IP Group         | 3                       | -                   | Alternative               |
|                              | 6     | 2                  | All          | IP Group         | 1                       | -                   | Route Row                 |
|                              | 7     | 3                  | All          | IP Group         | 2                       | -                   | Route Row                 |
|                              | 8     | 3                  | All          | IP Group         | 1                       | -                   | Alternative               |
| Always Emergency             | 1     | *                  | OPTIONS      | Dest Address     | -                       | Internal            | Route Row                 |
|                              | 2     | *                  | REGISTER     | Dest Address     | -                       | Internal            | Route Row                 |
|                              | 4     | 1                  | All          | IP Group         | 1                       | -                   | Route Row                 |
|                              | 5     | 1                  | All          | IP Group         | 3                       | -                   | Alternative               |
|                              | 8     | 3                  | All          | IP Group         | 1                       | -                   | Route Row                 |
| Auto Answer to Registrations | 1     | *                  | OPTIONS      | Dest Address     | -                       | Internal            | Route Row                 |
|                              | 2     | *                  | REGISTER     | Dest Address     | -                       | Internal            | Route Row                 |
|                              | 3     | 1                  | All          | IP Group         | 2                       | -                   | Route Row                 |
|                              | 4     | 1                  | All          | IP Group         | 1                       | -                   | Alternative               |
|                              | 5     | 1                  | All          | IP Group         | 3                       | -                   | Alternative               |
|                              | 6     | 2                  | All          | IP Group         | 1                       | -                   | Route Row                 |
|                              | 7     | 3                  | All          | IP Group         | 2                       | -                   | Route Row                 |
|                              | 8     | 3                  | All          | IP Group         | 1                       | -                   | Alternative               |

# Part VIII

## Stand-Alone Survivability Application

## 36 SAS Overview

The device's Stand-Alone Survivability (SAS) feature ensures telephony communication continuity (survivability) for enterprises using hosted IP services (such as IP Centrex) or IP-PBX in cases of failure of these entities. In case of failure of the IP Centrex, IP-PBX servers (or even WAN connection and access Internet modem), the enterprise typically loses its internal telephony service at any branch, between its offices, and with the external environment. Typically, these failures also lead to the inability to make emergency calls (e.g., 911 in North America). Despite these possible points of failure, the device's SAS feature ensures that the enterprise's telephony services (e.g., SIP IP phones or soft phones) are maintained, by routing calls to the PSTN (i.e., providing PSTN fallback).

**Notes:**

- The SAS application is available only if the device is installed with the SAS Software License Key.
- Throughout this section, the term *user agent* (UA) refers to the enterprise's LAN phone user (i.e., SIP telephony entities such as IP phones).
- Throughout this section, the term *proxy* or *proxy server* refers to the enterprise's centralized IP Centrex or IP-PBX.
- Throughout this section, the term SAS refers to the SAS application running on the device.

### 36.1 SAS Operating Modes

The device's SAS application can be implemented in one of the following main modes:

- **Outbound Proxy:** In this mode, SAS receives SIP REGISTER requests from the enterprise's UAs and forwards these requests to the external proxy (i.e., outbound proxy). When a connection with the external proxy fails, SAS enters SAS emergency state and serves as a proxy, by handling internal call routing for the enterprise's UAs - routing calls between UAs and if setup, routing calls between UAs and the PSTN. For more information, see 'SAS Outbound Mode' on page 490.
- **Redundant Proxy:** In this mode, the enterprise's UAs register with the external proxy and establish calls directly through the external proxy, without traversing SAS (or the device per se'). Only when connection with the proxy fails, do the UAs register with SAS, serving now as the UAs redundant proxy. SAS then handles the calls between UAs, and between the UAs and the PSTN (if setup). This mode is operational only during SAS in emergency state. This mode can be implemented, for example, for proxies that accept only SIP messages that are sent directly from the UAs. For more information, see 'SAS Redundant Mode' on page 491.

**Note:** It is recommended to implement the SAS outbound mode.

## 36.1.1 SAS Outbound Mode

This section describes the SAS outbound mode, which includes the following states:

- Normal state (see 'Normal State' on page 490)
- Emergency state (see 'Emergency State' on page 490)

### 36.1.1.1 Normal State

In normal state, SAS receives REGISTER requests from the enterprise's UAs and forwards them to the external proxy (i.e., outbound proxy). Once the proxy replies with a SIP 200 OK, the device records the Contact and address of record (AOR) of the UAs in its internal SAS registration database. Therefore, in this mode, SAS maintains a database of all the registered UAs in the network. SAS also continuously maintains a keep-alive mechanism toward the external proxy, using SIP OPTIONS messages. The figure below illustrates the operation of SAS outbound mode in normal state:

**Figure 36-1: SAS Outbound Mode in Normal State (Example)**

### 36.1.1.2 Emergency State

When a connection with the external proxy fails (detected by the device's keep-alive messages), the device enters SAS emergency state. The device serves as a proxy for the UAs, by handling internal call routing of the UAs (within the LAN enterprise).

**Note:** SAS can also enter Emergency state if no response is received from the proxy for sent OPTIONS, INVITE, or REGISTER messages. To configure this, set the SASEnteringEmergencyMode parameter to 1.

When the device receives calls, it searches its SAS registration database to locate the destination address (according to AOR or Contact). If the destination address is not found, SAS forwards the call to the default gateway. Typically, the default gateway is defined as the device itself (on which SAS is running), and if the device has PSTN interfaces, the enterprise preserves its capability for outgoing calls (from UAs to the PSTN network).

The routing logic of SAS in emergency state is described in detail in 'SAS Routing in Emergency State' on page 495.

The figure below illustrates the operation of SAS outbound mode in emergency state:

**Figure 36-2: SAS Outbound Mode in Emergency State (Example)**

When emergency state is active, SAS continuously attempts to communicate with the external proxy, using keep-alive SIP OPTIONS. Once connection to the proxy returns, the device exits SAS emergency state and returns to SAS normal state, as explained in 'Exiting Emergency and Returning to Normal State' on page 492.

### 36.1.2 SAS Redundant Mode

In SAS redundant mode, the enterprise's UAs register with the external proxy and establish calls directly through it, without traversing SAS (or the device per se). Only when connection with the proxy fails, do the UAs register with SAS, serving now as the UAs redundant proxy. SAS then handles the calls between UAs, and between the UAs and the PSTN (if setup).

This mode is operational only during SAS in emergency state.

**Note:** In this SAS deployment, the UAs (e.g., IP phones) must support configuration for primary and secondary proxy servers (i.e., proxy redundancy), as well as homing. Homing allows the UAs to switch back to the primary server from the secondary proxy once the connection to the primary server returns (UAs check this using keep-alive messages to the primary server). If homing is not supported by the UAs, you can configure SAS to ignore messages received from UAs in normal state (the 'SAS Survivability Mode' parameter must be set to 'Always Emergency' / 2) and thereby, "force" the UAs to switch back to their primary proxy.

### 36.1.2.1 Normal State

In normal state, the UAs register and operate directly with the external proxy.

**Figure 36-3: SAS Redundant Mode in Normal State (Example)**

### 36.1.2.2 Emergency State

If the UAs detect that their primary (external) proxy does not respond, they immediately register to SAS and start routing calls to it.

**Figure 36-4: SAS Redundant Mode in Emergency State (Example)**

### 36.1.2.3 Exiting Emergency and Returning to Normal State

Once the connection with the primary proxy is re-established, the following occurs:

- **UAs:** Switch back to operate with the primary proxy.
- **SAS:** Ignores REGISTER requests from the UAs, forcing the UAs to switch back to the primary proxy.

**Note:** This is applicable only if the 'SAS Survivability Mode' parameter is set to 'Always Emergency' (2).

## 36.2 SAS Routing

This section provides flowcharts describing the routing logic for SAS in normal and emergency states.

### 36.2.1 SAS Routing in Normal State

The flowchart below displays the routing logic for SAS in normal state for INVITE messages received from UAs:

**Figure 36-5: Flowchart of INVITE from UA's in SAS Normal State**

The flowchart below displays the routing logic for SAS in normal state for INVITE messages received from the external proxy:

**Figure 36-6: Flowchart of INVITE from Primary Proxy in SAS Normal State**

## 36.2.2 SAS Routing in Emergency State

The flowchart below shows the routing logic for SAS in emergency state:

**Figure 36-7: Flowchart for SAS Emergency State**

## Reader's Notes

## 37 SAS Configuration

SAS supports various configuration possibilities, depending on how the device is deployed in the network and the network architecture requirements. This section provides step-by-step procedures on configuring the SAS application, using the device's Web interface.

The SAS configuration includes the following:

- General SAS configuration that is common to all SAS deployment types (see 'General SAS Configuration' on page 497)
- SAS outbound mode (see 'Configuring SAS Outbound Mode' on page 500)
- SAS redundant mode (see 'Configuring SAS Redundant Mode' on page 500)
- Gateway and SAS applications deployed together (see 'Configuring Gateway Application with SAS' on page 501)
- Optional, advanced SAS features (see 'Advanced SAS Configuration' on page 504)

### 37.1 General SAS Configuration

This section describes the general configuration required for the SAS application. This configuration is applicable to all SAS modes.

#### 37.1.1 Enabling the SAS Application

Before you can configure SAS, you need to enable the SAS application on the device. Once enabled, the **SAS** menu and related pages appear in the device's Web interface.

**Note:** The SAS application is available only if the device is installed with the SAS Software License Key. If your device is not installed with the SAS feature, contact your AudioCodes representative.

➤ **To enable the SAS application:**

1. Open the Applications Enabling page (**Configuration** tab > **VoIP** menu > **Applications Enabling** > **Applications Enabling**).
2. From the 'SAS Application' drop-down list, select **Enable**.

3. Click **Submit**.
4. Save the changes to the flash memory with a device reset.

#### 37.1.2 Configuring Common SAS Parameters

The procedure below describes how to configure SAS settings that are common to all SAS modes. This includes various SAS parameters as well as configuring the Proxy Set for the SAS proxy (if required). The SAS Proxy Set ID defines the address of the UAs' external proxy.

➤ **To configure common SAS settings:**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. Define the port used for sending and receiving SAS messages. This can be any of the following port types:
  - UDP port - defined in the 'SAS Local SIP UDP Port' field
  - TCP port - defined in the 'SAS Local SIP TCP Port' field
  - TLS port - defined in the 'SAS Local SIP TLS Port' field

**Note:** This SAS port must be different than the device's local gateway port (i.e., that defined for the 'SIP UDP/TCP/TLS Local Port' parameter in the SIP General Parameters page - **Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**).

3. In the 'SAS Default Gateway IP' field, define the IP address and port (in the format *x.x.x.x:port*) of the device (i.e., Gateway application). Note that the port of the device is defined by the parameter 'SIP UDP Local Port' (refer to the note in Step 2 above).
4. In the 'SAS Registration Time' field, define the value for the SIP Expires header, which is sent in the 200 OK response to an incoming REGISTER message when SAS is in emergency state.
5. From the 'SAS Binding Mode' drop-down list, select the database binding mode:
  - **0-URI:** If the incoming AOR in the REGISTER request uses a 'tel:' URI or 'user=phone', the binding is done according to the Request-URI user part only. Otherwise, the binding is done according to the entire Request-URI (i.e., user and host parts - user@host).
  - **1-User Part Only:** Binding is done according to the user part only.

You must select **1-User Part Only** in cases where the UA sends REGISTER messages as SIP URI, but the INVITE messages sent to this UA include a Tel URI. For example, when the AOR of an incoming REGISTER is sip:3200@domain.com, SAS adds the entire SIP URI (e.g., sip:3200@domain.com) to its database (when the parameter is set to '0-URI'). However, if a subsequent Request-URI of an INVITE message for this UA arrives with sip:3200@10.1.2.3 user=phone, SAS searches its database for "3200", which it does not find. Alternatively, when this parameter is set to '1-User Part Only', then upon receiving a REGISTER message with sip:3200@domain.com, SAS adds only the user part (i.e., "3200") to its database. Therefore, if a Request-URI of an INVITE message for this UA arrives with sip:3200@10.1.2.3 user=phone, SAS can successfully locate the UA in its database.

**Figure 37-1: Configuring Common Settings**

|                               |                  |
|-------------------------------|------------------|
| SAS Local SIP UDP Port        | 5080             |
| SAS Default Gateway IP        |                  |
| SAS Registration Time         | 20               |
| SAS Local SIP TCP Port        | 5080             |
| SAS Local SIP TLS Port        | 5081             |
| SAS Proxy Set                 | 2                |
| SAS Emergency Numbers         |                  |
| SAS Binding Mode              | 1-User Part Only |
| SAS Survivability Mode        | Standard         |
| Enable ENUM                   | Disable          |
| Enable Record-Route           | Disable          |
| SAS Block Unregistered Users  | Un-Block         |
| Redundant SAS Proxy Set       | -1               |
| SAS Inbound Manipulation Mode | None             |

6. In the 'SAS Proxy Set' field, enter the Proxy Set used for SAS. The SAS Proxy Set must be defined only for the following SAS modes:

- **Outbound mode:** In SAS normal state, SAS forwards REGISTER and INVITE messages received from the UAs to the proxy servers defined in this Proxy Set.
- **Redundant mode and only if UAs don't support homing:** SAS sends keep-alive messages to this proxy and if it detects that the proxy connection has resumed, it ignores the REGISTER messages received from the UAs, forcing them to send their messages directly to the proxy.

If you define a SAS Proxy Set ID, you must configure the Proxy Set as described in Step 8 below.

7. Click **Submit** to apply your settings.
8. If you defined a SAS Proxy Set ID in Step 6 above, then you must configure the SAS Proxy Set ID:
- Open the Proxy Sets Table page (**Configuration** tab > **VoIP** menu > **Control Networks** > **Proxy Set Table**).
  - From the 'Proxy Set ID' drop-down list, select the required Proxy Set ID.

**Notes:**

- The selected Proxy Set ID number must be the same as that specified in the 'SAS Proxy Set' field in the 'SAS Configuration' page (see Step 6).
- Do not use Proxy Set ID 0.

- In the 'Proxy Address' field, enter the IP address of the external proxy server.
- From the 'Enable Proxy Keep Alive' drop-down list, select **Using Options**. This instructs the device to send SIP OPTIONS messages to the proxy for the keep-alive mechanism.

**Figure 37-2: Defining SAS Proxy Server**

|   | Proxy Address | Transport Type |
|---|---------------|----------------|
| 1 | 10.15.4.52    | TLS            |
| 2 |               |                |
| 3 |               |                |
| 4 |               |                |
| 5 |               |                |

|                             |                |
|-----------------------------|----------------|
| Enable Proxy Keep Alive     | Using Options  |
| Proxy Keep Alive Time       | 60             |
| Proxy Load Balancing Method | Disable        |

## 37.2 Configuring SAS Outbound Mode

This section describes how to configure the SAS outbound mode. These settings are in addition to the ones described in 'Configuring Common SAS Parameters' on page 497.

**Note:** The VoIP CPEs (such as IP phones or residential gateways) need to be defined so that their proxy and registrar destination addresses and ports are the same as that configured for the device's SAS IP address and SAS local SIP port. In some cases, on the UAs, it is also required to define SAS as their outbound proxy, meaning that messages sent by the UAs include the host part of the external proxy, but are sent (on Layer 3/4) to the IP address / UDP port of SAS.

➤ **To configure SAS outbound mode:**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. From the 'SAS Survivability Mode' drop-down list, select **Standard**.
3. Click **Submit**.

## 37.3 Configuring SAS Redundant Mode

This section describes how to configure the SAS redundant mode. These settings are in addition to the ones described in 'Configuring Common SAS Parameters' on page 497.

**Note:** The VoIP CPEs (such as IP phones or residential gateways) need to be defined so that their primary proxy is the external proxy, and their redundant proxy destination addresses and port is the same as that configured for the device's SAS IP address and SAS SIP port.

➤ **To configure SAS redundant mode:**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. From the 'SAS Survivability Mode' drop-down list, select one of the following, depending on whether the UAs support homing (i.e., they always attempt to operate with the primary proxy, and if using the redundant proxy, they switch back to the primary proxy whenever it's available):
  - **UAs support homing:** Select **Always Emergency**. This is because SAS does not need to communicate with the primary proxy of the UAs; SAS serves only as the redundant proxy of the UAs. When the UAs detect that their primary proxy is available, they automatically resume communication with it instead of with SAS.
  - **UAs do not support homing:** Select **Ignore REGISTER**. SAS uses the keep-alive mechanism to detect availability of the primary proxy (defined by the SAS Proxy Set). If the connection with the primary proxy resumes, SAS ignores the messages received from the UAs, forcing them to send their messages directly to the primary proxy.
3. Click **Submit**.

## 37.4 Configuring Gateway Application with SAS

If you want to run both the Gateway and SAS applications on the device, the configuration described in this section is required. The configuration steps depend on whether the Gateway application is operating with SAS in outbound mode or SAS in redundant mode.

**Note:** The Gateway application must use the same SAS operation mode as the SIP UAs. For example, if the UAs use the SAS application as a redundant proxy (i.e., SAS redundancy mode), then the Gateway application must do the same.

### 37.4.1 Gateway with SAS Outbound Mode

The procedure below describes how to configure the Gateway application with SAS outbound mode.

➤ **To configure Gateway application with SAS outbound mode:**

1. Define the proxy server address for the Gateway application:
  - a. Open the Proxy & Registration page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **Proxy & Registration**).
  - b. From the 'Use Default Proxy' drop-down list, select **Yes**.

**Figure 37-3: Enabling Proxy Server for Gateway Application**

|                   |     |
|-------------------|-----|
| Use Default Proxy | Yes |
| Proxy Set Table   |     |
| Proxy Name        |     |

- c. Click **Submit**.
- d. Open the Proxy Sets Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **Proxy Sets** Table).
- e. From the 'Proxy Set ID' drop-down list, select **0**.

- f. In the first 'Proxy Address' field, enter the IP address and port of the device (in the format *x.x.x.x:port*). This is the port as defined in the 'SAS Local UDP/TCP/TLS Port' field (see 'Configuring Common SAS Parameters' on page 497).

Figure 37-4: Defining Proxy Server for Gateway Application

|   | Proxy Address    | Transport Type |
|---|------------------|----------------|
| 1 | 202.10.13.1:5080 | UDP            |
| 2 |                  |                |
| 3 |                  |                |
| 4 |                  |                |
| 5 |                  |                |

|                             |                |
|-----------------------------|----------------|
| Enable Proxy Keep Alive     | Disable        |
| Proxy Keep Alive Time       | 60             |
| Proxy Load Balancing Method | Disable        |
| Is Proxy Hot Swap           | No             |
| Proxy Redundancy Mode       | Not Configured |
| SRD Index                   | 0              |
| Classification Input        | IP only        |

- g. Click **Submit**.
2. Disable use of user=phone in SIP URL:
  - a. Open the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **General Parameters**).
  - b. From the 'Use user=phone in SIP URL' drop-down list, select **No**. This instructs the Gateway application not to use *user=phone* in the SIP URL and therefore, REGISTER and INVITE messages use SIP URI. (By default, REGISTER messages are sent with *sip uri* and INVITE messages with *tel uri*.)

Figure 37-5: Disabling user=phone in SIP URL

| SIP General                 |                           |
|-----------------------------|---------------------------|
| NAT IP Address              | 0.0.0.0                   |
| PRACK Mode                  | Supported                 |
| Channel Select Mode         | Cyclic Ascending          |
| Enable Early Media          | Disable                   |
| 183 Message Behavior        | Progress                  |
| Session-Expires Time        | 0                         |
| Minimum Session-Expires     | 90                        |
| Session Expires Method      | Re-INVITE                 |
| Asserted Identity Mode      | Disabled                  |
| Fax Signaling Method        | No Fax                    |
| Detect Fax on Answer Tone   | Initiate T.38 on Preamble |
| SIP Transport Type          | UDP                       |
| SIP UDP Local Port          | 5060                      |
| SIP TCP Local Port          | 5060                      |
| SIP TLS Local Port          | 5061                      |
| Enable SIPS                 | Disable                   |
| Enable TCP Connection Reuse | Enable                    |
| TCP Timeout                 | 0                         |
| SIP Destination Port        | 5060                      |
| Use user=phone in SIP URL   | No                        |

- c. Click **Submit**.

## 37.4.2 Gateway with SAS Redundant Mode

The procedure below describes how to configure the Gateway application with SAS redundant mode.

➤ **To configure Gateway application with SAS redundant mode:**

1. Define the proxy servers for the Gateway application:
  - a. Open the Proxy & Registration page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **Proxy & Registration**).
  - b. From the 'Use Default Proxy' drop-down list, select **Yes**.

**Figure 37-6: Enabling Proxy Server for Gateway Application**

Use Default Proxy: Yes

Proxy Set Table

Proxy Name

- c. Click **Submit**.
- d. Open the Proxy Sets Table page (**Configuration** tab > **VoIP** menu > **Control Network** submenu > **Proxy Sets Table**).
- e. From the 'Proxy Set ID' drop-down list, select **0**.
- f. In the first 'Proxy Address' field, enter the IP address of the external proxy server.
- g. In the second 'Proxy Address' field, enter the IP address and port of the device (in the format x.x.x.x:port). This is the same port as defined in the 'SAS Local UDP/TCP/TLS Port' field (see 'Configuring Common SAS Parameters' on page 497).
- h. From the 'Proxy Redundancy Mode' drop-down list, select **Homing**.

**Figure 37-7: Defining Proxy Servers for Gateway Application**

Proxy Set ID: 0

|   | Proxy Address    | Transport Type |
|---|------------------|----------------|
| 1 | 202.10.13.1:5080 | UDP            |
| 2 | 10.13.4.1        | UDP            |
| 3 |                  |                |
| 4 |                  |                |
| 5 |                  |                |

Enable Proxy Keep Alive: Using Options

Proxy Keep Alive Time: 60

Proxy Load Balancing Method: Disable

Is Proxy Hot Swap: No

Proxy Redundancy Mode: Homing

SRD Index: 0

Classification Input: IP only

- i. Click **Submit**.

2. Disable the use of *user=phone* in the SIP URL:
  - a. Open the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **General Parameters**).
  - b. From the 'Use user=phone in SIP URL' drop-down list, select **No**. This instructs the Gateway application not to use *user=phone* in SIP URL and therefore, REGISTER and INVITE messages use SIP URI. (By default, REGISTER messages are sent with *sip uri* and INVITE messages with *tel uri*.)
  - c. Click **Submit**.

## 37.5 Advanced SAS Configuration

This section describes the configuration of advanced SAS features that can optionally be implemented in your SAS deployment.

### 37.5.1 Manipulating URI user part of Incoming REGISTER

There are scenarios in which the UAs register to the proxy server with their full phone number (for example, "976653434"), but can receive two types of INVITE messages (calls):

- INVITES whose destination is the UAs' full number (when the call arrives from outside the enterprise)
- INVITES whose destination is the last four digits of the UAs' phone number ("3434" in our example) when it is an internal call within the enterprise

Therefore, it is important that the device registers the UAs in the SAS registered database with their extension numbers (for example, "3434") in addition to their full numbers. To do this, you can define a manipulation rule to manipulate the SIP Request-URI user part of the AOR (in the To header) in incoming REGISTER requests. Once manipulated, it is saved in this manipulated format in the SAS registered users database in addition to the original (un-manipulated) AOR.

For example: Assume the following incoming REGISTER message is received and that you want to register in the SAS database the UA's full number as well as the last four digits from the right of the SIP URI user part:

```
REGISTER sip:10.33.38.2 SIP/2.0
Via: SIP/2.0/UDP 10.33.4.226:5050;branch=z9hG4bKac10827
Max-Forwards: 70
From: <sip: 976653434@10.33.4.226>;tag=1c30219
To: <sip: 976653434@10.33.4.226>
Call-ID: 16844@10.33.4.226
CSeq: 1 REGISTER
Contact: <sip: 976653434@10.10.10.10:5050>;expires=180
Allow:
REGISTER, OPTIONS, INVITE, ACK, CANCEL, BYE, NOTIFY, PRACK, REFER, INFO, SUB
SCRIBE, UPDATE
Expires: 180
User-Agent: Audiocodes-Sip-Gateway-/v.
Content-Length: 0
```

After manipulation, SAS registers the user in its database as follows:

- **AOR:** 976653434@10.33.4.226
- **Associated AOR:** 3434@10.33.4.226 (after manipulation, in which only the four digits from the right of the URI user part are retained)
- **Contact:** 976653434@10.10.10.10

The procedure below describes how to configure the above manipulation example.

- **To manipulate incoming Request-URI user part of REGISTER message:**
1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
  2. Under the **SAS Registration Manipulation** group, in the 'Leave From Right' field, enter the number of digits (e.g., "4") to leave from the right side of the user part. This field defines the number of digits to retain from the right side of the user part; all other digits in the user part are removed.

**Figure 37-8: Manipulating User Part in Incoming REGISTER**

|                               |                  |
|-------------------------------|------------------|
| SAS Local SIP UDP Port        | 5080             |
| SAS Default Gateway IP        | 10.0.0.2:5080    |
| SAS Registration Time         | 20               |
| SAS Local SIP TCP Port        | 5080             |
| SAS Local SIP TLS Port        | 5081             |
| SAS Proxy Set                 | 0                |
| SAS Emergency Numbers         |                  |
| SAS Binding Mode              | 0-URI            |
| SAS Survivability Mode        | Always Emergency |
| Enable ENUM                   | Disable          |
| Enable Record-Route           | Disable          |
| SAS Block Unregistered Users  | Un-Block         |
| Redundant SAS Proxy Set       | -1               |
| SAS Inbound Manipulation Mode | None             |

**SAS Registration Manipulation**

|                   |                  |
|-------------------|------------------|
| Remove From Right | Leave From Right |
| 0                 | 4                |

▼ SAS Routing

SAS Routing Table

3. Click **Submit**.

**Notes:**

- The device first does manipulation according to the Remove From Right parameter and only then according to the Leave From Right parameter.
- Only one manipulation rule can be configured.
- You can also configure SAS registration manipulation using the table ini file parameter, SASRegistrationManipulation or the CLI command, configure voip > sas sasregistrationmanipulation.

## 37.5.2 Manipulating Destination Number of Incoming INVITE

You can define a manipulation rule to manipulate the destination number in the Request-URI of incoming INVITE messages when SAS is in emergency state. This is required, for example, if the call is destined to a registered user but the destination number in the received INVITE is not the number assigned to the registered user in the SAS registration database. To overcome this and successfully route the call, you can define manipulation rules to change the INVITE's destination number so that it matches that of the registered user in the database. This is done using the IP to IP Inbound Manipulation table.

For example, in SAS emergency state, assume an incoming INVITE has a destination number "7001234" which is destined to a user registered in the SAS database as "55215551234". In this scenario, the received destination number needs to be manipulated to the number "55215551234". The outgoing INVITE sent by the device then also contains this number in the Request-URI user part.

In normal state, the numbers are not manipulated. In this state, SAS searches the number 55215551234 in its database and if found, it sends the INVITE containing this number to the UA.

➤ **To manipulate the destination number in SAS emergency state:**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. From the 'SAS Inbound Manipulation Mode' (*SASInboundManipulationMode*) drop-down list, select **Emergency Only**.
3. Click **Submit**; the **SAS Inbound Manipulation Mode Table**  button appears on the page.
4. Click this button to open the IP to IP Inbound Manipulation page.
5. Add your SAS manipulation rule as required. See the table below for descriptions of the parameters.
6. Click **Submit** to save your changes.

**Notes:**

- The following fields in the IP to IP Inbound Manipulation table are not applicable to SAS and must be left at their default values:
  - 'Additional Manipulation' - default is **0**
  - 'Manipulation Purpose' - default is **Normal**
  - 'Source IP Group' - default is **-1**
- The IP to IP Inbound Manipulation table can also be configured using the table ini file parameter, *IPInboundManipulation* or CLI command, `configure voip > sbc manipulations ip-inbound-manipulation`.

**SAS IP to IP Inbound Manipulation Parameters**

| Parameter                                                                                                               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics (Rule)</b>                                                                                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Additional Manipulation<br>CLI: is-additional-manipulation<br>[ <i>IPInboundManipulation_IsAdditionalManipulation</i> ] | Determines whether additional SIP URI user part manipulation is done for the table entry rule listed directly above it. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> No = (Default) Regular manipulation rule (not done in addition to the rule above it).</li> <li>▪ <b>[1]</b> Yes = If the above row entry rule matched the call, consider this row entry as a match as well and perform the manipulation specified by this rule.</li> </ul> <p><b>Note:</b> Additional manipulation can only be done on a different SIP URI, source or destination, to the rule configured in the row above as configured by the 'Manipulated URI' parameter (see below).</p> |
| Manipulation Purpose<br>CLI: purpose<br>[ <i>IPInboundManipulation_ManipulationPurpose</i> ]                            | Defines the purpose of the manipulation: <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Normal = (Default) Inbound manipulations affect the routing input and source and/or destination number.</li> <li>▪ <b>[1]</b> Routing input only = Inbound manipulations affect the routing input only, retaining the original source and destination number.</li> </ul>                                                                                                                                                                                                                                                                                                    |

| Parameter                                                                                                     | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Source IP Group ID<br>CLI: src-ip-group-id<br><b>[IPInboundManipulation_SrcIpGroup]</b>                       | Defines the IP Group from where the incoming INVITE is received.<br>For any IP Group, enter the value "-1".                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Source Username Prefix<br>CLI: src-user-name-prefix<br><b>[IPInboundManipulation_SrcUsernamePrefix]</b>       | Defines the prefix of the source SIP URI user name (usually in the From header).<br>For any prefix, enter the asterisk "*" symbol (default).<br><b>Note:</b> The prefix can be a single digit or a range of digits. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.                                                                                                                                                                                                            |
| Source Host<br>CLI: src-host<br><b>[IPInboundManipulation_SrcHost]</b>                                        | Defines the source SIP URI host name - full name (usually in the From header). For any host name, enter the asterisk "*" symbol (default).                                                                                                                                                                                                                                                                                                                                                                                    |
| Destination Username Prefix<br>CLI: dst-user-name-prefix<br><b>[IPInboundManipulation_DestUsernamePrefix]</b> | Defines the prefix of the destination SIP URI user name (usually in the Request-URI).<br>For any prefix, enter the asterisk "*" symbol (default).<br><b>Note:</b> The prefix can be a single digit or a range of digits. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.                                                                                                                                                                                                       |
| Destination Host<br>CLI: dst-host<br><b>[IPInboundManipulation_DestHost]</b>                                  | Defines the destination SIP URI host name - full name (usually in the Request URI).<br>For any host name, enter the asterisk "*" symbol (default).                                                                                                                                                                                                                                                                                                                                                                            |
| Request Type<br>CLI: request-type<br><b>[IPInboundManipulation_RequestType]</b>                               | Defines the SIP request type to which the manipulation rule is applied. <ul style="list-style-type: none"> <li><b>[0]</b> All = (Default) All SIP messages.</li> <li><b>[1]</b> INVITE = All SIP messages except REGISTER and SUBSCRIBE.</li> <li><b>[2]</b> REGISTER = Only REGISTER messages.</li> <li><b>[3]</b> SUBSCRIBE = Only SUBSCRIBE messages.</li> <li><b>[4]</b> INVITE and REGISTER = All SIP messages except SUBSCRIBE.</li> <li><b>[5]</b> INVITE and SUBSCRIBE = All SIP messages except REGISTER.</li> </ul> |
| Manipulated URI<br>CLI: manipulated-uri<br><b>[IPInboundManipulation_ManipulatedURI]</b>                      | Determines whether the source or destination SIP URI user part is manipulated. <ul style="list-style-type: none"> <li><b>[0]</b> Source = (Default) Manipulation is done on the source SIP URI user part.</li> <li><b>[1]</b> Destination = Manipulation is done on the destination SIP URI user part.</li> </ul>                                                                                                                                                                                                             |
| <b>Operation Rule (Action)</b>                                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Remove From Left<br>CLI: remove-from-left<br><b>[IPInboundManipulation_RemoveFromLeft]</b>                    | Defines the number of digits to remove from the left of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "n".                                                                                                                                                                                                                                                                                                                                                              |

| Parameter                                                                                     | Description                                                                                                                                                                                                                                                                                                       |
|-----------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Remove From Right<br>CLI: remove-from-right<br><b>[IPInboundManipulation_RemoveFromRight]</b> | Defines the number of digits to remove from the right of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "j".<br><b>Note:</b> If both 'Remove From Right' and 'Leave From Right' parameters are configured, the 'Remove From Right' setting is applied first. |
| Leave From Right<br>CLI: leave-from-right<br><b>[IPInboundManipulation_LeaveFromRight]</b>    | Defines the number of characters that you want retained from the right of the user name.<br><b>Note:</b> If both 'Remove From Right' and 'Leave From Right' parameters are configured, the 'Remove From Right' setting is applied first.                                                                          |
| Prefix to Add<br>CLI: prefix-to-add<br><b>[IPInboundManipulation_Prefix2Add]</b>              | Defines the number or string that you want added to the front of the user name. For example, if you enter 'user' and the user name is "john", the new user name is "userjohn".                                                                                                                                    |
| Suffix to Add<br>CLI: suffix-to-add<br><b>[IPInboundManipulation_Suffix2Add]</b>              | Defines the number or string that you want added to the end of the user name. For example, if you enter '01' and the user name is "john", the new user name is "john01".                                                                                                                                          |

### 37.5.3 SAS Routing Based on IP-to-IP Routing Table

SAS routing that is based on SAS Routing table rules is applicable for the following SAS states:

- Normal, if the 'SAS Survivability Mode' parameter is set to **Use Routing Table only in Normal mode**.
- Emergency,, if the 'SAS Survivability Mode' parameter is **not** set to **Use Routing Table only in Normal mode**.

