### ➤ To configure a ISDN-to-ISDN release cause mapping rule:

1. Open the Release Cause Mapping from ISDN to ISDN table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Release Cause ISDN > ISDN**).
2. Click **New**; the following dialog box appears:

GENERAL	
Index	0
Orig Q.850 Cause	1
Map Q.850 Cause	1

3. Configure a mapping rule according to the parameters described in the table below.

#### 4. Click **Apply**.

**Table 26-12:Release Cause Mapping ISDN to ISDN Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Orig. Q.850 Causes' orig-q850-cause [OrigIsdnReleaseCause]	Defines the originally received ISDN Q.850 cause code. For example, you can enter "127" (without quotation marks) to represent cause code 127 Interworking, Unspecified. The valid value (cause code) is 1 to 127.
'Map Q.850 Causes' map-q850-cause [MapIsdnReleaseCause]	Defines the ISDN Q.850 cause code to which you want to change the originally received cause code. For example, you can enter "16" (without quotation marks) to represent cause code 16 Normal Call Clearing. The valid value (cause code) is 1 to 127.

### SIP Reason Header for Release Cause

The device supports the SIP Reason header according to RFC 3326. The Reason header describes the disconnection cause of a call:

- **Sending Reason header:** If a call is disconnected from the Tel side (ISDN), the Reason header contains the value of the received Q.850 cause in the appropriate message (BYE/CANCEL/final failure response) and sent to the IP side. If the call is disconnected because of a SIP reason, the Reason header is set to the appropriate SIP response.
- **Receiving Reason header:** If a call is disconnected from the IP side and the SIP message includes the Reason header, it is sent to the Tel side according to the following logic:
  - If the Reason header includes a Q.850 cause, it is sent as is.
  - If the Reason header includes a SIP response:
    - ◆ If the message is a final response, the response status code is translated to Q.850 format and passed to ISDN.
    - ◆ If the message isn't a final response, it is translated to a Q.850 cause.
  - When the Reason header is received twice (i.e., SIP Reason and Q.850), the Q.850 takes precedence over the SIP reason and is sent to the Tel side.

### Mapping PSTN Release Cause to SIP Response for Analog Interfaces

The device's FXO interface interoperates between the SIP network and the PSTN/PBX. This interoperability includes the mapping of PSTN/PBX Call Progress tones to SIP 4xx or 5xx

responses for IP-to-Tel calls. The converse is also true - for Tel-to-IP calls, the SIP 4xx or 5xx responses are mapped to tones played to the PSTN/PBX.

When establishing an IP-to-Tel call, the following rules are applied:

- If the remote party (PSTN/PBX) is busy and the FXO device detects a busy tone, it sends a SIP 486 Busy response to IP. If it detects a reorder tone, it sends a SIP 404 Not Found (no route to destination) to IP. In both cases the call is released. Note that if you enable the 'Disconnect Call on Busy Tone Detection' parameter, the FXO device ignores the detection of busy and reorder tones and doesn't release the call.

- For all other FXS/FXO release types such as:

- no free channels in the Trunk Group,
- an appropriate call routing rule to a Trunk Group doesn't exist, or
- the phone number isn't found

the device sends a SIP response to the IP according to the 'Default Release Cause' parameter. The parameter defines Q.931 release causes. Its default value is **3**, which is mapped to the SIP 404 response. By changing its value to **34**, the SIP 503 response is sent. Other causes can be used as well.

## Numbering Plans and Type of Number

The IP-to-Tel destination or source number manipulation tables allow you to classify numbers by their Numbering Plan Indication (NPI) and Type of Number (TON). The device supports all NPI/TON classifications used in the ETSI ISDN variant, as shown in the table below:

**Table 26-13:NPI/TON Values for ETSI ISDN Variant**

NPI	TON	Description
Unknown [0]	Unknown [0]	A valid classification, but one that has no information about the numbering plan.
E.164 Public [1]	Unknown [0]	A public number in E.164 format, but no information on what kind of E.164 number.
	International-Level2 Regional [1]	A public number in complete

NPI	TON	Description
		international E.164 format, e.g., 16135551234.
	National-Level1 Regional [2]	A public number in complete national E.164 format, e.g., 6135551234.
	Network-PSTN Specific [3]	The type of number "network specific number" is used to indicate administration / service number specific to the serving network, e.g., used to access an operator.
	Subscriber-Level0 Regional [4]	A public number in complete E.164 format representing a local subscriber, e.g., 5551234.
	Abbreviated [6]	The support of this code is network dependent. The number provided in this information element presents a shorthand representation of the complete number in the

NPI	TON	Description
		specified numbering plan as supported by the network.
Private [9]	Unknown [0]	A private number, but with no further information about the numbering plan.
	International-Level2 Regional [1]	-
	National-Level1 Regional [2]	A private number with a location, e.g., 3932200.
	PISN Specific [3]	-
	Subscriber-Level0 Regional [4]	A private local extension number, e.g., 2200.

For NI-2 and DMS-100 ISDN variants, the valid combinations of TON and NPI for calling and called numbers include (Plan/Type):

- 0/0 - Unknown/Unknown
- 1/1 - International number in ISDN/Telephony numbering plan
- 1/2 - National number in ISDN/Telephony numbering plan
- 1/4 - Subscriber (local) number in ISDN/Telephony numbering plan
- 9/4 - Subscriber (local) number in Private numbering plan

## 27 Configuring DTMF and Dialing

This section describes configuration of dual-tone multi-frequency (DTMF) and dialing for the Gateway application.

### Dialing Plan Features

This section describes various dialing plan features.

#### Digit Mapping

You can use digit mapping to determine when the device stops collecting the digits of a dialed phone number from the Tel side (caller), after which it uses them for the destination number to establish the call. Digit mapping is typically used for closed numbering schemes.

The device stops collecting digits and starts sending the digits upon any of the following scenarios:

- **The maximum number of digits is received:** You can configure the maximum number of collected digits that can be received from the Tel side. When the number of collected digits reaches this maximum (or a digit map pattern is matched before the maximum), the device stops collecting more digits and uses the collected digits for the called destination number. To configure the maximum number of collected digits, use the [MaxDigits parameter] parameter.
- **The inter-digit timeout expires (e.g., for open numbering schemes):** The inter-digit timeout is the time that the device waits between each received (collected) digit. When the timeout expires, the device stops collecting more digits and uses the collected digits for the called destination number. To configure the timeout, use the [TimeBetweenDigits] parameter.
- **The phone's pound or number (#) key is pressed.**

The # key option is applicable only to analog interfaces.

- **The digits match one of the digit map patterns:** Digit map (pattern) rules are configured by the [DigitMapping] parameter. The digit map pattern can contain up to 52 options (rules), each separated by a vertical bar ("|"). The maximum length of the entire digit pattern is 152 characters. The digit mapping notations are described in the following table:

**Table 27-1: Digit Map Pattern Notations**

Notation	Description
[n-m]	Range of numbers (e.g., "1-7").
.	(Single dot) Repeat digits until the next notation (e.g., T).

Notation	Description
<b>x</b>	Any single digit. <b>Note:</b> This notation doesn't apply to some scenarios when using the * or # key. For example, the key sequence of "***" must be presented in the dial plan as "*x.s" (instead of xx).
<b>T</b>	Dial timeout between received digits, which is configured by the [TimeBetweenDigits] parameter.
<b>S</b>	Short timeout between received digits, which is configured by the [TimeBetweenDigits] parameter whose value is then divided by 2. For example, if you leave the parameter at its default (i.e., 4), then the short timeout is 2 (i.e., 4 divided by 2). You can use the short timeout when you configure a specific rule after a more general rule. For example, if the digit map is "99 998", the device terminates digit collection when the first two 9 digits are received. Therefore, the second rule "998" can never be matched. But if you configure the digit map as "99S 998", then after the first two 9 digits are dialed, the device waits another two seconds, within which the caller can dial the digit 8.

Below is an example of a digit map containing eight rules:

```
DigitMapping = 11xS|00[1-7]xxx|8xxxxxxx|#xxxxxxx|*xx|91xxxxxxxxxx|9011x|9011x.T
```

In the example, the rule:

- "00[1-7]xxx" denotes dialed numbers that begin with 00, and then any digit from 1 through 7, followed by three digits (of any number). Once the device receives these digits, it doesn't wait for additional digits, but starts sending the collected digits (dialed number) immediately.
- "9011x.T" can apply to International numbers where 9 is for the dialing tone, 011 the country code, and then any number of digits for the local number.

(For digital interfaces) Digit maps are used for Tel-to-IP ISDN overlap dialing (by configuring the [ISDNRxOverlap] parameter to 1) to reduce the dialing period. For more information, see [ISDN Overlap Dialing](#) on page 930.

- If you want the device to accept any number, make sure that the digit map contains the rule "xx.T"; otherwise, the device rejects all dialed numbers that can't be matched to any digit map.
- If you are using an external Dial Plan file for dialing plans (see Digit Mapping), the device first attempts to locate a matching digit pattern in the Dial Plan file. Only if not found, does the device search for a matching digit pattern in the digit map.
- It may be useful to configure both Dial Plan file and digit maps. For example, the digit map can be used for complex digit patterns (which are not supported by the Dial Plan) and the Dial Plan can be used for long lists of relatively simple digit patterns. In addition, as timeout between digits is not supported by the Dial Plan, the digit map can be used to configure digit patterns that are shorter than those configured in the Dial Plan ( [MaxDigits] parameter) or left at default. For example, the digit map "xx.T" uses the Dial Plan and if no matching digit pattern is found, the device waits for two more digits and then after a timeout ([TimeBetweenDigits] parameter), it sends the collected digits. Therefore, this ensures that calls are not rejected as a result of their digit pattern not been completed in the Dial Plan.

## Dial Plan Rules

You can configure dialing plans by using Dial Plan rules or loading a Dial Plan file. For more information, see [Configuring Dial Plans](#) on page 825.

## Interworking Keypad DTMFs for SIP-to-ISDN Calls

The device can interwork DTMF tones received from the IP to the PSTN, using the ISDN Keypad Facility information element (IE) in Q.931 INFORMATION messages.

The feature is applicable only to the Euro ISDN variant (User side).

If the device receives from the IP side an INVITE message whose called party number (To header) contains the asterisk (\*) or pound (#) character, or a SIP NOTIFY or SIP INFO message that contains these characters (e.g., 123#456), the device sends the character and the digits positioned to its right, as Keypad IE in the INFORMATION message. The device sends only the digits positioned before the character to the PSTN (in SETUP message) as the called party number. For example, if the device receives the below INVITE, it sends "123" to the PSTN as the called party number and #456 as Keypad IE in the INFORMATION message:

```
INVITE sip:%7B54443994-BDFF-413C-AE4F-
D039B0FFB134%7D@192.168.100.214:5064;transport=tcp;rinstance=9f25c4452
eff4acb SIP/2.0
To: sip:123#456@192.168.100.214;user=phone;x-type=unknown;x-
plan=unknown;x-pres=allowed
```

The destination number can be manipulated when this feature is enabled. Note that if manipulation before routing is required, the \* and # characters should not be used, as the device will handle them according to the above keypad protocol. For example, a manipulation rule should not be configured to add #456 to the destination number. If manipulation after routing is required, the destination number to be manipulated will not include the keypad part. For example, if you configure a manipulation rule to add the suffix 888 and the received INVITE contains the number 123#456, only 123 is manipulated and the number dialed toward the PSTN is 123888; #456 is sent as keypad.

To enable this feature, use the ISDNKeypadMode parameter.

## Configuring Hook Flash

The following procedure describes how to configure various hook-flash features.

### ➤ To configure hook-flash features:

1. Configure the digit pattern used by the Tel side to indicate a hook-flash event:
  - a. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).
  - b. In the 'Hook-Flash Code' (HookFlashCode) field, enter the digit pattern.

Hook-Flash Code

- c. Click **Apply**.
2. Configure the hook-flash transport type:
  - a. Open the DTMF & Dialing page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **DTMF & Dialing**).
  - b. From the 'Hook-Flash Option' (HookFlashOption) drop-down list, select the required transport type.

Hook-Flash Option

- c. Click **Apply**.
3. To configure the period by the device for detecting hook-flash initiated by analog interfaces:
  - a. Open the Analog Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Analog Settings**).
  - b. Configure the following:
    - ◆ 'Min. Hook-Flash Detection Period' (MinFlashHookTime): Defines the minimum time (in msec) for detection of a hook-flash event from an FXS interface. Detection is guaranteed for hook-flash periods of at least 60 msec (when configuring the

period to 25). The device ignores hook-flash signals lasting a shorter period of time.

- ◆ 'Max. Flash-Hook Detection Period' (FlashHookPeriod): Defines the maximum hook-flash period (in msec) for Tel and IP sides for FXS and FXO interfaces. For more information, see the Tel Profile parameter 'Flash Hook Period' in [Configuring Tel Profile](#) on page 755.

Min. Hook-Flash Detection Period [msec]	<input type="text" value="300"/>
Max. Hook-Flash Detection Period [msec]	<input type="text" value="700"/>

- c. Click **Apply**.

## 28 Configuring Supplementary Services

This section describes the Gateway application's SIP supplementary services that can enhance your telephone service.

- All call participants must support the specific supplementary service that is used.
- When working with certain application servers (such as BroadSoft's BroadWorks) in client server mode (the application server controls all supplementary services and keypad features by itself), the device's supplementary services must be disabled.

### Call Hold and Retrieve

**For analog interfaces:** Initiating call hold and retrieve:

- Active calls can be put on-hold by pressing the phone's hook-flash button.
- The party that initiates the hold is called the *holding* party; the other party is called the *held* party.
- After a successful hold, the holding party hears a dial tone (HELD\_TONE defined in the device's Call Progress Tones file).
- Call retrieve can be done only by the holding party while the call is held and active.
- The holding party performs the retrieve by pressing the telephone's hook-flash button.
- After a successful retrieve, the voice is connected again.
- Hold is done by sending a re-INVITE message with IP address 0.0.0.0 or a=sendonly in the SDP, according to the HoldFormat parameter.

**For digital interfaces:** Call hold and retrieve:

- The party that initiates the hold is called the *holding* party; the other party is called the *held* party.
- After a successful Hold, the holding party hears a dial tone (HELD\_TONE defined in the device's Call Progress Tones file).
- After a successful retrieve, the voice is connected again.
- The hold and retrieve functionalities are implemented by re-INVITE messages. The IP address 0.0.0.0 as the connection IP address or the string 'a=inactive' in the received re-INVITE SDP cause the device to enter Hold state and to play the held tone (configured in the device) to the PBX/PSTN. If the string 'a=sendonly' is received in the SDP message, the device stops sending RTP packets, but continues to listen to the incoming RTP packets. Usually, the remote party plays, in this scenario, Music on Hold (MOH) and the device forwards the MOH to the held party.

**For analog interfaces:** Receiving Hold/Retrieve:

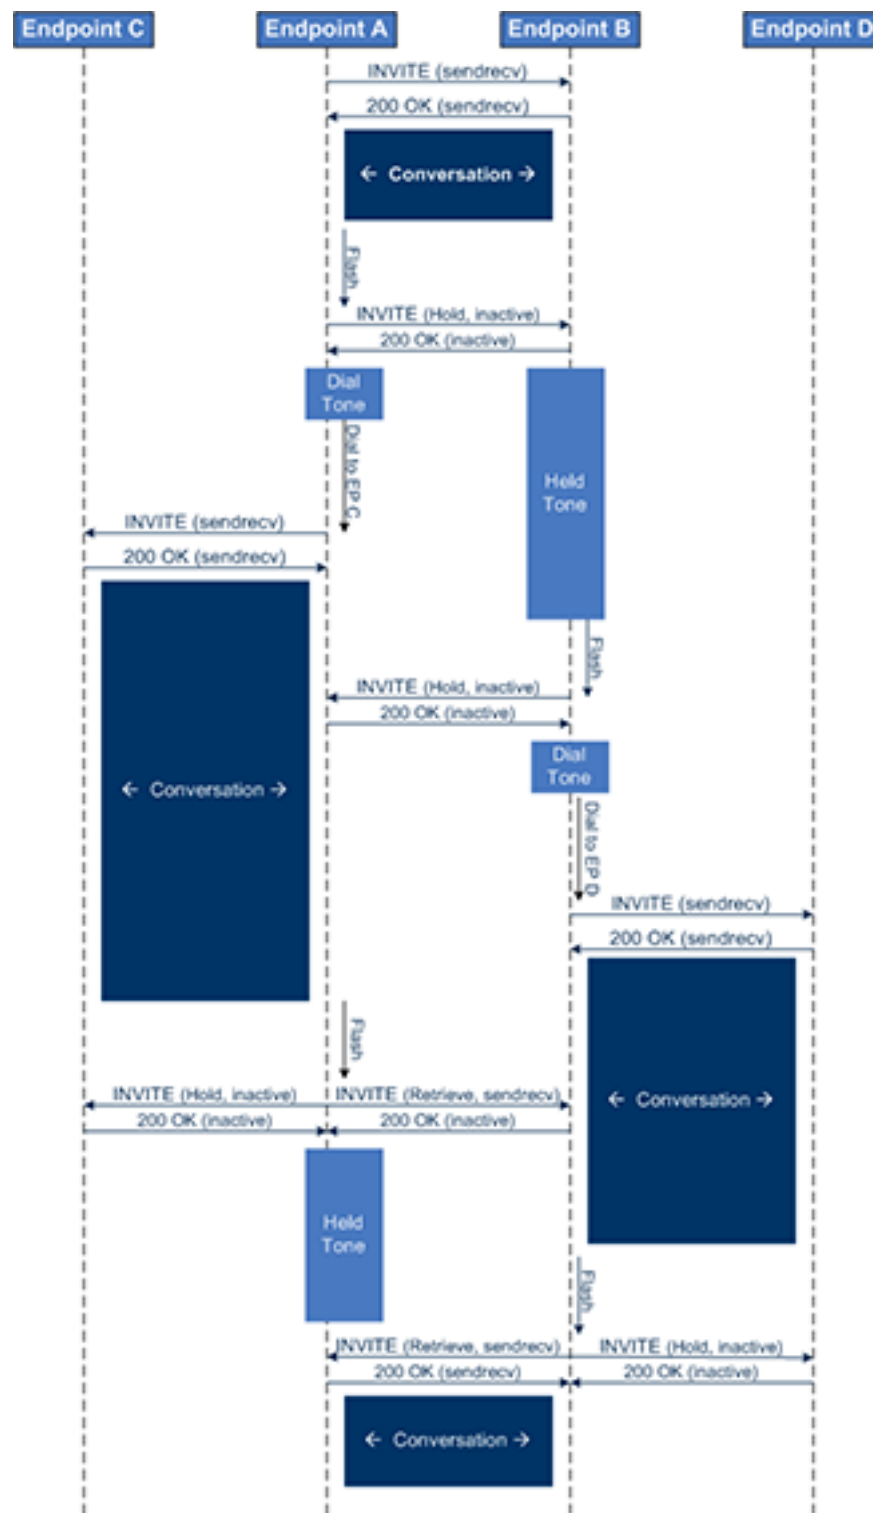

- When an active call receives a re-INVITE message with IP address 0.0.0.0 or 'inactive' string in SDP, the device stops sending RTP and plays a local held tone.
- When an active call receives a re-INVITE message with the 'sendonly' string in SDP, the device stops sending RTP and listens to the remote party. In this mode, it is expected that music on-hold (or any other hold tone) is played (over IP) by the remote party.

You can also configure the device to keep a call on-hold for a user-defined time after which the call is disconnected, using the [HeldTimeout] parameter.

When the Tel side puts the call on hold (hookflash), the device plays a dial tone to the Tel side (dial tone timeout starts according to the 'Dial Tone Duration' parameter, which is 16 sec. by default), expecting the Tel side to do some action (e.g., make another call, conferencing, or call transfer). If the 'Dial Tone Duration' parameter expires as no DTMF digits were collected (i.e., Tel side did nothing), the device plays a congestion tone to the Tel side (and if the Tel side goes on-hook, the phone rings and if the Tel side then goes off-hook, the IP side is retrieved).

The device also supports "double call hold" for FXS interfaces where the called party, which has been placed on-hold by the calling party, can then place the calling party on hold as well and make a call to another destination. The flowchart below provides an example of this type of call hold:

The flowchart above describes the following "double" call-hold scenario for analog interfaces:

1. A calls B and establishes a voice path.
2. A places B on hold; A hears a dial tone and B hears a held tone.
3. A calls C and establishes a voice path.
4. B places A on hold; B hears a dial tone.

5. B calls D and establishes a voice path.
6. A ends call with C; A hears a held tone.
7. B ends call with D.
8. B retrieves call with A.

For analog interfaces:

- If a party that is placed on hold (e.g., B in the above example) is called by another party (e.g., D), then the on-hold party receives a call waiting tone instead of the held tone.
- While in a Double Hold state, placing the phone on-hook disconnects both calls (i.e. call transfer is not performed).
- You can enable the device to handle incoming re-INVITE messages with 'a=sendonly' in the SDP, in the same way as if 'a=inactive' is received in the SDP. This is configured using the [SIPHoldBehavior] parameter. When enabled, the device plays a held tone to the Tel phone and responds with a 200 OK containing 'a=recvonly' in the SDP.

## Configuring MoH from External Audio Source

The device's Gateway application (FXS interfaces) can play Music on Hold (MoH) audio originating from an external, third-party media (audio) player, to call parties that are placed on hold. Implementing an external media source offers flexibility in the type of audio that you want played as MoH (e.g., radio, adverts, or music). If you are not using an external media source, the device plays its' local default hold tone or a hold tone from an installed PRT file (depending on your configuration). The device can forward this audio stream to any external IP-based system (for example, a softswitch, media gateway or SBC) or use it for SBC calls that it processes (applicable only to the SBC application). Thus, the device functions like an IP media server (audio streamer), except that the actual source of the media is from an external player.

The external media source is connected to the device's FXS port through a telephone adapter (for FXS emulation). The FXS port is always in off-hook state, continuously receiving media streams from the external media source. When the device receives a SIP INVITE for this port (IP-to-Tel call), it responds with a SIP 200 OK and forwards the audio stream to the sender of the INVITE.

Up to two FXS ports can be used for this feature, where each port can play media to up to 20 concurrent call sessions. In addition, each FXS port can play a specific media for MoH. For example, one port can play music while the other port can play advertising messages.

The following figure provides an example of this feature where each FXS port receives different audio from the external audio player, which the device forwards as music-on-hold to an external call processing system. The device determines which audio to play based on the phone number (destination) of the held call party.

➤ **To configure MoH from external audio streamer:**

1. Connect the external media player to one of the device's FXS ports through an FXS emulator (analog telephone adapter).
2. Open the Tel Profiles table (see [Configuring Tel Profile](#) on page 755), and then configure a Tel Profile with the following:
  - 'IP-to-Tel Cut-Through Call Mode' parameter configured to **CutThrough+Streaming**:

IP-to-Tel Cut-Through Call Mode

CutThrough+Streaming

- 'Coders Group' parameter assigned to the required Coder Group (configured with one coder).
3. Open the Trunk Groups table (see [Configuring Trunk Groups](#) on page 934), and then configure a Trunk Group for the FXS port to which the external media player is connected. Specify the phone number and Trunk Group ID, and assign it the Tel Profile that you configured in the previous step.

Group Index	Module	From Trunk	To Trunk	Channels	Phone Number	Trunk Group ID	Tel Profile Name
1	Module 2 FXS	1	1	1	4444	1	MoH

4. Open the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937), and then for the Trunk Group that you configured in the previous step, configure the 'Channel Select Mode' parameter to **By Dest Phone Number**.

INDEX ↕	NAME	TRUNK GROUP ID	CHANNEL SELECT MODE
0	MoH	1	By Dest Phone Number

5. Open the IP-to-Tel Routing table (see [Configuring IP-to-Tel Routing Rules](#) on page 960), and then configure a routing rule to route INVITE messages from the remote IP call entity to which you want to play MoH, to the FXS port. Configure the rule as follows:
  - 'Destination Type': **Trunk Group**
  - 'Trunk Group ID': **1** (as configured in Step 3 above)
  - Configure a specific matching characteristics, for example, 'Source Host Pattern': **mypizza.com**
6. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**), and then in the 'Maximum simultaneous streaming calls' field (MaxStreamingCalls), enter the maximum number of concurrent calls that the FXS port can service for playing MoH.
7. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

You can forcibly stop or start audio streaming on the FXS port(s) through CLI:

- To start audio streaming:

```
admin streaming start <FXS Channel>|all
```

- To stop audio streaming:

```
admin streaming stop <FXS Channel>|all
```

- The feature is applicable only to the Gateway application (FXS interfaces). However, you can also use this feature for playing MoH to SBC calls. For this scenario, you need to configure a routing rule between the SBC application (IP-to-IP Routing rule with 'Destination Type' parameter configured to **Gateway**) and the Gateway application (IP-to-Tel Routing table, as described above).
- You must configure the 'Maximum simultaneous streaming calls' parameter to a value greater than 0.
- Each FXS port that is used for this audio streaming service must be configured with its own dedicated Tel Profile, Trunk Group, and IP-to-Tel Routing rule.
- Only one coder can be configured for the port. If the device receives an INVITE/re-INVITE with a coder that is different to the one configured for the Tel Profile, the device rejects it.
- If the external audio streamer is disconnected or powered off, the FXS port changes to on-hook state and the device stops playing MoH to call parties that are currently on hold (by sending a SIP BYE).
- If the port goes on-hook or the number of concurrent sessions exceed the configured maximum, the device rejects all streaming sessions with a SIP BYE response.
- If your streaming service is working and you want to modify its configuration, after you have modified configuration you need to restart the service.

## Call Pickup

The Call Pickup feature allows any FXS user (endpoint) to pick up (answer) an incoming call (ringing) of another FXS user within the same Trunk Group ID. Call pickup is done by pressing (dialing) a user-defined sequence of phone keys (e.g., "#77"). When the FXS user presses this call-pickup key sequence and the phone of another FXS user is ringing, the incoming call is automatically forwarded to the FXS user attempting to pick up the call. For example, assume that three FXS phones are connected to the device and configured with the following:

- Phone numbers: 100, 200 and 300
- Trunk Group ID: #1
- Call-pickup key sequence: "#77"

If there is an incoming call for FXS user whose phone number is 100, FXS user whose phone number is 300 can pick up the call by dialing "#77".

- The Call Pickup feature is supported only for FXS endpoints within the same Trunk Group ID.
- For the Call Pickup feature, the channel select mode ('Channel Select Mode') of the FXS endpoints' Trunk Group must be configured to **By Dest Phone Number** (see [Configuring Trunk Group Settings](#) on page 937).
- If more than one FXS phone is ringing and an FXS user dials the call-pickup key sequence, the first phone number configured in the Trunk Groups table is picked up. In our example (above), if FXS endpoints 100 and 200 are ringing and FXS endpoint 300 dials the call-pickup key sequence, the incoming call for FXS endpoint 100 is picked up (forwarded to FXS endpoint 300).

➤ **To configure the call-pickup key sequence:**

1. Open the Keypad Features page (**Setup** menu > **Signaling & Media** tab > **Analog Gateway** folder > **Keypad Features**).
2. In the 'Call Pickup Key' field (KeyCallPickup), enter the sequence of phone keys for call pickup.

Call Pickup Key

3. Click **Apply**.

## BRI Suspend and Resume

The device supports call suspend and resume services initiated by ISDN BRI phones connected to the device. During an ongoing call, the BRI phone user can suspend the call by typically pressing the phone's "P" button or a sequence of keys (depending on the phone), and then on-hooking the handset. To resume the call, the phone user typically presses the same keys or button and then off-hooks the phone. During the suspended state, the device plays a howler tone to the remote party. This service is also supported when instead of pressing the call park button(s), the phone cable is disconnected (suspending the call) and then reconnected again (resuming the call). If the phone user doesn't resume the call within a user-defined interval (configured by the HeldTimeout parameter), the device releases the call.

Only one call can be suspended per trunk. If another suspend request is received from a BRI phone while there is already a suspended call (even if done by another BRI phone connected to the same trunk), the device rejects this suspend request.

## Consultation Feature

The device's Consultation feature allows you to place a call on hold and then make a second call to another party.

- After placing a call on hold (by pressing hook-flash), the holding party hears a dial tone and can initiate a new call, which is called a Consultation call.

- While hearing a dial tone or when dialing to the new destination (before dialing is complete), the user can retrieve the held call by pressing hook-flash.
- The held call can't be retrieved while ringback tone is heard.
- After the Consultation call is connected, the user can toggle between the held and active call by pressing the hook-flash key.

Consultation calls are applicable only to FXS interfaces.

## Call Transfer

This section describes configuration of call transfer for the Gateway application.

### Consultation Call Transfer

The device supports Consultation Call Transfer. For analog interfaces: It supports Consultation Call Transfer using the SIP REFER message and the Replaces header.

The common method to perform consultation transfer is described in the following example, which assumes three call parties:

- A = transferring party
  - B = transferred party
  - C = transferred to party
1. A Calls B.
  2. B answers.
  3. A presses the hook-flash button and places B on-hold (party B hears a hold tone).
  4. A dials C.
  5. After A completes dialing C, A on-hooks the phone to transfer the call so that the call is established between B and C.

The transfer can be initiated at any of the following stages of the call between A and C:

- Immediately after A completes dialing C (transfer at call setup)
- While A hears a ringback (transfer from alert)
- While A speaks to C (transfer from active)

For FXS interfaces: The device can also handle call transfers using SIP INVITE and re-INVITE messages, instead of REFER messages. This is useful when communicating with SIP UAs that do not support the receipt of REFER messages. This feature is applicable to FXS interfaces. To enable this support, use the `EnableCallTransferUsingReinvites` parameter.

**For BRI interfaces:** The device also supports attended (consultation) call transfer for BRI phones (user side) connected to the device and using the Euro ISDN protocol. BRI call transfer is according to ETSI TS 183 036, Section G.2 (Explicit Communication Transfer – ECT). Call transfer is enabled using the EnableTransfer and EnableHoldtoISDN parameters.