The SAS routing rule destination can be an IP Group, IP address, Request-URI, or ENUM query.

The IP-to-IP Routing Table page allows you to configure up to 120 SAS routing rules (for Normal and Emergency modes). The device routes the SAS call (received SIP INVITE message) once a rule in this table is matched. If the characteristics of an incoming call do not match the first rule, the call characteristics is then compared to the settings of the second rule, and so on until a matching rule is located. If no rule is matched, the call is rejected.

When SAS receives a SIP INVITE request from a proxy server, the following routing logic is performed:

- a. Sends the request according to rules configured in the IP-to-IP Routing table.
- b. If no matching routing rule exists, the device sends the request according to its SAS registration database.
- c. If no routing rule is located in the database, the device sends the request according to the Request-URI header.

**Note:** The IP-to-IP Routing table can also be configured using the table *ini* file parameter, IP2IPRouting (see 'Configuration Parameters Reference' on page 655) or CLI command, configure voip/sbc routing ip2ip-routing.

➤ **To configure the IP-to-IP Routing table for SAS:**

1. In the SAS Configuration page, click the **SAS Routing Table**  button; the IP-to-IP Routing Table page appears.
2. Click **Add**; the Add Record dialog box appears:

**Figure 37-9: Add Record Dialog Box of SAS IP2IP Routing Page**

3. Configure the rule according to the table below.
4. Click **Submit** to apply your changes.
5. To save the changes to flash memory, see 'Saving Configuration' on page 532.

**Note:** The following parameters are not applicable to SAS and must be ignored:

- 'Source IP Group ID'
- 'Destination IP Group ID'
- 'Destination SRD ID'
- 'Alternative Route Options'

#### SAS IP-to-IP Routing Table Parameters

| Parameter                                         | Description                                                                                                                                                                                                             |
|---------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Matching Characteristics</b>                   |                                                                                                                                                                                                                         |
| Source IP Group ID<br>[IP2IPRouting_SrcIPGroupID] | Selects the IP Group from where the IP-to-IP call originated. Typically, the IP Group of an incoming SIP dialog is determined (or classified) using the 'Classification' table (see Configuring Classification Rules on |

| Parameter                                                                                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLI: src-ip-group-id                                                                                 | page 456). If not used (i.e., any IP Group), simply leave the field empty. The default is -1.                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| Source Username Prefix<br><b>[IP2IPRouting_SrcUserNamePrefix]</b><br>CLI: src-user-name-prefix       | Defines the prefix of the user part of the incoming SIP dialog's source URI (usually the From URI). You can use special notations for denoting the prefix. For example, to denote any prefix, use the asterisk (*) symbol; to denote calls without a user part in the URI, use the \$ sign. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.<br>The default is * (i.e., any prefix).                                                                                                  |
| Source Host<br><b>[IP2IPRouting_SrcHost]</b><br>CLI: src-host                                        | Defines the host part of the incoming SIP dialog's source URI (usually the From URI). If this rule is not required, leave the field empty. To denote any host name, use the asterisk (*) symbol (default).                                                                                                                                                                                                                                                                                                                          |
| Destination Username Prefix<br><b>[IP2IPRouting_DestUserNamePrefix]</b><br>CLI: dst-user-name-prefix | Defines the prefix of the incoming SIP dialog's destination URI (usually the Request URI) user part. You can use special notations for denoting the prefix. For example, to denote any prefix, use the asterisk (*) symbol; to denote calls without a user part in the URI, use the \$ sign. For available notations, see 'Dialing Plan Notation for Routing and Manipulation' on page 653.<br>The default is * (i.e., any prefix).                                                                                                 |
| Destination Host<br><b>[IP2IPRouting_DestHost]</b><br>CLI: dst-host                                  | Defines the host part of the incoming SIP dialog's destination URI (usually the Request-URI). If this rule is not required, leave the field empty. The asterisk (*) symbol (default) can be used to denote any destination host.                                                                                                                                                                                                                                                                                                    |
| Request Type<br><b>[IP2IPRouting_RequestType]</b><br>CLI: request-type                               | Defines the SIP dialog request type of the incoming SIP dialog. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> All (default)</li> <li>▪ <b>[1]</b> INVITE</li> <li>▪ <b>[2]</b> REGISTER</li> <li>▪ <b>[3]</b> SUBSCRIBE</li> <li>▪ <b>[4]</b> INVITE and REGISTER</li> <li>▪ <b>[5]</b> INVITE and SUBSCRIBE</li> <li>▪ <b>[6]</b> OPTIONS</li> </ul>                                                                                                                                                                         |
| Message Condition<br><b>[IP2IPRouting_MessageCondition]</b><br>CLI: message-condition                | Selects a Message Condition rule. To configure Message Condition rules, see 'Configuring Condition Rules' on page 461.                                                                                                                                                                                                                                                                                                                                                                                                              |
| ReRoute IP Group ID<br><b>[IP2IPRouting_ReRouteIPGroupID]</b><br>CLI: re-route-ip-group-id           | Defines the IP Group that initiated (sent) the SIP redirect response (e.g., 3xx) or REFER message. This field is typically used for re-routing requests (e.g., INVITEs) when interworking is required for SIP 3xx redirect responses or REFER messages (for more information, see 'Interworking SIP 3xx Redirect Responses' on page 436 and 'Interworking SIP REFER Messages' on page 439, respectively). This parameter functions together with the 'Call Trigger' field (see below).<br>The default is -1 (i.e., not configured). |
| Call Trigger<br><b>[IP2IPRouting_Trigger]</b><br>CLI: trigger                                        | Defines the reason (i.e, trigger) for re-routing the SIP request: <ul style="list-style-type: none"> <li>▪ <b>[0]</b> Any = (Default) This routing rule is used for all scenarios (re-routes and non-re-routes).</li> <li>▪ <b>[1]</b> 3xx = Re-routes the request if it was triggered as a result of a SIP 3xx response.</li> <li>▪ <b>[2]</b> REFER = Re-routes the INVITE if it was triggered as a result of a</li> </ul>                                                                                                        |

| Parameter                                                                                                   | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <p>Destination Type<br/> <b>[IP2IPRouting_DestType]</b><br/>           CLI: dst-type</p>                    | <p>Determines the destination type to which the outgoing SIP dialog is sent.</p> <ul style="list-style-type: none"> <li>▪ <b>[0]</b> IP Group = (Default) The SIP dialog is sent to the IP Group's Proxy Set (SERVER-type IP Group) or registered contact from the database (if USER-type IP Group).</li> <li>▪ <b>[1]</b> Dest Address = The SIP dialog is sent to the address configured in the following fields: 'Destination SRD ID', 'Destination Address', 'Destination Port', and 'Destination Transport Type'.</li> <li>▪ <b>[2]</b> Request URI = The SIP dialog is sent to the address indicated in the incoming Request-URI. If the fields 'Destination Port' and 'Destination Transport Type' are configured, the incoming Request-URI parameters are overridden and these fields take precedence.</li> <li>▪ <b>[3]</b> ENUM = An ENUM query is sent to include the destination address. If the fields 'Destination Port' and 'Destination Transport Type' are configured, the incoming Request-URI parameters are overridden and these fields take precedence.</li> <li>▪ <b>[4]</b> Hunt Group = Used for call center survivability. For more information, see 'Call Survivability for Call Centers' on page 445.</li> <li>▪ <b>[5]</b> Dial Plan = The IP destination is determined by a Dial Plan index of the loaded Dial Plan file. The syntax of the Dial Plan index in the Dial Plan file is as follows: &lt;destination / called prefix number&gt;,0,&lt;IP destination&gt;</li> </ul> <p>Note that the second parameter "0" is ignored. An example of a configured Dial Plan (# 6) in the Dial Plan file is shown below:</p> <pre>[ PLAN6 ] 200,0,10.33.8.52      ; called prefix 200 is routed to destination 10.33.8.52 201,0,10.33.8.52 300,0,itsp.com       ; called prefix 300 is routed to destination itsp.com</pre> <p>Once the Dial Plan is defined, you need to assign it (0 to 7) to the routing rule as the destination in the 'Destination Address' parameter, where "0" denotes <b>[PLAN1]</b>, "1" denotes <b>[PLAN2]</b>, and so on.</p> <ul style="list-style-type: none"> <li>▪ <b>[7]</b> LDAP = LDAP-based routing.</li> </ul> |
| <p>Destination IP Group ID<br/> <b>[IP2IPRouting_DestIPGroupID]</b><br/>           CLI: dst-ip-group-id</p> | <p>Defines the IP Group ID to where you want to route the call. The SIP dialog messages are sent to the IP address defined for the Proxy Set associated with this IP Group. If you select an IP Group, it is unnecessary to configure a destination IP address (in the 'Destination Address' field). However, if both parameters are configured, then the IP Group takes precedence.</p> <p>If the destination IP Group is of USER type, the device searches for a match between the Request-URI (of the received SIP dialog) to an AOR registration record in the device's database. The SIP dialog is then sent to the IP address of the registered contact.</p> <p>The default is -1.</p> <p><b>Notes:</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

### 37.5.4 Blocking Calls from Unregistered SAS Users

To prevent malicious calls, for example, service theft, it is recommended to configure the feature for blocking SIP INVITE messages received from SAS users that are not registered in the SAS database. This applies to SAS in normal and emergency states.

➤ **To block calls from unregistered SAS users:**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. From the 'SAS Block Unregistered Users' drop-down list, select **Block**.
3. Click **Submit** to apply your changes.

### 37.5.5 Configuring SAS Emergency Calls

You can configure SAS to route emergency calls (such as 911 in North America) directly to the PSTN through its FXO interface or E1/T1 trunk. Thus, even during a communication failure with the external proxy, enterprise UAs can still make emergency calls.

You can define up to four emergency numbers, where each number can include up to four digits. When SAS receives a SIP INVITE (from a UA) that includes one of the user-defined emergency numbers in the SIP user part, it forwards the INVITE directly to the default gateway (see 'SAS Routing in Emergency State' on page 495). The default gateway is defined in the 'SAS Default Gateway IP' field, and this is the device itself. The device then sends the call directly to the PSTN.

This feature is applicable to SAS in normal and emergency states.

➤ **To configure SAS emergency numbers:**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. In the 'SAS Default Gateway IP' field, define the IP address and port (in the format *x.x.x.x:port*) of the device (Gateway application).

**Note:** The port of the device is defined in the 'SIP UDP/TCP/TLS Local Port' field in the SIP General Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **General Parameters**).

3. In the 'SAS Emergency Numbers' field, enter an emergency number in each field box.

**Figure 37-10: Configuring SAS Emergency Numbers**

|                               |                  |
|-------------------------------|------------------|
| SAS Local SIP UDP Port        | 5080             |
| SAS Default Gateway IP        | 10.13.4.12       |
| SAS Registration Time         | 20               |
| SAS Local SIP TCP Port        | 5080             |
| SAS Local SIP TLS Port        | 5081             |
| SAS Proxy Set                 | 0                |
| SAS Emergency Numbers         | 911              |
| SAS Binding Mode              | 1-User Part Only |
| SAS Survivability Mode        | Always Emergency |
| Enable ENUM                   | Disable          |
| Enable Record-Route           | Disable          |
| SAS Block Unregistered Users  | Block            |
| Redundant SAS Proxy Set       | -1               |
| SAS Inbound Manipulation Mode | None             |

4. Click **Submit** to apply your changes.

### 37.5.6 Adding SIP Record-Route Header to SIP INVITE

You can configure SAS to add the SIP Record-Route header to SIP requests (e.g. INVITE) received from enterprise UAs. SAS then sends the request with this header to the proxy. The Record-Route header includes the IP address of the SAS application. This ensures that future requests in the SIP dialog session from the proxy to the UAs are routed through the SAS application. If not configured, future request within the dialog from the proxy are sent directly to the UAs (and do not traverse SAS). When this feature is enabled, the SIP Record-Route header includes the URI "lr" parameter, indicating loose routing, as shown in the following example:

```
Record-Route: <sip:server10.biloxi.com;lr>
```

**Note:** This feature is applicable only to the SAS Outbound mode.

#### ➤ To enable the Record-Route header:

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. From the 'Enable Record-Route' drop-down list, select **Enable**.
3. Click **Submit** to apply your changes.

### 37.5.7 Re-using TCP Connections

You can enable the SAS application to re-use the same TCP connection for sessions (multiple SIP requests / responses) with the same SIP UA. The benefits of this feature include less CPU and memory usage because fewer TCP connections are open and reduced network congestion. For example, assume User A sends a REGISTER message to SAS with transport=TCP, and User B sends an INVITE message to A using SAS. In this scenario, the SAS application forwards the INVITE request using the same TCP connection that User A initially opened with the REGISTER message.

➤ **To re-use TCP connection sessions in SAS**

1. Open the SAS Configuration page (**Configuration** tab > **VoIP** menu > **SAS** > **Stand Alone Survivability**).
2. From the 'SAS Connection Reuse' drop-down list, select **Enable**.
3. Click **Submit** to apply your changes.

### 37.5.8 Replacing Contact Header for SIP Messages

You can configure SAS to change the SIP Contact header so that it points to the SAS host. This ensures that in the message, the top-most SIP Via header and the Contact header point to the same host.

**Notes:**

- This feature is applicable only to the SAS Outbound mode.
- The device may become overloaded if this feature is enabled, as all incoming SIP dialog requests traverse the SAS application.

Currently, this feature can be configured only by the *ini* file parameter, `SASEnableContactReplace` or the CLI command, `configure voip > sas stand-alone-survivability > sas-contact-replace`:

- **[0]** (Default): Disable - when relaying requests, SAS adds a new Via header (with the IP address of the SAS application) as the top-most Via header and retains the original Contact header. Thus, the top-most Via header and the Contact header point to different hosts.
- **[1]**: Enable - SAS changes the Contact header so that it points to the SAS host and therefore, the top-most Via header and the Contact header point to the same host.

## 37.6 Viewing Registered SAS Users

You can view all the users that are registered in the SAS registration database. This is displayed in the 'SAS/SBC Registered Users' page, as described in 'Viewing Registered Users' on page [595](#).

**Note:** You can increase the maximum number of registered SAS users, by implementing the SAS Cascading feature, as described in 'SAS Cascading' on page [517](#).

## 38 SAS Cascading

The SAS Cascading feature allows you to increase the number of SAS users above the maximum supported by the SAS gateway. This is achieved by deploying multiple SAS gateways in the network. For example, if the SAS gateway supports up to 600 users, but your enterprise has 1,500 users, you can deploy three SAS gateways to accommodate all users: the first SAS gateway can service 600 registered users, the second SAS gateway the next 600 registered users, and the third SAS gateway the rest (i.e., 300 registered users).

In SAS Cascading, the SAS gateway first attempts to locate the called user in its SAS registration database. Only if the user is not located, does the SAS gateway send it on to the next SAS gateway according to the SAS Cascading configuration.

There are two methods for configuring SAS Cascading. This depends on whether the users can be identified according to their phone extension numbers:

- **SAS Routing Table:** If users can be identified with unique phone extension numbers, then the SAS Routing table is used to configure SAS Cascading. This SAS Cascading method routes calls directly to the SAS Gateway (defined by IP address) to which the called SAS user is registered.

The following is an example of a SAS Cascading deployment of users with unique phone extension numbers:

- users registered to the first SAS gateway start with extension number "40"
- users registered to the second SAS gateway start with extension number "20"
- users registered to the third SAS gateway start with extension number "30"

The SAS Routing table rules for SAS Cascading are created using the destination (called) extension number prefix (e.g., "30") and the destination IP address of the SAS gateway to which the called user is registered. Such SAS routing rules must be configured at each SAS gateway to allow routing between the SAS users. The routing logic for SAS Cascading is similar to SAS routing in Emergency state (see the flowchart in 'SAS Routing in Emergency State' on page 495). For a description on the SAS Routing table, see 'SAS Routing Based on IP-to-IP Routing Table' on page 508.

The figure below illustrates an example of a SAS Cascading call flow configured using the SAS Routing table. In this example, a call is routed from SAS Gateway (A) user to a user on SAS Gateway (B).

**Figure 38-1: SAS Cascading Using SAS Routing Table - Example**

- **SAS Redundancy mode:** If users cannot be distinguished (i.e., associated to a specific SAS gateway), then the SAS Redundancy feature is used to configure SAS Cascading. This mode routes the call in a loop fashion, from one SAS gateway to the next, until the user is located. Each SAS gateway serves as the redundant SAS gateway (“redundant SAS proxy server”) for the previous SAS gateway (in a one-way direction). For example, if a user calls a user that is not registered on the same SAS gateway, the call is routed to the second SAS gateway, and if not located, it is sent to the third SAS gateway. If the called user is not located on the third (or last) SAS gateway, it is then routed back to the initial SAS gateway, which then routes the call to the default gateway (i.e., to the PSTN).

Each SAS gateway adds its IP address to the SIP via header in the INVITE message before sending it to the next (“redundant”) SAS gateway. If the SAS gateway receives an INVITE and its IP address appears in the SIP via header, it sends it to the default gateway (and not to the next SAS gateway), as defined by the SASDefaultGatewayIP parameter. Therefore, this mode of operation prevents looping between SAS gateways when a user is not located on any of the SAS gateways.

The figure below illustrates an example of a SAS Cascading call flow when configured using the SAS Redundancy feature. In this example, a call is initiated from a SAS Gateway (A) user to a user that is not located on any SAS gateway. The call is subsequently routed to the PSTN.

**Figure 38-2: SAS Cascading Using SAS Redundancy Mode - Example**

# Part IX

## IP Media Capabilities

## 39 Transcoding using Third-Party Call Control

The device supports transcoding using a third-party call control Application server. This support is provided by the following:

- Using RFC 4117 (see 'Using RFC 4117' on page 521)

**Note:** Transcoding can also be implemented using the IP-to-IP application and SBC application.

### 39.1 Using RFC 4117

The device supports RFC 4117 - Transcoding Services Invocation in the Session Initiation Protocol (SIP) Using Third Party Call Control (3pcc) - providing transcoding services (i.e., acting as a transcoding server). This is used in scenarios where two SIP User Agents (UA) would like to establish a session, but do not have a common coder or media type. When such incompatibilities are found, the UAs need to invoke transcoding services to successfully establish the session. Note that transcoding can also be performed using NetAnn, according to RFC 4240.

To enable the RFC 4117 feature, the parameter EnableRFC4117Transcoding must be set to 1 (and the device must be reset).

The 3pcc call flow is as follows: The device receives from one of the UAs, a single INVITE with an SDP containing two media lines. Each media represents the capabilities of each of the two UAs. The device needs to find a match for both of the media, and opens two channels with two different media ports to the different UAs. The device performs transcoding between the two voice calls.

In the example below, an Application Server sends a special INVITE that consists of two media lines to perform transcoding between G.711 and G.729:

```
m=audio 20000 RTP/AVP 0
c=IN IP4 A.example.com
m=audio 40000 RTP/AVP 18
c=IN IP4 B.example.com
```

## Reader's Notes

# Part X

## Data-Router Configuration

## 40 Introduction

**Note:** For data-router configuration, refer to the *MSBR Series CLI Reference Guide for Data Functionality*.

## Reader's Notes

# Part XI

## Maintenance

## 41 Basic Maintenance

The Maintenance Actions page allows you to perform the following:

- Reset the device - see 'Resetting the Device' on page 529
- Lock and unlock the device - see 'Locking and Unlocking the Device' on page 531
- Save configuration to the device's flash memory - see 'Saving Configuration' on page 532

➤ To access the Maintenance Actions page, do one of the following:

- On the toolbar, click the **Device Actions** button, and then from the drop-down menu, choose **Reset**.
- On the Navigation bar, click the **Maintenance** tab, and then in the Navigation tree, select the **Maintenance** menu and choose **Maintenance Actions**.

**Figure 41-1: Maintenance Actions Page**

|                       |                                      |
|-----------------------|--------------------------------------|
| ▼ Reset Configuration |                                      |
| Reset Board           | <input type="button" value="Reset"/> |
| Burn To FLASH         | Yes <input type="button" value="v"/> |
| Graceful Option       | No <input type="button" value="v"/>  |
| ▼ LOCK / UNLOCK       |                                      |
| Lock                  | <input type="button" value="LOCK"/>  |
| Graceful Option       | No <input type="button" value="v"/>  |
| Current Admin State   | UNLOCKED                             |
| ▼ Save Configuration  |                                      |
| Burn To FLASH         | <input type="button" value="BURN"/>  |

### 41.1 Resetting the Device

The Maintenance Actions page allows you to remotely reset the device. In addition, before resetting the device, you can choose the following options:

- Save the device's current configuration to the device's flash memory (non-volatile).
- Perform a graceful shutdown, whereby device reset starts only after a user-defined time (i.e., timeout) or after no more active traffic exists (the earliest thereof).

#### Notes:

- Throughout the Web interface, parameters displayed with a lightning ⚡ symbol are not applied on-the-fly and require that you reset the device for them to take effect.
- When you modify parameters that require a device reset, once you click the **Submit** button in the relevant page, the toolbar displays "Reset" (see 'Toolbar Description' on page 42) to indicate that a device reset is required.
- After you reset the device, the Web GUI is displayed in Basic view (see 'Displaying Navigation Tree in Basic and Full View' on page 43).
- Upon reboot, the device restores the settings from its configuration file. However, if reboot attempts fail three times consecutively, the device resets the configuration file by restoring factory defaults before attempting to reboot.

➤ **To reset the device:**

1. Open the Maintenance Actions page (see 'Basic Maintenance' on page 529).
2. Under the 'Reset Configuration' group, from the 'Burn To FLASH' drop-down list, select one of the following options:
  - **Yes:** The device's current configuration is saved (*burned*) to the flash memory prior to reset (default).
  - **No:** Resets the device without saving the current configuration to flash (discards all unsaved modifications).
3. Under the 'Reset Configuration' group, from the 'Graceful Option' drop-down list, select one of the following options:
  - **Yes:** Reset starts only after the user-defined time in the 'Shutdown Timeout' field (see Step 4) expires or after no more active traffic exists (the earliest thereof). In addition, no new traffic is accepted.
  - **No:** Reset starts regardless of traffic, and any existing traffic is terminated at once.
4. In the 'Shutdown Timeout' field (relevant only if the 'Graceful Option' in the previous step is set to **Yes**), enter the time after which the device resets. Note that if no traffic exists and the time has not yet expired, the device resets.
5. Click the **Reset** button; a confirmation message box appears, requesting you to confirm.

**Figure 41-2: Reset Confirmation Message Box**

6. Click **OK** to confirm device reset; if the parameter 'Graceful Option' is set to **Yes** (in Step 3), the reset is delayed and a screen displaying the number of remaining calls and time is displayed. When the device begins to reset, a message appears notifying you of this.

## 41.2 Remotely Resetting Device using SIP NOTIFY

The device can be remotely reset upon the receipt of a SIP NOTIFY that includes an Event header set to 'check-sync;reboot=true', as shown in the example below:

```
NOTIFY sip:<user>@<dsthost> SIP/2.0
To: sip:<user>@<dsthost>
From: sip:sipsak@<srchost>
CSeq: 10 NOTIFY
Call-ID: 1234@<srchost>
Event: check-sync;reboot=true
```

➤ **To enable remote reset upon receipt of SIP NOTIFY:**

1. Open the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**).
2. Under the Misc Parameters group, set the 'SIP Remote Rest' parameter to **Enable**.
3. Click **Submit**.

**Note:** This SIP Event header value is proprietary to AudioCodes.

## 41.3 Locking and Unlocking the Device

The Lock and Unlock option allows you to lock the device so that it doesn't accept any new calls and maintains only the current calls. This is useful when, for example, you are uploading new software files to the device and you don't want any traffic to interfere with the process.

➤ **To lock the device:**

1. Open the Maintenance Actions page (see 'Basic Maintenance' on page 529).
  2. Under the 'LOCK / UNLOCK' group, from the 'Graceful Option' drop-down list, select one of the following options:
    - **Yes:** The device is 'locked' only after the user-defined time in the 'Lock Timeout' field (see Step 3) expires or no more active traffic exists (the earliest thereof). In addition, no new traffic is accepted.
    - **No:** The device is 'locked' regardless of traffic. Any existing traffic is terminated immediately.
- Note:** These options are only available if the current status of the device is in the Unlock state.
3. In the 'Lock Timeout' field (relevant only if the parameter 'Graceful Option' in the previous step is set to **Yes**), enter the time (in seconds) after which the device locks. Note that if no traffic exists and the time has not yet expired, the device locks.
  4. Click the **LOCK** button; a confirmation message box appears requesting you to confirm device Lock.

**Figure 41-3: Device Lock Confirmation Message Box**

5. Click **OK** to confirm device Lock; if 'Graceful Option' is set to **Yes**, the lock is delayed and a screen displaying the number of remaining calls and time is displayed. Otherwise, the lock process begins immediately. The Current Admin State' field displays the current state - "LOCKED" or "UNLOCKED".

➤ **To unlock the device:**

1. Open the Maintenance Actions page (see 'Maintenance Actions' on page 529).
2. Under the 'LOCK / UNLOCK' group, click the **UNLOCK** button. Unlock starts immediately and the device accepts new incoming calls.

**Note:** The Home page's General Information pane displays whether the device is locked or unlocked (see 'Viewing the Home Page' on page 54).

## 41.4 Saving Configuration

The Maintenance Actions page allows you to save (*burn*) the current parameter configuration (including loaded auxiliary files) to the device's *non-volatile* memory (i.e., flash). The parameter modifications that you make throughout the Web interface's pages are temporarily saved (to the *volatile* memory - RAM) when you click the **Submit** button on these pages. Parameter settings that are saved only to the device's RAM revert to their previous settings after a hardware/software reset (or power failure). Therefore, to ensure that your configuration changes are retained, you must save them to the device's flash memory using the burn option described below.

➤ **To save the changes to the non-volatile flash memory :**

1. Open the Maintenance Actions page (see 'Basic Maintenance' on page 529).
2. Under the 'Save Configuration' group, click the **BURN** button; a confirmation message appears when the configuration successfully saves.

**Notes:**

- Saving configuration to the *non-volatile* memory may disrupt current traffic on the device. To avoid this, disable all new traffic before saving, by performing a graceful lock (see 'Locking and Unlocking the Device' on page 531).
- Throughout the Web interface, parameters displayed with the lightning ⚡ symbol are not applied on-the-fly and require that you reset the device for them to take effect (see 'Resetting the Device' on page 529).
- The Home page's General Information pane displays whether the device is currently "burning" the configuration (see 'Viewing the Home Page' on page 54).

## 42 Resetting Channels

### 42.1 Resetting an Analog Channel

You can inactivate (*reset*) an FXO or FXS analog channel. This is sometimes useful, for example, when the device (FXO) is connected to a PBX and the communication between the two can't be disconnected (e.g., when using reverse polarity). This is done in the Web interface's Home page.

➤ **To reset an analog channel:**

1. Open the Home page.
2. Click the required **FXS** or **FXO** port icon; a shortcut menu appears.
3. From the shortcut menu, choose **Reset Channel**; the channel is changed to inactive and the port icon is displayed in gray.

### 42.2 Restarting a B-Channel

You can restart a specific B-channel belonging to an ISDN or CAS trunk, using the SNMP MIB variable, `acTrunkISDNCommonRestartBChannel` or the EMS management tool (refer to the EMS User's Manual). This may be useful, for example, for troubleshooting specific voice channels.

**Notes:**

- If a voice call is currently in progress on the B-channel, it is disconnected when the B-channel is restarted.
- B-channel restart can only be done if the D-channel of the trunk to which it belongs is synchronized (Layer 2).
- B-channel restart does not affect the B-channel's configuration.