➤ **To configure call transfer for connected BRI phones:**

1. Open the Supplementary Services Settings page (Setup menu > Signaling & Media tab > Gateway folder > DTMF & Supplementary > Supplementary Services Settings).
2. Select the 'Enable Hold to ISDN' check box (EnableHoldtoISDN):

Enable Hold to ISDN ☒

3. Select the 'Enable Transfer' check box (EnableTransfer) to enable call transfer:

Enable Transfer ☒

4. Click **Apply**.

The Explicit Call Transfer (ECT, according to ETS-300-367, 368, 369) supplementary service is supported for BRI and PRI trunks. This service provides the served user who has two calls to ask the network to connect these two calls together and release its connection to both parties. The two calls can be incoming or outgoing calls. This service is similar to NI-2 Two B-Channel Transfer (TBCT) Supplementary Service. The main difference is that in ECT one of the calls must be in HELD state. The ECT standard defines two methods - Implicit and Explicit. In implicit method, the two calls must be on the same trunk. BRI uses the implicit mechanism. PRI uses the explicit mechanism.

## Consultation Transfer for QSIG Path Replacement

The device can interwork consultation call transfer requests for ISDN QSIG-to-IP calls. When the device receives a request for a consultation call transfer from the PBX, the device sends a SIP REFER message with a Replaces header to the SIP UA to transfer it to another SIP UA. Once the two SIP UA parties are successfully connected, the device requests the PBX to disconnect the ISDN call, thereby freeing resources on the PBX.

For example, assume legacy PBX user "A" has two established calls connected through the device – one with remote SIP UA "B" and the other with SIP UA "C". In this scenario, user "A" initiates a consultation call transfer to connect "B" with "C". The device receives the consultation call transfer request from the PBX and then connects "B" with "C", by sending "B" a REFER message with a Replaces header (i.e., replace caller "A" with "C"). Upon receipt of a SIP NOTIFY 200 message in response to the REFER, the device sends a Q.931 Disconnect messages to the PBX, notifying the PBX that it can disconnect the ISDN calls (of user "A").

This feature is enabled by the QSIGPathReplacementMode parameter.

The feature is applicable only to digital interfaces.

## Blind Call Transfer

Blind call transfer is done (using SIP REFER messages) after a call is established between call parties A and B, and party A decides to immediately transfer the call to C without first speaking to C. The result of the transfer is a call between B and C (similar to consultation transfer, but skipping the consultation stage).

### For digital interfaces:

You can also use the ManipulateIP2PSTNReferTo parameter to manipulate the destination number according to the number received in the SIP Refer-To header. This is applicable to all types of blind transfers to the PSTN (e.g., TBCT, ECT, RLT, QSIG, FXO, and CAS). During blind transfer, the device initiates a new call to the PSTN and the destination number of this call can be manipulated if the parameter is enabled. The following is an example of such a blind transfer:

1. IP phone A calls PSTN phone B, and the call is established.
2. A performs a blind transfer to PSTN phone C. It does this as follows:
  - a. A sends a SIP REFER message (with the phone number of C in the Refer-To header) to the device.
  - b. The device sends a Q.931 Setup message to C. This feature enables manipulating the called party number in this outgoing Setup message.

The manipulation is done as follows:

1. If you configure a value for the xferPrefix parameter, the value (string) is added as a prefix to the number in the Refer-To header.
2. This called party number is then manipulated using the Destination Phone Number Manipulation for IP-to-Tel Calls table.
3. The source number of the transferred call is taken from the original call, according to its initial direction:
  - Tel-to-IP call: source number of the original call.
  - IP-to-Tel call: destination number of the original call.
  - If the UseReferredByForCallingNumber parameter is set to 1, the source number is taken from the SIP Referred-By header if included in the received SIP REFER message.

This source number can also be used as the value for the 'Source Phone Pattern' field in the Destination Phone Number Manipulation for IP-to-Tel Calls table. The local IP address is used as the value for the 'Source IP Address' field.

Manipulation using the ManipulateIP2PSTNReferTo parameter doesn't affect IP-to-Trunk Group routing rules.

## Call Forward

### For digital interfaces:

The device supports Call Deflection (ETS-300-207-1) for Euro ISDN and QSIG (ETSI TS 102 393) for Network and User sides, which provides IP-ISDN interworking of call forwarding (call diversion) when the device receives a SIP 302 response.

Call forward performed by the SIP side: Upon receipt of a Facility message with Call Rerouting IE from the PSTN, the device initiates a SIP transfer process by sending a SIP 302 (including the Call Rerouting destination number) to the IP in response to the remote SIP entity's INVITE message. The device then responds with a Disconnect message to the PSTN side.

Call forward performed by the PSTN side: When the device sends the INVITE message to the remote SIP entity and receives a SIP 302 response, the device sends a Facility message with the same IE mentioned above to the PSTN, and waits for the PSTN side to disconnect the call. This is configured using the CallReroutingMode.

### For analog interfaces:

The following methods of call forwarding are supported:

- Immediate: incoming call is forwarded immediately and unconditionally.
- Busy: incoming call is forwarded if the endpoint is busy.
- No Reply: incoming call is forwarded if it isn't answered for a specified time.
- On Busy or No Reply: incoming call is forwarded if the port is busy or when calls are not answered after a specified time.
- Do Not Disturb: immediately reject incoming calls. Upon receiving a call for a Do Not Disturb, the 603 Decline SIP response code is sent.

Three forms of forwarding parties are available:

- Served party: party configured to forward the call (FXS device). To configure this type of forwarding party and per endpoint, see [Configuring Call Forward](#) on page 1099.
- Originating party: party that initiates the first call (FXS or FXO).
- Diverted party: new destination of the forwarded call (FXS or FXO).

- When call forward is initiated, the device sends a SIP 302 response with a contact that contains the phone number from the Call Forward table (see [Configuring Call Forward](#) on page 1099) and its corresponding IP address from the routing table (or when a proxy is used, the proxy's IP address).
- For receiving call forward, the device handles SIP 3xx responses for redirecting calls with a new contact.

## Enabling Call Forwarding

The following procedure describes how to enable call forwarding.

### ➤ To enable call forwarding:

1. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).
2. Select the 'Enable Call Forward' check box (EnableForward):

Enable Call Forward

3. Click **Apply**.

To configure call forwarding per analog interface port, see [Configuring Call Forward](#) on page 1099.

## Call Forward Reminder Ring

The device supports the Call Forward Reminder Ring feature for FXS interfaces whereby the device's FXS endpoint emits a short ring burst when a third-party Application server forwards an incoming call to another destination. The ring is emitted only when the endpoint is in on-hook state.

The feature is applicable only to FXS interfaces.

The feature is useful in that it notifies the endpoint user that a call forwarding service is currently being performed. The device generates a call forward reminder ring burst to the endpoint upon receipt of a SIP NOTIFY message containing a "reminder ring" xml body. The NOTIFY message is sent by the Application server to the device each time the server forwards an incoming call. The service is canceled when the device sends an UNSUBSCRIBE request or when the subscription time expires.

The following procedure describes how to configure the feature.

➤ **To configure call forward reminder ring:**

1. Open the Message Waiting Indicator Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Message Waiting Indicator Settings**).
2. From the 'AS Subscribe IP Group Name' drop-down list (ASSubscribeIPGroupName), select the IP Group representing the Application server providing the call forward reminder service:

AS Subscribe IP Group Name • #0 [Default\_IPG] [View](#)

3. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**), and then do the following:
  - a. Select the 'Enable NRT Subscription' check box (EnableNRTSubscription) to enable endpoint subscription to ring reminder event notification.
  - b. In the 'NRT Subscribe Retry Time' field (NRTSubscribeRetryTime), enter the retry period (in seconds) for dialog subscription to the Application server if a previous request fails.

Enable NRT Subscription • ☒

NRT Subscribe Retry Time

- c. Configure the reminder ring tone:
  - i. Configure a tone for the reminder ring in the Call Progress Tone (CPT) file (see [Call Progress Tones File](#) on page 1351).
  - ii. In the 'Call Forward Ring Tone ID' field (CallForwardRingToneID), enter the ID number of the tone that you defined in the previous step.

Call Forward Ring Tone ID

4. Click **Apply**.

## Call Forward Reminder (Off-Hook) Special Dial Tone

The device plays a special dial tone (stutter dial tone - Tone Type #15) to a specific FXS endpoint when the phone is off-hooked and when a third-party Application server (e.g., a softswitch) is used to forward calls intended for the endpoint to another destination. This is useful in that it reminds the FXS user of this service. The feature doesn't involve device subscription (SIP SUBSCRIBE) to the Application server.

The feature is applicable only to FXS interfaces.

Activation/deactivation of the service is notified by the server. An unsolicited SIP NOTIFY request is sent from the Application server to the device when the Call Forward service is activated or de-activated. Depending on this NOTIFY request, the device plays either the standard dial tone or the special dial tone for Call Forward.

For playing the special dial tone, the received SIP NOTIFY message must contain the following headers:

- **From and To:** contain the same information, indicating the specific endpoint
- **Event:** "ua-profile"
- **Content-Type:** "application/simserv+xml"
- Message body is the XML body and contains the "dial-tone-pattern" set to "special-condition-tone", which is the special tone indication:

```
<ss:dial-tone-pattern>special-condition-tone</ss:dial-tone-pattern>
```

To cancel the special dial tone and playing the regular dial tone, the received SIP NOTIFY message must contain the following headers:

- **From and To:** contain the same information, indicating the specific endpoint
- **Event:** ua-profile
- **Content-Type:** "application/simserv+xml"
- Message body is the XML body containing the "dial-tone-pattern" set to "standard-condition-tone", which is the regular dial tone indication:

```
<ss:dial-tone-pattern>standard-condition-tone</ss:dial-tone-pattern>
```

Therefore, the special dial tone is valid until another SIP NOTIFY is received that instructs otherwise (as described above).

If the MWI service is active, the MWI dial tone overrides this special Call Forward dial tone.

## Call Forward Reminder Dial Tone (Off-Hook) upon Spanish SIP Alert-Info

The device plays a special dial tone to FXS phones in off-hook state that are activated with the call forwarding service. The special dial tone is used as a result of the device receiving a SIP NOTIFY message from a third-party softswitch providing the call forwarding service with the following SIP Alert-Info header:

```
Alert-Info: <http://127.0.0.1/Tono-Espec-Invitacion>;lpi-aviso=Desvio-Inmediato
```

This special tone is a stutter dial tone (Tone Type = 15), as defined in the CPT file (see [Call Progress Tones File](#) on page 1351).

The FXS phone user, connected to the device, activates the call forwarding service by dialing a special number (e.g., \*21\*xxxxx) and as a result, the device sends a regular SIP INVITE message to the softswitch. The softswitch later notifies of the activation of the forwarding service by sending an unsolicited NOTIFY message with the Alert-Info header, as mentioned above. When the call forwarding service is de-activated, for example, by dialing #21# and sending an INVITE with this number, the softswitch sends another SIP NOTIFY message with the following Alert-Info header:

```
Alert-Info: <http://127.0.0.1/ Tono-Normal-Invitacion>; Aviso = Desvió-Inmediato
```

From this point on, the device plays a normal dial tone to the FXS phone when it goes off-hook.

The feature is applicable only to FXS interfaces.

## Remote Handling of BRI Call Forwarding

The device supports call forwarding (CF) services initiated by ISDN Basic BRI phones connected to it. Upon receipt of an ISDN Facility message for call forward from the BRI phone, the device sends a SIP INVITE to the softswitch with a user-defined code (see procedure below) in the SIP To header, indicating the call forward reason.

The feature is applicable only to BRI interfaces.

*call forward service* can be one of the following:

- “cfu-activate”: Call Forwarding Unconditional activated
- “cfu-deactivate”: Call Forwarding Unconditional deactivated
- “cfb-activate”: Call Forward on Busy activated

- “cfb-deactivate”: Call Forward on Busy deactivated
- “cfnr-activate”: Call Forward on No Reply activated
- “cfnr-deactivate”: Call Forward on No Reply deactivated

For example:

```
INVITE sip:400@10.33.2.48;user=phone;facility=cfu-activate SIP/2.0
```

To enable the feature, configure the UseFacilityInRequest ini file parameter to 1.

➤ **To configure the digit codes for call forwarding services by BRI phones:**

1. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).

BRI TO SIP SUPPLEMENTARY SERVICES CODES	
Call Forward Unconditional code	<input type="text"/>
Call Forward Unconditional Deactivation	<input type="text"/>
Call Forward on Busy Code	<input type="text"/>
Call Forward on Busy Deactivation	<input type="text"/>
Call Forward on No Reply Code	<input type="text"/>
Call Forward on No Reply Deactivation	<input type="text"/>

2. Under the BRI To SIP Supplementary Codes group, configure the reason codes for call forward:
  - 'Call Forward Unconditional code' (SuppServCodeCFU)
  - 'Call Forward Unconditional Deactivation' (SuppServCodeCFUDeact)
  - 'Call Forward on Busy Code' (SuppServCodeCFB)
  - 'Call Forward on Busy Deactivation' (SuppServCodeCFBDeact)
  - 'Call Forward on No Reply Code' (SuppServCodeCFNR)
  - 'Call Forward on No Reply Deactivation' (SuppServCodeCFNRDeact)
3. Click **Apply**.

The call forward codes must be configured according to the settings of the softswitch (i.e., the softswitch must recognize them).

Below is an example of an INVITE message sent by the device indicating an unconditional call forward (“\*72”) to extension number 100. The code is configured by the SuppServCodeCFU parameter.

```
INVITE sip:*72100@10.33.8.53;user=phone SIP/2.0
Via: SIP/2.0/UDP
10.33.2.5:5060;branch=z9hG4bKWDSUKUHWFEQSVUUVJGM
From: <sip:400@10.33.2.5;user=phone>;tag=DUOROSXSOYJLNBFRQTG
To: <sip:*72100@10.33.8.53;user=phone>
Call-ID: GMNOVQRRXUUCYCQSFAHS@10.33.2.5
CSeq: 1 INVITE
Contact: <sip:400@10.33.2.5:5060>
Supported: em,100rel,timer,replaces
Allow:
REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK,REFER,INFO,SUBSCRIBE
User-Agent: Sip Message Generator V1.0.0.5
User-to-User: 31323334;pd=4
Content-Type: application/sdp
Content-Length: 155
```

## Local Handling of BRI Call Forwarding

You can configure the device to handle BRI call forwarding per BRI extension line, using the Supplementary Services table.

The feature is applicable only to BRI interfaces.

Upon receipt of an ISDN Facility message from the BRI phone user, the device retrieves and stores the user's call forwarding information. This includes whether the user has activated or de-activated call forwarding as well as the type of call forwarding service (Call Forward Busy, Call Forward No Reply, and Call Forward Unconditional). When the device receives a call (INVITE message) for a user whose phone number is configured in the 'Local Phone Number' field of the Supplementary Services table and call forwarding has been activated by the user, the device replies to the calling party with a SIP 302 (Moved Temporarily) response containing the configured call forwarding number corresponding to the call forwarding type. The call forwarding type and original called number (user's phone number) is sent in the SIP Diversion header, for example:

```
Diversion: <sip:401>;reason=unconditional;counter=1
```

The call forwarding number is sent in the SIP Contact header, for example:

```
Contact: sip:567@10.33.77.17;user=phone
```

When call forwarding is activated and the user off-hooks the phone, the device plays the stutter dial tone (Tone Type #15) as a reminder to the user that call forwarding is activated.

➤ **To configure BRI call forwarding:**

1. Open the Supplementary Services table (see [Configuring Multi-Line Extensions and Supplementary Services](#) on page 1073), and then configure BRI line extensions with the required call forwarding parameters:

User Password	<input type="password"/>
CFB Phone Number	<input type="text"/>
CFNR Phone Number	<input type="text"/>
CFU Phone Number	<input type="text"/>
No Reply Time	<input type="text" value="30"/>

For more information, see [Configuring Multi-Line Extensions and Supplementary Services](#) on page 1073.

2. Enable BRI call forwarding, by using the following ini file parameter setting:

```
BRICallForwardHandling=1
```

3. Open the Trunk Groups table ([Configuring Trunk Groups](#) on page 934), and then configure a Trunk Group (e.g., 1) for the BRI ports.
4. Open the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937), and then for the Trunk Group ID to which the BRI ports belong, set the 'Channel Select Mode' parameter to **Select Trunk by Supp-Serv Table**:

Trunk Group ID	<input type="text" value="1"/>
Channel Select Mode	<input type="text" value="Select Trunk by Supp-Serv Table"/>

5. Open the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878), and then make sure that you configure the BRI ports with the following settings:
  - 'Protocol Type': **BRI EURO ISDN**
  - 'ISDN Termination Side': **Network Side**
  - 'BRI Layer2 Mode': **Point to Multipoint**

GENERAL	
Module ID	2
Trunk ID	1
Trunk Configuration State	Inactive
Protocol Type	BRI EURO ISDN

BRI CONFIGURATION	
Auto Clock Trunk Priority	0
Trace Level	No Trace
ISDN Termination Side	Network side
BRI Layer2 Mode	Point To Multipoint

## Enabling Call Waiting

The Call Waiting feature enables busy FXS endpoints connected to the device to accept an additional (second) call. If an incoming IP call is designated to a busy port, the called FXS endpoint hears a call waiting tone (several configurable short beeps) and can view the Caller ID of the incoming call (for Bellcore and ETSI Caller IDs). The calling party hears a call waiting ringback tone. The called party can accept the new call using hook-flash and can toggle between the two calls. To indicate call waiting, the device sends a SIP 182 (Call Queued) response. The device identifies call waiting when a 182 (Call Queued) response is received.

- The feature is applicable only to FXS and FXO interfaces. FXS interfaces support the calling and called sides. FXO interfaces support only the calling side.
- You can enable call waiting per port in the Call Waiting table (see [Configuring Call Waiting](#) on page 1103). For ports that are not configured in the table, call waiting is according to the global parameter, as described in the procedure below.

### ➤ To enable and configure call waiting:

1. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).
2. Select the 'Enable Call Waiting' check box (EnableCallWaiting):

Enable Call Waiting

3. Configure call waiting indication and call waiting ringback tones in the Call Progress Tones file (see [Call Progress Tones File](#) on page 1351). You can configure up to four call waiting indication tones (see the FirstCallWaitingToneID parameter). To configure call waiting tones per FXS port(s) based on source or destination number, see [Configuring FXS Distinctive Ringing and Call Waiting Tones per Source/Destination Number](#) on page 1105.

4. In the 'Number of Call Waiting Indications' field (NumberOfWaitingIndications), enter the number of call waiting indications that can be played to the endpoint.
5. In the 'Time Between Call Waiting Indications' field (TimeBetweenWaitingIndications), enter the time (in seconds) between consecutive call waiting indications.
6. In the 'Time Before Waiting Indications' field (TimeBeforeWaitingIndication), enter the delay interval before a call waiting indication tone is played to the busy endpoint. This enables the caller to hang up before disturbing the called party with call waiting indications.
7. In the 'Waiting Beep Duration' field (WaitingBeepDuration), enter the duration (in msec) that the call waiting indication is played to the endpoint.
8. Select the 'Enable Hold' check box (EnableHold) to enable call hold:

Enable Hold

## Message Waiting Indication

The device supports Message Waiting Indication (MWI) according to IETF RFC 3842. The device also supports subscribing to an MWI server (using SIP SUBSCRIBE messages).

For FXS interfaces: The device can accept a SIP MWI NOTIFY message that indicates waiting messages or cleared messages. Users are informed of these messages by a stutter dial tone. You can define the stutter and confirmation tones in the CPT file. If the MWI display is configured, the number of waiting messages is also displayed. If the MWI lamp is configured, the phone's lamp (on a phone that is equipped with an MWI lamp) is lit. The device can subscribe to the MWI server per port (usually used on FXS) or per device (used on FXO).

For more information on configuring IP-based voice mail, refer to the *IP Voice Mail CPE Configuration Guide*.

To configure MWI, use the following parameters:

- EnableMWI
- MWIServerIP, or MWISubscribeIPGroupID and ProxySet
- MWIAnalogLamp (FXS interfaces only)
- MWIDisplay (FXS interfaces only)
- StutterToneDuration (FXS interfaces only)
- EnableMWISubscription
- MWIExpirationTime
- SubscribeRetryTime
- SubscriptionMode

- CallerIDType - determines the standard for detection of MWI signals (FXS interfaces only)
- ETSIVMWITypeOneStandard (FXS interfaces only)
- BellcoreVMWITypeOneStandard (FXS interfaces only)
- VoiceMailInterface
- EnableVMURI

The device supports the following PSTN-based (digital) MWI features:

- ISDN BRI: The device supports MWI for its BRI phones, using the Euro ISDN BRI variant. When this feature is activated and a voice mail message is recorded to the mail box of a BRI extension, the softswitch sends a notification to the device. In turn, the device notifies the BRI extension and a red light flashes on the BRI extension's phone. Once the voice message is retrieved, the MWI light on the BRI phone turns off. This is configured by setting the VoiceMailInterface parameter to 8 ("ETSI") and enabled by the EnableMWI parameter.
- Euro-ISDN MWI: The device supports Euro-ISDN MWI for IP-to-Tel calls. The device interworks SIP MWI NOTIFY messages to Euro-ISDN Facility information element (IE) MWI messages. This is configured by setting the VoiceMailInterface parameter to 8.
- ISDN PRI NI-2: The device support the interworking of the SIP MWI NOTIFY messages to ISDN PRI NI-2 Message Waiting Notification (MWN), sent in the ISDN Facility IE message. This is applicable when the device is connected to a PBX through an ISDN PRI trunk configured to NI-2. This is configured by setting the VoiceMailInterface parameter to [9].
- QSIG MWI: The device supports the interworking of QSIG MWI to IP (in addition to interworking of SIP MWI NOTIFY to QSIG Facility MWI messages). This provides interworking between an ISDN PBX with voice mail capabilities and a softswitch, which requires information on the number of messages waiting for a specific user. To enable this feature, use the 'MWI Interrogation Type' parameter in the Trunk Group Settings table, which defines the device's handling of MWI Interrogation messages. The process for sending the MWI status upon request from a softswitch is as follows:
  - a. The softswitch sends a SIP SUBSCRIBE message to the device.
  - b. The device responds by sending an empty SIP NOTIFY to the softswitch, and then sending an ISDN Setup message with Facility IE containing an MWI Interrogation request to the PBX.
  - c. The PBX responds by sending to the device an ISDN Connect message containing Facility IE with an MWI Interrogation result, which includes the number of voice messages waiting for the specific user.
  - d. The device sends another SIP NOTIFY to the softswitch, containing this MWI information.
  - e. The SIP NOTIFY messages are sent to the IP Group defined by the [NotificationIPGroupName] parameter.

When a change in the status occurs (e.g., a new voice message is waiting or the user has retrieved a message from the voice mail), the PBX initiates an ISDN Setup message with

Facility IE containing an MWI Activate request, which includes the new number of voice messages waiting for the user. The device forwards this information to the softswitch by sending a SIP NOTIFY.

Depending on PBX support, the MWIInterrogationType parameter can be configured to handle these MWI Interrogation messages in different ways. For example, some PBXs support only the MWI Activate request (and not MWI Interrogation request). Some support both these requests. Therefore, the device can be configured to disable this feature or enable it with one of the following support:

- Responds to MWI Activate requests from the PBX by sending SIP NOTIFY MWI messages (i.e., doesn't send MWI Interrogation messages).
- Send MWI Interrogation message, but don't use its result. Instead, wait for MWI Activate requests from the PBX.
- Send MWI Interrogation message, use its result, and use the MWI Activate requests.

## Caller ID

This section describes the device's Caller ID support.

The feature is applicable only to analog interfaces.

## Enabling Caller ID Generation and Detection on Tel Side

The device's Caller ID support depends on the type of analog interface:

- FXS interfaces: The device sends (generates) the Caller ID signal to the device's FXS port.
- FXO interfaces: The device detects the Caller ID signal from the FXO port.

You can enable Caller ID generation (FXS interfaces) and detection (FXO interfaces) per port in the Caller ID Permissions table (see [Configuring Caller ID Permissions](#) on page 1101). For ports that are not configured in the table, Caller ID is according to the global parameter, as described in the procedure below.

The following procedure describes how to enable Caller ID for all analog ports.

### ➤ To enable Caller ID:

1. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).
2. Select the 'Enable Caller ID' check box (EnableCallerID):

Enable Caller ID

3. Click **Apply**.

Additional Caller ID parameters includes the following:

- **CallerIDType:** Defines the Caller ID standard. The configured standard Caller ID must match the standard used on the PBX or phone.
- **BellcoreCallerIDTypeOneSubStandard:** Defines the Bellcore Caller ID sub-standard.
- **ETSCallerIDTypeOneSubStandard:** Defines the ETSI FSK Caller ID sub-standard.
- **EnableCallerIDTypeTwo:** Enables generation of Caller ID type 2 when the phone is off-hooked (used for call waiting).
- **RingsBeforeCallerID:** (FXO interfaces only) Defines the number of rings before the device starts detection of Caller ID. By default, the device detects Caller ID between the first and second rings.
- **AnalogCallerIDTimingMode:** (FXS interfaces only) Defines the time period when a Caller ID signal is generated. By default, Caller ID is generated between the first two rings.
- **PolarityReversalType:** (FXS interfaces only) Defines reversal polarity and/or wink signals for Caller ID signals. It is recommended to configure the parameter to 1 (Hard).
- **UseSourceNumberAsDisplayName and UseDisplayNameAsSourceNumber:** Defines Caller ID interworking.

## Debugging a Caller ID Detection on FXO

The following procedure describes how to debug caller ID detection on FXO interfaces.

### ➤ To debug a Caller ID detection on an FXO interface:

1. Verify that the parameter `EnableCallerID` is set to 1.
2. Verify that the caller ID standard (and substandard) of the device matches the standard of the PBX (using the parameters `CallerIDType`, `BellcoreCallerIDTypeOneSubStandard`, and `ETSCallerIDTypeOneSubStandard`).
3. Define the number of rings before the device starts the detection of caller ID (using the parameter `RingsBeforeCallerID`).
4. Verify that the correct FXO coefficient type is configured (`[FXOCountryCoefficients]` parameter in [Analog Coefficient Types](#) on page 1107) because the device is unable to recognize caller ID signals that are distorted.
5. Connect a phone to the analog line of the PBX (instead of to the device's FXO interface) and verify that it displays the caller ID.

If the above doesn't solve the problem, you need to record the caller ID signal (and send it to AudioCodes), as described below.

### ➤ To record the caller ID signal using the debug recording mechanism:

1. Access the device's Admin Page, by appending "AdminPage" to the device's IP address in your browser's URL address field (e.g., 10.1.1.1/AdminPage).
2. In the left navigation pane, click **Cmd Shell**; the command shell interface opens.

3. In the 'Command Line' field, type the following:

```
dr  
ait <IP address of PC to collect the debug traces sent from the device>  
AddChannelIdTrace ALL-WITH-PCM <port number, which starts from 0>  
Start
```

4. Click **Enter**.
5. Make a call to the FXO.
6. To stop debug recording, at the CLI prompt, type **STOP**.

## Caller ID on IP Side

Caller ID for analog interfaces (Tel-to-IP calls) is provided by the SIP From header, containing the caller's name and "number", for example:

```
From: "John" <SIP:101@10.33.2.2>;tag=35dfsgasd45dg
```

If caller ID is restricted (received from Tel or configured), the From header is set to:

```
From: "anonymous" <anonymous@anonymous.invalid>; tag=35dfsgasd45dg
```

The P-Asserted (or P-Preferred) headers present the originating party's caller ID even when caller ID is restricted. These headers are used together with the Privacy header.

### ■ If Caller ID is restricted:

- The From header is set to "anonymous" <anonymous@anonymous.invalid>.
- The 'Privacy: id' header is included.
- The P-Asserted-Identity (or P-Preferred-Identity) header contains the caller ID.

### ■ If Caller ID is allowed:

- The From header contains the caller ID.
- The 'Privacy: none' header is included.
- The P-Asserted-Identity (or P-Preferred-Identity) header contains the caller ID.

The caller ID (and presentation) can also be displayed in the Calling Remote-Party-ID header.

The Caller Display Information table (see [Configuring Caller Display Information](#) on page 1097) is used for Tel-to-IP calls:

- **FXS interfaces:** Defines caller ID per FXS port that is sent to IP.

- **FXO interfaces:** Defines caller ID per FXO port that. The caller ID is sent to the IP side if caller ID isn't detected on the Tel side or when the [EnableCallerID] parameter is configured to 0.
- **FXS and FXO interfaces:** Defines the presentation of caller ID (allowed or restricted).
- **To maintain backward compatibility:** When the strings 'Private' or 'Anonymous' are set in the Caller ID/Name field, the caller ID is restricted and the value in the Presentation field is ignored.

The value of the 'Presentation' parameter in the Caller Display Information table can be overridden by configuring the 'Presentation' parameter in the Source Phone Number Manipulation for Tel-to-IP Calls table (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983). Therefore, this table can be used to configure the presentation for specific calls according to source / destination prefixes.

The caller ID can be restricted/allowed (per port) using keypad features [KeyCLIR] and [KeyCLIRDeact] (FXS only).

The [AssertedIdMode] parameter configures the header that is used (in the generated INVITE request) to deliver the caller ID (P-Asserted-Identity or P-Preferred-Identity). Use the parameter [UseTelURIForAssertedID] to configure the format of the URI in these headers (sip: or tel:).

The parameter [EnableRPIheader] enables Remote-Party-ID (RPI) headers for calling and called numbers for Tel-to-IP calls.

This section is applicable only to analog interfaces.

## Three-Way Conferencing

The device supports three-way conference calls. Three-way conferencing occurs when an endpoint connected to the FXS or BRI port initiates a call and invites two remote IP-based participants. The device also supports multiple, concurrent three-way conference calls.

The feature is applicable only to FXS and BRI interfaces.