## Reader's Notes

## 43 Software Upgrade

The **Software Update** menu allows you to do the following:

- Load Auxiliary files (see 'Loading Auxiliary Files' on page 535)
- Load a Software Upgrade Key (see 'Software Upgrade Key' on page 553)
- Upgrade the device using the Software Upgrade Wizard (see 'Software Upgrade Wizard' on page 556)
- Load/save Configuration file (see 'Backing Up and Loading Configuration File' on page 559)

### 43.1 Loading Auxiliary Files

Various Auxiliary files can be installed on the device. These Auxiliary files provide the device with additional configuration settings. The table below lists the different types of Auxiliary files:

**Auxiliary Files**

| File                | Description                                                                                                                                                                                                                                                                                                                   |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| INI                 | Configures the device. The Web interface enables practically full device provisioning. However, some features may only be configured by ini file or you may wish to configure your device using the ini file. For more information on using the ini file to configure the device, see 'INI File-Based Management' on page 89. |
| CAS                 | CAS auxiliary files containing the CAS Protocol definitions for CAS-terminated trunks (for various types of CAS signaling). You can use the supplied files or construct your own files. Up to eight different CAS files can be installed on the device. For more information, see CAS Files on page 541.                      |
| Call Progress Tones | Region-specific, telephone exchange-dependent file that contains the Call Progress Tones (CPT) levels and frequencies for the device. The default CPT file is U.S.A. For more information, see 'Call Progress Tones File' on page 537.                                                                                        |
| Dial Plan           | Provides dialing plans, for example, to know when to stop collecting dialed digits and start forwarding them or for obtaining the destination IP address for outbound IP routing. For more information, see 'Dial Plan File' on page 541.                                                                                     |
| User Info           | The User Information file maps PBX extensions to IP numbers. This file can be used to represent PBX extensions as IP phones in the global 'IP world'. For more information, see 'User Information File' on page 547.                                                                                                          |

The Auxiliary files can be loaded to the device using one of the following methods:

- Web interface.
- TFTP: This is done by specifying the name of the Auxiliary file in an *ini* file (see Auxiliary and Configuration Files Parameters) and then loading the *ini* file to the device. The Auxiliary files listed in the *ini* file are then automatically loaded through TFTP during device startup. If the *ini* file does not contain a specific auxiliary file type, the device uses the last auxiliary file of that type that was stored on its non-volatile memory.

**Notes:**

- You can schedule automatic loading of updated auxiliary files using HTTP/HTTPS. For more information on automatic updates, see 'Automatic Update' on page 561.
- When loading an *ini* file using this Web page, parameters that are excluded from the loaded *ini* file retain their current settings (*incremental*).
- Saving an auxiliary file to flash memory may disrupt traffic on the device. To avoid this, disable all traffic on the device by performing a graceful lock as described in 'Locking and Unlocking the Device' on page 531.
- For deleting auxiliary files, see 'Viewing Device Information' on page 577.

The procedure below describes how to load Auxiliary files using the Web interface.

➤ **To load auxiliary files to the device using the Web interface:**

1. Open the Load Auxiliary Files page (**Maintenance** tab > **Software Update** menu > **Load Auxiliary Files**).

**Note:** The appearance of certain file load fields depends on the installed Software License Key.

2. Click the **Browse** button corresponding to the file type that you want to load, navigate to the folder in which the file is located, and then click **Open**; the name and path of the file appear in the field next to the **Browse** button.
3. Click the **Load File** button corresponding to the file you want to load.
4. Repeat steps 2 through 3 for each file you want to load.
5. Save the loaded auxiliary files to flash memory, see 'Saving Configuration' on page 532 and reset the device (if you have loaded a Call Progress Tones file), see 'Resetting the Device' on page 529.

### 43.1.1 Call Progress Tones File

The Call Progress Tones (CPT) and Distinctive Ringing (applicable to analog interfaces) auxiliary file is comprised of two sections:

- The first section contains the definitions of the Call Progress Tones (levels and frequencies) that are detected/generated by the device.
- The second section contains the characteristics of the Distinctive Ringing signals that are generated by the device (see Distinctive Ringing on page 539).

You can use one of the supplied auxiliary files (.dat file format) or create your own file. To create your own file, it's recommended to modify the supplied *usa\_tone.ini* file (in any standard text editor) to suit your specific requirements and then convert the modified *ini* file into binary format, using AudioCodes DConvert utility. For a description on converting a CPT *ini* file into a binary *dat* file, refer to the *DConvert Utility User's Guide*.

**Note:** Only the *dat* file format can be loaded to the device.

You can create up to 32 different Call Progress Tones, each with frequency and format attributes. The frequency attribute can be single or dual-frequency (in the range of 300 to 1980 Hz) or an Amplitude Modulated (AM). Up to 64 different frequencies are supported. Only eight AM tones, in the range of 1 to 128 kHz, can be configured (the detection range is limited to 1 to 50 kHz). Note that when a tone is composed of a single frequency, the second frequency field must be set to zero.

The format attribute can be one of the following:

- **Continuous:** A steady non-interrupted sound (e.g., a dial tone). Only the 'First Signal On time' should be specified. All other on and off periods must be set to zero. In this case, the parameter specifies the detection period. For example, if it equals 300, the tone is detected after 3 seconds (300 x 10 msec). The minimum detection time is 100 msec.
- **Cadence:** A repeating sequence of on and off sounds. Up to four different sets of on/off periods can be specified.
- **Burst:** A single sound followed by silence. Only the 'First Signal On time' and 'First Signal Off time' should be specified. All other on and off periods must be set to zero. The burst tone is detected after the off time is completed.

You can specify several tones of the same type. These additional tones are used only for tone detection. Generation of a specific tone conforms to the first definition of the specific tone. For example, you can define an additional dial tone by appending the second dial tone's definition lines to the first tone definition in the *ini* file. The device reports dial tone detection if either of the two tones is detected.

The Call Progress Tones section of the *ini* file comprises the following segments:

- **[NUMBER OF CALL PROGRESS TONES]:** Contains the following key: 'Number of Call Progress Tones' defining the number of Call Progress Tones that are defined in the file.
- **[CALL PROGRESS TONE #X]:** containing the Xth tone definition, starting from 0 and not exceeding the number of Call Progress Tones less 1 defined in the first section (e.g., if 10 tones, then it is 0 to 9), using the following keys:
  - **Tone Type:** Call Progress Tone types:
    - ◆ **[1]** Dial Tone
    - ◆ **[2]** Ringback Tone

- ◆ **[3]** Busy Tone
- ◆ **[4]** Congestion Tone
- ◆ **[6]** Warning Tone
- ◆ **[7]** Reorder Tone
- ◆ **[8]** Confirmation Tone
- ◆ **[9]** Call Waiting Tone - heard by the called party
- ◆ **[15]** Stutter Dial Tone
- ◆ **[16]** Off Hook Warning Tone
- ◆ **[17]** Call Waiting Ringback Tone - heard by the calling party
- ◆ **[18]** Comfort Tone
- ◆ **[23]** Hold Tone
- ◆ **[46]** Beep Tone
- **Tone Modulation Type:** Amplitude Modulated (1) or regular (0)
- **Tone Form:** The tone's format can be one of the following:
  - ◆ Continuous (1)
  - ◆ Cadence (2)
  - ◆ Burst (3)
- **Low Freq [Hz]:** Frequency (in Hz) of the lower tone component in case of dual frequency tone, or the frequency of the tone in case of single tone. This is not relevant to AM tones.
- **High Freq [Hz]:** Frequency (in Hz) of the higher tone component in case of dual frequency tone, or zero (0) in case of single tone (not relevant to AM tones).
- **Low Freq Level [-dBm]:** Generation level 0 dBm to -31 dBm in dBm (not relevant to AM tones).
- **High Freq Level:** Generation level of 0 to -31 dBm. The value should be set to 32 in the case of a single tone (not relevant to AM tones).
- **First Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the first cadence on-off cycle. For continuous tones, this parameter defines the detection period. For burst tones, it defines the tone's duration.
- **First Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the first cadence on-off cycle (for cadence tones). For burst tones, this parameter defines the off time required after the burst tone ends and the tone detection is reported. For continuous tones, this parameter is ignored.
- **Second Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the second cadence on-off cycle. Can be omitted if there isn't a second cadence.
- **Second Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the second cadence on-off cycle. Can be omitted if there isn't a second cadence.
- **Third Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the third cadence on-off cycle. Can be omitted if there isn't a third cadence.
- **Third Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the third cadence on-off cycle. Can be omitted if there isn't a third cadence.
- **Fourth Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the fourth cadence on-off cycle. Can be omitted if there isn't a fourth cadence.
- **Fourth Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the fourth cadence on-off cycle. Can be omitted if there isn't a fourth cadence.
- **Carrier Freq [Hz]:** Frequency of the carrier signal for AM tones.
- **Modulation Freq [Hz]:** Frequency of the modulated signal for AM tones (valid range from 1 to 128 Hz).
- **Signal Level [-dBm]:** Level of the tone for AM tones.

- **AM Factor [steps of 0.02]:** Amplitude modulation factor (valid range from 1 to 50). Recommended values from 10 to 25.

**Notes:**

- When the same frequency is used for a continuous tone and a cadence tone, the 'Signal On Time' parameter of the continuous tone must have a value that is greater than the 'Signal On Time' parameter of the cadence tone. Otherwise, the continuous tone is detected instead of the cadence tone.
- The tones frequency must differ by at least 40 Hz between defined tones.

For example, to configure the dial tone to 440 Hz only, enter the following text:

```
[NUMBER OF CALL PROGRESS TONES]
Number of Call Progress Tones=1
#Dial Tone
[CALL PROGRESS TONE #0]
Tone Type=1
Tone Form =1 (continuous)
Low Freq [Hz]=440
High Freq [Hz]=0
Low Freq Level [-dBm]=10 (-10 dBm)
High Freq Level [-dBm]=32 (use 32 only if a single tone is
required)
First Signal On Time [10msec]=300; the dial tone is detected after
3 sec
First Signal Off Time [10msec]=0
Second Signal On Time [10msec]=0
Second Signal Off Time [10msec]=0
```

#### 43.1.1.1 Distinctive Ringing

Distinctive Ringing is applicable only to FXS interfaces. Using the Distinctive Ringing section of the Call Progress Tones auxiliary file, you can create up to 16 Distinctive Ringing patterns. Each ringing pattern configures the ringing tone frequency and up to four ringing cadences. The same ringing frequency is used for all the ringing pattern cadences. The ringing frequency can be configured in the range of 10 to 200 Hz with a 5 Hz resolution.

Each of the ringing pattern cadences is specified by the following parameters:

- **Burst Ring On Time:** Configures the cadence to be a burst cadence in the entire ringing pattern. The burst relates to On time and the Off time of the same cadence. It must appear between 'First/Second/Third/Fourth' string and the 'Ring On/Off Time'. This cadence rings once during the ringing pattern. Otherwise, the cadence is interpreted as cyclic: it repeats for every ringing cycle.
- **Ring On Time:** Specifies the duration of the ringing signal.
- **Ring Off Time:** Specifies the silence period of the cadence.

The Distinctive Ringing section of the *ini* file format contains the following strings:

- **[NUMBER OF DISTINCTIVE RINGING PATTERNS]:** Contains the following key:
  - 'Number of Distinctive Ringing Patterns' defining the number of Distinctive Ringing signals that are defined in the file.
- **[Ringing Pattern #X]:** Contains the Xth ringing pattern definition (starting from 0 and not exceeding the number of Distinctive Ringing patterns defined in the first section minus 1) using the following keys:

- **Ring Type:** Must be equal to the Ringing Pattern number.
- **Freq [Hz]:** Frequency in hertz of the ringing tone.
- **First (Burst) Ring On Time [10 msec]:** 'Ring On' period (in 10 msec units) for the first cadence on-off cycle.
- **First (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the first cadence on-off cycle.
- **Second (Burst) Ring On Time [10 msec]:** 'Ring On' period (in 10 msec units) for the second cadence on-off cycle.
- **Second (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the second cadence on-off cycle.
- **Third (Burst) Ring On Time [10 msec]:** 'Ring On' period (in 10 msec units) for the third cadence on-off cycle.
- **Third (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the third cadence on-off cycle.
- **Fourth (Burst) Ring On Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the fourth cadence on-off cycle.
- **Fourth (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the fourth cadence on-off cycle.

**Note:** In SIP, the Distinctive Ringing pattern is selected according to the Alert-Info header in the INVITE message. For example:  
Alert-Info:<Bellcore-dr2>, or Alert-Info:<http://.../Bellcore-dr2>  
'dr2' defines ringing pattern #2. If the Alert-Info header is missing, the default ringing tone (0) is played.

An example of a **ringing burst** definition is shown below:

#Three ringing bursts followed by repeated ringing of 1 sec on and 3 sec off.

**[NUMBER OF DISTINCTIVE RINGING PATTERNS]**

Number of Ringing Patterns=1

**[Ringing Pattern #0]**

Ring Type=0

Freq [Hz]=25

First Burst Ring On Time [10msec]=30

First Burst Ring Off Time [10msec]=30

Second Burst Ring On Time [10msec]=30

Second Burst Ring Off Time [10msec]=30

Third Burst Ring On Time [10msec]=30

Third Burst Ring Off Time [10msec]=30

Fourth Ring On Time [10msec]=100

Fourth Ring Off Time [10msec]=300

An example of **various ringing signals** definition is shown below:

**[NUMBER OF DISTINCTIVE RINGING PATTERNS]**

Number of Ringing Patterns=3

#Regular North American Ringing Pattern

**[Ringing Pattern #0]**

Ring Type=0

Freq [Hz]=20

First Ring On Time [10msec]=200

First Ring Off Time [10msec]=400

#GR-506-CORE Ringing Pattern 1

**[Ringing Pattern #1]**

Ring Type=1

Freq [Hz]=20

```
First Ring On Time [10msec]=200
First Ring Off Time [10msec]=400
#GR-506-CORE Ringing Pattern 2
[Ring Pattern #2]
Ring Type=2
Freq [Hz]=20
First Ring On Time [10msec]=80
First Ring Off Time [10msec]=40
Second Ring On Time [10msec]=80
Second Ring Off Time [10msec]=400
```

### 43.1.2 CAS Files

The CAS auxiliary files contain the CAS Protocol definitions that are used for CAS-terminated trunks. You can use the supplied files or construct your own files. Up to eight files can be loaded to the device. Different files can be assigned to different trunks (CASTableIndex\_x) and different CAS tables can be assigned to different B-channels (CASChannelIndex).

The CAS files can be loaded to the device using the Web interface or *ini* file (see 'Loading Auxiliary Files' on page 535).

**Note:** All CAS files loaded together must belong to the same Trunk Type (i.e., either E1 or T1).

### 43.1.3 Dial Plan File

The Dial Plan file can be used for various digit mapping features, as described in this section.

#### 43.1.3.1 Creating a Dial Plan File

Creating a Dial Plan file is similar between all Dial Plan features. The main difference is the syntax used in the Dial Plan file and the method for selecting the Dial Plan index to use for the specific feature.

The Dial Plan file is a text-based file that can contain up to eight Dial Plans (Dial Plan indices) and up to 8,000 rules (lines). The general syntax rules for the Dial Plan file are as follows (syntax specific to the feature is described in the respective section):

- Each Dial Plan index must begin with a Dial Plan name enclosed in square brackets "[...]" on a new line.
- Each line under the Dial Plan index defines a rule.
- Empty lines are ignored.
- Lines beginning with a semicolon ";" are ignored. The semicolon can be used for comments.

➤ **To create a Dial Plan file:**

1. Create a new file using a text-based editor (such as Notepad) and configure your Dial Plans, as required.
2. Save the file with the *ini* file extension name (e.g., mydialplanfile.ini).
3. Convert the *ini* file to a *dat* binary file, using AudioCodes DConvert utility. For more information, refer to *DConvert Utility User's Guide*.

4. Install the converted file on the device, as described in 'Loading Auxiliary Files' on page 535.
5. Select the Dial Plan index that you want to use. This depends on the feature and is described in the respective section.

### 43.1.3.2 Dialing Plans for Digit Collection

The device enables you to configure multiple dialing plans in an external Dial Plan file, which can be installed on the device. If a Dial Plan file is implemented, the device first attempts to locate a matching digit pattern in a specified Dial Plan index listed in the file and if not found, attempts to locate a matching digit pattern in the Digit Map. The Digit Map is configured by the 'Digit Mapping Rules' parameter, located in the DTMF & Dialing page (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **DTMF and Supplementary** > **DTMF & Dialing**).

The Dial Plan is used for the following:

- ISDN Overlap Dialing, FXS, and FXO collecting digit mode (Tel-to-IP calls): The file allows the device to know when digit collection ends, after which it starts sending all the collected (or dialed) digits in the outgoing INVITE message. This also provides enhanced digit mapping.
- CAS E1 MF-CR2 (Tel-to-IP calls): Useful for E1 MF-CR2 variants that do not support I-15 terminating digits (e.g., in Brazil and Mexico). The Dial Plan file allows the device to detect end-of-dialing in such cases. The `CasTrunkDialPlanName_x` ini file parameter determines which dial plan (in the Dial Plan file) to use for a specific trunk.

#### Notes:

- To use the Dial Plan file, you must also use a special CAS .dat file that supports this feature. For more information, contact your AudioCodes sales representative.
- For E1 CAS MFC-R2 variants, which don't support terminating digit for the called party number, usually I-15, the Dial Plan file and the DigitMapping parameter are ignored. Instead, you can define a Dial Plan template per trunk using the parameter `CasTrunkDialPlanName_x`.

The Dial Plan file can contain up to eight Dial Plans (Dial Plan indices), with a total of up to 8,000 dialing rules (lines) of distinct prefixes (e.g. area codes, international telephone number patterns) for the PSTN to which the device is connected.

The Dial Plan file is created in a textual *ini* file with the following syntax:

```
<called number prefix>,<total digits to wait before sending>
```

- Each new Dial Plan index begins with a Dial Plan name enclosed in square brackets "[...]" on a new line.
- Each line under the Dial Plan index defines a dialing prefix and the number of digits expected to follow that prefix. The prefix is separated by a comma "," from the number of additional digits.
- The prefix can include numerical ranges in the format [x-y], as well as multiple numerical ranges [n-m][x-y] (no comma between them).
- The prefix can include the asterisk "\*" and number "#" signs.
- The number of additional digits can include a numerical range in the format x-y.
- Empty lines are ignored.
- Lines beginning with a semicolon ";" are ignored. The semicolon can be used for comments.

Below shows an example of a Dial Plan file (in *ini*-file format), containing two dial plans:

```
; Example of dial-plan configuration.
; This file contains two dial plans:
[PLAN1]
; Destination cellular area codes 052, 054, and 050 with 8 digits.
052,8
054,8
050,8
; Defines International prefixes 00, 012, 014.
; The number following these prefixes may
; be 7 to 14 digits in length.
00,7-14
012,7-14
014,7-14
; Defines emergency number 911. No additional digits are expected.
911,0
[PLAN2]
; Defines area codes 02, 03, 04.
; In these area codes, phone numbers have 7 digits.
0[2-4],7
; Operator services starting with a star: *41, *42, *43.
; No additional digits are expected.
*4[1-3],0
```

The procedure below provides a summary on how to create a Dial Plan file and select the required Dial Plan index.

➤ **To create a Dial Plan file:**

1. Create a new file using a text-based editor (such as Notepad) and configure your Dial Plans, as required.
2. Save the file with the *ini* file extension name (e.g., mydialplans.ini).
3. Convert the *ini* file to a *dat* binary file, using AudioCodes DConvert utility. For more information, refer to *DConvert Utility User's Guide*.
4. Install the converted file on the device, as described in 'Loading Auxiliary Files' on page 535.
5. The required Dial Plan is selected using the 'Dial Plan Index' parameter. This parameter can be set to 0 through 7, where 0 denotes PLAN1, 1 denotes PLAN2, and so on.

**Notes:**

- The Dial Plan file must not contain overlapping prefixes. Attempting to process an overlapping configuration by the DConvert utility results in an error message specifying the problematic line.
- The Dial Plan index can be selected globally for all calls (as described in the previous procedure), or per specific calls using Tel Profiles.
- It may be useful to configure both Dial Plan file and Digit Maps. For example, the Digit Map can be used for complex digit patterns (which are not supported by the Dial Plan) and the Dial Plan can be used for long lists of relatively simple digit patterns. In addition, as timeout between digits is not supported by the Dial Plan, the Digit Map can be used to configure digit patterns that are shorter than those defined in the Dial Plan or left at default (MaxDigits parameter). For example, the "xx.T" digit map instructs the device to use the Dial Plan and if no matching digit pattern is found, it waits for two more digits and then after a timeout (TimeBetweenDigits parameter), it sends the collected digits. Therefore, this ensures that calls are not rejected as a result of their digit pattern not been completed in the Dial Plan.
- By default, if no matching digit pattern is found in both the Dial Plan and Digit Map, the device rejects the call. However, if you set the DisableStrictDialPlan parameter to 1, the device attempts to complete the call using the MaxDigits and TimeBetweenDigits parameters. In such a setup, it collects the number of digits configured by the MaxDigits parameters. If more digits are received, it ignores the settings of this parameter and collects the digits until the inter-digit timeout configured by the TimeBetweenDigits parameter is exceeded.

### 43.1.3.3 Dial Plan Prefix Tags for IP-to-Tel Routing

The device supports the use of string labels (or "tags") in the external Dial Plan file for tagging incoming IP-to-Tel calls. The special "tag" is added as a prefix to the called party number, and then the Inbound IP Routing Table uses this "tag" instead of the original prefix. Manipulation is then performed after routing in the Manipulation table, which strips the "tag" characters before sending the call to the endpoint.

This feature resolves the limitation of entries in the Inbound IP Routing Table (IP-to-Tel call routing) for scenarios in which many different routing rules are required. For example, a city may have many different area codes, some for local calls and others for long distance calls (e.g. 425-202-xxxx for local calls, but 425-200-xxxx for long distance calls).

For using tags, the Dial Plan file is defined as follows:

- Number of dial plan (text)
- Dial string prefix (ranges can be defined in brackets)
- User-defined routing tag (text)

**Note:** Dial Plan Prefix Tags are not applicable to FXS and FXO interfaces.

The example configuration below assumes a scenario where multiple prefixes exist for local and long distance calls:

➤ **To use Dial Plan file routing tags:**

1. Load an *ini* file to the device that selects Dial Plan index (e.g., 1) for routing tags, as shown below:

```
IP2TelTaggingDestDialPlanIndex = 0
```

2. Define the external Dial Plan file with two routing tags (as shown below):

- "LOCL" - for local calls
- "LONG" - for long distance calls

```
[PLAN1]
42520[3-5], 0, LOCL
425207, 0, LOCL
42529, 0, LOCL
425200, 0, LONG
425100, 0, LONG
```

For example, if an incoming IP call to destination prefix 425203 is received, the device adds the prefix tag "LOCL" as specified in the Dial Plan file, resulting in the number "LOCL425203".

3. Assign the different tag prefixes to different Trunk Groups in the Inbound IP Routing Table (**Configuration** tab > **VoIP** menu > **GW and IP to IP** > **Routing** > **IP to Trunk Group Routing**):
  - The Dest. Phone Prefix' field is set to the value "LOCL" and this rule is assigned to a local Trunk Group (e.g. Trunk Group ID 1).
  - The Dest. Phone Prefix' field is set to the value "LONG" and this rule is assigned to a long distance Trunk Group (e.g. Trunk Group ID 2).

**Figure 43-1: Configuring Dial Plan File Label for IP-to-Tel Routing**

| <div> <div>Routing Index</div> <div>1-12</div> </div> <div> <div>IP To Tel Routing Mode</div> <div>Route calls before manipulation</div> </div> |                   |                    |                    |                     |                   |               |
|-------------------------------------------------------------------------------------------------------------------------------------------------|-------------------|--------------------|--------------------|---------------------|-------------------|---------------|
|                                                                                                                                                 | Dest. Host Prefix | Source Host Prefix | Dest. Phone Prefix | Source Phone Prefix | Source IP Address | Hunt Group ID |
| 1                                                                                                                                               |                   |                    | LOCL               |                     |                   | 1             |
| 2                                                                                                                                               |                   |                    | LONG               |                     |                   | 2             |

The above routing rules are configured to be performed before manipulation (described in the step below).

4. Configure manipulation in the Destination Phone Number Manipulation Table for IP to Tel Calls table (**Configuration** tab > **VoIP** menu > **GW and IP to IP** submenu > **Manipulations** submenu > **Dest Number IP->Tel**) for removing the first four characters of the called party number "tag" (in our example, "LOCL" and "LONG"):
  - The Destination Prefix' field is set to the value "LOCL" and the 'Stripped Digits From Left' field is set to '4'.
  - The Destination Prefix' field is set to the value "LONG" and the 'Stripped Digits From Left' field is set to '4'.

**Figure 43-2: Configuring Manipulation for Removing Label**

| Index | Destination Prefix | Source Prefix | Source IP Address | Stripped Digits From Left |
|-------|--------------------|---------------|-------------------|---------------------------|
| 1     | LOCL               | *             | *                 | 4                         |
| 2     | LONG               | *             | *                 | 4                         |

#### 43.1.3.4 Obtaining IP Destination from Dial Plan File

You can use a Dial Plan index listed in a loaded Dial Plan file for determining the IP destination of Tel-to-IP /IP-to-IP calls and SBC calls. This enables the mapping of called numbers to IP addresses (in dotted-decimal notation) or FQDNs (up to 15 characters).

➤ **To configure routing to an IP destination based on Dial Plan:**

1. Create the Dial Plan file. The syntax of the Dial Plan index for this feature is as follows:

```
<destination / called prefix number>,0,<IP destination>
```

Note that the second parameter "0" is not used and ignored.

An example of a configured Dial Plan (# 6) in the Dial Plan file is shown below:

```
[PLAN6]
200,0,10.33.8.52 ; called prefix 200 is routed to
10.33.8.52
201,0,10.33.8.52
300,0,itsp.com ; called prefix 300 is routed to itsp.com
```

2. Convert the file to a loadable file and then load it to the device.
3. Assign the Dial Plan index to the required routing rule:
  - SBC Calls: In the SBC IP-to-IP Routing table, do the following:
    - a. Set the 'Destination Type' field to Dial Plan.
    - b. In the 'Destination Address' field, enter the required Dial Plan index, where "0" denotes [PLAN1] in the Dial Plan file, "1" denotes [PLAN2], and so on.
  - Tel-to-IP or IP-to-IP Calls (Gateway/IP-to-IP application): In the Outbound IP Routing table, do the following:
    - ◆ In the 'Destination Address' field, enter the required Dial Plan index using the following syntax:  
*DialPlan<index>*  
 Where "DialPlan0" denotes [PLAN1] in the Dial Plan file, "DialPlan1" denotes [PLAN2], and so on.

**Note:** The "DialPlan" string is case-sensitive.

#### 43.1.3.5 Modifying ISDN-to-IP Calling Party Number

The device can use the Dial Plan file to change the Calling Party Number value (source number) of the incoming ISDN call when sending to IP. For this feature, the Dial Plan file supports the following syntax:

```
<ISDN Calling Party Number>,0,<new calling number>
```

- The first number contains the calling party number (or its prefix) received in the ISDN call SETUP message. The source number can also be a range, using the syntax [x-y] in the Dial Plan file. This number is used as the display name in the From header of the outgoing INVITE.
- The second number must always be set to "0".
- The third number is a string of up to 12 characters containing the mapped number that is used as the URI user part in the From and Contact headers of the outgoing INVITE.

The Dial Plan index used in the Dial Plan file for this feature is defined by the Tel2IPSourceNumberMappingDialPlanIndex parameter.

An example of such a configuration in the Dial Plan file is shown below:

```
[PLAN1]
; specific received number changed to 04343434181.
0567811181,0,04343434181
; number range that changes to 04343434181.
056788118[2-4],0,04343434181
```

If we take the first Dial Plan rule in the example above (i.e., "0567811181,0,04343434181"), the received Calling Number Party of 0567811181 is changed to 04343434181 and sent to the IP with a SIP INVITE as follows:

```
Via: SIP/2.0/UDP 211.192.160.214:5060;branch=z9hG4bK3157667347
From: <sip:04343434181@kt.co.kr:5060>;tag=de0004b1
To: sip:01066557573@kt.co.kr:5060
Call-ID: 585e60ec@211.192.160.214
CSeq: 1 INVITE
Contact:<sip:04343434181@211.192.160.214:5060;transport=udp>
```

The initial Dial Plan text file must be converted to \*.dat file format using the DConvert utility. This is done by clicking the DConvert's **Process Dial Plan File** button. For more information, refer to *DConvert Utility User's Guide*.

You can load this \*.dat file to the device using the Web interface (see 'Loading Auxiliary Files' on page 535), AcBootP utility, or using the Auto-update mechanism from an external HTTP server.

#### Notes:

- Tel-to-IP routing is performed on the original source number if the parameter 'Tel to IP Routing Mode' is set to 'Route calls before manipulation'.
- Tel-to-IP routing is performed on the modified source number as defined in the Dial Plan file, if the parameter 'Tel To IP Routing Mode' is set to 'Route calls after manipulation'.
- Source number Tel-to-IP manipulation is performed on the modified source number as defined in the Dial Plan file.

### 43.1.4 User Information File

This section describes the various uses of the User Info file.

You can load the User Info file using any of the following methods:

- Web interface (see 'Loading Auxiliary Files' on page 535)
- *ini* file - using the UserInfoFileName parameter, e.g., UserInfoFileName = 'UserInformationFile.txt' (see 'Auxiliary and Configuration File Name Parameters' on page 889)
- Automatic update mechanism - using the UserInfoFileURL parameter, e.g., UserInfoFileUrl = 'http://192.168.0.250/Audiocodes/ UserInformationFile.txt' (see 'Automatic Update' on page 561)

**Note:** Instead of using a User Info file, you can configure the User Info table using the CLI, as described in 'Configuring User Info Table using CLI' on page 550.

#### 43.1.4.1 User Information File for PBX Extensions and "Global" Numbers

The User Info file contains a User Info table that can be used for the following Gateway-related:

- **Mapping (Manipulating) PBX Extension Numbers with Global Phone Numbers:** maps PBX extension number, connected to the device, with any "global" phone number (alphanumerical) for the IP side. In this context, the "global" phone number serves as a routing identifier for calls in the "IP world" and the PBX extension uses this mapping to emulate the behavior of an IP phone. This feature is especially useful in scenarios where unique or non-consecutive number translation per PBX is needed. This number manipulation feature supports the following call directions:
  - IP-to-Tel Calls: Maps the called "global" number (in the Request-URI user part) to the PBX extension number. For example, if the device receives an IP call destined for "global" number 638002, it changes this called number to the PBX extension number 402, and then sends the call to the PBX extension on the Tel side.

**Note:** If you have configured regular IP-to-Tel manipulation rules (see 'Configuring Source/Destination Number Manipulation' on page 297), the device applies these rules before applying the mapping rules of the User Info table.

- Tel-to-IP Calls: Maps the calling (source) PBX extension to the "global" number. For example, if the device receives a Tel call from PBX extension 402, it changes this calling number to 638002, and then sends call to the IP side with this calling number. In addition to the "global" phone number, the display name (caller ID) configured for the PBX user in the User Info table is used in the SIP From header.

**Note:** If you have configured regular Tel-to-IP manipulation rules (see 'Configuring Source/Destination Number Manipulation' on page 297), the device applies these rules before applying the mapping rules of the User Info table.

- IP-to-IP Calls: Maps SIP From (calling number) and To (called number) of IP PBX extension numbers with "global" numbers. For example, if the device receives a call from IP PBX extension number 402 (calling / SIP From) that is destined to IP PBX extension number 403 (called / SIP To), the device changes both these numbers into their "global" numbers 638002 and 638003, respectively.
- **Registering Users:** The device can register each PBX user configured in the User Info table. For each user, the device sends a SIP REGISTER to an external IP-based Registrar server, using the "global" number in the From/To headers. If authentication is necessary for registration, the device sends the user's username and password, configured in the User Info table, in the SIP MD5 Authorization header.