The device supports the following three-way conference modes:

- **Conference Managed by External AudioCodes Conferencing (Media) Server:** The conference-initiating INVITE sent by the device uses the ConferenceID concatenated with a unique identifier as the Request-URI. This same Request-URI is set as the Refer-To header value in the REFER messages that are sent to the two remote parties. To enable this mode, configure the [3WayConferenceMode] parameter to [0] (default.)

To join a conference, the Request-URI includes the Conference ID string preceded by the number of the participants in the conference and terminated by a unique number. INVITE messages with the same URI join the same conference. For example:

```
INVITE sip:4conf1234@10.1.10.10
```

■ **Conference Managed by External, Third-party Conferencing Server: Two optional modes of operation:**

- The conference-initiating INVITE sent by the device uses only the ConferenceID as the Request-URI. The Conferencing server sets the Contact header of the 200 OK response to the actual unique identifier (Conference URI) to be used by the participants. The device includes this Conference URI in the SIP Refer-To header value in the REFER messages sent by the device to the remote parties. The remote parties join the conference by sending INVITE messages to the Conferencing server using this conference URI. To enable this mode, configure the [3WayConferenceMode] parameter to [1].
- The conference-initiating INVITE sent by the device uses only the ConferenceID as the Request-URI. The Conferencing server sets the Contact header of the 200 OK response to the actual unique identifier (Conference URI) to be used by the participants. The Conference URI is included in the URI of the REFER with a Replaces header sent by the device to the Conferencing server. The Conferencing server then sends an INVITE with a Replaces header to the remote participants. To enable this mode, configure the [3WayConferenceMode] parameter to [3].

When the device is used for Gateway and SBC applications, it can also support conference calls initiated by third-party network entities (e.g., Skype for Business) that use the same Conference server. To support these conference calls, you can do one of the following:

- ◆ Configure the third-party network entity with a Conference ID that is different from the Conference ID configured for the device.
- ◆ Configure the device with an Inbound Manipulation rule that is applied to calls received from the third-party network entity so that the device considers conference calls as regular calls and forwards them to the Conference server without getting involved in the conferencing setup.

To join a conference, the Request-URI includes the Conference ID string preceded by the number of the participants in the conference and terminated by a unique number. INVITE messages with the same URI join the same conference. For example:

```
INVITE sip:4conf1234@10.1.10.10
```

Three-way conferencing using an external conference server is applicable only to FXS interfaces.

- **Local, On-board Conferencing:** The conference is established on the device without the need for an external Conferencing server. The device supports up to five simultaneous, on-board, three-way conference calls. This feature supports local mixing and transcoding of

the three-way conferencing legs on the device and multiple codec conference calls. You can configure the maximum number of simultaneous, on-board conferences, using the [MaxInBoardConferenceCalls] parameter.

The device uses resources from DSPs for on-board conferencing calls. However, if there are no available resources from the device's pool of DSPs, the device obtains resources from idle FXS ports to establish the conference call. You can specify ports that you don't want to be used as a resource for conference calls that are initiated by other ports, using the [3WayConfNoneAllocateablePorts] parameter.

To enable this mode, configure the [3WayConferenceMode] parameter to [2].

- Three-way conferencing is applicable only to FXS and BRI interfaces.
- Instead of using the flash-hook button to establish a three-way conference call, you can dial a user-defined hook-flash code (e.g., "\*1"), configured by the HookFlashCode parameter.
- Three-way conferencing support for the BRI phones connected to the device complies with ETS 300 185.
- The device supports high definition, three-way conferencing using wideband codecs (e.g., G.722 and AMR-WB). This allows conference participants to experience wideband voice quality. Call conferences can also include narrowband and wideband participants.

The following example demonstrates three-way conferencing using the device's local, on-board conferencing feature. In the example, telephone "A" connected to the device establishes a three-way conference call with two remote IP phones, "B" and "C":

1. A establishes a regular call with B.
2. A places B on hold, by pressing the telephone's flash-hook button and the number "1" key.
3. A hears a dial tone and then makes a call to C.
4. C answers the call.
5. A establishes a three-way conference call with B and C, by pressing the flash-hook button and the number "3" key.

➤ **To configure three-way conferencing:**

1. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).

CONFERENCE	
Enable 3-Way Conference	<input type="checkbox"/> ⚡
Establish Conference Code	<input type="text" value="!"/>
Conference ID	<input type="text" value="conf"/>
3-Way Conference Mode	<input type="text" value="AudioCodes Media Server"/> ▼
Max. 3-Way Conference	<input type="text" value="2"/> ⚡
Non Allocatable Ports	<input type="text" value="0 x"/> ×

2. Select the 'Enable 3-Way Conference' check box (Enable3WayConference) to enable three-way conferencing.
3. From the '3-Way Conference Mode' drop-down list (3WayConferenceMode), select the three-way conference mode (e.g, **On Board**).
4. For the **On Board** mode:
  - In the 'Max. 3-Way Conference' field (MaxInBoardConferenceCalls), enter the maximum number of simultaneous, on-board three-way conference calls.
  - In the 'Non Allocatable Ports' field (3WayConfNoneAllocateablePorts), enter the FXS ports that you don't want to use to obtain resources for conference calls when there are unavailable DSP resources.
5. In the 'Conference ID' field (ConferenceID), enter the Conference Identification string. The valid value is a string of up to 16 characters. The default is "conf".
6. Configure one of the following for how the device recognizes a three-way conference request:
  - On the the Supplementary Services Settings page: In the 'Establish Conference Code' field (ConferenceCode), enter the DTMF digit pattern (e.g., hook flash) that upon detection generates the conference call.
  - On the Analog Settings (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Analog Settings**): From the 'Flash Keys Sequence Style' drop-down list (FlashKeysSequenceStyle), select **Sequence 1** or **Sequence 2** to use the flash + 3 key-combination to create the three way conference call.
7. Click **Apply** and then restart the device with a save-to-flash for your settings to take effect.

## Emergency E911 Phone Number Services

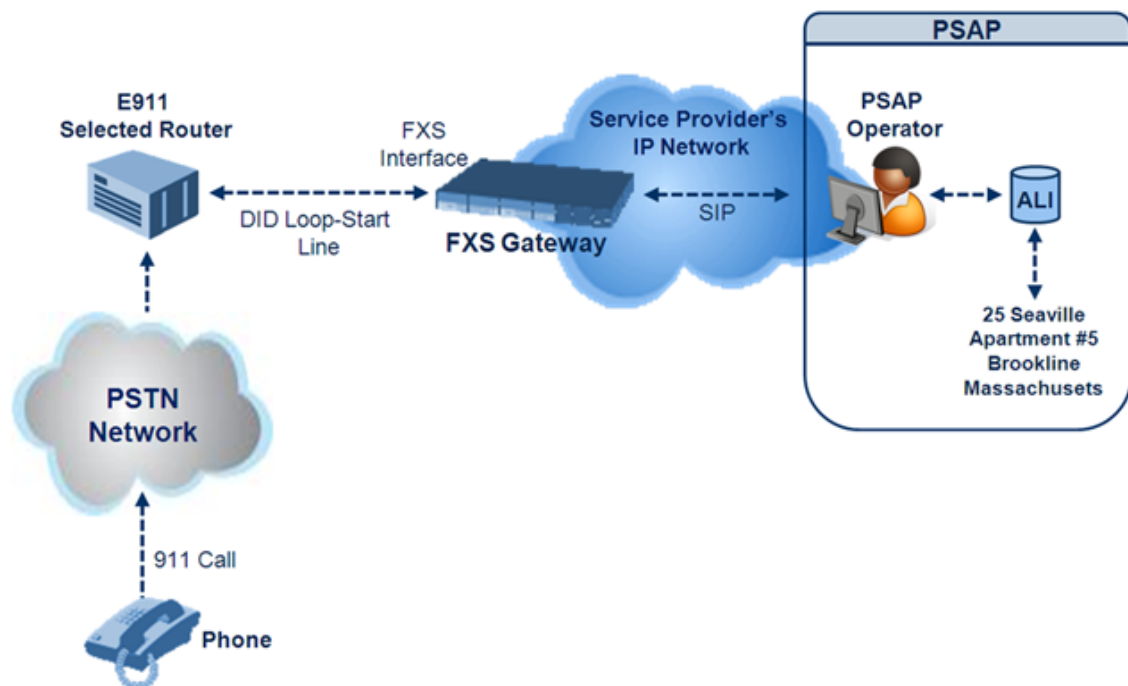

This section describes the device's support for emergency phone number services.

The device supports the North American emergency telephone number system known as Enhanced 911 (E911), according to the TR-TSY-000350 and Bellcore's GR-350-Jun2003 standards. The E911 emergency system automatically associates a physical address with the calling party's telephone number, and routes the call to the most appropriate (closest) Public Safety Answering Point (PSAP), allowing the PSAP to quickly dispatch emergency response (e.g., police) to the caller's location.

Typically, the dialed emergency number is routed to the appropriate PSAP by the telephone company's switch, known as a 911 Selective Router (or E911 tandem switch). If the PSAP receives calls from the telephone company on old-style digital trunks, they are specially formatted Multi-Frequency (MF) trunks that pass only the calling party's number (known as Automatic Number Identification - ANI). Once the PSAP receives the call, it searches for the physical address that is associated with the calling party's telephone number (in the Automatic Location Identification database - ALI).

### FXS Device Emulating PSAP using DID Loop-Start Lines

The device's FXS interface can be configured to emulate PSAP (using DID loop start lines), according to the Telcordia GR-350-CORE specification.

The call flow of an E911 call to the PSAP is as follows:

1. The E911 tandem switch seizes the line.
2. The FXS device detects the line seize, and then generates a wink signal (nominal 250 msec). The wink can be delayed by configuring the parameter [DelayBeforeDIDWink] to 200 (for 200 msec or a higher value).
3. The switch detects the wink and then sends the MF Spill digits with ANI and (optional) Pseudo-ANI (P ANI).

4. The FXS device collects the MF digits, and then sends a SIP INVITE message to the PSAP with all collected MF digits in the SIP From header as one string.
5. The FXS device generates a mid-call wink signal (two subsequent polarity reversals) toward the E911 tandem switch upon either detection of an RFC 2833 "hookflash" telephony event, or if a SIP INFO message with a "hookflash" body is received from the PSAP (see the example below). The duration of this "hookflash" wink signal is configured using the parameter [FlashHookPeriod] (usually 500 msec). Usually the wink signal is followed by DTMF digits sent by PSAP to perform call transfer. Another way to perform the call transfer is to use SIP REFER messages, as described below.
6. The FXS device supports call transfer initiated by the PSAP. If it receives a SIP REFER message with the Refer-To URI host part containing an IP address that is equal to the device's IP address, the FXS device generates a 500-msec wink signal (double polarity reversals), and then (after a user-defined interval configured by the parameter [WaitForDialTime]), plays DTMF digits according to the transfer number received in the SIP Refer-To header URI userpart.
7. When the call is answered by the PSAP operator, the PSAP sends a SIP 200 OK to the FXS device, and the FXS device then generates a polarity reversal signal to the E911 switch.
8. After the call is disconnected by the PSAP, the PSAP sends a SIP BYE to the FXS device, and the FXS device reverses the polarity of the line toward the tandem switch.

The following parameters need to be configured:

- [EnableDIDWink = 1]
- [EnableReversalPolarity = 1]
- [PolarityReversalType = 1]
- [FlashHookPeriod = 500] - for 500 msec "hookflash" mid-call Wink
- [WinkTime = 250] - for 250 msec signalling Wink generated by the FXS device after it detects the line seizure
- [EnableTransfer = 1] - for call transfer
- [LineTransferMode = 1] - for call transfer
- [WaitforDialTime = 1000] - for call transfer
- [SwapTEI2IPCalled&CallingNumbers = 1]
- [DTMFDetectorEnable = 0]
- [MFR1DetectorEnable = 1]
- [DelayBeforeDIDWink = 200] - for 200 msec and can be configured in the range from 0 (default) to 1000

Modification of the [WinkTime] parameter requires a device restart.

The outgoing SIP INVITE message contains the following headers:

```

INVITE sip:Line@DomainName
From: <sip:*81977820#@sipgw>;tag=1c143
To: <sip:Line@DomainName>

```

Where:

- *Line* = as configured in the Endpoint Phone Number Table
- *SipGtw* = configured by the [SIPGatewayName] parameter
- *From* header/user part = calling party number as received from the MF spill

The ANI and the pseudo-ANI numbers are sent to the PSAP either in the From and/or P-AssertedID SIP header.

Typically, the MF spills are sent from the E911 tandem switch to the PSAP, as shown in the table below:

**Table 28-1: Dialed MF Digits Sent to PSAP**

Digits of Calling Number	Dialed MF Digits
8 digits "nnnnnnnn" (ANI)	"KPnnnnnnnnST"
12 digits "nnnnnnnnnnnn" (ANI)	"KPnnnnnnnnnnnnSTP"
12 digits ANI and 10 digits PANI	"KPnnnnnnnnnnnnSTKPmmmmmmmmmmST"
two digits "nn"	"KPnnSTP"

The MF KP, ST, and STP digits are mapped as follows:

- \* for KP
- # for ST
- B for STP

For example, if ANI and PANI are received, the SIP INVITE contains the following From header:

```

From: <sip:*nnnnnnnnnnnn#*mmmmmmmmmm#@10.2.3.4>;tag=1c14

```

It is possible to remove the \* and # characters, using the device's number manipulation rules.

If the device receives the SIP INFO message below, it then generates a "hookflash" mid-call Wink signal:

```

INFO sip:4505656002@192.168.13.40:5060 SIP/2.0
Via: SIP/2.0/UDP 192.168.13.2:5060

```

```

From: port1vega1 <sip:06@192.168.13.2:5060>
To: <sip:4505656002@192.168.13.40:5060>;tag=132878796-1040067870294
Call-ID: 0010-0016-D69A7DA8-1@192.168.13.2

Content-Type: application/broadsoft
Content-Length: 17
event flashhook

```

## FXO Device Interworking SIP E911 Calls from Service Provider's IP Network to PSAP DID Lines

The device's FXO interface can interwork SIP emergency E911 calls from the Service Provider's IP network to the analog PSAP DID lines. The standards that define this interface include TR-TSY-000350 or Bellcore's GR-350-Jun2003. This protocol defines signaling between the E911 tandem switch (E911 Selective Router) and the PSAP, using analog loop-start lines. The FXO device can be implemented instead of an E911 switch, by connecting directly to the PSAP DID loop-start lines.

When an IP phone subscriber dials 911, the device receives the SIP INVITE message and makes a call to the PSAP as follows:

1. The FXO device seizes the line.
2. PSAP sends a Wink signal (250 msec) to the device.

3. Upon receipt of the Wink signal, the device dials MF digits after a user-defined time (WaitForDialTime) containing the caller's ID (ANI) obtained from the SIP headers From or P-Asserted-Identity.
4. When the PSAP operator answers the call, the PSAP sends a polarity reversal to the device, and the device then sends a SIP 200 OK to the IP side.
5. After the PSAP operator disconnects the call, the PSAP reverses the polarity of the line, causing the device to send a SIP BYE to the IP side.
6. If, during active call state, the device receives a Wink signal (typically of 500 msec) from the PSAP, the device generates a SIP INFO message that includes a "hookflash" body, or sends RFC 2833 hookflash Telephony event (according to the HookFlashOption parameter).
7. Following the "hookflash" Wink signal, the PSAP sends DTMF digits. These digits are detected by the device and forwarded to the IP, using RFC 2833 telephony events (or inband, depending on the device's configuration). Typically, this Wink signal followed by the DTMF digits initiates a call transfer.

For supporting the E911 service, used the following configuration parameter settings:

- Enable911PSAP = 1 (also forces the EnableDIDWink and EnableReversalPolarity)
- HookFlashOption = 1 (generates the SIP INFO hookflash message) or 4 for RFC 2833 telephony event
- WinkTime = 700 (defines detection window of 50 to 750 msec for detection of both winks - 250 msec wink sent by the PSAP for starting the device's dialing; 500 msec wink during the call)
- IsTwoStageDial = 0
- EnableHold = 0
- EnableTransfer = 0
  - Use RFC 2833 DTMF relay:
    - ◆ RxDTMFOption = 3
    - ◆ FirstTxDTMFOption = 4
    - ◆ RFC2833PayloadType = 101
- TimeToSampleAnalogLineVoltage = 100
- WaitForDialTime = 1000 (default is 1 sec)
- SetDefaultLinePolarityState = 0 (you need to verify that the RJ-11 two-wire cable is connected without crossing, Tip to Tip, Ring to Ring. Typically, the Tip line is positive compared to the Ring line.)

If the two-wire cable is crossed, the SetDefaultLinePolarityState parameter must be set to 1.

The device expects to receive the ANI number in the From and/or P-Asserted-Identity SIP header. If the pseudo-ANI number exists, it should be sent as the display name in these headers.

**Table 28-2: Dialed Number by Device Depending on Calling Number**

Digits of Calling Number (ANI)	Digits of Displayed Number	Number Dialed MF Digits
8 "nnnnnnnn"	-	MF dialed "KPnnnnnnnnST"
12 "nnnnnnnnnnnn"	None	"KPnnnnnnnnnnnnSTP"
12 "nnnnnnnnnnnn"	10 "mmmmmmmmmm" (pANI)	"KPnnnnnnnnnnnnSTKPmmmmmmmmmmS T"
2 "nn"	None	"KPnnSTP"
1 "n"	-	MF dialed "KPnST" For example:

Table notes:

- For all other cases, a SIP 484 response is sent.
- KP is for .
- ST is for #.
- STP is for B.

The MF duration of all digits, except for the KP digit is 60 msec. The MF duration of the KP digit is 120 msec. The gap duration is 60 msec between any two MF digits.

- Manipulation rules can be configured for the calling (ANI) and called number (but not on the "display" string), for example, to strip 00 from the ANI "00INXXYYYY".
- The called number, received as userpart of the Request URI ("301" in the example below), can be used to route incoming SIP calls to FXO specific ports, using the TrunkGroup and PSTNPrefix parameters.
- When the PSAP party off-hooks and then immediately on-hooks (i.e., the device detects wink), the device releases the call sending SIP response "403 Forbidden" and the release reason 21 (i.e., call rejected) "Reason: Q.850 ;cause=21" is sent. Using the cause mapping parameter, it is possible to change the 403 to any other SIP reason, for example, to 603.
- Sometimes a wink signal sent immediately after the FXO device seizes the line is not detected. To overcome this problem, configure the parameter TimeToSampleAnalogLineVoltage to 100 (instead of 1000 msec, which is the default value). The wink is then detected only after this timeout + 50 msec (minimum 150 msec).

Below are two examples for a) INVITE messages and b) INFO messages generated by hook-flash.

■ **Example A:** INVITE message with ANI = 333333444444 and pseudo-ANI = 0123456789:

```
INVITE sip:301@10.33.37.79;user=phone SIP/2.0

```

## Pre-empting Existing Calls for E911 IP-to-Tel Calls

If the device receives an emergency call (E911) from the IP network destined to the Tel and there are unavailable channels (e.g., all busy), the device terminates one of the current calls (arbitrary) and then sends the emergency call to that channel. The preemption is done only on a channel belonging to the same Trunk Group for which the emergency call was initially destined and if the 'Channel Select Mode' parameter (ChannelSelectMode) is configured with a value other than **By Dest Phone Number** (0). Call preemption is done only if the incoming IP-to-Tel call is identified as an emergency call.

### ➤ To configure call preemption for emergency calls:

1. Enable call preemption for emergency calls:
  - **For all calls:** Open the Priority & Emergency page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Priority and Emergency**), and then from the 'Call Priority Mode' drop-down list (CallPriorityMode), select **Emergency**:

Call Priority Mode

Emergency ▼

- **For specific calls:** Open the Tel Profiles table (see [Configuring Tel Profile](#) on page 755), and then for the required Tel Profile, configure the 'Call Priority Mode' drop-down list to **Emergency**.
2. Configure the [EmergencyCallAlertInfoUri] parameter with a value that if the SIP Alert-Info header in the incoming INVITE message contains the same value, then the INVITE is considered an emergency call. If not configured, the call is not considered an emergency call (even if the header is present).

3. (Optional) Block device restarts that are triggered through CLI (`reload` command) during and after emergency calls, by configuring the `[ReloadTimeoutForEmergencyCall]` parameter to a non-zero value. This value is the duration for blocking restarts after the call has ended (regardless of whether it was successfully established or not). A value of -1 disables this feature.
4. (Optional) Configure emergency telephone numbers (e.g., 911). Open the Priority & Emergency page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Priority and Emergency**), and then in the 'Emergency Number' fields (`EmergencyNumbers`), configure the emergency numbers:

Emergency Number 1	<input type="text" value="911"/>
Emergency Number 2	<input type="text"/>
Emergency Number 3	<input type="text"/>
Emergency Number 4	<input type="text"/>

The device identifies the IP-to-Tel call as an emergency call if the destination number matches one of these configured emergency numbers. For E911, you must configure the parameter to "911".

- The feature is applicable to the following interfaces:
  - ✓ FXO
  - ✓ ISDN
  - ✓ CAS
- The device also identifies emergency calls if the Priority header of the incoming SIP INVITE message contains the "emergency" value.
- For Trunk Groups configured with call preemption, you must configure all to **MLPP** or all to **Emergency**.
- If you are using a Tel Profile, you must configure the 'Call Priority Mode' parameter in the Tel Profile table and on the Priority & Emergency page with the same value; otherwise, the Tel Profile parameter is not applied.
- If you configure call preemption using the global parameter, and you subsequently add a new Tel Profile, the Tel Profile parameter 'Call Priority Mode' automatically acquires the same setting.
- For FXO interfaces, the preemption is done only on existing IP-to-Tel calls. In other words, if all the current FXO channels are busy with calls that were answered by the FXO device (i.e., Tel-to-IP calls), new incoming emergency IP-to-Tel calls are rejected.

## Multilevel Precedence and Preemption

The device supports Multilevel Precedence and Preemption (MLPP) service. MLPP is a call priority scheme, which does the following:

- Assigns a precedence level (priority level) to specific phone calls or messages.

- Allows higher priority calls (*precedence call*) and messages to preempt lower priority calls and messages (i.e., terminates existing lower priority calls) that are recognized within a user-defined domain (*MLPP domain ID*). The domain specifies the collection of devices and resources that are associated with an MLPP subscriber. When an MLPP subscriber that belongs to a particular domain places a precedence call to another MLPP subscriber that belongs to the same domain, MLPP service can preempt the existing call that the called MLPP subscriber is on for a higher-precedence call. MLPP service availability doesn't apply across different domains.

MLPP is typically used in the military where, for example, high-ranking personnel can preempt active calls during network stress scenarios such as a national emergency or degraded network situations.

MLPP can be enabled for all calls, using the global parameter, *CallPriorityMode*, or for specific calls using the Tel Profile parameter, *CallPriorityMode*.

- For digital interfaces, MLPP is applicable only to PRI and BRI interfaces.
- The device provides MLPP interworking between SIP and ISDN (both directions).
- For Trunk Groups configured with call preemption, you must configure all to **MLPP** or all to **Emergency**.
- The global parameter must be set to the same value as that of the Tel Profile parameter; otherwise, the Tel Profile parameter is not applied.
- If you configure call preemption using the global parameter, and you subsequently add a new Tel Profile, the Tel Profile parameter 'Call Priority Mode' automatically acquires the same setting.
- If required, you can exclude the "resource-priority" tag from the SIP Require header in INVITE messages for Tel-to-IP calls when MLPP priority call handling is used. This is configured using the [RPRequired] parameter.
- For a complete list of the MLPP parameters, see [MLPP and Emergency Call Parameters](#) on page 1973.

The Resource Priority value in the Resource-Priority SIP header can be any one of those listed in the table below.

For digital interfaces: A default MLPP call Precedence Level (configured by the *SIPDefaultCallPriority* parameter) is used if the incoming SIP INVITE or ISDN Setup message contains an invalid priority or Precedence Level value respectively.

For each MLPP call priority level, the Multiple Differentiated Services Code Points (DSCP) can be set to a value from 0 to 63.

**Table 28-3: MLPP Call Priority Levels (Precedence) and DSCP Configuration Parameters**

MLPP Precedence Level	Precedence Level in Resource-Priority SIP Header	DSCP Configuration Parameter
0 (lowest)	routine	MLPPRoutineRTPDSCP
2	priority	MLPPPRIORITYRTPDSCP

MLPP Precedence Level	Precedence Level in Resource-Priority SIP Header	DSCP Configuration Parameter
4	immediate	MLPPImmediateRTPDSCP
6	flash	MLPPFlashRTPDSCP
8	flash-override	MLPPFlashOverRTPDSCP
9 (highest)	flash-override-override	MLPPFlashOverOverRTPDSCP

**For digital interfaces:**

The device automatically interworks the network identity digits (NI) in the ISDN Q.931 Precedence Information Element (IE) to the network domain subfield of the INVITE's Resource-Priority header, and vice versa. The SIP Resource-Priority header contains two fields, namespace and priority. The namespace is subdivided into two subfields, network-domain and precedence-domain. Below is an example of a Resource-Priority header whose network-domain subfield is "uc", r-priority field is "priority" (2), and precedence-domain subfield is "000000":

Resource-Priority: uc-000000.2

The MLPP Q.931 Setup message contains the Precedence IE. The NI digits are presented by four nibbles found in octets 5 and 6. The device checks the NI digits according to the translation table of the Department of Defense (DoD) Unified Capabilities (UC) Requirements (UCR 2008, Changes 3) document, as shown below:

**Table 28-4: NI Digits in ISDN Precedence**

Level IE	Network Domain in SIP Resource-Priority Header
0000	uc
0001	cuc
0002	dod
0003	nato

- If the received ISDN message contains NI digits that are not listed in the translation table, the device sets the network-domain to "uc" in the outgoing SIP message.
- If the received SIP message contains a network-domain value that is not listed in the translation table, the device sets the NI digits to "0000" in the outgoing ISDN message.
- If the received ISDN message doesn't contain a Precedence IE, you can configure the namespace value - dsn (default), dod, drsn, uc, or cuc - in the SIP Resource-Priority header of the outgoing INVITE message. This is done using the MLPPDefaultNamespace parameter. You can also configure up to 32 user-defined namespaces, using the table ini file parameter, ResourcePriorityNetworkDomains. Once defined, you need to set the MLPPDefaultNamespace parameter value to the desired table row index.

By default, the device maps the received Resource-Priority field of the SIP Resource-Priority header to the outgoing ISDN Precedence Level (priority level) field as follows:

- If the network-domain field in the Resource-Priority header is "uc", then the device sets the Precedence Level field in the ISDN Precedence Level IE according to Table 5.3.2.12-4 (Mapping of RPH r-priority Field to ISDN Precedence Level Value):

**Table 28-5: Mapping of SIP Resource-Priority Header to ISDN Precedence Level for MLPP**

MLPP Precedence Level	ISDN Precedence Level	SIP Resource-Priority Header Field
Routine	4	0
Priority	3	2
Immediate	2	4
Flash	1	6
Flash Override	0	8

- If the network-domain field in the Resource-Priority header is any value other than "uc", then the device sets the Precedence Level field to "0 1 0 0" (i.e., "routine").

This can be modified using the EnableIp2TelInterworkingtable field of the ini file parameter, ResourcePriorityNetworkDomains.

## MLPP Preemption Events in SIP Reason Header

The device sends the SIP Reason header (as defined in RFC 4411) to indicate the reason and type of a preemption event. The device sends a SIP BYE or CANCEL request, or SIP 480, 486, 488 response (as appropriate) with a Reason header whose Reason-params can includes one of the following preemption cause classes:

- Reason: preemption ;cause=1 ;text="UA Preemption"

- Reason: preemption ;cause=2 ;text="Reserved Resources Preempted"
- Reason: preemption ;cause=3 ;text="Generic Preemption"
- Reason: preemption ;cause=4 ;text="Non-IP Preemption"

This Reason cause code indicates that the session preemption has occurred in a non-IP portion of the infrastructure. The device sends this code in the following scenarios:

- The device performs a network preemption of a busy call (when a high priority call is received), the device sends a SIP BYE or CANCEL request with this Reason cause code.
- The device performs a preemption of a B-channel for a Tel-to-IP outbound call request from the softswitch for which it has not received an answer response (e.g., Connect), and the following sequence of events occurs:
  - i. The device sends a Q.931 DISCONNECT over the ISDN MLPP to the partner switch to preempt the remote end instrument.
  - ii. The device sends a 488 (Not Acceptable Here) response with this Reason cause code.

- Reason: preemption; cause=5; text="Network Preemption"

This Reason cause code indicates preempted events in the network. Within the Defense Switched Network (DSN) network, the following SIP request messages and response codes for specific call scenarios have been identified for signaling this preemption cause:

- SIP:BYE - If an active call is being preempted by another call
- CANCEL - If an outgoing call is being preempted by another call
- 480 (Temporarily Unavailable), 486 (User Busy), 488 (Not Acceptable Here) - Due to incoming calls being preempted by another call.

The device receives SIP requests with preemption reason cause=5 in the following cases:

- The softswitch performs a network preemption of an active call - the following sequence of events occurs:
  - i. The softswitch sends the device a SIP BYE request with this Reason cause code.
  - ii. The device initiates the release procedures for the B-channel associated with the call request and maps the preemption cause to ISDN Cause = #8 'Preemption'. This value indicates that the call is being preempted. For ISDN, it also indicates that the B-channel is not reserved for reuse.
  - iii. The device sends a SIP 200 OK in response to the received BYE, before the SIP end instrument can proceed with the higher precedence call.
- The softswitch performs a network preemption of an outbound call request for the device that has not received a SIP 2xx response - the following sequence of events occur:
  - i. The softswitch sends the device a SIP 488 (Not Acceptable Here) response code with this Reason cause code. The device initiates the release procedures for the B-

channel associated with the call request and maps the preemption cause to ISDN Cause = #8 'Preemption'.

- ii. The device deactivates any user signaling (e.g., ringback tone) and when the call is terminated, it sends a SIP ACK message to the softswitch.

## Precedence Ring Tone

**For analog interfaces:** You can assign a ring tone that is defined in the CPT file to be played when a precedence call is received from the IP side. This is configured by the [PrecedenceRingingType] parameter. Emergency Telecommunications Services (ETS) calls (e.g., E911) can be configured with a higher priority than any MLPP call (default), using the [E911MLPPBehavior] parameter.