**Notes:**

- To enable the User Info table, see 'Enabling the User Info Table' on page 552.
- To modify the Use Info table, you need to load a new User Info table containing your modifications. However, instead of loading a new User Info file, you can modify the User Info table using CLI, as described in 'Configuring User Info Table using CLI' on page 550.
- To enable user registration, set the following parameters on the Proxy & Registration page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Proxy & Registration**) as shown:
  - ✓ 'Enable Registration' parameter set to **Enable** (IsRegisterNeeded is set to 1).
  - ✓ 'Registration Mode' parameter set to **Per Endpoint** (AuthenticationMode is set to 0).
- For FXS ports, when the device needs to send a new SIP request with the Authorization header (e.g., after receiving a SIP 401 response), it uses the username and password configured in the Authentication table (see 'Configuring Authentication per Port' on page 395). To use the username and password configured in the User Info file, set the 'Password' parameter to any value other than its default value.

The User Info file is a text-based file that you can create using any text-based program such as Notepad. To add mapping rules to this file, use the following syntax:

```
[GW]
FORMAT
PBXExtensionNum,GlobalPhoneNum,DisplayName,UserName,Password
```

Where:

- *PBXExtensionNum* is the PBX extension number (up to 10 characters)
- *GlobalPhoneNum* is the "global" phone number (up to 20 characters) for the IP side
- *DisplayName* is the Caller ID (string of up to 30 characters) of the PBX extension
- *UserName* is the username (string of up to 40 characters) for registering the user when authentication is necessary
- *Password* is the password (string of up to 20 characters) for registering the user when authentication is necessary

Each line in the file represents a mapping rule of a single PBX extension user.

You can add up to 1,000 mapping rules. The maximum size of the User Info file is 10,800 bytes for analog interfaces and 108,000 bytes for digital interfaces.

**Note:** Make sure that the last line in the User Info file ends with a carriage return (i.e., by pressing the <Enter> key).

An example of a configured User Info file is shown below:

```
[GW]
FORMAT
PBXExtensionNum,GlobalPhoneNum,DisplayName,UserName,Password
401 , 638001 , Mike , miked , 1234
402 , 638002 , Lee , leep , 4321
403 , 638003 , Sue , suer , 8790
404 , 638004 , John , johnd , 7694
```

```
405 , 638005 , Pam , pame, 3928
406 , 638006 , Steve , steveg, 1119
407 , 638007 , Fred , frede, 8142
408 , 638008 , Maggie , maggiew , 9807
```

#### 43.1.4.2 User Information File for SBC User Database

You can create a User Info table of SBC users from a loaded User Info file. This User Info file is the same file used for the GW / IP-to-IP application.

The device can use the SBC User Info for the following:

- Registering each user to an external registrar server.
- Authenticating (for any SIP request and as a client) each user if challenged by an external server.
- Authenticating as a server incoming user requests (for SBC security).

If the device registers on behalf of users and the users do not perform registration, any SIP request destined to the user is routed to the Proxy Set associated with the user's IP Group.

The User Info file is a text-based file that you can create using any text-based program such as Notepad. To add SBC users to this file, use the following syntax:

```
[SBC]
FORMAT LocalUser,UserName,Password,IPGroupID
john,john_user,john_pass,2
sue,sue_user,sue_pass,1
```

where:

- *LocalUser* is the user and is used as the Request-URI user part for the AOR in the database
- *UserName* is the user's authentication username
- *Password* is the user's authentication password
- *IPGroupID* is the IP Group ID to which the user belongs and is used as the Request-URI source host part for the AOR in the database

##### Notes:

- To enable the User Info table, see 'Enabling the User Info Table' on page 552.
- To modify the User Info table, you need to load a new User Info table containing your modifications. However, instead of loading a new User Info file, you can modify the User Info table using CLI, as described in 'Configuring User Info Table using CLI' on page 550.

#### 43.1.4.3 Configuring User Info Table using CLI

Instead of using the User Info file to configure the Gateway and SBC User Info tables, you can configure these tables through CLI. The CLI lets you add, edit, delete, and search users in the User Info table.

##### Notes:

- If you load a User Info file to the device, all previous User Info table entries are deleted and replaced with the entries in the loaded User Info file.
- To enable the User Info table, see 'Enabling the User Info Table' on page 552.

The CLI path to these tables is as follows:

```
configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info <gw-user-info (for Gateway) |
sbcs-user-info (for SBC)>
```

The following commands can be used:

- To view all table entries, use the display command, as shown in the example below:

- SBC:

```
(sip-def-proxy-and-reg)# user-info sbcs-user-info display
---- sbcs-user-info-0 ----
 local-user (JohnDee)
 username (userJohn)
 password (s3fn+fn=)
 ip-group-id (1)
 status (not-resgistered)
---- sbcs-user-info-1 ----
 local-user (SuePark)
 username (userSue)
 password (t6sn+un=)
 ip-group-id (1)
 status (not-resgistered)
```

- Gateway:

```
(sip-def-proxy-and-reg)# user-info gw-user-info display
---- gw-user-info-0 ----
 pbx-ext (405)
 global-phone-num (405)
 display-name (Ext405)
 username (user405)
 password (0aGzoKfh5uI=)
 status (not-resgistered)
```

- To view a specific entry, enter the table index number and display command:

```
(sip-def-proxy-and-reg)# user-info sbcs-user-info 1
(sbc-user-info-1)# display
 local-user (SuePark)
 username (userSue)
 password (t6sn+un=)
 ip-group-id (1)
 status (not-resgistered)
```

- To add and/or define a user, use the set command, as shown in the example below:

```
(sip-def-proxy-and-reg)# user-info sbcs-user-info 1
(sbc-user-info-1)# set username JohnDee
```

- To apply your changes, use the exit or activate command per user addition or modification (not per parameter):

```
(sbcs-user-info-1)# <activate | exit>
```

- To search a user (by pbx-ext for Gateway or local-user for SBC), use the find command, as shown in the example below:

```
sip-def-proxy-and-reg)# user-info find <pbx-ext e.g., 300
local-user, e.g., JohnDoe>
JohnDee: Found at index 3 in SBC user info table, not
registered
```

The search locates the table index belonging to the searched user.

- To delete a user, use the no command, as shown in the example below:

```
(sip-def-proxy-and-reg)# no user-info sbc-user-info <database
index entry, e.g., 1)
```

#### 43.1.4.4 Enabling the User Info Table

The procedure below describes how to load a User Info file to the device and enable the use of the User Info table:

➤ **To enable the User Info table:**

1. Open the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**).
2. Set the 'Enable User-Information Usage' parameter to **Enable**.

## 43.2 Software License Key

The device is shipped with a pre-installed Software License Key, which determines the device's supported features, capabilities, and available resources. You can upgrade or change your device's supported features by purchasing and installing a new Software License Key to match your requirements.

**Note:** The availability of certain Web pages depends on the installed Software License Key.

### 43.2.1 Obtaining the Software License Key File

Before you can install a new Software License Key, you need to obtain a Software License Key file for your device with the required features from your AudioCodes representative. The Software License Key is an encrypted key in string format that is associated with the device's serial number ("S/N") and supplied in a text-based file.

If you need a Software License Key for more than one device, the Software License Key file can include multiple Software License Keys (see figure below). In such cases, each Software License Key in the file is associated with a unique serial number identifying the specific device. When loading such a Software License Key file, the device installs only the Software License Key that is associated with its serial number.

**Figure 3: Software License Key File with Multiple S/N Lines**

```
sample.ini - Notepad
File Edit Format Help
[LicenseKeys]
;Board Type 29
S/N241182 =

```

➤ **To obtain a Software License Key:**

1. Make a note of the MAC address and/or serial number of the device:
  - a. Open the Device Information page (**Status & Diagnostics** tab > **System Status** menu > **Device Information**).
  - b. The MAC address is displayed in the "MAC Address" field and the serial number in the "Serial Number" field.
2. If you need a Software License Key for more than one device, repeat Step 1 for each device.
3. Request the required Software License Key from your AudioCodes representative and provide them with the MAC address and/or serial number of the device(s).
4. When you receive the new Software License Key file, check the file as follows:
  - a. Open the file with any text-based program such as Notepad.
  - b. Verify that the first line displays "[LicenseKeys]".
  - c. Verify that the file contains one or more lines in the following format:

"S/N<serial number> = <Software License Key string>".  
For example: "S/N370604 = jCx6r5tovCIKaBBbhPtT53Yj..."

- d. Verify that the "S/N" value reflects the serial number of your device. If you have multiple Software License Keys, ensure that each "S/N" value corresponds to a device.

**Warning:** Do not modify the contents of the Software License Key file.

5. Install the Software License Key on the device as described in 'Installing the Software License Key' on page 554.

## 43.2.2 Installing the Software License Key

Once you have received your Software License Key file from your AudioCodes representative, you can install it on the device using one of the following management tools:

- Web interface - see 'Installing the Software License Key using Web' on page 554
- CLI – see 'Installing the Software License Key using CLI' on page 555
- AudioCodes EMS - refer to the EMS User's Manual or EMS Product Description

**Note:** When you install a new Software License Key, it is loaded to the device's non-volatile flash memory and overwrites the previously installed Software License Key.

### 43.2.2.1 Installing the Software License Key using Web

The procedure below describes how to install the Software License Key using the Web interface.

- **To install the Software License Key using the Web interface:**

1. Open the Software Upgrade Key Status page (**Maintenance** tab > **Software Update** menu > **Software Upgrade Key**).

**Current Key** ISN2r5toqBQ8bBt581xJu6l9j3Zcf3ta41wnehcs8hofalNeb1b1R5ZPQ9ncypf5xZAxc8xfamhSah4Za24

**Key features:**  
Board Type: Mediant 850 - MSBG  
Security: IPSEC MediaEncryption StrongEncryption EncryptControlProtocol  
Coders: G723 G729 G728 NETCODER GSM-FR GSM-EFR AMR EVRC-QCELP G727 ILBC EVRC-B  
AMR-WB G722 EG711 MS-RTA-NB MS-RTA-WB SILK-NB SILK-WB  
QOE features: VoiceQualityMonitoring MediaEnhancement  
FSN FALLBACK supported  
DSP Voice features: RTCP-XR AMRPolicyManagement V150=1  
E1Trunks=4  
T1Trunks=4  
rpsports=8

**Add a Software Upgrade Key**

Load "Upgrade Key" file from your computer to the device

Reset with flash burn is required after file is loaded.

2. As a precaution, backup the Software License Key currently installed on the device. If the new Software License Key does not comply with your requirements, you can re-load this backup to restore the device's original capabilities.
  - a. In the 'Current Key' field, select the entire text string and copy it to any standard text file (e.g., Notepad).
  - b. Save the text file with any file name and file extension (e.g., key.txt) to a folder on your computer.
3. Depending on whether you are loading a Software License Key file with a single Software License Key (i.e., one "S/N") or with multiple Software License Keys (i.e., more than one "S/N"), do one of the following:
  - **Loading a File with a Single Software License Key:**
    - a. Open the Software License Key file using a text-based program such as Notepad.
    - b. Copy-and-paste the string from the file to the 'Add a Software Upgrade Key' field.
    - c. Click the **Add Key** button.
  - **Loading a File with Multiple Software License Keys:**
    - a. In the 'Load Upgrade Key file ...' field, click the **Browse** button and navigate to the folder in which the Software License Key file is located on your computer.
    - b. Click **Load File**; the new key is installed on the device.

If the Software License Key is valid, it is burned to the device's flash memory and displayed in the 'Current Key' field.
4. Verify that the Software License Key was successfully installed, by doing one of the following:
  - In the Software Upgrade Key Status page, check that the listed features and capabilities activated by the installed Software License Key match those that were ordered.
  - Access the Syslog server and ensure that the following message appears in the Syslog server:  
"S/N\_\_\_ Key Was Updated. The Board Needs to be Reloaded with ini file\n"
5. Reset the device; the new capabilities and resources enabled by the Software License Key are active.

**Note:** If the Syslog server indicates that the Software License Key was unsuccessfully loaded (i.e., the "SN\_" line is blank), do the following preliminary troubleshooting procedures:

1. Open the Software License Key file and check that the "S/N" line appears. If it does not appear, contact AudioCodes.
2. Verify that you have loaded the correct file. Open the file and ensure that the first line displays "[LicenseKeys]".
3. Verify that the content of the file has not been altered.

#### 43.2.2.2 Installing the Software License Key using CLI

To install the Software License Key using CLI, use the following commands:

- To install the Software License Key:  
`(config-system)# feature-key`
- To view the Software License Key:  
`show system feature-key`

## 43.3 Software Upgrade Wizard

The Software Upgrade Wizard allows you to upgrade the device's firmware. The firmware file has the .cmp file extension name. The wizard also enables you to load an *ini* file and/or auxiliary files (typically loaded using the Load Auxiliary File page described in 'Loading Auxiliary Files' on page 535). However, it is mandatory when using the wizard to first load a .cmp file to the device. You can then choose to also load an *ini* file and/or auxiliary files, but this cannot be done without first loading a .cmp file. For the *ini* and each auxiliary file type, you can choose to load a new file or not load a file but use the existing file (i.e., maintain existing configuration) running on the device.

**Warning:** The Software Upgrade Wizard requires the device to be reset at the end of the process, which may disrupt traffic. To avoid this, disable all traffic on the device before initiating the wizard by performing a graceful lock (see 'Basic Maintenance' on page 529).

### Notes:

- You can get the latest software files from AudioCodes Web site at <http://www.audiocodes.com/downloads>.
- Before upgrading the device, it is recommended that you save a copy of the device's configuration settings (i.e., *ini* file and data file) to your computer. If an upgrade failure occurs, you can then restore your configuration settings by uploading the backup file to the device. For saving and restoring configuration, see 'Backing Up and Loading Configuration File' on page 559.
- If you wish to also load an *ini* or auxiliary file, it is mandatory to first load a .cmp file.
- When you activate the wizard, the rest of the Web interface is unavailable. After the files are successfully loaded, access to the full Web interface is restored.
- If you upgraded your .cmp and the "SW version mismatch" message appears in the Syslog or Web interface, then your Software License Key does not support the new .cmp file version. If this occurs, contact AudioCodes support for assistance.
- If you use the wizard to load an *ini* file, parameters excluded from the *ini* file are assigned default values (according to the .cmp file running on the device) thereby, overriding values previously defined for these parameters.
- You can schedule automatic loading of these files using HTTP/HTTPS (see 'Automatic Update' on page 561).
- You can also upgrade the device's firmware by loading a .cmp file from an external USB hard drive connected to the device's USB port. For more information, see USB Storage Capabilities on page 573.

➤ **To load files using the Software Upgrade Wizard:**

1. Stop all traffic on the device using the Graceful Lock feature (refer to the warning bulletin above).
2. Open the Software Upgrade wizard, by performing one of the following:
  - Select the **Maintenance** tab, click the **Software Update** menu, and then click **Software Upgrade Wizard**.
  - On the toolbar, click **Device Actions**, and then choose **Software Upgrade Wizard**.

**Figure 43-4: Start Software Upgrade Wizard Screen**

3. Click the **Start Software Upgrade** button; the wizard starts, requesting you to browse to a .cmp file for uploading.

**Note:** At this stage, you can quit the Software Update Wizard, by clicking **Cancel** , without requiring a device reset. However, once you start uploading a cmp file, the process must be completed with a device reset. If you choose to quit the process in any of the subsequent pages, the device resets.

4. Click the **Browse** button, navigate to the .cmp file, and then click **Load File**; a progress bar appears displaying the status of the loading process. When the .cmp file is successfully loaded to the device, a message appears notifying you of this.
5. If you want to load **only** a .cmp file, then click the **Reset**  button to reset the device with the newly loaded .cmp file, utilizing the existing configuration (*ini*) and auxiliary files. To load additional files, skip to the next Step.

**Note:** Device reset may take a few minutes depending on cmp file version (this may even take up to 10 minutes).

6. Click the **Next**  button; the wizard page for loading an *ini* file appears. You can now perform one of the following:

- Load a new *ini* file: Click **Browse**, navigate to the *ini* file, and then click **Send File**; the *ini* file is loaded to the device and you're notified as to a successful loading.
  - Retain the existing configuration (*ini* file): Do not select an *ini* file, and ensure that the 'Use existing configuration' check box is selected (default).
  - Return the device's configuration settings to factory defaults: Do not select an *ini* file, and clear the 'Use existing configuration' check box.
7. Click the **Next**  button to progress to the relevant wizard pages for loading the desired auxiliary files. To return to the previous wizard page, click the **Back**  button. As you navigate between wizard pages, the relevant file type corresponding to the Wizard page is highlighted in the left pane.
8. When you have completed loading all the desired files, click the **Next**  button until the last wizard page appears ("FINISH" is highlighted in the left pane).
9. Click the **Reset**  button to complete the upgrade process; the device 'burns' the newly loaded files to flash memory and then resets the device.

**Note:** Device reset may take a few minutes (depending on .cmp file version, this may even take up to 30 minutes).

After the device resets, the End of Process wizard page appears displaying the new .cmp and auxiliary files loaded to the device.

**Figure 43-5: Software Upgrade Process Completed Successfully**

10. Click **End Process** to close the wizard; the Web Login dialog box appears.
11. Enter your login user name and password, and then click **OK**; a message box appears informing you of the new .cmp file.
12. Click **OK**; the Web interface becomes active, reflecting the upgraded device.

## 43.4 Backing Up and Loading Configuration File

You can save a copy/backup of the device's current configuration settings as an *ini* file to a folder on your computer, using the Configuration File page. The saved *ini* file includes only parameters that were modified and parameters with other than default values. The Configuration File page also allows you to load an *ini* file to the device. If the device has "lost" its configuration, you can restore the device's configuration by loading the previously saved *ini* file or by simply loading a newly created *ini* file.

### Notes:

- When loading an *ini* file using this Web page, parameters not included in the *ini* file are reset to default settings.
- You can also save the current configuration to and update configuration from an external USB hard drive connected to the device's USB port. For more information, see USB Storage Capabilities on page 573.

### ➤ To save the *ini* / data file:

1. Open the Configuration File page by doing one of the following:
  - From the Navigation tree, click the **Maintenance** tab, click the **Software Update** menu, and then click **Configuration File**.
  - On the toolbar, click **Device Actions**, and then from the drop-down menu, choose **Load Configuration File** or **Save Configuration File**.

Figure 43-6: Configuration File Page

2. To save the Voice *ini* file to a folder on your computer, do the following:
  - a. Click the **Save INI File** button; the File Download dialog box appears.
  - b. Click the **Save** button, navigate to the folder where you want to save the *ini* file, and then click **Save**.

3. To save the Data configuration ini file to a folder on your computer, do the following:
  - a. Under the 'Save the Data configuration file to the PC' group, click the Save File button; the 'File Download' dialog box appears.
  - b. Click the Save button, navigate to the folder in which you want to save the file on your PC, and then click Save; the device saves the Data ini file to the selected folder.
4. To load the Voice *ini* file to the device, do the following:
  - a. Click the **Browse** button, navigate to the folder where the *ini* file is located, select the file, and then click **Open**; the name and path of the file appear in the field beside the **Browse** button.
  - b. Click the **Load INI File** button, and then at the prompt, click **OK**; the device uploads the *ini* file and then resets (from the *cmp* version stored on the flash memory). Once complete, the Web Login screen appears, requesting you to enter your user name and password.
5. To load the Data configuration ini file to the device, do the following:
  - a. Under the 'Send the Data Configuration file to the device' group, click the Browse button, navigate to the folder in which the file is located, select the file, and then click Open; the name and path of the file appear in the field beside the Browse button.
  - b. Click the Load File button, and then at the prompt, click OK; the device uploads the file and then resets (from the *cmp* version stored on the flash memory). Once complete, the Web Login screen appears, requesting you to enter your user name and password.

## 44 Automatic Update

Automatic provisioning is useful for large-scale deployment of devices. In some cases, the devices are shipped to the end customer directly from the manufacturer. In other cases, they may pass through a staging warehouse. Configuration may occur at the staging warehouse or at the end-customer premises.

The devices may be pre-configured during the manufacturing process (commonly known as *private labeling*). Typically, a two-stage configuration process is implemented such that initial configuration includes only basic configuration, while the final configuration is done when the device is deployed in a live network. In addition, the devices may be deployed without configuration and then automatically provisioned by triggering the Automatic Update feature using the Zero Configuration mechanism (see [Configuring Zero Configuration](#) on page 567).

Automatic provisioning can be used to update the following files:

- Software file (*cmp*)
- Auxiliary files (e.g., Call Progress Tones)
- Configuration file

The configuration file can be one of the following types, depending on required configuration:

- ini File: File containing ini file parameters only, which configures only System and VoIP functionalities.
- CLI script file: File containing CLI commands only. This can be used for configuring all the device's functionalities (i.e., System, VoIP, and Data Routing). You can use one of the following types of CLI script files, the only difference being in the way they configure the device:
  - ◆ CLI script file: This file updates the device's configuration only according to the file's configuration settings. The device's other existing configuration settings (not included in the file) are retained. The URL of the server where this file is located is configured by the AUPDCliScriptURL parameter.
  - ◆ Startup CLI script file: This file updates the device's configuration according to the file's configuration settings and sets all other parameters that were not included in the file to factory defaults. This script file causes two device resets. The URL of the server where this file is located is configured by the AUPDStartupScriptURL parameter.

### Notes:

- The CLI script files can have any filename extension.
- If a device reset is required to apply certain configuration settings, you can include the following CLI command in the CLI script file: reload if-needed. This command must be added at the end of the file.

The Automatic Update mechanism is applied per file, using specific parameters that define the URLs to the servers where the files are located, and the file names (see [Automatic Update Parameters](#) on page 890). These files can be stored on any standard Web, FTP, or NFS server and can be loaded periodically to the device using HTTP, HTTPS, FTP, or NFS. This mechanism can be used even for devices that are installed behind NAT and firewalls.

The Automatic Update mechanism can be triggered by the following:

- Upon device startup.
- At a user-defined time of day (e.g., 18:00), configured by the *ini* file parameter AutoUpdatePredefinedTime.

- Periodically (e.g., every 60 minutes), configured by the *ini* file parameter `AutoUpdateFrequency`.
- Upon startup but before the device is operational, if the Secure Startup feature is enabled (see 'Loading Files Securely by Disabling TFTP' on page 566).
- Upon receipt of a special SIP Notify message (see 'Remotely Triggering Auto Update using SIP NOTIFY' on page 567)

When implementing Automatic Updates using HTTP/S, the device determines whether the file on the provisioning server is an updated one as follows:

- **Configuration file:** The device checks the timestamp according to the HTTP server response. Cyclical Redundancy Check (CRC) is only checked if the `AUPDCheckIfIniChanged` parameter is enabled. The device downloads the configuration file only if it was modified since the last successful configuration update.
- **Software file (cmp):** The device first downloads the file and then checks if its version number is different from the software version file currently stored on the device's flash memory.
- **Auxiliary files (e.g., CPT):** These files are updated only once. To update the auxiliary file again, you must modify the settings of the related parameter that configures its URL.

## 44.1 Configuring Automatic Update

The procedure below describes how to configure the Automatic Update feature. It describes a scenario where the devices download a "master" configuration file with common settings from an HTTP server. This "master" file applies common configuration and instructs each device to download a specific configuration file based on the device's MAC address from an HTTP server.

**Warning:** Do not use the Web interface to configure the device when the Automatic Update feature is implemented. If you do and save (burn) the new settings to the device's flash memory, the `IniFileURL` parameter is automatically set to 0 and Automatic Updates is consequently disabled. To enable Automatic Updates again, you would need to re-load the ini file (using the Web interface or BootP) with the correct `IniFileURL` settings. As a safeguard to an unintended burn-to-flash when resetting the device, if the device is configured for Automatic Updates, the 'Burn To FLASH' field under the Reset Configuration group in the Web interface's Maintenance Actions page is automatically set to **No** by default.

### Notes:

- For a description of all the Automatic Update *ini* file parameters, see Automatic Update Parameters on page 890.
- For a description of the CLI parameters relating to Automatic Update, refer to the *MSBR Series CLI Reference Guide for System and VoIP Functionalities*.

### ➤ To configure the Automatic Update feature (ini file example):

1. Setup a Web server (e.g., `http://www.corp.com`) and place all the required configuration files on this server.
2. For each device, preconfigure the following parameter (DHCP / DNS are assumed):  
`IniFileURL = 'http://www.corp.com/master_configuration.ini'`

3. Create a file named *master\_configuration.ini* with the following text:

```
Common configuration for all devices

CptFileURL = 'http://www.corp.com/call_progress.dat'
Check for updates every 60 minutes
AutoUpdateFrequency = 60
Additional configuration per device

Each device loads a file named based on its MAC address
(e.g., config_00908F033512.ini)
IniFileURL = 'http://www.corp.com/config_<MAC>.ini'
Reset the device after configuration is updated.
The device resets after all files are processed.
ResetNow = 1
```

You can modify the *master\_configuration.ini* file (or any of the *config\_<MAC>.ini* files) at any time. The device queries for the latest version every 60 minutes and applies the new settings immediately.

4. For additional security, use HTTPS or FTPS. The device supports HTTPS (RFC 2818) and FTPS using the AUTH TLS method <draft-murray-auth-ftp-ssl-16>.
5. To download configuration files from an NFS server, the NFS file system parameters should be defined in the *ini* file. The following is an example of an *ini* file for downloading files from NFS servers using NFS version 2:

```
Define NFS servers for Automatic Update
[NFSServers]
FORMAT NFSServers_Index = NFSServers_HostOrIP,
NFSServers_RootPath, NFSServers_NfsVersion;
NFSServers 1 = 10.31.2.10, /usr/share, 2 ;
NFSServers 2 = 192.168.100.7, /d/shared, 2 ;
[\NFSServers]
CptFileUrl =
'file://10.31.2.10/usr/share/public/usa_tones.dat'
VpFileUrl =
'file://192.168.100.7/d/shared/gateways/voiceprompt.dat'
```

The following *ini* file example can be used to activate the Automatic Update mechanism.

```
DNS is required for specifying domain names in URLs
[InterfaceTable]
FORMAT InterfaceTable_Index = InterfaceTable_ApplicationTypes,
InterfaceTable_InterfaceMode, InterfaceTable_IPAddress,
InterfaceTable_PrefixLength, InterfaceTable_Gateway,
InterfaceTable_VlanID, InterfaceTable_InterfaceName,
InterfaceTable_PrimaryDNSServerIPAddress,
InterfaceTable_SecondaryDNSServerIPAddress,
InterfaceTable_UnderlyingInterface;
InterfaceTable 0 = 6, 10, 10.13.4.12, 16, 10.13.0.1, 1, Mng,
10.1.1.11, 0.0.0.0, ;
[\InterfaceTable]
Load an extra configuration ini file using HTTP
IniFileURL = 'http://webserver.corp.com/Gateway/inifile.ini'
Load Call Progress Tones file using HTTPS
CptFileUrl = 'https://10.31.2.17/usa_tones.dat'
Load Voice Prompts file using FTPS with user 'root' and password
'wheel'
VPFileUrl = 'ftps://root:wheel@ftpserver.corp.com/vp.dat'
Update every day at 03:00 AM
AutoUpdatePredefinedTime = '03:00'
```

# Note: The cmp file isn't updated since it's disabled by default (AutoUpdateCmpFile).

#### Notes:

- The Automatic Update mechanism assumes that the external Web server conforms to the HTTP standard. If the Web server ignores the If-Modified-Since header, or doesn't provide the current date and time during the HTTP 200 OK response, the device may reset itself repeatedly. To overcome this problem, modify the update frequency, using the AutoUpdateFrequency parameter.
- To load a different configuration file (ini file) per device, add the string "<MAC>" to the URL (e.g., IniFileURL = 'http://www.corp.com/config\_<MAC>.ini'). This mnemonic is replaced with the device's hardware MAC address, resulting in an ini file name request that contains the device's MAC address (e.g., config\_00908F033512.ini).
- To prevent the device from accidentally upgrading its software, by default the Automatic Update feature does not apply a downloaded *cmp* file even if its URL was configured (using the CmpFileURL parameter). To enable this, set the AutoUpdateCmpFile parameter to 1.
- To enable the device to automatically reset after an ini file has been loaded, set the ResetNow parameter to 1. This is important if the downloaded configuration file includes parameters that require a device reset for its settings to be applied.
- By default, parameters that are not included in the downloaded configuration file are set to default. To retain the current settings of these parameters, set the SetDefaultOnINIFileProcess parameter to 0.

## 44.2 Automatic Configuration Methods

This section describes available methods that can be used for automatic device configuration.

### 44.2.1 DHCP-based Configuration Server

The DHCP server can be configured to automatically provide each device with a temporary IP address so that individual MAC addresses are not required. Configuration occurs at a staging warehouse for this method.

#### ➤ To enable DHCP for obtaining an IP address:

1. Open the Application Settings page (**Configuration** tab > **System** menu > **Application Settings**).

Figure 44-1: Enabling DHCP - Application Settings Page

| DHCP Settings |        |
|---------------|--------|
| Enable DHCP   | Enable |

2. From the 'Enable DHCP' drop-down list, select **Enable**.
3. Click **Submit**.

**Note:** When using DHCP to acquire an IP address, the Multiple Interface table, VLANs and other advanced configuration options are disabled.

Below is an example configuration file for Linux DHCP server (dhcpd.conf). The devices are allocated temporary IP addresses in the range 10.31.4.53 to 10.31.4.75. TFTP is assumed to be on the same computer as the DHCP server (alternatively, the "next-server" directive may be used).

```
ddns-update-style ad-hoc;
default-lease-time 60;
max-lease-time 60;
class "gateways" {
 match if(substring(hardware, 1, 3) = 00:90:8f);
}
subnet 10.31.0.0 netmask 255.255.0.0 {
 pool {
 allow members of "audiocodes";
 range 10.31.4.53 10.31.4.75;
 filename "SIP_F6.60A.217.003.cmp -fb;device.ini";
 option routers 10.31.0.1;
 option subnet-mask 255.255.0.0;
 }
}
```

## 44.2.2 HTTP-based Automatic Updates

An HTTP/S server can be placed in the customer's network where configuration and software updates are available for download. This does not require additional servers at the customer premises and is NAT-safe.

For example, assume the core network HTTPS server is <https://www.corp.com>. A master configuration *ini* file should be placed on the server, e.g., <https://www.corp.com/gateways/master.ini>. This file could point to additional *ini* files, auxiliary files (e.g., call progress tones), and software files (cmp), all on the same HTTP server or different HTTP servers in the network.

The main advantage of this method is that the HTTP configuration can be checked periodically when the device is deployed at the customer site. HTTP(S) is not sensitive to NAT devices, enabling configuration whenever needed without on-site intervention.

For additional security, the URL may contain a different port, and username and password. The devices should only be pre-configured with the URL of the initial *ini* file, using one of the following methods:

- Methods described in 'DHCP-based Configuration Server' on page [564](#) or above, via TFTP at a staging warehouse. The configuration URL is configured using the IniFileURL parameter.
- Private labeling.
- Manually on-site, using the RS-232 port or Web interface.

When the device is deployed at the customer site, local DHCP server provides the devices with IP addressing and DNS server information. From the URL provided in the DHCP response, the device can then contact the HTTP server at the core network and automatically download its configuration. The URL can be a simple file name or contain the device's MAC or IP address, e.g.:

- <http://corp.com/config-<MAC>.ini> - which becomes, for example, <http://corp.com/config-00908f030012.ini>
- <http://corp.com/<IP>/config.ini> - which becomes, for example, <http://corp.com/192.168.0.7/config.ini>

### 44.2.3 Configuration using FTP or NFS

Some networks block access to HTTP(S). The Automatic Update feature provides limited support for FTP/FTPS connectivity. Periodic polling for updates is not possible since these protocols don't support conditional fetching, i.e., updating files only if it is changed on the server.

The only difference between this method and those described in 'HTTP-based Automatic Updates' on page 565 is that the protocol in the URL is "ftp" (instead of "http").

#### Notes:

- Unlike FTP, NFS is not NAT-safe.
- NFS v2/v3 is also supported.

### 44.2.4 Configuration using AudioCodes EMS

AudioCodes EMS server functions as a core-network provisioning server. The device's SNMP Manager should be configured with the IP address of the EMS server, using one of the methods detailed in the previous sections. As soon as a registered device contacts the EMS server through SNMP, the EMS server handles all required configuration automatically, upgrading software as needed. This alternative method doesn't require additional servers at the customer premises, and is NAT-safe.

## 44.3 Loading Files Securely by Disabling TFTP

The TFTP protocol is not considered secure and some network operators block it using a firewall. It is possible to disable TFTP completely, using the *ini* file parameter EnableSecureStartup (set to 1). This way, secure protocols such as HTTPS may be used to fetch the device configuration.

#### ➤ To download the ini file to the device using HTTPS instead of TFTP:

1. Prepare the device's configuration file on an HTTPS server and obtain a URL to the file (e.g., https://192.168.100.53/gateways.ini).
2. Enable DHCP, if necessary.
3. Enable SSH and connect to it.
4. In the CLI, use the *ini* file parameters IniFileURL (for defining the URL of the configuration file) and EnableSecureStartup (for disabling TFTP), and then restart the device with the new configuration:

```
/conf/scp IniFileURL https://192.168.100.53/gateways.ini
/conf/scp EnableSecureStartup 1
/conf/sar bootp
```

**Note:** Once Secure Startup has been enabled, it can only be disabled by setting EnableSecureStartup to 0 using the CLI. Loading a new *ini* file using BootP/TFTP is not possible until EnableSecureStartup is disabled.

## 44.4 Remotely Triggering Auto Update using SIP NOTIFY

The device can be remotely triggered to start the Automatic Update process upon receipt of a SIP NOTIFY that includes an Event header set to 'check-sync;reboot=false', as shown in the example below:

```
NOTIFY sip:<user>@<dsthost> SIP/2.0
To: sip:<user>@<dsthost>
From: sip:sipsak@<srchost>
CSeq: 10 NOTIFY
Call-ID: 1234@<srchost>
Event: check-sync;reboot=false
```

For this feature to function, Automatic Update must be enabled on the device. In other words, it must have a loaded ini file with the Automatic Update settings.

➤ **To enable remote trigger of Auto Update upon receipt of SIP NOTIFY:**

1. Open the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**).
2. Under the **Misc Parameters** group, set the 'SIP Remote Reset' parameter to **Enable**.
3. Click **Submit**.

**Notes:**

- This SIP Event header value is proprietary to AudioCodes.
- This feature does not trigger the Zero Configuration feature.

## 44.5 Configuring Zero Configuration

The Zero Configuration feature enables automatic, remote configuration of newly deployed, non-configured devices, using AudioCodes HTTPS Redirect Server. This feature offers an almost plug-and-play experience for quick-and-easy initial deployment of multiple devices at the end-customer premises. Zero Configuration requires only minimal preconfiguration of the device for WAN connectivity. Once an Internet connection is established, all that is needed is a device reset to activate the Zero Configuration mechanism.

Zero Configuration operates in combination with the Automatic Update feature. It redirects the device to an HTTP/S provisioning server from where the configuration file, configured with Automatic Update settings, can be downloaded and applied to the device. The device then performs the regular Automatic Update process according to these Automatic Update settings.

Once the device is powered up and connectivity to the WAN established, it automatically sends an HTTP request to AudioCodes HTTPS Redirect server. If the device's MAC address is listed on the server, the server responds to the device with an HTTP Redirect response containing the URL of the HTTP/S server (typically, a provisioning server maintained by the Service Provider) where the configuration file is located. The device then downloads the configuration file from this provisioning server and updates its configuration. Typically, this configuration file only enables the Automatic Update mechanism and therefore, once downloaded, the device executes the Automatic Update mechanism accordingly.

Figure 44-2: Zero Configuration Process

1. Device sends HTTPS request to AudioCodes HTTPS Redirect server.
2. Redirect server sends HTTPS response with redirect URL.
3. Device sends HTTPS request to redirected URL (i.e., provisioning server).
4. Device downloads configuration file for enabling the regular Automatic Update feature.

The configuration file contains only CLI commands for configuration, which its settings are applied to the device, in addition to the device's current configuration. The device resets only if the configuration file contains an explicit command instructing it to reset.

To enable Zero Configuration, the customer needs to define the devices on the HTTPS Redirect server by entering their MAC addresses and the configuration file URL. This may be done either through the corresponding Web interface or through SOAP/XML interface (that may be integrated with the Service Provider's provisioning system). For more information, contact AudioCodes support.

If the regular Automatic Update process succeeds, the device repeats the Zero Configuration process **only** if it undergoes a reset to factory defaults. If the Automatic Update process fails, the device repeats the Zero Configuration process at the next device reset or power up.

For security, communication between the device and the HTTPS Redirect server is encrypted (HTTPS) and setup with mutual authentication. The device uses a special factory-set certificate to authenticate itself with the HTTPS Redirect server and to verify authenticity of the latter. If the redirect URL (where the configuration file is stored) also uses the HTTPS protocol, the device can use a regular certificate or the Zero Configuration certificate to authenticate itself and validate the server's certificate if a trusted root certificate (regular) is configured. This is determined by the `AupdUseZeroConfCerts` parameter.

**Notes:**

- If the Automatic Update feature has been configured, the Zero Configuration process is performed first. Only after Zero Configuration completes (successfully or not), does the Automatic Update process begin.
- If the device is configured with multiple WAN interfaces, Zero Configuration is attempted on all configured WAN interfaces, sequentially.
- The recommended method for using both Zero Configuration and Automatic Update is as follows:
  - ✓ Zero Configuration is done to redirect the non-configured device to the URL of the provisioning server which contains only the configuration for the Automatic Update feature (e.g., CLI script URL and timeout for periodic update check).
  - ✓ Once the Zero Configuration process completes (i.e., the device has downloaded the configuration file and applied the Automatic Update settings) without undergoing a reset, the Automatic Update mechanism begins.

➤ **To set up and activate Zero Configuration:**

1. Configure the HTTPS Redirect server with the following:
  - MAC addresses of the devices you want to provision.
  - Redirect URL of the provisioning server where the configuration file with the Automatic Update settings is located.
  - Name of the configuration file.
2. Establish a CLI session with the device and configure Zero Configuration:
  - a. Enable Zero Configuration (default), by running the following command:
 

```
configure system
(config-system)# automatic-update
(automatic-update)# set zero-conf <on|off>
```
  - b. Configure the URL of AudioCodes HTTPS Redirect server, by running the following command:
 

```
(automatic-update)# set zero-conf-server <URL>
```

The default URL is `https://redirect.audiocodes.com/<MAC address>`.
3. Create a CLI-based configuration file with settings relating to the Automatic Update feature (see 'Configuring Automatic Update' on page 562) and place it on the HTTP/S redirected provisioning server.
4. Place the configuration, software (cmp), and/or auxiliary files on a provisioning server. This server can be the same provisioning server or any other server(s).
5. Configure the device's WAN interface and cable the device to the WAN network.
6. Power down and then power up the device.

## Reader's Notes

## 45 Restoring Factory Defaults

You can restore the device's configuration to factory defaults using one of the following methods:

- CLI (see 'Restoring Defaults using CLI' on page [571](#))
- Hardware reset pinhole button (see Restoring Defaults using Hardware Reset Button on page [572](#))
- Loading an empty *ini* file (see 'Restoring Defaults using an ini File' on page [572](#))

### 45.1 Restoring Defaults using CLI

The device can be restored to factory defaults using CLI, as described in the procedure below.

➤ **To restore factory defaults using CLI:**

1. Access the CLI:
  - a. Connect the RS-232 serial port of the device to the communication port on your computer. For serial cabling, refer to the *Hardware Installation Manual*.
  - b. Establish serial communication with the device using a serial communication program (such as HyperTerminal™) with the following communication port settings:
    - ◆ **Baud Rate:** 115,200 bps
    - ◆ **Data Bits:** 8
    - ◆ **Parity:** None
    - ◆ **Stop Bits:** 1
    - ◆ **Flow Control:** None
2. At the CLI prompt, type the username (default is "Admin" - case sensitive), and then press Enter:

```
Username: Admin
```
3. At the prompt, type the password (default is "Admin" - case sensitive), and then press Enter:

```
Password: Admin
```
4. At the prompt, type the following, and then press Enter:

```
enable
```
5. At the prompt, type the password again, and then press Enter:

```
Password: Admin
```
6. At the prompt, type the following to reset the device to default settings, and then press Enter:

```
write factory
```

## 45.2 Restoring Defaults using Hardware Reset Button

The device's hardware reset pinhole button can be used to reset the device to default settings.

- **To restore default settings using the hardware reset pinhole button:**
  - With a paper clip or any other similar pointed object, press and hold down the reset pinhole button, located on the front panel for at least 12 seconds (but no more than 25 seconds).

## 45.3 Restoring Defaults using an ini File

You can restore the device to factory default settings by loading an empty *ini* file to the device. This is done using the Web interface's Configuration File page (see 'Backing Up and Loading Configuration File' on page 559). If the *ini* file does include content (e.g., parameters), ensure that they are on lines beginning with comment signs (i.e., semicolons ";") so that the device ignores them.

**Note:** The only settings that are not restored to default are the management (OAMP) LAN IP address and the Web interface's login user name and password.

## 46 USB Storage Capabilities

The device enables USB storage using an external USB hard drive or flash disk (disk on key) connected to its USB port. The storage capabilities include the following:

- Updating the device's firmware from the USB, using the following CLI command:  
`# copy firmware from usb://<the .cmp file name>`
- Updating the device's configuration from the USB, using the following CLI command:  
`# copy voice-configuration from usb://<the .ini configuration file name>`
- Saving current configuration to the USB, using the following CLI command:  
`# copy voice-configuration to usb://<the .ini configuration file name>`

**Note:** Only a single USB storage (formatted to FAT/FAT32) operation is supported at any given time.

## Reader's Notes

# Part XII

## Status, Performance Monitoring and Reporting

## 47 System Status

This section describes how to view various system statuses.

### 47.1 Viewing Device Information

The Device Information page [displays](#) various hardware and software information of the device. This page also lists any Auxiliary files that have been installed on the device and allows you to remove them.

➤ **To access the Device Information page:**

- Open the Device Information page (**Status & Diagnostics** tab > **System Status** menu > **Device Information**).

|                              |                        |
|------------------------------|------------------------|
| ▼ General Settings           |                        |
| Voip MAC Address:            | 00:90:8f:3C:81:B0      |
| LAN MAC Address:             | 00:90:8f:3C:81:B1      |
| WAN MAC Address:             | 00:90:8f:3C:81:B2      |
| Serial Number:               | 3965360                |
| Board Type:                  | Mediant 850 - MSBG     |
| Device Up Time:              | 0d:2h:51m:49s:65th     |
| Device Administrative State: | Unlocked               |
| Device Operational State:    | Enabled                |
| Flash Size [Mbytes]:         | 64                     |
| RAM Size [Mbytes]:           | 367                    |
| CPU Speed [MHz]:             | 500                    |
| ▼ Versions                   |                        |
| Version ID:                  | 6.60.014.013           |
| DSP Type:                    | 1                      |
| DSP Software Version:        | 66015                  |
| DSP Software Name:           | 5014AE3_R_LD           |
| Flash Version:               | 710                    |
| ▼ Loaded Files               |                        |
| Loaded Call Progress Tones:  | Default Progress Tones |
| Loaded Coder Table :         | Default CODERTABLE     |

➤ **To delete a loaded file:**

- Click the **Delete** button corresponding to the file that you want to delete. Deleting a file takes effect only after device reset (see 'Resetting the Device' on page [529](#)).

### 47.2 Viewing Ethernet Port Information

The Ethernet Port Information page [displays](#) read-only information on the Ethernet port connections. This includes information such as activity status, duplex mode, and speed as well as PoE.

**Note:** The Ethernet Port Information page [can](#) also be accessed from the Home page (see 'Viewing the Home Page' on page [54](#)).

➤ To view Ethernet port information:

- Open the Ethernet Port Information page (**Status & Diagnostics** tab > **System Status** menu > **Ethernet Port Information**).

|    | Active | Speed     | Duplex Mode | Power Over Ethernet Status | Power Over Ethernet Allocated Power |
|----|--------|-----------|-------------|----------------------------|-------------------------------------|
| 1  | Yes    | 1000 Mbps | Full Duplex | Invalid signature          | N/A                                 |
| 2  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 3  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 4  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 5  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 6  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 7  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 8  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 9  | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 10 | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 11 | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |
| 12 | No     | 10 Mbps   | Half Duplex | Enabled                    | N/A                                 |

|                            |                |
|----------------------------|----------------|
| ▼ System Power Information |                |
| Power Budget               | 120000 [mWatt] |
| Allocated Power            | 0 [mWatt]      |
| Remaining Power            | 120000 [mWatt] |

### Ethernet Port Information Parameters

| Parameter                           | Description                                                                                                                                                                            |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active                              | Displays whether the port is active or not.                                                                                                                                            |
| Speed                               | Displays the speed (in Mbps) of the Ethernet port.                                                                                                                                     |
| Duplex Mode                         | Displays whether the port is half- or full-duplex.                                                                                                                                     |
| State                               | Displays the state of the port: <ul style="list-style-type: none"> <li>▪ "Forwarding": Active port (data is being received and sent)</li> <li>▪ "Disabled": Redundancy port</li> </ul> |
| Power Over Ethernet Status          | Displays whether Power over Ethernet (PoE) is active on the port.                                                                                                                      |
| Power Over Ethernet Allocated Power | Displays the power allocated to the port.                                                                                                                                              |
| Power Budget                        | Displays the power budget.                                                                                                                                                             |
| Allocated Power                     | Displays the power allocated to the ports.                                                                                                                                             |
| Remaining Power                     | Displays the power available for additional ports.                                                                                                                                     |

## 48 Carrier-Grade Alarms

This section describes how to view the following types of alarms:

- Active alarms - see 'Viewing Active Alarms' on page 579
- Alarm history - see 'Viewing Alarm History' on page 580

### 48.1 Viewing Active Alarms

The Active Alarms page displays a list of currently active alarms. You can also access this page from the Home page (see 'Viewing the Home Page' on page 54).

➤ To view the list of active alarms:

- Open the Active Alarms page (**Status & Diagnostics** tab > **System Status** menu > **Carrier-Grade Alarms** > **Active Alarms**).

| Sequential number | Severity | Source                  | Description                                      | Date                |
|-------------------|----------|-------------------------|--------------------------------------------------|---------------------|
| 3                 | Major    | Board#1/WanLink#1       | WAN link alarm. FE interface 1 is down.          | 23.2.2010 , 2:13:31 |
| 4                 | Minor    | Board#1/EthernetLink#2  | Ethernet link alarm. LAN port number 2 is down.  | 23.2.2010 , 2:13:31 |
| 5                 | Minor    | Board#1/EthernetLink#3  | Ethernet link alarm. LAN port number 3 is down.  | 23.2.2010 , 2:13:31 |
| 6                 | Minor    | Board#1/EthernetLink#4  | Ethernet link alarm. LAN port number 4 is down.  | 23.2.2010 , 2:13:31 |
| 7                 | Minor    | Board#1/EthernetLink#5  | Ethernet link alarm. LAN port number 5 is down.  | 23.2.2010 , 2:13:31 |
| 8                 | Minor    | Board#1/EthernetLink#6  | Ethernet link alarm. LAN port number 6 is down.  | 23.2.2010 , 2:13:31 |
| 9                 | Minor    | Board#1/EthernetLink#7  | Ethernet link alarm. LAN port number 7 is down.  | 23.2.2010 , 2:13:31 |
| 10                | Minor    | Board#1/EthernetLink#8  | Ethernet link alarm. LAN port number 8 is down.  | 23.2.2010 , 2:13:31 |
| 11                | Minor    | Board#1/EthernetLink#9  | Ethernet link alarm. LAN port number 9 is down.  | 23.2.2010 , 2:13:31 |
| 12                | Minor    | Board#1/EthernetLink#10 | Ethernet link alarm. LAN port number 10 is down. | 23.2.2010 , 2:13:31 |
| 13                | Minor    | Board#1/EthernetLink#11 | Ethernet link alarm. LAN port number 11 is down. | 23.2.2010 , 2:13:31 |
| 14                | Minor    | Board#1/EthernetLink#12 | Ethernet link alarm. LAN port number 12 is down. | 23.2.2010 , 2:13:31 |

For each alarm, the following information is provided:

- **Severity:** severity level of the alarm:
  - Critical (red)
  - Major (orange)
  - Minor (yellow)
- **Source:** unit from which the alarm was raised
- **Description:** brief explanation of the alarm
- **Date:** date and time that the alarm was generated

You can view the next 20 alarms (if exist), by clicking the **Go to page** button.

## 48.2 Viewing Alarm History

The Alarms History page displays a list of alarms that have been raised and traps that have been cleared.

➤ **To view the list of history alarms:**

- Open the Alarms History page (**Status & Diagnostics** tab > **System Status** menu > **Carrier-Grade Alarms** > **Alarms History**).

| Sequential number | Severity | Source                 | Description                                                                                | Date                |
|-------------------|----------|------------------------|--------------------------------------------------------------------------------------------|---------------------|
| 1                 | Major    | Board#1                | Controller failure alarm Proxy Set 0: Proxy lost. looking for another proxy                | 6.1.2010 , 14:1:26  |
| 2                 | Cleared  | Board#1                | Alarm cleared: Controller failure alarm Proxy Set 0: Proxy lost. looking for another proxy | 6.1.2010 , 14:1:36  |
| 3                 | Major    | Board#1                | Controller failure alarm Proxy Set ID 0                                                    | 6.1.2010 , 14:1:26  |
| 4                 | Major    | Board#1/WanLink#1      | WAN link alarm. FE interface 1 is down.                                                    | 6.1.2010 , 14:1:29  |
| 5                 | Minor    | Board#1/EthernetLink#2 | Ethernet link alarm. LAN port number 2 is down.                                            | 6.1.2010 , 14:1:29  |
| 6                 | Major    | Board#1                | NTP server alarm. No connection to NTP server.                                             | 6.1.2010 , 14:11:14 |

For each alarm, the following information is provided:

- **Severity:** severity level of the alarm:
  - Critical (red)
  - Major (orange)
  - Minor (yellow)
  - Cleared (green)
- **Source:** unit from which the alarm was raised
- **Description:** brief explanation of the alarm
- **Date:** date and time that the alarm was generated

You can view the next 20 alarms (if exist), by clicking the **Go to page** button.

➤ **To delete all the alarms in the table:**

1. Click the **Delete History Table** button; a confirmation message box appears.
2. Click **OK** to confirm.

## 49 Performance Monitoring

This section describes how to view performance monitoring.

### 49.1 Viewing MOS per Media Realm

The MOS Per Media Realm page displays statistics on Media Realms (configured in 'Configuring Media Realms' on page 168). This page provides two graphs:

- Upper graph: displays the Mean Opinion Score (MOS) quality in RTCP data per selected Media Realm.
- Lower graph: displays the bandwidth of transmitted media (in Kbps) in RTCP data per Media Realm.

➤ To view the MOS per Media Realm graph:

1. Open the MOS Per Media Realm page (**Status & Diagnostics** tab > **Performance Monitoring** menu > **MOS Per Media Realm**).

Figure 49-1: MOS Per Media Realm Graph

2. From the 'Media Realm' drop-down list, select the Media Realm for which you want to view.

Use the **Zoom In**  button to increase the displayed time resolution or the **Zoom Out**  button to decrease it. Instead of using these zoom buttons, you can use the slide ruler. As you increase the resolution, more data is displayed on the graph. The minimum resolution is about 30 seconds; the maximum resolution is about an hour.

To pause the graph, click the **Pause** button; click **Play** to resume.

## 49.2 Viewing Trunk Utilization

The Trunk Utilization page [provides](#) an X-Y graph that displays the number of active channels per trunk over time. The x-axis indicates the time; the y-axis indicates the number of active trunk channels.

### Notes:

- This page is available only if you have trunks and the SBC application is disabled.
- If you navigate to a different page, the data displayed in the graph and all its settings are cleared.

### ➤ To view the number of active trunk channels

1. Open the Trunk Utilization page (**Status & Diagnostics** tab > **Performance Monitoring** menu > **Trunk Utilization**).

Figure 49-2: Trunk Utilization Page

2. From the 'Trunk' drop-down list, select the trunk for which you want to view active channels.

For more graph functionality, see the following table:

**Additional Graph Functionality for Trunk Utilization**

| Button                              | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Add</b> button                   | Displays additional trunks in the graph. Up to five trunks can be displayed simultaneously in the graph. To view another trunk, click this button and then from the new 'Trunk' drop-down list, select the required trunk.<br><br>Each trunk is displayed in a different color, according to the legend shown in the top-left corner of the graph.                                                                                                                                                                                                                            |
| <b>Remove</b> button                | Removes the selected trunk display from the graph.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Disable</b> check box            | Hides or shows an already selected trunk. Select this check box to temporarily hide the trunk display; clear this check box to show the trunk. This is useful if you do not want to remove the trunk entirely (using the <b>Remove</b> button).                                                                                                                                                                                                                                                                                                                               |
| <b>Get Most Active</b> button       | Displays only the trunk with the most active channels (i.e., trunk with the most calls).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Pause</b> button                 | Pauses the display in the graph.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Play</b> button                  | Resumes the display in the graph.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Zoom</b> slide ruler and buttons | Increases or reduces the trunk utilization display resolution concerning time. The <b>Zoom In</b>  button increases the time resolution; the <b>Zoom Out</b>  button decreases it. Instead of using the buttons, you can use the slide ruler. As you increase the resolution, more data is displayed on the graph. The minimum resolution is about 30 seconds; the maximum resolution is about an hour. |

## 49.3 Viewing Quality of Experience

The Quality Of Experience page provides statistical information on calls per SRD or IP Group. The statistics can be further filtered to display incoming and/or outgoing call direction, and type of SIP dialog (INVITE, SUBSCRIBE, or all).

**Note:** This page is available only if the SBC application has been enabled.

This page provides three pie charts:

- Dialog Success Ratio: displays the SIP call and subscribe (SUBSCRIBE) dialog success-failed ratio.
- Dialog Failed Attempts: displays the failed call attempts. This includes the number of calls and subscribes which were successfully and abnormally terminated.
- Dialog Termination Ratio: displays call termination by reason (e.g., due to no answer).

➤ **To view Quality of Experience:**

1. Open the Quality Of Experience page (**Status & Diagnostics** tab > **Performance Monitoring** menu > **Quality Of Experience**).

**Figure 49-3: Quality Of Experience Graph**

2. From the 'SRD/IpGroup' drop-down list, select whether you want to view QoE for an SRD or IP Group.
3. From the 'Index' drop-down list, select the SRD or IP Group index.
4. From the 'Dir' drop-down list, select the call direction:
  - **In** - incoming calls
  - **Out** - outgoing calls
  - **Both** - incoming and outgoing calls
5. From the 'Type' drop-down list, select the SIP message type:
  - **Invite** - INVITE
  - **Subscribe** - SUBSCRIBE
  - **Other** - all SIP messages

To refresh the charts, click **Refresh**. To reset the counters, click **Reset Counters**.

## 49.4 Viewing Average Call Duration

The Average Call Duration page displays information about a specific SRD or IP Group. This page includes two graphs:

- Upper graph: displays the number of calls (INVITEs).
- Lower graph: displays the average call duration.

**Note:** This page is available only if the SBC application has been enabled.

➤ **To view average call duration:**

1. Open the Average Call Duration page (**Status & Diagnostics** tab > **Performance Monitoring** menu > **Average Call Duration**).

**Figure 49-4: Average Call Duration Graph**

2. From the 'SRD/IpGroup' drop-down list, select whether you want to view information for an SRD or IP Group.
3. From the 'Index' drop-down list, select the SRD or IP Group index.

Use the **Zoom In**  button to increase the displayed time resolution or the **Zoom Out**  button to decrease it. Instead of using these zoom buttons, you can use the slide ruler. As you increase the resolution, more data is displayed on the graph. The minimum resolution is about 30 seconds; the maximum resolution is about an hour.

To pause the graph, click the **Pause** button; click **Play** to resume.

## 49.5 Network Monitoring (Probing) Two Devices

The device can be configured to monitor the quality of the network path (network quality monitoring - NQM) between it and other AudioCodes devices. The path monitoring is done by sending packets from a "sender" device to a "responder" device and then calculating the round-trip time (RTT), packet loss (PL), and jitter. Since both responder and sender nodes are AudioCodes devices, the monitoring is done by sending RTP/RTCP packets in a way that accurately predicts the WAN service-level agreement (SLA) granted for real VoIP calls by the network.

**Note:** If the packets sent mimic a G.711 or G.729 stream, the following quality measurements are also done:

- Listener quality MOS per ITU-T specification
- Conversation quality MOS per ITU-T specification

You can configure up to 10 network quality probing paths. For example, you can configure three probing paths, where your device is configured as a sender for three different responder devices, as shown in the figure below:

**Figure 49-5: Network Quality Probing Example**

You can periodically poll the device for the latest VoIP quality metrics and specify thresholds for the quality metrics mentioned above. If these thresholds are crossed, the device generates the following SNMP traps to AudioCodes EMS or third-party SNMP-based manager:

- NqmConnectivityAlarm: Connectivity with monitored probe destination is lost
- NqmRttAlarm: High RTP detected toward probe destination
- NqmJitterAlarm: High jitter detected toward probe destination
- NqmPacketLossAlarm: High packet loss detected toward probe destination

This feature is configured using the CLI. Below is a list of some of the CLI commands. For a full list and description of the related CLI commands, refer to the *MSBR Series CLI Reference Guide for System and VoIP Functionalities*.

- nqm responder-table – adds a responder (IP address and port)
- nqm probing-table – defines the polling attributes (duration and frequency)

- `nqm sender-table` - adds a sender (including RTT, PL, and jitter thresholds; associates probing definition; responder address; local interface)

The following procedure describes how to quickly configure network quality probing.

➤ **To configure network quality probing:**

1. Configure the "sender termination" side:

- a. Bind a WAN interface to the NQM service:

```
(config-system) bind GigabitEthernet 0/0 nqm
```

**Note:** The chosen WAN interface should be the interface on which the NQM packets are planned to flow bi-directionally and binding is necessary to create the corresponding static NAT rules. If the NQM session is planned to flow within the LAN then no binding is needed and this step can be skipped.

- b. Configure a row in the Probing table:

```
(config-system)# nqm probing-table 0
(probing-table-0)# set probe-name voip_probe_1 ;
identifies this line
(probing-table-0)# set start-time now ; starting time of
this probe
(probing-table-0)# exit ; activates the probe
```

- c. Configure a row in the Sender table to define a sender termination:

```
(config-system)# nqm sender-table 0
(sender-table-0)# set sender-name
main_office_voip_checker_1 ; identifies specific sender
(sender-table-0)# set target-ip 10.4.3.98 ; IP address
of responder termination
(sender-table-0)# set target-port 3900 ; listening port
number at responder termination
```

**Note:** A responder termination defined by the pair <target IP address, target port> can be defined only once for a single sender line; multiple senders can't be defined to send packets to the same responder termination.

```
(sender-table-0)# set probe-name voip_probe_1 ; name
of probing row previously configured to be used by this
sender
```

**Note:** A single row in the Probing table may be shared by several senders, thereby sharing and simplifying common attributes.

```
(sender-table-0)# set source-interface-name NQM_WAN ;
name of network interface to send packets from
```

**Note:** If you want to output packets to the WAN interface, simply set NQM\_WAN as the source interface name; otherwise, set the interface name to a specific interface name listed in the network interface table.

```
(sender-table-0)# exit ; activates the sender line
```

2. Configure the "responder termination" side:

a. Bind a WAN interface to the NQM service:

```
(config-system) bind GigabitEthernet 0/0 nqm
```

**Note:** The chosen WAN interface should be the interface on which the NQM packets are planned to flow bi-directionally and binding is necessary to create the corresponding static NAT rules. If the NQM session is planned to flow within the LAN then no binding is needed and this step can be skipped.

b. Configure a row in the Responder table:

```
(config-system)# nqm responder-table 0
(responder-table-0)# set responder-name
vmain_office_voip_responder_1 ; name tag to identify
this line
(responder-table-0)# set local-port 3900 ; listening
port number at responder termination
(responder-table-0)# exit ; activates the probe line
```

**Note:** Ensure that the local-port value is the same as the target-port value set for the corresponding sender termination.

```
(responder-table-0)# set source-interface-name NQM_WAN ;
name of network interface to send packets from
```

**Notes:**

- If you want to listen to the WAN interface, simply set NQM\_WAN as the source interface name; otherwise, set the interface name to a specific interface name listed in the network interface table.
- Ensure that the network interface the responder termination is listening upon is in-sync with the target-ip value set for the corresponding sender termination.

```
(responder-table-0)# exit ; activates the responder line
```

➤ To view NQM results:

- On the sender termination device, type the following command to view eight result rows of sender "0":

```
show system nqm 0 8
```

Figure 49-6: Example of NQM Results

## 50 VoIP Status

This section describes how to view VoIP status and statistics.

## 50.1 Viewing Trunks & Channels Status

The Trunks & Channels Status page displays the status of the device's trunks and corresponding channels. It also enables you to view trunk configuration and channel information.

- **To view the status of the device's trunks and channels:**
  1. Open the Home page.
  2. On the graphical display of the device, click the required trunk, and then from the shortcut menu, choose Port Settings; the Trunks & Channels Status page appears.

**Figure 50-1: Trunks and Channels Status Screen**

| Trunks                                                                                    |                                                                                   | Channels                                                                          |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                   |                                                                                    |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |                                                                                     |    |

| Call Duration [sec]:                                                                                                                                                                                                                                                                                                                                                                     | 0             |
| Call Type:                                                                                                                                                                                                                                                                                                                                                                               | Voice         |
| Call Destination:                                                                                                                                                                                                                                                                                                                                                                        | 10.13.4.12    |
| Coder:                                                                                                                                                                                                                                                                                                                                                                                   | Transparent   |

To view additional channel information, click the required tab (**SIP**, **RTP/RTCP**, and **Voice Settings**).