**For digital interfaces:** You can configure the duration for which the device plays a preemption tone to the Tel and IP sides if a call is preempted, using the [PreemptionToneDuration] parameter.

## Denial of Collect Calls

You can configure the device to reject (disconnect) incoming Tel-to-IP collect calls and to signal this denial to the PSTN. This capability is required, for example, in the Brazilian telecommunication system to deny collect calls. When the feature is enabled upon rejecting the incoming call, the device sends a sequence of signals to the PSTN. This consists of an off-hook, an on-hook after one second, and then an off-hook after two seconds. In other words, this is in effect, a double-answer sequence.

This feature can be enabled for all calls, using the EnableFXODoubleAnswer "global" parameter, or it can be enabled for specific calls, by enabling this feature in a Tel Profile.

- The feature is applicable only to FXO interfaces.
- If automatic dialing is also configured for an FXO port enabled with Denial of Collect Calls, the FXO line doesn't answer the incoming call (ringing) until a SIP 200 OK is received from the remote destination. When a 200 OK is received, a double answer is sent from the FXO line.
- Ensure that the PSTN side is configured to identify this double-answer signal.

## Configuring Multi-Line Extensions and Supplementary Services

The Supplementary Services table lets you configure up to 100 supplementary services for endpoints connected to the device.

The feature is applicable only to FXS and BRI interfaces.

You can use the table for the following functionality:

- Configuring multiple phone line extension numbers per port, supporting point-to-multipoint configuration of several phone numbers per channel.
- Registration of each line extension (endpoint), using a user-defined user ID and password, to a third-party softswitch for authentication and/or billing. For each line extension, the device sends a SIP REGISTER to the softswitch, using the global number in the From/To headers. If authentication is necessary for registration, the device sends the endpoint's user ID and password in the SIP MD5 Authorization header. For viewing registration status, see [Viewing Registration Status](#) on page 1489.
- Caller ID name per line extension, which is displayed to the called party (if enabled).
- Enabling receipt by the line extension of caller ID from incoming calls.
- BRI call forwarding services for point-to-multipoint configurations (according to ETSI 300 207-1) - Call Forward Busy (CFB), Call Forward No Reply (CFNR), and Call Forward Unconditional (CFU).
- Routing IP-to-Tel calls (including voice and fax) to specific endpoints based on called line extension number (*local* number). To enable this functionality, in the Trunk Group Settings table, set the 'Channel Select Mode' field to **Select Trunk by Supplementary Services Table** for the Trunk Group to which the port belongs (see [Configuring Trunk Group Settings](#) on page 937).
- Mapping local numbers (line extension number) with global phone numbers (E.164). The endpoint can be configured with two numbers – *local* and *global*. The local number represents the endpoint's line extension number (e.g., PBX extension number); the global number represents the corresponding E.164 number used for the IP side in the SIP message:
  - IP-to-Tel calls: Maps the called global number in the user part of the SIP Request-URI in the incoming SIP message to the local number sent to the Tel side. For example, the device receives an incoming IP call with a destination (called) that is a global number 638002 and then sends the call to the Tel side with the destination number manipulated to the corresponding local number of 402.
  - Tel-to-IP Calls: Maps the calling (source) local number of the Tel side to the global number sent to the IP side (in the From and To headers of the outgoing SIP message). For example, if the device receives a Tel call from line extension local number 402, it changes this calling number to 638002 and then sends the call to the IP side with this calling number. This functionality in effect, validates the calling number.

- If you have configured regular Tel-to-IP or IP-to-Tel manipulation rules (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983), the device applies them before applying the local-global mapping rules configured in the table.
- To allow the end user to hear a dial tone when picking up the BRI phone, it's recommended to set the Progress Indicator in the Setup Ack bit ( $0 \times 10000 = 65536$ ). Therefore, the recommended value is  $0 \times 10000 + 0 \times 1000 = 65536 + 4096 = 69632$  (i.e., configure the [ISDNInCallsBehavior] parameter to 69632).

The following procedure describes how to configure the Supplementary Services table through the Web interface. You can also configure it through ini file [ISDNSuppServ] or CLI (`configure voip > gateway digital isdn-supp-serv`).

➤ **To configure endpoint supplementary services:**

1. Open the Supplementary Services table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services**).
2. Click **New**; the following dialog box appears:

GENERAL		CALLER ID	
Index	1	Caller ID Enabled	<input type="checkbox"/>
Global Phone Number		Caller ID Name	
Local Phone Number		Presentation	<input type="checkbox"/>
Module	0		
Port	0		
User ID			
User Password			
CFB Phone Number			
CFNR Phone Number			
CFU Phone Number			
No Reply Time	30		

3. Configure a supplementary service according to the parameters described in the table below.
4. Click **Apply**.

The figure below displays an example of multiple-line extensions configured in the Supplementary Services table:

INDEX ↕	GLOBAL PHONE NUMBER	LOCAL PHONE NUMBER	MODULE	PORT	USER ID	USER PASSWORD	CALLER ID NAME	PRESENTATION	CALLER ID ENABLED
0	+15032638002	402	1	1	JoeV	*	Joe	Allowed	Enabled
1	+15032638003	403	1	1	SueK	*	Sue	Allowed	Enabled
2	+15032638004	404	1	2	LeeM	*	Lee	Allowed	Enabled
3	+15032638005	405	1	2	MikeD	*	Mike	Allowed	Enabled

You can also register and un-register an endpoint configured in the table:

➤ **To register or un-register an endpoint:**

1. In the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937), configure the registration method using the 'Registration Mode' parameter.
2. In the Supplementary Services table, select the required endpoint.
3. From the 'Action' drop-down list, select **Register**. To unregister the endpoint, select **Un-Register**.

**Table 28-6: Supplementary Services Table Parameter Description**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Global Phone Number' phone-number [PhoneNumber]	Defines a global telephone extension number for the endpoint. The global number is used for the following functionality: <ul style="list-style-type: none"> <li>■ Endpoint registration</li> <li>■ IP-to-Tel routing</li> <li>■ Mapping between local and global (E.164) numbers between Tel and IP sides respectively</li> </ul>
'Local Phone Number' local-phone-number [LocalPhoneNumber]	Defines a local telephone extension number for the endpoint (e.g., the PBX extension number). The local number is used for the following functionality: <ul style="list-style-type: none"> <li>■ Validation of source (calling) number for Tel-to-IP calls</li> <li>■ Mapping between local and global (E.164) numbers between Tel and IP sides respectively</li> </ul>
'Module' module [Module]	Defines the device's module number to which the endpoint is connected.
'Port'	Defines the port number on the module to which the

Parameter	Description
port [Port]	endpoint is connected.
'User ID' user-id [UserId]	Defines the User ID for registering the endpoint to a third-party softswitch for authentication and/or billing. The valid value is a string of up to 60 characters. By default, no value is defined.
'User Password' user-password [UserPassword]	Defines the user password for registering the endpoint to a third-party softswitch for authentication and/or billing. <b>Note:</b> <ul style="list-style-type: none"> <li>■ For security, the password is displayed as an asterisk (*).</li> <li>■ The password cannot be configured with wide characters.</li> </ul>
'CFB Phone Number' cfb-to_phone-number [CFB2PhoneNumber]	Defines the phone number for BRI Call Forward Busy (CFB) services. If the BRI extension is currently in use, the device forwards the call to this number. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to BRI interfaces.</li> <li>■ To enable BRI call forwarding services, see the [BRICallForwardHandling] parameter.</li> <li>■ For more information on configuring local handling of BRI call forwarding, see <a href="#">Local Handling of BRI Call Forwarding</a> on page 1048.</li> </ul>
'CFNR Phone Number' cfnr-to_phone-number [CFNR2PhoneNumber]	Defines the phone number for BRI Call Forward No Reply (CFNR) services. If the BRI extension doesn't answer the call within a user-defined timeout (see the 'No Reply Time' parameter below), the device forwards the call to this number. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to BRI interfaces.</li> <li>■ To enable BRI call forwarding services, see the [BRICallForwardHandling] parameter.</li> <li>■ For more information on configuring local handling of BRI call forwarding, see <a href="#">Local Handling of BRI Call Forwarding</a> on page 1048.</li> </ul>

Parameter	Description
'CFU Phone Number' <code>cfu-to_phone-number</code>  [CFU2PhoneNumber]	Defines the phone number for BRI Call Forward Unconditional (CFU) services. The device always forwards the call to this number.  <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to BRI interfaces.</li> <li>■ To enable BRI call forwarding services, see the [BRICallForwardHandling] parameter.</li> <li>■ For more information on configuring local handling of BRI call forwarding, see <a href="#">Local Handling of BRI Call Forwarding</a> on page 1048.</li> </ul>
'No Reply Time' <code>no-reply-time</code> [NoReplyTime]	Defines the timeout (in seconds) that if the BRI extension doesn't answer before it expires, the device forwards the call to the phone number as defined by the 'CFNR Phone Number' parameter (see above).  The default is 30.  <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to BRI interfaces.</li> <li>■ To enable BRI call forwarding services, see the [BRICallForwardHandling] parameter.</li> <li>■ For more information on configuring local handling of BRI call forwarding, see <a href="#">Local Handling of BRI Call Forwarding</a> on page 1048.</li> </ul>
Caller ID	
'Caller ID Enabled' <code>caller-id-enable</code> [IsCallerIDEnabled]	Enables the receipt of Caller ID.  <ul style="list-style-type: none"> <li>■ [0] <b>Disabled</b> = The device doesn't send Caller ID information to the endpoint.</li> <li>■ [1] <b>Enabled</b> = The device sends Caller ID information to the endpoint.</li> </ul>
'Caller ID Name' <code>caller-id-number</code> [CallerID]	Defines the caller ID name of the endpoint (sent to the IP side).  The valid value is a string of up to 18 characters.
'Presentation' <code>presentation-restricted</code>	Defines if the endpoint sends its Caller ID information to the IP when a call is made.  <ul style="list-style-type: none"> <li>■ [0] <b>Allowed</b> = The device sends the string defined in the</li> </ul>

Parameter	Description
[IsPresentationRestricted]	<p>'Caller ID' field when this endpoint makes a Tel-to-IP call.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Restricted</b> = The string defined in the 'Caller ID' field is not sent.</li> </ul>

## Detecting Collect Calls

The device detects collect calls (reverse charge calls) using any of the following information elements (IE) in the received Q.931 ISDN Setup message for Tel-to-IP calls:

- Reverse Charging Indication IE
- Facility IE

When the device detects a collect call, it adds a proprietary header (*X-Siemens-Call-Type: collect call*) to the outgoing SIP INVITE message.

No special configuration is required for the feature.

The feature is applicable only to the Euro ISDN protocol variant.

## Advice of Charge Services for Euro ISDN

Advice of charge (AOC) is a pre-billing function that tasks the rating engine with calculating the cost of using a service and relaying that information back to the customer (caller). This allows users to obtain call charging information periodically during the call (AOC-D) or at the end of the call (AOC-E).

AOC messages are sent in the EURO ISDN Facility Information Element (IE) message. The device interworks these ISDN messages with SIP by converting the AOC messages into SIP INFO (during call) and BYE messages (end of call) using the AudioCodes proprietary SIP AOC header, and vice versa. The device supports both currency (monetary units) and pulse (non-monetary units) AOC messages.

This feature can typically be implemented in the hotel industry, where external calls made by guests can be billed accurately. In such a setup, the device is connected on one side to a PBX through an ISDN line (Euro ISDN), and on the other side to a SIP trunk provided by an ITSP. When a call is made by a guest, the device first sends an AOC-D Facility message to the PBX indicating the connection charge unit, and then sends subsequent AOC-D messages every user-defined interval to indicate the charge unit during the call. When the call ends, the device sends an AOC-E Facility message to the PBX indicating the total number of charged units.

The feature is applicable only to Euro ISDN PRI and BRI.

The device supports various AOC methods:

- **Tel-to-IP Direction:** The device converts the AOC messages received in the EURO ISDN Facility IE messages into SIP INFO and BYE messages using the proprietary SIP AOC header.
- **Device Generation of AOC to Tel:** The device generates the metering tones according to user-defined amounts, intervals, currency type, and multiplier. For more information, see [Configuring Charge Codes](#) on page 1082.
- **IP-to-Tel Direction:**
  - SIP-to-Tel interworking: The device uses the AOC header from the IP side and sends to Tel in EURO ISDN Facility IE messages. Below shows the SIP AOC header:

```
AOC: charged; <parameters>
```

Where parameters can be:

- ◆ state="active" or "terminated"
- ◆ charging-info="currency" or "pulse"

If "currency", the following parameters are available:

- ◆ currency=<string>
- ◆ currency-type="iso4217-a" or <string>
- ◆ amount=<number>
- ◆ multiplier=("0.001", "0.01", "0.1", "1", "10", "100", "1000")

If "pulse", the following parameter is available:

- ◆ recorded-units=<number>

The device can also receive AOC data in the SIP INFO message containing an 'application/vnd.etsi.aoc+xml' body. For example:

```
INFO sip:103@10.10.12.188:5060 SIP/2.0
Via: SIP/2.0/UDP 10.10.12.159:5061;branch=z9hG4bK-1-18439@10.10.12.159;rport
From: "2110017: Bob" <sip:4988@10.10.12.188>;tag=1
To: <sip:103@10.10.12.188;user=phone>;tag=pmvsivy1ju
Call-ID: 1-18439@10.10.12.159
CSeq: 3 INFO
Max-Forwards: 70
Contact: <sip:4988@10.10.12.159:5061;line=qhpk806>;reg-id=1
Content-Type: application/vnd.etsi.aoc+xml
Content-Length: 405
```

```
<?xml version="1.0" encoding="UTF-8"?>
<aoc xmlns="http://uri.etsi.org/ngn/params/xml/simservs/aoc">
```

```

<aoc-d>
  <charging-info>subtotal</charging-info>
  <recorded-charges>
    <recorded-currency-units>
      <currency-id>EUR</currency-id>
      <currency-amount>0.1</currency-amount>
    </recorded-currency-units>
  </recorded-charges>
  <billing-id>normal-charging</billing-id>
</aoc-d>
</aoc>

```

In such a case, you should use message manipulation rules on the SIP INFO message to convert the advice of charge data in the XML to the AOC SIP header with the relevant format (parameters) as discussed above:

Parameter	Value	
'Index'	1	2
'Name'	Add AOC header	Remove XML body
'Manipulation Set ID'	0	0
'Row Rule'	<b>Use Current Condition</b>	<b>Use Previous Condition</b>
'Message Type'	Any	
'Condition'	body.application/vnd.etsi.aoc+xml REGEX (<currency-amount>)(\d+) (</currency-amount>)	body.application/vnd.etsi.aoc+xml exists
'Action Subject'	Header.AOC	body.application/vnd.etsi.aoc+xml
'Action Type'	<b>Add</b>	<b>Remove</b>
'Action Value'	'charged;charging-info=pulse;recorded-units='+\$2	

- TELES proprietary method
- Cirpack proprietary methods

For more information on the proprietary methods, see the PayPhoneMeteringMode parameter in [Metering Tone Parameters](#) on page 2039.