- To view the settings of a specific trunk, click the required trunk icon, and then from the shortcut menu, choose **Port Settings**; the Trunk Settings page opens, displaying the trunk's settings. If needed, you can modify the settings (see 'Configuring Trunk Settings' on page [271](#)).

## 50.2 Viewing Analog Port Information

The Home page allows you to view detailed information on selected FXS and FXO analog ports such as RTP/RTCP and voice settings.

➤ **To view information on an analog port:**

1. Open the Home page.
2. On the graphical display of the device, click the required analog port; a shortcut menu appears.
3. From the shortcut menu, choose **Port Settings**; the Basic Channel Information page appears with the **Basic** tab selected (displayed in green):

**Figure 50-3: Basic Channel Information Page**

|                                                  |               |
|--------------------------------------------------|---------------|
| ◆ SIP ◆ <b>Basic</b> ◆ RTP/RTCP ◆ Voice Settings |               |
| ▼                                                |               |
| Channel Identifier:                              | 55            |
| Status:                                          | Inactive      |
| Call ID:                                         | 0             |
| Endpoint ID:                                     | Not Available |
| Call Duration [sec]:                             | 0             |
| Call Type:                                       | Voice         |
| Call Destination:                                | 10.13.4.12    |
| Coder:                                           | Transparent   |

4. To view additional channel information, click the required tab - **SIP**, **RTP/RTCP**, and **Voice Settings**.

## 50.3 Viewing NFAS Groups and D-Channel Status

The NFAS Group & D-Channel Status page displays the status of the device's D-channels and NFAS groups. The status of a D-channel and NFAS group can be "In Service" or "Out of Service". This page also indicates whether the D-channel is a primary or backup D-channel.

This page also enables you to manually switchover between active and standby D-channels belonging to the same NFAS group. This is done using the **Switch Activity** button. For more information, see 'Performing Manual D-Channel Switchover in NFAS Group' on page 286.

**Note:** This page is applicable only to T1 ISDN protocols supporting NFAS, and only if the NFAS group is configured with two D-channels.

- To view the status of the D-channels and NFAS groups:
- Open the NFAS Group & D-Channel Status page (**Status & Diagnostics** tab > **VoIP Status** menu > **NFAS Group & D-Channel Status**).

**Figure 50-4: NFAS Group & D-Channel Status Page**

▼ NFAS Group #2

Status: **In Service**

D-Channels:

Trunk#1

Configuration: Primary

Status: **In Service**

NFAS Status: Active

Trunk#2

Configuration: Backup

Status: **Out Of Service**

NFAS Status: Not Applicable

## 50.4 Viewing Active IP Interfaces

The IP Interface Status page displays the device's active IP interfaces that are listed in the Multiple Interface Table page (see 'Configuring IP Network Interfaces' on page 107).

- To view the active IP network interfaces:
- Open the IP Interface Status page (**Status & Diagnostics** tab > **VoIP Status** menu > **IP Interface Status**).

| Index | Application Type | Address Type | Interface Mode | IP Address      | Prefix Length | Gateway         | VLAN ID | Interface Name |
|-------|------------------|--------------|----------------|-----------------|---------------|-----------------|---------|----------------|
| 0     | O+M+C            | IPv4         | IPv4 Manual    | 10.13.4.12      | 16            | 10.13.0.1       | 1       | Voice          |
| NA    | Internal         | IPv4         | IPv4 Manual    | 169.254.254.254 | 30            | 169.254.254.253 | 4001    | InternalIF     |

## 50.5 Viewing Performance Statistics

The Basic Statistics page provides read-only, device performance statistics. This page is refreshed every 60 seconds. The duration that the currently displayed statistics has been collected is displayed above the statistics table.

- **To view performance statistics:**
  - Open the Basic Statistics page (**Status & Diagnostics** tab > **VoIP Status** menu > **Performance Statistics**).

**Figure 50-5: Basic Statistics Page**

(Statistics for 759525 seconds)

|                           |      |
|---------------------------|------|
| Active TDM channels       | 0    |
| Active DSP resources      | 0    |
| Active analog channels    | 0    |
| Active G.711 channels     | 0    |
| Average voice delay (ms)  | 5    |
| Average voice jitter (ms) | 11   |
| Total RTP packets TX      | 4250 |
| Total RTP packets RX      | 4241 |
| Total call attempts       | 6    |

The duration that the displayed statistics were collected is displayed in seconds above the table. To reset the performance statistics to zero, click the **Reset Statistics** button.

## 50.6 Viewing Call Counters

The IP to Tel Calls Count page and Tel to IP Calls Count page provide you with statistical information on incoming (IP-to-Tel) and outgoing (Tel-to-IP) calls. The statistical information is updated according to the release reason that is received after a call is terminated (during the same time as the end-of-call Call Detail Record or CDR message is sent). The release reason can be viewed in the 'Termination Reason' field in the CDR message.

You can reset the statistical data displayed on the page (i.e., refresh the display), by clicking the **Reset Counters** button located below the table.

- **To view IP-to-Tel and Tel-to-IP call counters:**
  - Open the Call Counters page that you want to view (**Status & Diagnostics** tab > **VoIP Status** menu > **IP to Tel Calls Count** or **Tel to IP Calls Count**); the figure below shows the IP to Tel Calls Count page.

**Figure 50-6: Calls Count Page**

|                                                       |           |
|-------------------------------------------------------|-----------|
| ▼                                                     |           |
| Number of Attempted Calls                             | 19        |
| Number of Established Calls                           | 14        |
| Percentage of Successful Calls(ASR)                   | 73.684211 |
| Number of Calls Terminated due to a Busy Line         | 2         |
| Number of Calls Terminated due to No Answer           | 0         |
| Number of Calls Terminated due to Forward             | 0         |
| Number of Failed Calls due to No Route                | 0         |
| Number of Failed Calls due to No Matched Capabilities | 0         |
| Number of Failed Calls due to No Resources            | 0         |
| Number of Failed Calls due to Other Failures          | 0         |
| Average Call Duration(ACD)[sec]                       | 25        |
| Attempted Fax Calls Counter                           | 0         |
| Successful Fax Calls Counter                          | 0         |

The fields in this page are described in the following table:

**Call Counters Description**

| Counter                                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Number of Attempted Calls</b>                             | Indicates the number of attempted calls. It is composed of established and failed calls. The number of established calls is represented by the 'Number of Established Calls' counter. The number of failed calls is represented by the failed-call counters. Only one of the established / failed call counters is incremented every time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Number of Established Calls</b>                           | <p>Indicates the number of established calls. It is incremented as a result of one of the following release reasons if the duration of the call is greater than zero:</p> <ul style="list-style-type: none"> <li>GWAPP_REASON_NOT_RELEVANT (0)</li> <li>GWAPP_NORMAL_CALL_CLEAR (16)</li> <li>GWAPP_NORMAL_UNSPECIFIED (31)</li> </ul> <p>And the internal reasons:</p> <ul style="list-style-type: none"> <li>RELEASE_BECAUSE_UNKNOWN_REASON</li> <li>RELEASE_BECAUSE_REMOTE_CANCEL_CALL</li> <li>RELEASE_BECAUSE_MANUAL_DISC</li> <li>RELEASE_BECAUSE_SILENCE_DISC</li> <li>RELEASE_BECAUSE_DISCONNECT_CODE</li> </ul> <p><b>Note:</b> When the duration of the call is zero, the release reason GWAPP_NORMAL_CALL_CLEAR increments the 'Number of Failed Calls due to No Answer' counter. The rest of the release reasons increment the 'Number of Failed Calls due to Other Failures' counter.</p> |
| <b>Percentage of Successful Calls (ASR)</b>                  | The percentage of established calls from attempted calls.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Number of Calls Terminated due to a Busy Line</b>         | Indicates the number of calls that failed as a result of a busy line. It is incremented as a result of the following release reason: GWAPP_USER_BUSY (17)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Number of Calls Terminated due to No Answer</b>           | Indicates the number of calls that weren't answered. It's incremented as a result of one of the following release reasons: <ul style="list-style-type: none"> <li>GWAPP_NO_USER_RESPONDING (18)</li> <li>GWAPP_NO_ANSWER_FROM_USER_ALERTED (19)</li> <li>GWAPP_NORMAL_CALL_CLEAR (16) (when the call duration is zero)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Number of Calls Terminated due to Forward</b>             | Indicates the number of calls that were terminated due to a call forward. The counter is incremented as a result of the following release reason: RELEASE_BECAUSE_FORWARD                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Number of Failed Calls due to No Route</b>                | Indicates the number of calls whose destinations weren't found. It is incremented as a result of one of the following release reasons: <ul style="list-style-type: none"> <li>GWAPP_UNASSIGNED_NUMBER (1)</li> <li>GWAPP_NO_ROUTE_TO_DESTINATION (3)</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Number of Failed Calls due to No Matched Capabilities</b> | Indicates the number of calls that failed due to mismatched device capabilities. It is incremented as a result of an internal identification of capability mismatch. This mismatch is reflected to CDR via the value of the parameter DefaultReleaseReason (default is GWAPP_NO_ROUTE_TO_DESTINATION (3)) or by the GWAPP_SERVICE_NOT_IMPLEMENTED_UNSPECIFIED (79) reason.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| Counter                                             | Description                                                                                                                                                                                                                                                                                          |
|-----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Number of Failed Calls due to No Resources</b>   | Indicates the number of calls that failed due to unavailable resources or a device lock. The counter is incremented as a result of one of the following release reasons: <ul style="list-style-type: none"> <li>GWAPP_RESOURCE_UNAVAILABLE_UNSPECIFIED</li> <li>RELEASE_BECAUSE_GW_LOCKED</li> </ul> |
| <b>Number of Failed Calls due to Other Failures</b> | This counter is incremented as a result of calls that failed due to reasons not covered by the other counters.                                                                                                                                                                                       |
| <b>Average Call Duration (ACD) [sec]</b>            | The average call duration (ACD) in seconds of established calls. The ACD value is refreshed every 15 minutes and therefore, this value reflects the average duration of all established calls made within a 15 minute period.                                                                        |
| <b>Attempted Fax Calls Counter</b>                  | Indicates the number of attempted fax calls.                                                                                                                                                                                                                                                         |
| <b>Successful Fax Calls Counter</b>                 | Indicates the number of successful fax calls.                                                                                                                                                                                                                                                        |

## 50.7 Viewing Registered Users

The SAS/SBC Registered Users page displays a list of registered SAS/SBC users recorded in the device's database.

➤ **To view registered SAS/SBC users:**

- Open the Registration Status page (**Status & Diagnostics** tab > **VoIP Status** menu > **Registered Users**).

**Figure 50-7: SAS/SBC Registered Users Page**

| Address Of Record | Contact                                                 |
|-------------------|---------------------------------------------------------|
| 1000@10.8.5.71    | <sip:1000@10.8.5.71:5060>;expires=180; Active status: 1 |
| 1001@10.8.5.71    | <sip:1001@10.8.5.71:5060>;expires=180; Active status: 1 |
| 1100@10.8.5.71    | <sip:1100@10.8.5.71:5060>;expires=180; Active status: 1 |
| 1101@10.8.5.71    | <sip:1101@10.8.5.71:5060>;expires=180; Active status: 1 |
| 2000@10.8.5.72    | <sip:2000@10.8.5.72:5060>;expires=180; Active status: 1 |

**SAS/SBC Registered Users Parameters**

| Column Name              | Description                                                                                                                                                                      |
|--------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Address of Record</b> | An address-of-record (AOR) is a SIP or SIPS URI that points to a domain with a location service that can map the URI to another URI (Contact) where the user might be available. |
| <b>Contact</b>           | SIP URI that can be used to contact that specific instance of the User Agent for subsequent requests.                                                                            |

## 50.8 Viewing Registration Status

The Registration Status page displays whether the device as a whole, its endpoints (FXS / FXO / BRI), and SIP Accounts are registered to a SIP Registrar/Proxy server.

➤ **To view the registration status:**

- Open the Registration Status page (**Status & Diagnostics** tab > **VoIP Status** menu > **Registration Status**).

|                                |            |                |        |
|--------------------------------|------------|----------------|--------|
| Registered Per Gateway         |            | NO             |        |
| ▼ Ports Registration Status    |            |                |        |
| Gateway Port                   |            | Status         |        |
| Module 3 Port 1 FXS            |            | NOT REGISTERED |        |
| Module 3 Port 2 FXS            |            | NOT REGISTERED |        |
| Module 3 Port 3 FXS            |            | NOT REGISTERED |        |
| Module 3 Port 4 FXS            |            | NOT REGISTERED |        |
| ▼ Accounts Registration Status |            |                |        |
| Index                          | Group Type | Group Name     | Status |
| ▼ BRI Phone Numbers Status     |            |                |        |
| Phone Number                   |            | Module / Port  | Status |

- **Registered Per Gateway:**
  - "YES" = Registration is per device
  - "NO" = Registration is not per device
- **Ports Registration Status:**
  - "REGISTERED" = channel is registered
  - "NOT REGISTERED" = channel not registered
- **Accounts Registration Status:** registration status based on the Accounts table (configured in 'Configuring Account Table' on page 219):
  - **Group Type:** type of served group - Trunk Group or IP Group
  - **Group Name:** name of the served group, if applicable
  - **Status:** indicates whether or not the group is registered ("Registered" or "Unregistered")
- **BRI Phone Number Status:**
  - **Phone Number:** phone number of BRI endpoint
  - **Module/Port:** module/port number of BRI endpoint
  - **Status:** indicates whether or not the BRI endpoint is registered ("Registered" or "Unregistered")

**Note:** The registration mode (i.e., per device, endpoint, account. or no registration) is configured in the Hunt Group Settings table (see 'Configuring Hunt Group Settings' on page 291) or using the TrunkGroupSettings *ini* file parameter.

## 50.9 Viewing Call Routing Status

The Call Routing Status page provides you with information on the current routing method used by the device. This information includes the IP address and FQDN (if used) of the Proxy server with which the device currently operates.

➤ **To view call routing status:**

- Open the Call Routing Status page (**Status & Diagnostics** tab > **VoIP Status** menu > **Call Routing Status**).

**Figure 50-8: Call Routing Status Page**

| Call-Routing Method        |                             | Routing Table |
|----------------------------|-----------------------------|---------------|
| ▼ Active Proxy Sets Status |                             |               |
| ID                         | IP Address                  | State         |
| 0                          | Not Used (--)               | --            |
| 1                          | 10.8.230.64 (10.8.230.64)   | OK            |
| 2                          | 10.9.244.80 (10.9.244.80)   | OK            |
| 3                          | 10.10.244.80 (10.10.244.80) | OK            |
| 4                          | 10.11.244.80 (10.11.244.80) | OK            |
| 5                          | 10.12.244.80 (10.12.244.80) | OK            |
| 6                          | Not Used (--)               | --            |
| 7                          | Not Used (--)               | --            |
| 8                          | Not Used (--)               | --            |
| 9                          | 10.8.244.81 (10.8.244.81)   | OK            |
| 10                         | Not Used (--)               | --            |
| 11                         | Not Used (--)               | --            |
| 12                         | Not Used (--)               | --            |

**Call Routing Status Parameters**

| Parameter                  | Description                                                                                                                                                                                                           |
|----------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Call-Routing Method</b> | <ul style="list-style-type: none"> <li>▪ Proxy/GK = Proxy server is used to route calls.</li> <li>▪ Routing Table = Outbound IP Routing table is used to route calls.</li> </ul>                                      |
| <b>IP Address</b>          | <ul style="list-style-type: none"> <li>▪ Not Used = Proxy server isn't defined.</li> <li>▪ IP address and FQDN (if exists) of the Proxy server with which the device currently operates.</li> </ul>                   |
| <b>State</b>               | <ul style="list-style-type: none"> <li>▪ N/A = Proxy server isn't defined.</li> <li>▪ OK = Communication with the Proxy server is in order.</li> <li>▪ Fail = No response from any of the defined Proxies.</li> </ul> |

## 50.10 Viewing IP Connectivity

The IP Connectivity page displays on-line, read-only network diagnostic connectivity information on all destination IP addresses configured in the Outbound IP Routing Table page (see 'Configuring Outbound IP Routing Table' on page 321).

**Note:** The information in columns 'Quality Status' and 'Quality Info' (per IP address) is reset if two minutes elapse without a call to that destination.

➤ **To view IP connectivity information:**

1. In the Routing General Parameters page, set the 'Enable Alt Routing Tel to IP' parameter (AltRoutingTel2IPMode) to **Enable** or **Status Only** (see 'Configuring General Routing Parameters' on page 321).
2. Open the IP Connectivity page (**Status & Diagnostics** tab > **VoIP Status** menu > **IP Connectivity**).

**Figure 50-9: IP Connectivity Page**

|    | IP Address | Host Name | Connectivity Method | Connectivity Status | Quality Status | Quality Info | DNS Status |
|----|------------|-----------|---------------------|---------------------|----------------|--------------|------------|
| 1  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 2  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 3  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 4  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 5  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 6  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 7  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 8  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 9  | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 10 | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 11 | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |
| 12 | Unused     | ---       | Ping                | ---                 | ---            | ---          | ---        |

**IP Connectivity Parameters**

| Column Name                | Description                                                                                                                                                                                                                                                                                              |
|----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>IP Address</b>          | The IP address can be one of the following: <ul style="list-style-type: none"> <li>IP address defined as the destination IP address in the Outbound IP Routing Table.</li> <li>IP address resolved from the host name defined as the destination IP address in the Outbound IP Routing Table.</li> </ul> |
| <b>Host Name</b>           | Host name (or IP address) as defined in the Outbound IP Routing Table.                                                                                                                                                                                                                                   |
| <b>Connectivity Method</b> | The method according to which the destination IP address is queried periodically (SIP OPTIONS request).                                                                                                                                                                                                  |
| <b>Connectivity Status</b> | The status of the IP address' connectivity according to the method in the 'Connectivity Method' field. <ul style="list-style-type: none"> <li>OK = Remote side responds to periodic connectivity queries.</li> <li>Lost = Remote side didn't respond for a short period.</li> </ul>                      |

| Column Name    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                | <ul style="list-style-type: none"><li>▪ Fail = Remote side doesn't respond.</li><li>▪ Init = Connectivity queries not started (e.g., IP address not resolved).</li><li>▪ Disable = The connectivity option is disabled, i.e., parameter 'Alt Routing Tel to IP Mode' (AltRoutingTel2IPMode <i>ini</i>) is set to 'None' or 'QoS'.</li></ul>                                                                                                                                                                                |
| Quality Status | <p>Determines the QoS (according to packet loss and delay) of the IP address.</p> <ul style="list-style-type: none"><li>▪ Unknown = Recent quality information isn't available.</li><li>▪ OK</li><li>▪ Poor</li></ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"><li>▪ This parameter is applicable only if the parameter 'Alt Routing Tel to IP Mode' is set to 'QoS' or 'Both' (AltRoutingTel2IPMode = 2 or 3).</li><li>▪ This parameter is reset if no QoS information is received for 2 minutes.</li></ul> |
| Quality Info.  | <p>Displays QoS information: delay and packet loss, calculated according to previous calls.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"><li>▪ This parameter is applicable only if the parameter 'Alt Routing Tel to IP Mode' is set to 'QoS' or 'Both' (AltRoutingTel2IPMode = 2 or 3).</li><li>▪ This parameter is reset if no QoS information is received for 2 minutes.</li></ul>                                                                                                                       |
| DNS Status     | <p>DNS status can be one of the following:</p> <ul style="list-style-type: none"><li>▪ DNS Disable</li><li>▪ DNS Resolved</li><li>▪ DNS Unresolved</li></ul>                                                                                                                                                                                                                                                                                                                                                               |

## Reader's Notes

## 51 Reporting Information to External Party

This section describes features for reporting various information to an external party.

### 51.1 RTP Control Protocol Extended Reports (RTCP XR)

RTP Control Protocol Extended Reports (RTCP XR) is a VoIP management control that defines a set of metrics containing information for assessing VoIP call quality and for diagnosing problems. RTCP XR (RFC 3611) extends the RTCP reports defined in RFC 3550 by providing additional VoIP metrics. RTCP XR information publishing is implemented in the device according to <draft-johnston-sipping-rtcp-summary-07>. This draft defines how a SIP User Agent (UA) publishes the detailed information to a defined collector. RTCP XR measures VoIP call quality such as packet loss, delay, signal / noise / echo levels, estimated R-factor, and mean opinion score (MOS). RTCP XR measures these parameters using metrics as listed in the table below.

**Note:** RTCP XR is a customer ordered feature and thus, must be included in the Software License Key installed on the device.

RTCP XR messages containing key call-quality-related metrics are exchanged periodically (user-defined) between the device and the SIP UA. This allows an analyzer to monitor these metrics midstream, or a device to retrieve them using SNMP. The device can send RTCP XR reports to an Event State Compositor (ESC) server using PUBLISH messages. These reports can be sent at the end of each call and according to a user-defined interval between consecutive reports.

**RTCP XR Published VoIP Metrics**

| Group                      | Metric Name                      |
|----------------------------|----------------------------------|
| <b>General</b>             | Start Timestamp                  |
|                            | Stop Timestamp                   |
|                            | Call-ID                          |
|                            | Local Address (IP, Port & SSRC)  |
|                            | Remote Address (IP, Port & SSRC) |
| <b>Session Description</b> | Payload Type                     |
|                            | Payload Description              |
|                            | Sample Rate                      |
|                            | Frame Duration                   |
|                            | Frame Octets                     |
|                            | Frames per Packets               |
|                            | Packet Loss Concealment          |
|                            | Silence Suppression State        |
| <b>Jitter Buffer</b>       | Jitter Buffer Adaptive           |
|                            | Jitter Buffer Rate               |

| Group                    | Metric Name                |
|--------------------------|----------------------------|
|                          | Jitter Buffer Nominal      |
|                          | Jitter Buffer Max          |
|                          | Jitter Buffer Abs Max      |
| <b>Packet Loss</b>       | Network Packet Loss Rate   |
|                          | Jitter Buffer Discard Rate |
| <b>Burst Gap Loss</b>    | Burst Loss Density         |
|                          | Burst Duration             |
|                          | Gap Loss Density           |
|                          | Gap Duration               |
|                          | Minimum Gap Threshold      |
| <b>Delay</b>             | Round Trip Delay           |
|                          | End System Delay           |
|                          | One Way Delay              |
|                          | Interarrival Jitter        |
|                          | Min Absolute Jitter        |
|                          | Signal                     |
|                          | Signal Level               |
|                          | Noise Level                |
|                          | Residual Echo Return Noise |
| <b>Quality Estimates</b> | Listening Quality R        |
|                          | RLQ Est. Algorithm         |
|                          | Conversational Quality R   |
|                          | RCQ Est. Algorithm         |
|                          | External R In              |
|                          | Ext. R In Est. Algorithm   |
|                          | External R Out             |
|                          | Ext. R Out Est. Algorithm  |
|                          | MOS-LQ                     |
|                          | MOS-LQ Est. Algorithm      |
|                          | MOS-CQ                     |
|                          | MOS-CQ Est. Algorithm      |
|                          | QoE Est. Algorithm         |

➤ **To configure RTCP XR:**

1. Open the RTP/RTCP Settings page (**Configuration** tab > **VoIP** menu > **Media** > **RTP/RTCP Settings**). The RTCP XR parameters are listed under the 'RTCP XR Settings' group, as shown below:

**Figure 51-1: RTCP XR Parameters in RTP/RTCP Settings Page**

| ▼ RTCP XR Settings                       |                    |
|------------------------------------------|--------------------|
| Burst Threshold                          | -1                 |

| R-Value Delay Threshold                  | -1                 |
| ⚡ Enable RTCP XR                         | CE_VQMON_DISABLE ▼ |
| Minimum Gap Size                         | 16                 |
| RTCP XR Report Mode                      | Disable ▼          |
| RTCP XR Packet Interval                  | 0                  |
| Disable RTCP XR Interval Randomization   | Disable ▼          |
| RTCP XR Collection Server                |                    |
| RTCP XR Collection Server Transport Type | Not Configured ▼   |

2. Configure the RTCP XR parameters, as required:
  - 'Enable RTCP XR' (*VQMonEnable*) - enables voice quality monitoring and RTCP XR.
  - 'Minimum Gap Size' (*VQMonGMin*) - defines the voice quality monitoring - minimum gap size (number of frames).
  - 'Burst Threshold' (*VQMonBurstTHR*) - defines the voice quality monitoring - excessive burst alert threshold.
  - 'Delay Threshold' (*VQMonDelayTHR*) - defines the voice quality monitoring - excessive delay alert threshold.
  - 'R-Value Delay Threshold' (*VQMonEOCRValTHR*) - defines the voice quality monitoring - end of call low quality alert threshold.
  - 'RTCP XR Report Mode' (*RTCPXRReportMode*) - determines whether RTCP XR reports are sent to the ESC and defines the interval in which they are sent.
  - 'RTCP XR Packet Interval' (*RTCPInterval*) - defines the time interval between adjacent RTCP reports.
  - 'Disable RTCP XR Interval Randomization' (*DisableRTCPRandomize*) - determines whether RTCP report intervals are randomized or whether each report interval accords exactly to the parameter RTCPInterval.
  - 'RTCP XR Collection Server' (*RTCPXREscIP*) - defines the IP address of the Event State Compositor (ESC).
  - 'RTCP XR Collection Server Transport Type' (*RTCPXRESCTransportType*) - determines the transport layer for outgoing SIP dialogs initiated by the device to the RTCP XR Collection Server.
3. Click **Submit**.
4. Reset the device for the settings to take effect.

## 51.2 Generating Call Detail Records

The Call Detail Record (CDR) contains vital statistic information on calls made from the device. The device can be configured to generate and report CDRs for various stages of the call, including SIP messages and/or media. You can configure when CDRs for a call are generated, for example, only at the end of the call or only at the start and end of the call. Once generated, the device sends the CDRs to a user-defined Syslog server.

The CDR Syslog message complies with RFC 3161 and is identified by Facility 17 (local1) and Severity 6 (Informational).

For CDR in RADIUS format, see 'RADIUS Accounting CDR Attributes' on page 614.

### 51.2.1 Configuring CDR Reporting

The procedure below describes how to configure CDR reporting.

➤ **To configure CDR reporting:**

1. Enable the Syslog feature for sending log messages generated by the device to a collecting log message server. For more information, see 'Configuring Syslog' on page 625.
2. Open the Advanced Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** > **Advanced Parameters**). The CDR parameters appear under the 'CDR and Debug' group, as shown below:

**Figure 51-2: CDR Parameters in Advanced Parameters Page**

| CDR and Debug          |                              |
|------------------------|------------------------------|
| CDR Server IP Address  | 10.8.6.55                    |
| CDR Report Level       | Start & End & Connect Call ▼ |
| Media CDR Report Level | End Media ▼                  |

3. Configure the parameters as required. For a description of the parameters, see 'Syslog, CDR and Debug Parameters' on page 674.
4. Click **Submit**.

**Note:** If the CDR server IP address is not configured, the CDRs are sent to the Syslog server, configured in 'Configuring Syslog' on page 625.

## 51.2.2 CDR Field Description

This section describes the CDR fields that are generated by the device.

### 51.2.2.1 CDR Fields for SBC Signaling

The CDR fields for SBC signaling are listed in the table below. The signaling CDRs are published for each SBC leg.

**CDR Fields for SBC Signaling**

| CDR Field Name         | Description                                                                                                                                                                                        |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>SBCReportType</b>   | Report Type: <ul style="list-style-type: none"><li>▪ <b>CALL_START</b></li><li>▪ <b>CALL_CONNECT</b></li><li>▪ <b>CALL_END</b></li><li>▪ <b>DIALOG_START</b></li><li>▪ <b>DIALOG_END</b></li></ul> |
| <b>EPTyp</b>           | Endpoint type ( <b>SBC</b> )                                                                                                                                                                       |
| <b>SIPMethod</b>       | SIP message type                                                                                                                                                                                   |
| <b>SIPCallId</b>       | Unique ID of call                                                                                                                                                                                  |
| <b>SessionId</b>       | Unique Session ID                                                                                                                                                                                  |
| <b>Orig</b>            | Call originator: <ul style="list-style-type: none"><li>▪ <b>LCL</b> - for local</li><li>▪ <b>RMT</b> - for remote</li></ul>                                                                        |
| <b>SourceIp</b>        | Source IP address                                                                                                                                                                                  |
| <b>SourcePort</b>      | Source UDP port                                                                                                                                                                                    |
| <b>DestIp</b>          | Destination IP address                                                                                                                                                                             |
| <b>DestPort</b>        | Destination UDP port                                                                                                                                                                               |

### 51.2.2.2 CDR Fields for SBC Media

The CDR fields for SBC media are listed in the table below. The media CDRs are published for each active media stream, thereby allowing multiple media CDRs, where each media CDR has a unique call ID corresponding to the signaling CDR.

**CDR Fields for SBC Media**

| CDR Field Name         | Description                               |
|------------------------|-------------------------------------------|
| <b>MediaReportType</b> | Report type (media start, update, or end) |
| <b>SIPCallId</b>       | Unique call ID                            |
| <b>Cid</b>             | Channel CID                               |
| <b>MediaType</b>       | Media type (audio, video, or text)        |
| <b>Coder</b>           | Coder name                                |
| <b>PacketInterval</b>  | Coder packet interval                     |
| <b>LocalRtpIp</b>      | Local RTP IP address                      |
| <b>LocalRtpPort</b>    | Local RTP port                            |
| <b>RemoteRtpIp</b>     | Remote RTP IP address                     |
| <b>RemoteRtpPort</b>   | Remote RTP port                           |
| <b>InPackets</b>       | Number of received packets                |

| CDR Field Name  | Description                                                                                                                               |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| OutPackets      | Number of sent packets                                                                                                                    |
| LocalPackLoss   | Local packet loss                                                                                                                         |
| RemotePackLoss  | Remote packet loss                                                                                                                        |
| RTPdelay        | RTP delay                                                                                                                                 |
| RTPjitter       | RTP jitter                                                                                                                                |
| TxRTPssrc       | Tx RTP SSRC                                                                                                                               |
| RxRTPssrc       | Local RTP SSRC                                                                                                                            |
| LocalRFactor    | Local conversation quality                                                                                                                |
| RemoteRFactor   | Remote conversation quality                                                                                                               |
| LocalMosCQ      | Local MOS for conversation                                                                                                                |
| RemoteMosCQ     | Remote MOS for conversation                                                                                                               |
| TxRTPIPDiffServ | Media IP DiffServ                                                                                                                         |
| LatchedRtPlp    | Remote IP address of the incoming RTP stream that the device "latched" on to as a result of the RTP latching mechanism for NAT traversal. |
| LatchedRtpPort  | Remote RTP port of the incoming RTP stream that the device "latched" on to as a result of the RTP latching mechanism for NAT traversal.   |

### 51.2.2.3 CDR Fields for Gateway/IP-to-IP Application

The CDR fields for the Gateway / IP-to-IP application are listed in the table below.

**CDR Fields for Gateway/IP-to-IP Application**

| Field Name   | Description                                                                                                       |
|--------------|-------------------------------------------------------------------------------------------------------------------|
| GWReportType | Report type: <ul style="list-style-type: none"> <li>CALL_START</li> <li>CALL_CONNECT</li> <li>CALL_END</li> </ul> |
| Cid          | Port number                                                                                                       |
| SessionId    | SIP session identifier                                                                                            |
| Trunk        | Physical trunk number<br><b>Note:</b> This field is applicable only to the Gateway application.                   |
| BChan        | Selected B-channel<br><b>Note:</b> This field is applicable only to the Gateway application.                      |
| ConId        | SIP conference ID<br><b>Note:</b> This field is applicable only to the Gateway application.                       |
| TG           | Trunk Group ID<br><b>Note:</b> This field is applicable only to the Gateway application.                          |

| Field Name             | Description                                                                                                                                                                                                                                                                             |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EPTyp</b>           | Endpoint type: <ul style="list-style-type: none"> <li>▪ FXO</li> <li>▪ FXS</li> <li>▪ EANDM</li> <li>▪ ISDN</li> <li>▪ CAS</li> <li>▪ DAA</li> <li>▪ IPMEDIA</li> <li>▪ NETANN</li> <li>▪ STREAMING</li> <li>▪ TRANSPARENT</li> <li>▪ MSCML</li> <li>▪ VXML</li> <li>▪ IP2IP</li> </ul> |

| <b>SipTermDesc</b>    | Description of SIP termination reason: <ul style="list-style-type: none"> <li>SIP Reason header, if exists, for example: SIP ;cause=200 ;text="Call completed elsewhere".</li> <li>If no SIP Reason header exists, the description is taken from the reason text, if exists, of the SIP response code, for example: "417 Unknown Resource-Priority".</li> <li>If no reason text exists in the SIP response code, the description is taken from an internal SIP response mapping mechanism. For example, if the device receives a SIP response "422", it sends in the CDR "422 Session Interval Too Small method" as the description.</li> </ul> |
| <b>PstnTermReason</b> | Q.850 protocol termination reason (0-127).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>LatchedRtPlp</b>   | Remote IP address of the incoming RTP stream that the device "latched" on to as a result of the RTP latching mechanism for NAT traversal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>LatchedRtpPort</b> | Remote RTP port of the incoming RTP stream that the device "latched" on to as a result of the RTP latching mechanism for NAT traversal.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

#### 51.2.2.4 Release Reasons in CDR

The possible reasons for call termination for the Gateway / IP-to-IP application which is represented in the CDR field **TrmReason** are listed below:

- "REASON N/A"
- "RELEASE\_BECAUSE\_NORMAL\_CALL\_DROP"
- "RELEASE\_BECAUSE\_DESTINATION\_UNREACHABLE"
- "RELEASE\_BECAUSE\_DESTINATION\_BUSY"
- "RELEASE\_BECAUSE\_NOANSWER"
- "RELEASE\_BECAUSE\_UNKNOWN\_REASON"
- "RELEASE\_BECAUSE\_REMOTE\_CANCEL\_CALL"
- "RELEASE\_BECAUSE\_UNMATCHED\_CAPABILITIES"
- "RELEASE\_BECAUSE\_UNMATCHED\_CREDENTIALS"
- "RELEASE\_BECAUSE\_UNABLE\_TO\_HANDLE\_REMOTE\_REQUEST"
- "RELEASE\_BECAUSE\_NO\_CONFERENCE\_RESOURCES\_LEFT"
- "RELEASE\_BECAUSE\_CONFERENCE\_FULL"
- "RELEASE\_BECAUSE\_VOICE\_PROMPT\_PLAY\_ENDED"
- "RELEASE\_BECAUSE\_VOICE\_PROMPT\_NOT\_FOUND"
- "RELEASE\_BECAUSE\_TRUNK\_DISCONNECTED"
- "RELEASE\_BECAUSE\_RSRC\_PROBLEM"
- "RELEASE\_BECAUSE\_MANUAL\_DISC"
- "RELEASE\_BECAUSE\_SILENCE\_DISC"
- "RELEASE\_BECAUSE\_RTP\_CONN\_BROKEN"
- "RELEASE\_BECAUSE\_DISCONNECT\_CODE"
- "RELEASE\_BECAUSE\_GW\_LOCKED"
- "RELEASE\_BECAUSE\_NORTEL\_XFER\_SUCCESS"
- "RELEASE\_BECAUSE\_FAIL"
- "RELEASE\_BECAUSE\_FORWARD"

- "RELEASE\_BECAUSE\_ANONYMOUS\_SOURCE"
- "RELEASE\_BECAUSE\_IP\_PROFILE\_CALL\_LIMIT"
- "GWAPP\_UNASSIGNED\_NUMBER"
- "GWAPP\_NO\_ROUTE\_TO\_TRANSIT\_NET"
- "GWAPP\_NO\_ROUTE\_TO\_DESTINATION"
- "GWAPP\_CHANNEL\_UNACCEPTABLE"
- "GWAPP\_CALL\_AWARDED\_AND "
- "GWAPP\_PREEMPTION"
- "PREEMPTION\_CIRCUIT\_RESERVED\_FOR\_REUSE"
- "GWAPP\_NORMAL\_CALL\_CLEAR"
- "GWAPP\_USER\_BUSY"
- "GWAPP\_NO\_USER\_RESPONDING"
- "GWAPP\_NO\_ANSWER\_FROM\_USER\_ALERTED"
- "MFCR2\_ACCEPT\_CALL"
- "GWAPP\_CALL\_REJECTED"
- "GWAPP\_NUMBER\_CHANGED"
- "GWAPP\_NON\_SELECTED\_USER\_CLEARING"
- "GWAPP\_INVALID\_NUMBER\_FORMAT"
- "GWAPP\_FACILITY\_REJECT"
- "GWAPP\_RESPONSE\_TO\_STATUS\_ENQUIRY"
- "GWAPP\_NORMAL\_UNSPECIFIED"
- "GWAPP\_CIRCUIT\_CONGESTION"
- "GWAPP\_USER\_CONGESTION"
- "GWAPP\_NO\_CIRCUIT\_AVAILABLE"
- "GWAPP\_NETWORK\_OUT\_OF\_ORDER"
- "GWAPP\_NETWORK\_TEMPORARY\_FAILURE"
- "GWAPP\_NETWORK\_CONGESTION"
- "GWAPP\_ACCESS\_INFORMATION\_DISCARDED"
- "GWAPP\_REQUESTED\_CIRCUIT\_NOT\_AVAILABLE"
- "GWAPP\_RESOURCE\_UNAVAILABLE\_UNSPECIFIED"
- "GWAPP\_PERM\_FR\_MODE\_CONN\_OUT\_OF\_S"
- "GWAPP\_PERM\_FR\_MODE\_CONN\_OPERATIONAL"
- "GWAPP\_PRECEDENCE\_CALL\_BLOCKED"
  - "RELEASE\_BECAUSE\_PREEMPTION\_ANALOG\_CIRCUIT\_RESERVED\_FOR\_REUSE"
  - "RELEASE\_BECAUSE\_PRECEDENCE\_CALL\_BLOCKED"
- "GWAPP\_QUALITY\_OF\_SERVICE\_UNAVAILABLE"
- "GWAPP\_REQUESTED\_FAC\_NOT\_SUBSCRIBED"
- "GWAPP\_BC\_NOT\_AUTHORIZED"
- "GWAPP\_BC\_NOT\_PRESENTLY\_AVAILABLE"
- "GWAPP\_SERVICE\_NOT\_AVAILABLE"
- "GWAPP\_CUG\_OUT\_CALLS\_BARRED"
- "GWAPP\_CUG\_INC\_CALLS\_BARRED"
- "GWAPP\_ACCES\_INFO\_SUBS\_CLASS\_INCONS"

- "GWAPP\_BC\_NOT\_IMPLEMENTED"
- "GWAPP\_CHANNEL\_TYPE\_NOT\_IMPLEMENTED"
- "GWAPP\_REQUESTED\_FAC\_NOT\_IMPLEMENTED"
- "GWAPP\_ONLY\_RESTRICTED\_INFO\_BEARER"
- "GWAPP\_SERVICE\_NOT\_IMPLEMENTED\_UNSPECIFIED"
- "GWAPP\_INVALID\_CALL\_REF"
- "GWAPP\_IDENTIFIED\_CHANNEL\_NOT\_EXIST"
- "GWAPP\_SUSPENDED\_CALL\_BUT\_CALL\_ID\_NOT\_EXIST"
- "GWAPP\_CALL\_ID\_IN\_USE"
- "GWAPP\_NO\_CALL\_SUSPENDED"
- "GWAPP\_CALL\_HAVING\_CALL\_ID\_CLEARED"
- "GWAPP\_INCOMPATIBLE\_DESTINATION"
- "GWAPP\_INVALID\_TRANSIT\_NETWORK\_SELECTION"
- "GWAPP\_INVALID\_MESSAGE\_UNSPECIFIED"
- "GWAPP\_NOT\_CUG\_MEMBER"
- "GWAPP\_CUG\_NON\_EXISTENT"
- "GWAPP\_MANDATORY\_IE\_MISSING"
- "GWAPP\_MESSAGE\_TYPE\_NON\_EXISTENT"
- "GWAPP\_MESSAGE\_STATE\_INCONSISTENCY"
- "GWAPP\_NON\_EXISTENT\_IE"
- "GWAPP\_INVALID\_IE\_CONTENT"
- "GWAPP\_MESSAGE\_NOT\_COMPATIBLE"
- "GWAPP\_RECOVERY\_ON\_TIMER\_EXPIRY"
- "GWAPP\_PROTOCOL\_ERROR\_UNSPECIFIED"
- "GWAPP\_INTERWORKING\_UNSPECIFIED"
- "GWAPP\_UNKNOWN\_ERROR"
- "RELEASE\_BECAUSE\_HELD\_TIMEOUT"

## 51.3 Configuring RADIUS Accounting

The the RADIUS Parameters page allows you to enable RADIUS accounting of SIP calls by a RADIUS accounting server. The device can send the accounting messages to the RADIUS server upon call release, call connection and release, or call setup and release.

### Notes:

- For RADIUS accounting settings to take effect, you must save the settings to flash memory with a device reset.
- For a description of the RADIUS accounting parameters, see 'RADIUS Parameters' on page [689](#).

➤ **To configure RADIUS accounting:**

1. Open the RADIUS Parameters page (**Configuration** tab > **VoIP** menu > **SIP Definitions** submenu > **RADIUS Parameters Settings**).

**Figure 51-3: RADIUS Accounting Parameters Page**

|                                |                 |
|--------------------------------|-----------------|
| ⚡ Enable RADIUS Access Control | Enable          |
| Accounting Server IP Address   | 0.0.0.0         |
| Accounting Port                | 1646            |
| RADIUS Accounting Type         | At Call Release |
| AAA Indications                | None            |

2. Configure the parameters as required.
3. Click **Submit**.

The table below describes the RADIUS Accounting CDR attributes included in the communication packets transmitted between the device and a RADIUS server.

**Supported RADIUS Accounting CDR Attributes**

| Attribute Number          | Attribute Name        | Vendor Specific Attribute (VSA) No. | Purpose                                                    | Value Format                | Example               | AAA                   |
|---------------------------|-----------------------|-------------------------------------|------------------------------------------------------------|-----------------------------|-----------------------|-----------------------|
| <b>Request Attributes</b> |                       |                                     |                                                            |                             |                       |                       |
| 1                         | user-name             | -                                   | Account number or calling party number or blank            | String up to 15 digits long | 5421385747            | Start Acc<br>Stop Acc |
| 4                         | nas-ip-address        | -                                   | IP address of the requesting device                        | Numeric                     | 192.168.14.43         | Start Acc<br>Stop Acc |
| 6                         | service-type          | -                                   | Type of service requested                                  | Numeric                     | 1: login              | Start Acc<br>Stop Acc |
| 26                        | h323-incoming-conf-id | 1                                   | SIP call identifier                                        | Up to 32 octets             | -                     | Start Acc<br>Stop Acc |
| 26                        | h323-remote-address   | 23                                  | IP address of the remote gateway                           | Numeric                     | -                     | Stop Acc              |
| 26                        | h323-conf-id          | 24                                  | H.323/SIP call identifier                                  | Up to 32 octets             | -                     | Start Acc<br>Stop Acc |
| 26                        | h323-setup-time       | 25                                  | Setup time in NTP format 1                                 | String                      | -                     | Start Acc<br>Stop Acc |
| 26                        | h323-call-origin      | 26                                  | The call's originator: Answering (IP) or Originator (PSTN) | String                      | Answer, Originate etc | Start Acc<br>Stop Acc |
| 26                        | h323-call-type        | 27                                  | Protocol type or family used on this leg of the call       | String                      | VoIP                  | Start Acc<br>Stop Acc |

| Attribute Number | Attribute Name        | Vendor Specific Attribute (VSA) No. | Purpose                                                                                                       | Value Format | Example           | AAA                   |
|------------------|-----------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------|--------------|-------------------|-----------------------|
| 26               | h323-connect-time     | 28                                  | Connect time in NTP format                                                                                    | String       | -                 | Stop Acc              |
| 26               | h323-disconnect-time  | 29                                  | Disconnect time in NTP format                                                                                 | String       | -                 | Stop Acc              |
| 26               | H323-Disconnect-Cause | 30                                  | Q.931 disconnect cause code                                                                                   | Numeric      | -                 | Stop Acc              |
| 26               | h323-gw-id            | 33                                  | Name of the gateway                                                                                           | String       | SIPIDString       | Start Acc<br>Stop Acc |
| 26               | sip-call-id           | 34                                  | SIP Call ID                                                                                                   | String       | abcde@ac.com      | Start Acc<br>Stop Acc |
| 26               | call-terminator       | 35                                  | The call's terminator: PSTN-terminated call (Yes); IP-terminated call (No).                                   | String       | Yes, No           | Stop Acc              |
| 30               | called-station-id     | -                                   | Destination phone number (Gateway / IP-to-IP application) or Destination URI (SBC application)                | String       | 8004567145        | Start Acc             |
| 31               | calling-station-id    | -                                   | Calling Party Number (ANI) (Gateway / IP-to-IP application) or Source URI (SBC application)                   | String       | 5135672127        | Start Acc<br>Stop Acc |
| 40               | acct-status-type      | -                                   | Account Request Type (start or stop)<br><b>Note:</b> 'start' isn't supported on the Calling Card application. | Numeric      | 1: start, 2: stop | Start Acc<br>Stop Acc |
| 41               | acct-delay-time       | -                                   | No. of seconds tried in sending a particular record                                                           | Numeric      | 5                 | Start Acc<br>Stop Acc |
| 42               | acct-input-octets     | -                                   | Number of octets received for that call duration (Gateway / IP-to-IP application)                             | Numeric      | -                 | Stop Acc              |
| 43               | acct-output-octets    | -                                   | Number of octets sent for that call duration (Gateway / IP-to-IP application)                                 | Numeric      | -                 | Stop Acc              |
| 44               | acct-session-id       | -                                   | A unique accounting identifier - match start & stop                                                           | String       | 34832             | Start Acc<br>Stop Acc |

| Attribute Number           | Attribute Name     | Vendor Specific Attribute (VSA) No. | Purpose                                                             | Value Format | Example            | AAA                   |
|----------------------------|--------------------|-------------------------------------|---------------------------------------------------------------------|--------------|--------------------|-----------------------|
| 46                         | acct-session-time  | -                                   | For how many seconds the user received the service                  | Numeric      | -                  | Stop Acc              |
| 47                         | acct-input-packets | -                                   | Number of packets received during the call                          | Numeric      | -                  | Stop Acc              |
| 48                         | acct-ouput-packets | -                                   | Number of packets sent during the call                              | Numeric      | -                  | Stop Acc              |
| 61                         | nas-port-type      | -                                   | Physical port type of device on which the call is active            | String       | 0: Asynchronous    | Start Acc<br>Stop Acc |
| <b>Response Attributes</b> |                    |                                     |                                                                     |              |                    |                       |
| 26                         | h323-return-code   | 103                                 | The reason for failing authentication (0 = ok, other number failed) | Numeric      | 0 Request accepted | Stop Acc              |
| 44                         | acct-session-id    | -                                   | A unique accounting identifier – match start & stop                 | String       | -                  | Stop Acc              |

Below is an example of RADIUS Accounting, where the non-standard parameters are preceded with brackets:

```
Accounting-Request (361)
user-name = 111
acct-session-id = 1
nas-ip-address = 212.179.22.213
nas-port-type = 0
acct-status-type = 2
acct-input-octets = 4841
acct-output-octets = 8800
acct-session-time = 1
acct-input-packets = 122
acct-output-packets = 220
called-station-id = 201
calling-station-id = 202
// Accounting non-standard parameters:
(4923 33) h323-gw-id =
(4923 23) h323-remote-address = 212.179.22.214
(4923 1) h323-ivr-out = h323-incoming-conf-id:02102944 600a1899
3fd61009 0e2f3cc5
(4923 30) h323-disconnect-cause = 22 (0x16)
(4923 27) h323-call-type = VOIP
(4923 26) h323-call-origin = Originate
(4923 24) h323-conf-id = 02102944 600a1899 3fd61009 0e2f3cc5
```

## 51.4 Querying Device Channel Resources using SIP OPTIONS

The device reports its maximum and available channel resources in SIP 200 OK responses upon receipt of SIP OPTIONS messages. The device sends this information in the SIP X-Resources header with the following parameters:

- **telchs:** Specifies the total telephone channels and the number of free (available) telephone channels.
- **mediachs:** Not applicable.

Below is an example of the X-Resources:

```
X-Resources: telchs= 12/4;mediachs=0/0
```

In the example above, "telchs" specifies the number of available channels and the number of occupied channels (4 channels are occupied and 12 channels are available).

**Note:** This feature is applicable only to the Gateway / IP-to-IP application.

# Part XIII

## Diagnostics

## 52 Syslog and Debug Recordings

Syslog is an event notification protocol that enables a device to send event notification messages across IP networks to event message collectors, also known as Syslog servers. The device contains an embedded Syslog client, which sends error reports / events that it generates to a remote Syslog server using the IP / UDP protocol. This information is a collection of error, warning, and system messages that records every internal operation of the device.

For receiving Syslog messages generated by the device, you can use any of the following Syslog servers:

- **Device's embedded Syslog server:** The device provides an embedded Syslog server, which is accessed through the Web interface. This provides limited Syslog server functionality.
- **Wireshark:** Third-party network protocol analyzer (<http://www.wireshark.org>).
- **Third-party, Syslog server:** Any third-party Syslog server program that enables filtering of messages according to parameters such as priority, IP sender address, time, and date.

### 52.1 Syslog Message Format

The Syslog message is sent from the device to a Syslog server as an ASCII (American Standard Code for Information Interchange) message. Syslog uses UDP as its underlying transport layer mechanism. By default, UDP port 514 is assigned to Syslog, but this can be changed (see 'Configuring Syslog' on page 625).

Below is an example of a Syslog message:

```
13:10:57.811 : 10.13.4.12 : NOTICE : [S=235][SID:1034099026] (
lgr_flow)(63) UdpTransportObject#0- Adding socket event
for address 10.33.2.42:5060 [Time: 04-19-2012@18:29:39]
```

**Syslog Message Format Description**

| Message Item                                      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Message Types</b>                              | <p>Syslog generates the following types of messages:</p> <ul style="list-style-type: none"> <li>■ <b>ERROR:</b> Indicates that a problem has been identified that requires immediate handling.</li> <li>■ <b>WARNING:</b> Indicates an error that might occur if measures are not taken to prevent it.</li> <li>■ <b>NOTICE:</b> Indicates that an unusual event has occurred.</li> <li>■ <b>INFO:</b> Indicates an operational message.</li> <li>■ <b>DEBUG:</b> Messages used for debugging.</li> </ul> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The INFO and DEBUG messages are required only for advanced debugging. Therefore, by default, they are not sent by the device.</li> <li>■ When viewing Syslog messages in the Web interface, these message types are color coded.</li> </ul> |
| <b>Message Sequence Number [S=&lt;number&gt;]</b> | <p>Syslog messages are sequentially numbered in the format [S=&lt;number&gt;], for example, "[S=643]".</p> <p>A skip in the number sequence of messages indicates a loss of message packets. For example, in the below Syslog message generation, messages 238 through 300 were not received. In other words, three Syslog messages were lost</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Message Item                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Log Number (lgr)(number)</b> | Ignore this number; it has been replaced by the Message Sequence Number (described previously).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Session ID</b>               | <p>Automatically assigned (random), unique session identifier (session-id / SID) number per call in the CDR of sent Syslog messages and debug recording packets. This enables you to filter the information (such as SIP, Syslog, and media) according to the SID.</p> <ul style="list-style-type: none"> <li>Gateway/IP-to-IP application: A call session is considered either as a Tel-to-IP leg or an IP-to-Tel leg, where each leg is assigned a unique SID.</li> <li>SBC application: A session is considered as both the outgoing and incoming legs, where both legs share the same SID.</li> </ul> <p>The benefit of this unique numbering is that it enables you to filter the information (such as SIP, Syslog, and media) according to a specific SID.</p> <p><b>Note:</b> Forked legs and alternative legs share the same SID.</p> |
| <b>Message Body</b>             | Describes the message.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Timestamp</b>                | When the Network Time Protocol (NTP) is enabled, a timestamp string [ <b>hour</b> :minutes:seconds] is added to all Syslog messages.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

### 52.1.1 Event Representation in Syslog Messages

The Syslog message events that the device sends are represented by unique abbreviations. An example of an abbreviated event in a Syslog message indicating packet loss (PL) is shown below:

```

Apr 4 12:00:12 172.30.1.14 PL:5 [Code:3a002] [CID:3294] [Time:
20:17:00]

```

The table below lists these unique event abbreviations:

### Syslog Error Name Descriptions

| Error Abbreviation | Error Name Description                                 |
|--------------------|--------------------------------------------------------|
| AA                 | Invalid Accumulated Packets Counter                    |
| AC                 | Invalid Channel ID                                     |
| AL                 | Invalid Header Length                                  |
| AO                 | Invalid Codec Type                                     |
| AP                 | Unknown Aggregation Payload Type                       |
| AR                 | Invalid Routing Flag Received                          |
| AT                 | Simple Aggregation Packets Lost                        |
| CC                 | Command Checksum Error                                 |
| CE                 | Invalid Cell Coder Code                                |
| CS                 | Command Sequence Error                                 |
| ES                 | 8 sec Timeout Before Disconnect                        |
| HO                 | Host Received Overrun                                  |
| IA                 | Invalid AMR Payload                                    |
| IC                 | Invalid CID Error                                      |
| IG                 | Invalid G723 Code                                      |
| IP                 | Invalid payload length                                 |
| IR                 | Invalid RTCP Packet                                    |
| IS                 | Invalid SID Length                                     |
| LC                 | Transmitter Received Illegal Command                   |
| LF                 | Lost Fax Frames In High Speed Mode                     |
| LM                 | Lost Modem Frames In High Speed Mode                   |
| MI                 | Misalignment Error                                     |
| MR                 | Modem Relay Is Not Supported                           |
| OR                 | DSP JB Overrun                                         |
| PH                 | Packet Header Error                                    |
| PL                 | RTP Packet Loss                                        |
| RB                 | Counts the number of BFI Frames Received From The Host |
| RD                 | No Available Release Descriptor                        |
| RO                 | RTP Reorder                                            |
| RP                 | Unknown RTP Payload Type                               |
| RS                 | RTP SSRC Error                                         |
| UF                 | Unrecognized Fax Relay Command                         |
| AA                 | Invalid Accumulated Packets Counter                    |

| Error Abbreviation | Error Name Description           |
|--------------------|----------------------------------|
| AC                 | Invalid Channel ID               |
| AL                 | Invalid Header Length            |
| AO                 | Invalid Codec Type               |
| AP                 | Unknown Aggregation Payload Type |
| AR                 | Invalid Routing Flag Received    |

## 52.1.2 Unique Device Identification in Syslog Messages

The Syslog messages include a unique string to identify the device.

Syslog messages relating to VoIP functionality are marked with "host"; those relating to Data Routing are marked with "DATA".

```
12/12 12:46:40.921 : 10.8.5.70 : NOTICE : host: 10.8.5.78 (sip_stack)(24) Resource SIPMessage deleted - #267
```

```
11/24 08:14:09.311 : 10.3.2.100 : WARNING : DATA: Failed to set device eth0 netmask: Cannot assign requested address
```

## 52.1.3 Identifying AudioCodes Syslog Messages using Facility Levels

The device's Syslog messages can easily be identified and distinguished from Syslog messages from other equipment, by setting its Facility level. The Facility levels of the device's Syslog messages are numerically coded with decimal values. Facility level may use any of the "local use" facilities (0 through 7), according to RFC 3164. Implementing Facility levels is useful, for example, if you collect the device's as well as other equipments' Syslog messages on the same server. Therefore, in addition to filtering Syslog messages according to IP address, the messages can be filtered according to Facility level.

The Facility level is configured using the SyslogFacility ini file parameter, which provides the following options:

**Syslog Facility Levels**

| Numerical Value     | Facility Level       |
|---------------------|----------------------|
| <b>16 (default)</b> | local use 0 (local0) |
| <b>17</b>           | local use 1 (local1) |
| <b>18</b>           | local use 2 (local2) |
| <b>19</b>           | local use 3 (local3) |
| <b>20</b>           | local use 4 (local4) |
| <b>21</b>           | local use 5 (local5) |
| <b>22</b>           | local use 6 (local6) |
| <b>23</b>           | local use 7 (local7) |

Syslog messages begin with a less-than (" $<$ ") character, followed by a number, which is followed by a greater-than (" $>$ ") character. This is optionally followed by a single ASCII space. The number is known as the *Priority* and represents both the Facility level and the Severity level. A Syslog message with Facility level 16 is shown below:

```
Facility: LOCAL0 - reserved for local use (16)
```

### 52.1.4 SNMP Alarms in Syslog Messages

SNMP alerts are sent to the Syslog server using the following formats:

- **Raised Alarms:** RAISE-ALARM: <Alarm Name>; Textual Description: <Textual Description>; Severity <Alarm Severity>; Source <Alarm Source>; Unique ID: <Alarm Unique ID >.

If additional information exists in the alarm, then these are also added: Additional Info1:/ Additional Info2:/ Additional Info3

The Messages' Severity is as follows:

**Syslog Message Severity**

| ITU Perceived Severity<br>(SNMP Alarm's Severity) | AudioCodes' Syslog Severity |
|---------------------------------------------------|-----------------------------|
| Critical                                          | RecoverableMsg              |
| Major                                             | RecoverableMsg              |
| Minor                                             | RecoverableMsg              |
| Warning                                           | Notice                      |
| Indeterminate                                     | Notice                      |
| Cleared                                           | Notice                      |

- **Cleared Alarms:** CLEAR-ALARM: <Alarm Name>; Textual Description: <Textual Description>; Severity <Alarm Severity>; Source <Alarm Source>; Unique ID: <Alarm Unique ID >; If exists Additional Info1:/ Additional Info2:/ Additional Info3:

## 52.2 Configuring Syslog Settings

The procedure below describes how to configure Syslog. This includes defining the Syslog server address as well as selecting the activities on the device (for example, a parameter value change) that you want reported to the server.

**Notes:**

- For configuring CDR reporting, see 'Configuring CDR Reporting' on page [604](#).
- For viewing Syslog messages in the Web interface, see 'Viewing Syslog Messages' on page [630](#).
- For a detailed description on the Syslog parameters, see 'Syslog, CDR and Debug Parameters' on page [674](#).
- To configure the network interface (WAN or VoIP LAN OAMP) from where the device sends Syslog messages to a Syslog server, use the OampDefaultNetworkSource parameter.

➤ **To configure Syslog :**

1. Open the Syslog Settings page (**Configuration** tab > **System** menu > **Syslog Settings**).

**Figure 52-1: Syslog Settings Page**

|                                                        |                          |
|--------------------------------------------------------|--------------------------|
| ▼ Syslog Settings                                      |                          |
| Enable Syslog                                          | Enable ▼                 |
| Syslog Server IP Address                               | 10.8.2.4                 |
| Syslog Server Port                                     | 514                      |
| Debug Level                                            | 5 ▼                      |
| ▼ Activity Types to Report via 'Activity Log' Messages |                          |
| Parameters Value Change                                | <input type="checkbox"/> |
| Auxiliary Files Loading                                | <input type="checkbox"/> |
| Device Reset                                           | <input type="checkbox"/> |
| Flash Memory Burning                                   | <input type="checkbox"/> |
| Device Software Update                                 | <input type="checkbox"/> |
| Access to Restricted Domains                           | <input type="checkbox"/> |
| Non-Authorized Access                                  | <input type="checkbox"/> |
| Sensitive Parameters Value Change                      | <input type="checkbox"/> |
| Login and Logout                                       | <input type="checkbox"/> |

2. Enable the Syslog feature by setting the 'Enable Syslog' to **Enable**.
3. Define the Syslog server using the 'Syslog Server IP Address' and 'Syslog Server Port' parameters.
4. Configure the debug level using the 'Debug Level' parameter.
5. Under the 'Activity Types to Report ...' group, select the activities to report.
6. Click **Submit** to apply your changes.

## 52.3 Configuring Debug Recording

The device enables you to activate debug recording and send debug recording packets to a defined capturing server. When the debug recording is activated, the device duplicates all messages that are sent and/or received by it and then sends them to an external IP address. The debug recording can be done for different types of traffic for example, RTP/RTCP, T.38, ISDN, CAS, and SIP.

Debug recording is used for advanced debugging when you need to analyze internal messages and signals. Debug recording is also useful for recording network traffic in environments where hub or port mirroring is unavailable and for recording internal traffic between two endpoints on the same device.

**Note:** Debug recording is collected only on the device's OAMP interface.

➤ **To configure and activate debug recording:**

1. Open the Logging Settings page (**Configuration** tab > **System** menu > **Logging** > **Logging Settings**).

**Figure 52-2: Logging Settings Page**

| ▼ Debug Recording                |            |
|----------------------------------|------------|
| Debug Recording Destination IP   | 10.13.4.22 |
| Debug Recording Destination Port | 925        |
| Debug Recording Status           | Start ▼    |

2. Configure the debug capturing server using the 'Debug Recording Destination IP' and 'Debug Recording Destination Port' parameters.
3. From the 'Debug Recording Status' drop-down list, select **Start** to start the debug recording or **Stop** to end the recording.
4. Click **Submit** to apply your changes.

## 52.4 Filtering Syslog Messages and Debug Recordings

The device can filter Syslog messages and debug recording (DR) packets, sent by the device to a Syslog server and packet capturing application (such as Wireshark) respectively. This can be useful to reduce CPU consumption and minimize negative impact on VoIP performance.

You can configure up to 30 filtering rules, each based on a selected filtering criteria (e.g., an IP Group). Each filtering criteria can be configured with a range. For example, you can filter Syslog messages for IP Groups 1 through 4. For each filter criteria, you can enable or disable Syslog messages and debug recording.

Debug recording can also be filtered using various filtering criteria such as SIP signaling or signaling and media.

➤ **To configure logging filtering rules:**

1. Open the Logging Filters Table page (**Configuration** tab > **System** menu > **Logging** > **Logging Filters Table**).
2. Click the **Add** button; the Add Record dialog box appears:

**Figure 52-3: Logging Filters Table - Add Record Dialog Box**

| Add Record                                                                               |                     |
|------------------------------------------------------------------------------------------|---------------------|
| Index                                                                                    | 1                   |
| Type                                                                                     | Any Filter ▼        |
| Value                                                                                    |                     |
| Syslog                                                                                   | Enable ▼            |
| Capture Type                                                                             | Signaling + Media ▼ |
| <div> <input type="button" value="Submit"/> <input type="button" value="Cancel"/> </div> |                     |

3. Configure the logging filter, as required. See the table below for a description of the parameters.
4. Click **Submit** to save your changes.

**Notes:**

- To configure the Syslog debug level, use the 'Debug Level' parameter (see 'Configuring Syslog' on page 625).
- The Logging Filters table can also be configured using the table ini file parameter, LoggingFilters or the CLI command configure system > logging > logging-filters.

**Logging Filters Table Parameters Description**

| Parameter                                                       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

### 52.4.1 Filtering IP Network Traces

You can filter Syslog and debug recording messages for IP network traces, by setting the 'Filter Type' parameter to **IP Trace** in the Logging Filters table. IP traces are used to record any IP stream, according to destination and/or source IP address, or port and Layer-4 protocol (UDP, TCP or any other IP type as defined by <http://www.iana.com>).

When the **IP Trace** option is selected, only the 'Value' parameter is applicable; the 'Syslog' and 'Capture Type' parameters are not relevant. The 'Value' parameter configures the Wireshark-like filtering expressions for your IP trace. The following Wireshark-like expressions are supported:

#### Supported Wireshark-like Expressions for 'Value' Parameter

| Expression                             | Description                                                                                   |
|----------------------------------------|-----------------------------------------------------------------------------------------------|
| ip.src, ip.dst                         | Source and destination IP address                                                             |
| ip.addr                                | IP address - up to two IP addresses can be entered                                            |
| ip.proto                               | IP protocol type (PDU) entered as an enumeration value (e.g., 1 is ICMP, 6 is TCP, 17 is UDP) |
| udp, tcp, icmp, sip, ldap, http, https | Single expressions for protocol type                                                          |

| Expression               | Description                          |
|--------------------------|--------------------------------------|
| udp.port, tcp.port       | Transport layer                      |
| udp.srcport, tcp.srcport | Transport layer for source port      |
| udp.dstport, tcp.dstport | Transport layer for destination port |
| and, &&, ==, <, >        | Between expressions                  |

Below are examples of configured expressions for the 'Value' parameter:

- udp && ip.addr==10.8.6.55
- ip.src==10.8.6.55 && udp.port>=5000 and udp.port<6000
- ip.dst==10.8.0.1/16
- ip.addr==10.8.6.40

For conditions requiring the "or" / "|" expression, add multiple table rows. For example, the Wireshark condition "(ip.src == 1.1.1.1 or ip.src == 2.2.2.2) and ip.dst == 3.3.3.3" can be configured using the following two table row entries:

1. ip.src == 1.1.1.1 and ip.dst == 3.3.3.3
2. ip.src == 2.2.2.2 and ip.dst == 3.3.3.3

**Note:** If the 'Value' field is left empty, the device will record all IP traffic types.

## 52.5 Viewing Syslog Messages

You can use the following tools to view the Syslog messages sent by the device:

- Web interface's Message Log page (see below).
- CLI -The device sends the error messages (e.g. Syslog messages) to the CLI console as well as to the original configured destination. Use the following commands:

```
debug log ; Starts the debug
no debug log ; Stops the debug
no debug log all ; Stops all debug process
```

- Any third-party Syslog server (e.g., Wireshark).

The procedure below describes how to view Syslog messages in the Web interface.

### Notes:

- It's not recommended to keep a Message Log session open for a prolonged period. This may cause the device to overload. For prolonged (and detailed) debugging, use an external Syslog server.
- You can select the Syslog messages in this page, and copy and paste them into a text editor such as Notepad. This text file (*txt*) can then be sent to AudioCodes Technical Support for diagnosis and troubleshooting.

- **To activate the Web interface's Message Log:**
  1. Enable Syslog (see 'Configuring Syslog' on page 625).
  2. Open the Message Log page (**Status & Diagnostics** tab > **System Status** menu > **Message Log**); the Message Log page is displayed and the log is activated.

Figure 52-4: Message Log Page

Log is Activated

```

11d:14h:43m:9s (lgr_psbrdex) (2662) recv <-- ON_HOOK Ch:1

11d:14h:43m:9s (lgr_psbrdif) (2674) #1:PSOSBoardInterface::StopPlayTone- Called
11d:14h:43m:9s (lgr_psbrdex) (2675) recv <-- OFF_HOOK Ch:1
11d:14h:43m:9s (lgr_flow) (2676) #1:OFF_HOOK_EV
11d:14h:43m:9s (lgr_flow) (2677) | #1:OFF_HOOK_EV
11d:14h:43m:9s (lgr_psbrdif) (2678) UpdateChannelParams, Channel 1
11d:14h:43m:9s (lgr_psbrdif) (2679) #1:ConfigFaxModemChannelParams NSEMode=0, CNGDetMode=0
11d:14h:43m:9s (lgr_psbrdif) (2680) ActivateDigitMap for channel : 1, MaxDialStringLength

```

The displayed logged messages are color-coded as follows:

- Yellow - fatal error message
- Blue - recoverable error message (i.e., non-fatal error)
- Black - notice message

- **To stop and clear the Message Log:**
  - Close the Message Log page by accessing any another page in the Web interface.

## 52.6 Collecting Debug Recording Messages

To collect debug recording packets, the open source program Wireshark is used. AudioCodes proprietary plug-in files for Wireshark, which are shipped in your software kit, are also required.

### Notes:

- The default debug recording port is 925. You can change the port in Wireshark (**Edit** menu > **Preferences** > **Protocols** > **AC DR**).
- The plug-ins are per major software release and are applicable to Wireshark Ver. 1.62.
- The plug-ins are backward compatible.
- From Wireshark Ver. 99.08, the tpncp.dat file must be located in the folder, ...WireShark\tpncp.

➤ **To install Wireshark and the plug-ins for debug recording:**

1. Install Wireshark on your computer. The Wireshark program can be downloaded from <http://www.wireshark.org>.
2. Copy the supplied AudioCodes plug-in files to the directory in which you installed Wireshark, as follows:

| Copy this file         | To this folder          |
|------------------------|-------------------------|
| ...\dtds\cdr.dtd       | Wireshark\dtds\         |
| ...\plugins\1.6.2*.dll | Wireshark\plugins\1.6.2 |
| ...\tpncp\tpncp.dat    | Wireshark\tpncp         |

3. Start Wireshark.
4. In the Filter field, type "acdr" (see the figure below) to view the debug recording messages. Note that the source IP address of the messages is always the OAMP IP address of the device.

The device adds the header "AUDIOCODES DEBUG RECORDING" to each debug recording message, as shown below:

For ISDN trace messages, the additional header, "NetBricks Trace" is added below the "AUDIOCODES DEBUG RECORDING" header, as shown in the example below:

```

AUDIOCODES DEBUG RECORDING
NetBricks Trace
System time: 3559
 Direction: Message received from internal server queue (73)
From (Entity origination ID): DL_D (DL LAPD Q.921) (100)
To (Entity destination ID): PH_D (D channel physical) (68)
Primitive code: 67
NAI (Network Access ID): 0 -> number of trunk
SAPI: 1
Connection ID: 0
Congestion flag: 0
Allocated message: 2
Allocated buffer: 3
Allocated timer cell: 141

```

```
IT Message stack counter: 120
IT Buffer stack counter: 120
Message congestion counter: 0
Buffer congestion counter: 0
IT Stack message congestion counter: 0
IT Stack buffer congestion counter: 0
Pointer to message: 689
Pointer to buffer: 0
Data size: 33
Link Access Procedure, Channel D (LAPD)
Q.931
 Protocol discriminator: Q.931
 Call reference value length: 2
 Call reference flag: Message sent from originating side
 Call reference value: 0300 - > can be used as a filter to
identify entire ISDN call
 Message type: SETUP (0x05)
 Bearer capability
 Channel identification
 Calling party number: '201'
 Called party number: '102'
 Sending complete
```

For CAS trace messages, the additional header "CAS Trace" is added below the "AUDIOCODES DEBUG RECORDING" header, as shown in the example below:

```
AUDIOCODES DEBUG RECORDING
CAS Trace
 Timer: 1145504439
 From: DSP (0)
 Current State: 7
 Event: EV_DIAL_ENDED (15)
 Next State: -1
 Function Use: Unknown (-1)
 Parameter 1: -1
 Parameter 2: -1
 Parameter 3: -1
 Trunk Number: 3
 BChannel Number: 23
 Call Handle: 0
```

## 52.7 Capturing VoIP and Data-Router Network Traffic

You can capture VoIP and data-router network traffic by sending traces to the CLI or to a file that is later sent to a TFTP server. The traffic can be captured using the following CLI commands to start the debug capture process:

```
debug capture voip
debug capture data
```

## 53 Self-Testing

The device features the following self-testing modes to identify faulty hardware components:

- **Detailed Test (Configurable):** This test verifies the correct functioning of the different hardware components on the device. This test is done when the device is taken out of service (i.e., not in regular service for processing calls). The test is performed on startup when initialization of the device completes.

To enable this test, set the ini file parameter, EnableDiagnostics to 1 or 2, and then reset the device. Upon completion of the test and if the test fails, the device sends information on the test results of each hardware component to the Syslog server.

The following hardware components are tested:

- RAM - when EnableDiagnostics = 1 or 2
- Flash memory - when EnableDiagnostics = 1 or 2
- DSPs - when EnableDiagnostics = 1 or 2
- Physical Ethernet ports - when EnableDiagnostics = 1 or 2
- Analog interfaces - when EnableDiagnostics = 1 or 2

**Notes:**

- To return the device to regular operation and service, disable the test by setting the ini file parameter, EnableDiagnostics to 0, and then reset the device.
- While the test is enabled, ignore errors sent to the Syslog server.

- **Startup Test (automatic):** This hardware test has minor impact in real-time. While this test is executed, the regular operation of the device is disabled. If an error is detected, an error message is sent to the Syslog.

## Reader's Notes

## 54 Analog Line Testing

The device can test the telephone lines connected to its FXS and FXO ports, using the SNMP `acAnalogFxsLineTestTable` table and `acAnalogFxoLineTestTable` table respectively. These tests provide various line measurements. In addition to these tests (detailed below), a keep-alive test is also done every 100 msec on each of the analog ports to detect communication problems with the analog equipment and overheating of the FXS ports.

■ FXS line tests:

- Hardware revision number
- Temperature (above or below limit, only if a thermometer is installed)
- Hook state
- Coefficients checksum
- Message waiting indication status
- Ring state
- Reversal polarity state

■ FXO line tests:

- Line Current (mA)
- Line Voltage (V)
- Hook (0 = on-hook; 1 = off-hook)
- Ring (0 - Off; 1 - On)
- Line Connected (0 = Disconnected; 1 = Connected)
- Polarity state (0 = Normal; 1 = Reversed, 2 = N/A)
- Line polarity (0 = Positive; 1 = Negative)
- Message Waiting Indication (0 = Off; 1 = On)

**Note:** Use the Analog Line testing mechanism only for monitoring and never when there are calls in progress.

## Reader's Notes

## 55 Testing SIP Signaling Calls

A simulated endpoint can be configured on the device to test SIP signaling of calls between it and a remote destination. This feature is useful in that it can remotely verify SIP message flow without involving the remote end side in the debug process. The SIP test call simulates the SIP signaling process - call setup, SIP 1xx responses, and through to completing the SIP transaction with a 200 OK.

The test call sends Syslog messages to a Syslog server, showing the SIP message flow, DTMF signals, termination reasons, as well as voice quality statistics.

### 55.1 Configuring Test Call Endpoints

The Test Call table enables you to test the SIP signaling (setup and registration) of calls and media (DTMF signals) between a simulated phone on the device and a remote endpoint. These tests involve both incoming and outgoing calls, where the test endpoint can be configured as the caller or called party. Test calls can be dialed automatically at a user-defined interval and/or manually when required. The simulated phone and remote endpoints are defined as SIP URIs (user@host) and the remote destination can be defined as an IP Group, IP address, or according to an Outbound IP Routing rule. You can also enable automatic registration of the endpoint.

When a SIP test call is initiated, the device generates a SIP INVITE towards the remote endpoint (e.g., a SIP proxy server or softswitch). It simulates the SIP call setup process, managing SIP 1xx responses and completing the SIP transaction with a 200 OK.

#### Notes:

- By default, you can configure up to five test calls. This maximum can be increased by installing the relevant Software License Key. For more information, contact your AudioCodes sales representative.
- The Test Call Endpoint table can also be configured using the table ini file parameter Test\_Call (see 'SIP Test Call Parameters' on page 673) or CLI command, configure system > test-call > test-call-table.

#### ➤ To configure test calls:

1. Open the Test Call Table page (**Configuration** tab > **System** menu > **Test Call** > **Test Call Table**).
2. Click the **Add** button; the following dialog box appears:

**Figure 55-1: General Tab of Test Call Table**

| General                                                                     |            |
|-----------------------------------------------------------------------------|------------|
| Index                                                                       | 0          |
| Endpoint URI                                                                |            |
| Called URI                                                                  |            |
| Route By                                                                    | GW Tel2IP  |
| IP Group ID                                                                 | -1         |
| Destination Address                                                         |            |
| Destination Transport Type                                                  |            |
| SRD                                                                         | 0          |
| Application Type                                                            | GW & IP2IP |
| <input type="button" value="Submit"/> <input type="button" value="Cancel"/> |            |

3. Configure the test endpoint parameters as desired. See the table below for a description of these parameters.
4. Click **Submit** to apply your settings.

**Test Call Table Parameters**

| Parameter                                                                         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>General Tab</b>                                                                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| Endpoint URI<br>[Test_Call_EndpointURI]<br>CLI: endpoint-uri                      | Defines the endpoint's URI. This can be defined as a user or user@host. The device identifies this endpoint only by the URI's user part. The URI's host part is used in the SIP From header in REGISTER requests.<br>The valid value is a string of up to 150 characters. By default, this parameter is not configured.                                                                                                                                                                                                                                                                                                                                                                                      |
| Called URI<br>[Test_Call_CalledURI]<br>CLI: called-uri                            | Defines the destination (called) URI (user@host).<br>The valid value is a string of up to 150 characters. By default, this parameter is not configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Route By<br>[Test_Call_DestType]<br>CLI: route-by                                 | Defines the type of routing method. This applies to incoming and outgoing calls. <ul style="list-style-type: none"> <li>[0] GW Tel2IP = (Default) Calls are matched by (or routed to) an SRD and Application type (defined in the SRD and Application Type parameters below).</li> <li>[1] IP Group = Calls are matched by (or routed to) an IP Group ID.</li> <li>[2] Dest Address = Calls are matched by (or routed to) an SRD and application type.</li> </ul> <b>Notes:</b> <ul style="list-style-type: none"> <li>For REGISTER messages, the option [0] cannot be used as the routing method.</li> <li>For REGISTER messages, if option [1] is used, only Server-type IP Groups can be used.</li> </ul> |
| IP Group ID<br>[Test_Call_IPGroupID]<br>CLI: ip-group-id                          | Defines the IP Group ID to which the test call is sent or from which it is received.<br><b>Notes:</b> <ul style="list-style-type: none"> <li>This parameter is applicable only if option [1] is configured for the 'Route By' parameter.</li> <li>This IP Group is used for incoming and outgoing calls.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                          |
| Destination Address<br>[Test_Call_DestAddress]<br>CLI: dst-address                | Defines the destination host. This can be defined as an IP address[:port] or DNS name[:port].<br><b>Note:</b> This parameter is applicable only if the 'Route By' parameter is set to [2] (Dest Address).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Destination Transport Type<br>[Test_Call_DestTransportType]<br>CLI: dst-transport | Defines the transport type for outgoing calls. <ul style="list-style-type: none"> <li>[-1] Not configured (default)</li> <li>[0] UDP</li> <li>[1] TCP</li> <li>[2] TLS</li> </ul> <b>Note:</b> This parameter is applicable only if the 'Route By' parameter is set to [2] (Dest Address).                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Parameter                                                                                                                        | Description                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SRD<br><b>[Test_Call_SRD]</b><br>CLI: srd                                                                                        | Defines the SRD for the endpoint.<br>The default is SRD 0.<br><b>Note:</b> This parameter is applicable only if the 'Route By' parameter is set any option except <b>[1]</b> (IP Group).                                                                                                                                                                                                          |
| Application Type<br><b>[Test_Call_ApplicationType]</b><br>CLI: application-type                                                  | Defines the application type for the endpoint. This, in effect, associates the IP Group and SRD to a specific SIP interface. <ul style="list-style-type: none"> <li>▪ <b>[0]</b> GW &amp; IP2IP (default)</li> <li>▪ <b>[2]</b> SBC</li> </ul>                                                                                                                                                    |
| <b>Authentication Tab</b>                                                                                                        |                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Note:</b> These parameters are applicable only if the test endpoint is set to <b>Caller</b> (see the 'Call Party' parameter). |                                                                                                                                                                                                                                                                                                                                                                                                   |
| Auto Register<br><b>[Test_Call_AutoRegister]</b><br>CLI: auto-register                                                           | Enables automatic registration of the endpoint. The endpoint can register to the device itself or to the 'Destination Address' or 'IP Group ID' parameter settings (see above). <ul style="list-style-type: none"> <li>▪ <b>[0]</b> False (default)</li> <li>▪ <b>[1]</b> True</li> </ul>                                                                                                         |

| Schedule Interval<br><b>[Test_Call_ScheduleInterval]</b><br>CLI: schedule-interval | <p>Defines the interval (in minutes) between automatic outgoing test calls.</p> <p>The valid value range is 0 to 100000. The default is 0 (i.e., scheduling is disabled).</p> <p><b>Note:</b> This parameter is applicable only if 'Call Party' is set to <b>Caller</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

### 55.1.1 Starting, Stopping and Restarting Test Calls

The procedure below describes how to start, stop, and restart test calls.

➤ **To start, stop, and restart a test call:**

1. In the Test Call table, select the required test call entry; the **Actions** button appears above the table.
2. From the **Actions** drop-down list, choose the required command:
  - **Dial:** starts the test call (this action is applicable only if the test call party is the caller).
  - **Drop Call:** stops the test call.
  - **Restart:** ends all established calls and then starts the test call session again.

The status of the test call is displayed in the 'Test Status' field of the Test Call table:

- "Idle": test call is not active.
- "Scheduled": test call is planned to run (according to 'Schedule Interval' parameter settings)
- "Running": test call has been started (i.e., the **Dial** command was clicked)
- "Receiving": test call has been automatically activated by calls received for the test call endpoint from the remote endpoint (when all these calls end, the status returns to "Idle")
- "Terminating": test call is in the process of terminating the currently established calls (this occurs if the **Drop Call** command is clicked to stop the test)
- "Done": test call has been successfully completed (or was prematurely stopped by clicking the **Drop Call** command)

A more detailed description of this field is displayed below the table when you click the **Show/Hide** button (see 'Viewing Test Call Statistics' on page 643).

## 55.1.2 Viewing Test Call Statistics

In addition to viewing a brief status description of the test call in the 'Test Status' field (as described in 'Starting, Stopping and Restarting Test Calls' on page 642), you can also view a more detailed status description which includes test call statistics.

### ➤ To view statistics of a test call:

1. Open the Test Call Table page (**Configuration** tab > **System** menu > **Test Call** > **Test Call Table**).
2. Select the test call table entry whose call statistics you want to view.
3. Click the **Show/Hide** button; the call statistics are displayed in the **Test Statistics** pane located below the table, as shown in the figure below:

Figure 55-2: Viewing Test Call Statistics

The screenshot shows the 'Test Call Table' with one entry in 'Running' status. Below the table, the 'Test Statistics' pane is expanded, showing the following information:

| Test Call Table #0              |                                        |
|---------------------------------|----------------------------------------|
| Endpoint URI: 101               | Called URI: 102                        |
| Route By: GW Tel2IP             | IP Group ID: -1                        |
| Destination Address: 10.13.4.12 | Destination Transport Type: GW & IP2IP |
| SRD: 0                          | Application Type: GW & IP2IP           |
| Auto Register: Disable          | User Name: Caller                      |
| Password:                       | Call Party: Caller                     |
| Maximum Channels for Session: 4 | Call Duration (seconds): 20            |
| Calls per Second: 10            | Test Mode: Once                        |
| Test Duration (minutes): 4      | Play: DTMF                             |
| Schedule Interval (minutes): 0  |                                        |

| Test Statistics                               |                                |
|-----------------------------------------------|--------------------------------|
| Elapsed Time [HH:MM:SS]: 00:00:11             | Active Calls: 2                |
| Call Attempts: 4                              | Total Established Calls: 2     |
| Total Failed Attempts: 2                      | Remote Disconnections Count: 0 |
| Test Status: Running                          | Average CPS:                   |
| Detailed Status: Running (Calls: 2, ASR: 50%) |                                |

The 'Test Statistics' pane displays the following test session information:

- **Elapsed Time:** Duration of the test call since it was started (or restarted).
- **Active Calls:** The number of currently active test calls.
- **Call Attempts:** The number of calls that were attempted.
- **Total Established Calls:** The total number of calls that were successfully established.
- **Total Failed Attempts:** The total number of calls that failed to be established.

- **Remote Disconnections Count:** Number of calls that were disconnected by the remote side.
- **Average CPS:** The average calls per second.
- **Test Status:** Displays the status (brief description) as displayed in the 'Test Status' field (see 'Starting, Stopping and Restarting Test Calls' on page 642).
- **Detailed Status:** Displays a detailed description of the test call status::
  - "Idle": The test call is currently not active.
  - "Scheduled - Established Calls: <established calls>, ASR: <%>": The test call is planned to run (according to 'Schedule Interval' parameter settings) and also shows the following summary of completed test calls:
    - ◆ Total number of test calls that were established.
    - ◆ Number of successfully answered calls out of the total number of calls attempted (ASR).
  - "Running (Calls: <number of active calls>, ASR: <%>)": The test call has been started (i.e., the **Dial** command was clicked) and shows the following:
    - ◆ Number of currently active test calls.
    - ◆ Number of successfully answered calls out of the total number of calls attempted (Answer Seizure Ratio or ASR).
  - "Receiving (<number of active calls>)": The test call has been automatically activated by calls received for this configured test call endpoint from the configured remote endpoint. When all these calls terminate, the status returns to "Idle".
  - "Terminating (<number of active calls>)": The **Drop Call** command has been clicked to stop the test call and the test call is in the process of terminating the currently active test calls.
  - "Done - Established Calls: <established calls>, ASR: <%>": The test call has been successfully completed (or was prematurely stopped by clicking the **Drop Call** command) and shows the following:
    - ◆ Total number of test calls that were established.
    - ◆ Number of successfully answered calls out of the total number of calls attempted (ASR).

**Note:** On the receiving side, when the first call is accepted in "Idle" state, statistics are reset.

## 55.2 Configuring DTMF Tones for Test Calls

By default, no DTMF signal is played to an answered test call (incoming or outgoing). However, you can enable this per configured test call in the Test Call table (see 'Configuring Test Call Endpoints' on page 639). If enabled, the default DTMF signal that is played is "3212333". You can change this as described below.

### Notes:

- The DTMF signaling type (e.g., out-of-band or in-band) can be configured using the 'DTMF Transport Type' parameter. For more information, see 'Configuring DTMF Transport Types' on page 163.
- To generate DTMF tones, the device's DSP resources are required.

➤ **To configure the played DTMF signal to answered test call:**

1. Open the Test Call Settings page (**Configuration** tab > **System** menu > **Test Call** > **Test Call Settings**).

|                       |         |
|-----------------------|---------|
| Test Call DTMF String | 3212333 |
|-----------------------|---------|

2. In the 'Test Call DTMF String' field, enter the DTMF string (up to 15 digits).
3. Click **Submit**.

## 55.3 Configuring Basic Test Call

The Basic Test Call feature tests incoming Gateway / IP-to-IP calls from a remote SIP endpoint to a simulated test endpoint on the device. The only required configuration is to assign a prefix number (*test call ID*) to the simulated endpoint. All incoming calls with this called (destination) prefix number is identified as a test call and sent to the simulated endpoint. The figure below displays a basic test call example.

**Figure 55-3: Incoming Test Call Example**

➤ **To configure basic call testing:**

1. Open the Test Call Settings page (**Configuration** tab > **System** menu > **Test Call** > **Test Call Settings**).

**Figure 55-4: Test Call Settings Page**

|              |                      |
|--------------|----------------------|
| Test Call ID | <input type="text"/> |
| SBC Test ID  | <input type="text"/> |

2. In the 'Test Call ID' field, enter a prefix for the simulated endpoint.
3. Click **Submit** to apply your settings.

**Notes:**

- The Basic Test Call feature tests incoming calls only and is initiated only upon receipt of incoming calls with the configured prefix.
- For a full description of this parameter, see 'SIP Test Call Parameters' on page 673.
- This call test is done on all SIP interfaces.
- This call test is applicable only to the Gateway/IP-to-IP application.

## 55.4 Configuring SBC Test Call with External Proxy

The SBC Test Call feature tests incoming SBC SIP call flow between a simulated test endpoint on the device and a remote SIP endpoint, when registration and routing is done through an external proxy/registrar server such as a hosted IP PBX in the WAN. In other words, the complete SIP flow, including the path to/from the external proxy/registrar can be tested.

As this test call type involves an SBC call, you need to configure regular SBC rules such as classification and IP-to-IP routing. Therefore, this test call also allows you to verify correct SBC configuration.

For this test call, you also need to configure the following call IDs:

- Test Call ID - prefix number of the simulated endpoint on the device.
- SBC Test ID - prefix number of called number for identifying incoming call as SBC test call. The device removes this prefix, enabling it to route the call according to the IP-to-IP Routing rules to the external proxy/registrar, instead of directly to the simulated endpoint. Only when the device receives the call from the proxy/registrar, does it route the call to the simulated endpoint.

The figure below displays an example of an SBC test call:

**Figure 55-5: SBC Test Call Example**

3. The call is received from the remote endpoint with the called number prefix "8101".
4. As the 'SBC Test ID' parameter is set to "8", the device identifies this call as a test call and removes the digit "8" from the called number prefix, leaving it as "101".
5. The device performs the regular SBC processing such as classification and manipulation.
6. The device routes the call, according to the configured SBC IP-to-IP routing rules, to the proxy server.
7. The device receives the call from the proxy server.
8. As the 'Test Call ID' parameter is set to "101", the device identifies the incoming call as a test call and sends it directly to the simulated test endpoint "101".

➤ **To configure SBC call testing:**

1. Configure the test call parameters:
  - a. Open the Test Call Settings page (**Configuration** tab > **System** menu > **Test Call** > **Test Call Settings**).

**Figure 55-6: Test Call Settings Page**

|              |                      |
|--------------|----------------------|
| Test Call ID | <input type="text"/> |
| SBC Test ID  | <input type="text"/> |

- b. In the 'Test Call ID' field, enter a prefix number for the simulated test endpoint on the device.
  - c. In the 'SBC Test ID' field, enter a called prefix number for identifying the call as an SBC test call.
  - d. Click **Submit** to apply your settings.
2. Configure regular SBC call processing rules for called number prefix "101", such as classification and IP-to-IP routing through a proxy server.

**Notes:**

- For a full description of this parameter, see 'SIP Test Call Parameters' on page 673.
- This test call is initiated only upon receipt of incoming calls and with the configured prefix.
- This call test is done on all SIP interfaces.
- This test call is applicable only to the SBC application.

## 55.5 Test Call Configuration Examples

Below are a few examples of test call configurations.

- **Single Test Call Scenario:** This example describes the configuration of a simple test call scenario that includes a single test call between a simulated test endpoint on the device and a remote endpoint.

**Figure 55-7: Single Test Call Example**

- Test Call table configuration:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "201"
  - ◆ Route By: Dest Address
  - ◆ Destination Address: "10.30.40.01"

- ◆ Call Party: Caller
- ◆ Test Mode: Once (default)

Alternatively, if you want to route the test call using the Outbound IP Routing table for the Gateway / IP-to-IP application, configure the following:

- Test Call table configuration:
  - ◆ Endpoint URI: 101@10.0.0.1
  - ◆ Route By: GW Tel2IP
  - ◆ Called URI: [201@10.30.40.1](#)
  - ◆ Call Party: Caller
- Outbound IP Routing table configuration:
  - ◆ Dest. Phone Prefix: 201 (i.e., the Called URI user-part)
  - ◆ Source Phone Prefix: 101 (i.e., the Endpoint URI user-part)
  - ◆ Dest. IP Address: 10.30.40.1

- **Batch Test Call Scenario:** This example describes the configuration of a batch test call setup for scheduled and continuous call testing of multiple endpoints. The test call is done between two AudioCodes devices - Device A and Device B - with simulated test endpoints. This eliminates the need for phone users, who would otherwise need to answer and end calls many times for batch testing. The calls are initiated from Device A, where Device B serves as the remote answering endpoint.

**Figure 55-8: Batch Test Call Example**

- Test Call table configuration at Device A:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "201"
  - ◆ Route By: Dest Address
  - ◆ Destination Address: "10.13.4.12"
  - ◆ Call Party: Caller
  - ◆ Maximum Channels for Session: "3" (this setting configures three endpoints - "101", "102" and "103")
  - ◆ Call Duration: "5" (seconds)
  - ◆ Calls per Sec: "1"
  - ◆ Test Mode: Continuous
  - ◆ Test Duration: "3" (minutes)
  - ◆ Schedule Interval: "180" (minutes)
- Test Call table configuration at Device B:
  - ◆ Endpoint URI: "201"
  - ◆ Call Party: Caller
  - ◆ Maximum Channels for Session: "3" (this setting configures three endpoints - "201", "202" and "203")

- **Registration Test Call Scenario:** This example describes the configuration for testing the registration and authentication (i.e., username and password) process of a simulated test endpoint on the device with an external proxy/registrar server. This is useful, for example, for verifying that endpoints located in the LAN can register with an external proxy and subsequently, communicate with one another.

**Figure 55-9: Test Call Registration Example**

This example assumes that you have configured your device for communication between LAN phone users such as IP Groups to represent the device (10.13.4.12) and the proxy server, and IP-to-IP routing rules to route calls between these IP Groups.

- Test Call table configuration:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "itsp"
  - ◆ Route By: Dest Address
  - ◆ Destination Address: "10.13.4.12" (this is the IP address of the device itself)
  - ◆ Auto Register: Enable
  - ◆ User Name: "testuser"
  - ◆ Password: "12345"
  - ◆ Call Party: Caller

## Reader's Notes

# Part XIV

## Appendix

## 56 Dialing Plan Notation for Routing and Manipulation

The device supports flexible dialing plan notations for denoting the prefix and/or suffix source and/or destination numbers and SIP URI user names in the routing and manipulation tables.

### Dialing Plan Notations for Prefixes and Suffixes

| Notation            | Description                                                                                                                                                                                                                                                                                                                                                                                                       |