➤ **To configure AOC:**

1. Make sure that the PSTN protocol for the trunk line is configured to Euro ISDN and network side.
2. Make sure that the date and time of the device is correct. For accuracy, it is recommended to use an NTP server to obtain the date and time. For more information, see [Date and Time](#) on page 136.
3. Configure the required AOC method:

- **Device Generation of AOC to Tel:**

- i. Open the Supplementary Services page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**), and then configure the 'Generate Metering Tones' parameter (PayPhoneMeteringMode) to **Charge Code Table**.

Generate Metering Tones

Charge Code Table ▼

- ii. In the Charge Codes table, configure Charge Codes (see [Configuring Charge Codes](#) below).
  - iii. In the Tel-to-IP Routing table, assign the Charge Code index to the relevant Tel-to-IP routing rule (see [Configuring Tel-to-IP Routing Rules](#) on page 946).
- **AOC in Tel-to-IP Direction:** Open the Supplementary Services Settings page, and then select the 'AoC Support' check box to send AOC to IP:

AoC Support

- **AOC in IP-to-Tel Direction:** Open the Supplementary Services page, and then configure the 'Generate Metering Tones' parameter (PayPhoneMeteringMode) to one of the following: **SIP Interval Provided**, **SIP RAW Data Provided**, **SIP RAW Data Incremental Provided**, or **SIP-to-Tel Interworking**.

## Configuring Charge Codes

The Charge Codes table lets you configure metering tones:

- **Analog interfaces:** Metering tones that the device generates to the Tel side on its FXS interfaces.
- **Digital interfaces:** Advice of Charge (AOC) services for Euro ISDN trunks (see [Advice of Charge Services for Euro ISDN](#) on page 1079).

You can configure up to 25 different Charge Codes, where each table row represents a Charge Code. Each Charge Code can include up to four different time periods in a day (24 hours). The device selects the time period by comparing the device's current time to the end time of each time period of the selected Charge Code. The device generates the number of pulses (units) upon call connection (answer), and from that point on, it generates a pulse (unit) for each

interval. If a call starts at a certain time period and crosses to the next period, the information of the next time period is used. For Advice of Charge services (digital interfaces only), you can also configure the currency type in the sent AOC messages as well as a multiplier that is applied to the charged units.

To assign Charge Codes to Tel-to-IP calls, use the Tel-to-IP Routing table.

- The Charge Codes table is applicable only to the following interfaces:
  - ✓ FXS
  - ✓ Euro ISDN PRI
  - ✓ Euro ISDN BRI
- Analog interfaces: To enable generation of metering tones, see [Configuring Metering Tones](#) on page 1092.

The following procedure describes how to configure Charge Codes through the Web interface. You can also configure it through ini file [ChargeCode] or CLI (`configure voip > gateway dtmf-supp-service charge-code`).

#### ➤ To configure a Charge Code:

1. Open the Charge Codes table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Charge Codes**).
2. Click **New**; the following dialog box appears:

GENERAL	
Index	0
Name	
End Time 1	
Interval 1	
Amount On Answer 1	
End Time 2	
Interval 2	
Amount On Answer 2	
End Time 3	
Interval 3	
Amount On Answer 3	
End Time 4	

3. Configure a Charge Code according to the parameters described in the table below.
4. Click **Apply**.

**Table 28-7: Charge Codes Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' charge-code-name [ChargeCodeName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
'End Time (1 - 4)' end-time-<1-4> [EndTime<1-4>]	Defines the time at which this charging code ends. The valid value is a time in 24-hour format ( <i>hh</i> ). For example, to denote 4 AM, configure the parameter to "04" (without quotation marks). <b>Note:</b> <ul style="list-style-type: none"> <li>■ The first time period always starts at midnight (00).</li> <li>■ It is mandatory that the last time period of each rule end at midnight (00). This prevents undefined time frames in a day.</li> </ul>
'Interval (1 - 4)' interval-<1-4> [PulseInterval<1-4>]	Defines the interval (in tenths of a second) for charging the call. The first interval starts from when the call is answered (connected). <ul style="list-style-type: none"> <li>■ FXS interfaces: Defines the interval between every generated pulse.</li> <li>■ Digital (Euro ISDN) interfaces: Defines the interval between every sent AOC-D message, which is included in the ISDN Facility information element (IE) message.</li> </ul> <p>For example, if you configure the parameter to 20, the device sends a charge every 2 seconds (i.e., 20 x 0.1). If the call duration is 10 seconds, the total call charge amount (excluding the connection charge, which is configured by the 'Amount On Answer' parameter) is 5. In other words, 10 seconds divided by 2-second intervals is 5, and then 5 multiplied by the default interval charge of 1 is 5.</p> <b>Note:</b> <ul style="list-style-type: none"> <li>■ By default, the charged amount sent per interval is <b>one</b> pulse (unit). However, for digital interfaces, you can configure this charge, using the ISDNAoCAmountPerInterval parameter.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Digital interfaces: If you configure the 'Multiplier of Amount' parameter (see below), then the actual interval charge is multiplied by the 'Multiplier of Amount' parameter value. For example, if the interval charge is 1 (default) and you configure the 'Multiplier of Amount' parameter to 0.1, then the interval charge is 0.1 (i.e., 1 x 0.1).</li> <li>■ Digital interfaces: You can configure the interval for sending the AOC messages, using the ISDNAoCMinIntervalGeneration global parameter. This doesn't affect the interval charge. If this global parameter value is less than the 'Interval' parameter, the global parameter is ignored. For example, if you configure the 'Interval' parameter to 20 (i.e., 2 seconds) and the ISDNAoCMinIntervalGeneration parameter to 40 (i.e., 4 seconds), the device sends AOC messages every 0.4 seconds, but charges the call every 2 seconds.</li> </ul>
'Amount On Answer (1-4)' amount-on-answer-<1-4> [PulsesOnAnswer<1-4>]	<p>Defines the one-time call charge upon call connection (call answer).</p> <ul style="list-style-type: none"> <li>■ FXS interfaces: Defines the number of charging pulses that the device generates to the Tel side when the call is answered.</li> <li>■ Digital (Euro ISDN) interfaces: Defines the number of charging units or amount that the device generates when the call is answered, which it sends as the first AOC-D message in the ISDN Facility information element (IE) message.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Digital interfaces: If you configure the 'Currency' parameter (see below), the charge is sent with this currency (e.g., 5 USD).</li> <li>■ Digital interfaces: If you configure the 'Multiplier of Amount' parameter (see below), then the actual charge is the value of the 'Amount On Answer' parameter multiplied by the 'Multiplier of Amount' parameter value. For example, if you configure the 'Amount On Answer' parameter to 50 and the 'Multiplier of Amount' parameter to 0.1, then the charge sent is 5 (i.e., 50 x 0.1).</li> </ul>
'Currency' currency [Currency]	<p>Defines the currency of the charge.</p> <p>The valid value is a string of up to 10 characters. For example, "USD" (without quotation marks). By default, no value is</p>

Parameter	Description
	<p>defined. The device includes the currency in AOC messages in IA5 format.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Euro ISDN protocol (Advice of Charge supplementary services).</li> <li>■ The parameter is applicable only to Tel-to-IP calls.</li> </ul>
'Multiplier of Amount' multiplier [Multiplier]	<p>Defines the multiplier of the call connection charge (configured by the 'Amount On Answer' parameter) and the interval charge.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0.001</b></li> <li>■ [1] <b>0.01</b> (default)</li> <li>■ [2] <b>0.1</b></li> <li>■ [3] <b>1</b></li> <li>■ [4] <b>10</b></li> <li>■ [5] <b>100</b></li> <li>■ [6] <b>1000</b></li> </ul> <p>For example, if you configure the parameter to <b>0.1</b> and the 'Amount On Answer' parameter to 50, the sent call connection charge is 5 (i.e., 50 x 0.1). In addition, if the interval charge is 1 (default), the charge for every interval is 0.1 (i.e., 1 x 0.1).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Euro ISDN protocol (Advice of Charge supplementary services).</li> <li>■ The parameter is applicable only to Tel-to-IP calls.</li> </ul>

## Configuring Voice Mail

The Voice Mail Settings page lets you configure voice mail.

- For more information on voice mail, refer to the document *IP-based Voice Mail Configuration Note*.
- For a detailed description of the voice mail parameters, see [Voice Mail Parameters](#) on page 1940.
- Voice mail is applicable only to FXO, CAS, QSIG, Euro ISDN, and NI2 interfaces.

### ➤ To configure voice mail:

1. Open the Supplementary Services Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Supplementary Services Settings**).

- 'Line Transfer Mode' (LineTransferMode): Defines the call transfer method used by the device.
2. Open the Message Waiting Indicator Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Message Waiting Indicator Settings**).
- 'Voice Mail Interface' (VoiceMailInterface): Enables the device's Voice Mail feature and defines the communication method between the device and PBX.
  - Configure the digit codes used by the device for relaying message waiting indication information to the PBX:
    - ◆ 'MWI Off Digit Pattern' (MWIOffCode): Defines the digit code indicating no messages waiting for a specific extension.
    - ◆ 'MWI On Digit Pattern' (MWIONCode): Defines the digit code indicating messages waiting for a specific extension.
    - ◆ 'MWI Suffix Pattern' (MWISuffixCode): Defines the digit code used as a suffix for 'MWI On Digit Pattern' and 'MWI Off Digit Pattern'.
    - ◆ 'MWI Source Number' (MWISourceNumber): Defines the calling party's phone number in the Q.931 MWI Setup message to PSTN.
  - Configure Simplified Message Desk Interface (SMDI):
    - ◆ 'Enable SMDI' (SMDI): Enables SMDI interface on the device.
    - ◆ 'SMDI Timeout' (SMDITimeOut): Defines the time (in msec) that the device waits for an SMDI Call Status message before or after a Setup message is received.
3. Open the DTMF & Dialing page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **DTMF & Dialing**).
- Under the Digit Patterns group, configure the digit patterns used by the PBX to indicate various services:
    - ◆ 'Forward on Busy Digit Pattern Internal' (DigitPatternForwardOnBusy): Defines the digit pattern to indicate 'call forward on busy' when the original call is received from an internal extension.
    - ◆ 'Forward on No Answer Digit Pattern Internal' (DigitPatternForwardOnNoAnswer): Defines the digit pattern to indicate 'call forward on no answer' when the original call is received from an internal extension.
    - ◆ 'Forward on Do Not Disturb Digit Pattern Internal' (DigitPatternForwardOnDND): Defines the digit pattern to indicate 'call forward on do not disturb' when the original call is received from an internal extension.
    - ◆ 'Forward on No Reason Digit Pattern Internal' (DigitPatternForwardNoReason): Defines the digit pattern to indicate 'call forward with no reason' when the original call is received from an internal extension.

- ◆ 'Forward on Busy Digit Pattern External' (DigitPatternForwardOnBusyExt): Defines the digit pattern to indicate 'call forward on busy' when the original call is received from an external line.
- ◆ 'Forward on No Answer Digit Pattern External' (DigitPatternForwardOnNoAnswerExt): Defines the digit pattern to indicate 'call forward on no answer' when the original call is received from an external line.
- ◆ 'Forward on Do Not Disturb Digit Pattern External' (DigitPatternForwardOnDNDExt): Defines the digit pattern to indicate 'call forward on do not disturb' when the original call is received from an external line.
- ◆ 'Forward on No Reason Digit Pattern External' (DigitPatternForwardNoReasonExt): Defines the digit pattern to indicate 'call forward with no reason' when the original call is received from an external line.
- ◆ 'Internal Call Digit Pattern' (DigitPatternInternalCall): Defines the digit pattern to indicate an internal call.
- ◆ 'External Call Digit Pattern' (DigitPatternExternalCall): Defines the digit pattern to indicate an external call.
- ◆ 'Disconnect Call Digit Pattern' (TelDisconnectCode): Defines a digit pattern that when received from the Tel side indicates the device to disconnect the call.
- ◆ 'Digit To Ignore Digit Pattern' (DigitPatternDigitToIgnore): Defines a digit pattern that if received as Src (S) or Redirect (R) numbers is ignored and not added to that number.

4. Click **Apply**.

## Converting Accented Characters from IP to Tel

The Char Conversion table lets you configure up to 40 Character Conversion rules. A Character Conversion rule maps (converts) accented characters (Unicode / UTF-8) received from the IP side into simple ASCII characters (ISO-8859) for sending to the Tel side. Typically, the device receives the caller ID and calling name in Unicode characters (in the SIP INVITE message). Unicode characters consist of two bytes, while ASCII characters consist of one byte. Accented characters are used in various languages such as German. An example of such a character is the umlaut (or diaeresis), which consists of two dots placed over a letter, as in ä. The importance of this conversion feature is that it allows Tel entities that do not support accented characters, to receive ASCII characters. For example, the device can convert the Unicode character ä into the ASCII character "ae".

The table functions together with the [ISO8859CharacterSet] parameter. When the parameter is set to [0] (Latin only), it converts accented characters into ASCII (e.g., ä to "a"). However, the table can be used to overwrite these "basic" conversions and customize them (e.g., ä to "ae" instead of the default "a").

The following procedure describes how to configure Character Conversion rules through the Web interface. You can also configure it through ini file [CharConversion] or CLI (configure voip > gateway dtmf- supp- service dtmf- and- dialing > char- conversion).

➤ **To configure a Character Conversion rule:**

1. Open the Char Conversion table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **Char Conversion**).
2. Click **New**; the following dialog box appears:

The screenshot shows a web-based configuration window titled "Char Conversion". It contains a "GENERAL" tab with the following fields and values:

Field	Value
Index	0
Character Name	a with Diaeresis
First Byte	195
Second Byte	164
Converted Output	ae

The figure above shows a configuration example where ä is converted to ae.

3. Configure a Character Conversion rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 28-8: Char Conversion Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Character Name' char-name [CharName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> Configure each row with a unique name.
'First Byte' first-byte [FirstByte]	Defines the first byte of the Unicode character (e.g., 195). The default is 194.

Parameter	Description
'Second Byte' second-byte [SecondByte]	Defines the second byte of the Unicode character (e.g., 164). The default is 128.
'Converted Output' converted-output [ConvertedOutput]	Defines the ASCII character (e.g., "ae") to which the Unicode character must be converted. The valid value is a string of up to four characters. The valid value is up to four ASCII characters. This can include any ASCII character - alphanumeric (e.g., a, A, 6) and/or symbols (e.g., !, ?, _, &).

## 29 Analog Gateway

This section describes configuration of analog settings for the Gateway application.

### Configuring Keypad Features

The Keypad Features page lets you configure key sequences that can be pressed on the keypad of the phones that are connected to the device's FXS ports, for the following features:

- Activating and deactivating call forwarding
- Activating and deactivating caller ID restriction
- Activating and deactivating hotline for automatic dialing
- Activating and deactivating call waiting
- Activating and deactivating rejection of anonymous calls
- Activating and deactivating call pickup
- Configuring phone numbers

- This section is applicable only to FXS interfaces.
- The method used by the device to collect dialed numbers is identical to the method used during a regular call (i.e., max digits, interdigit timeout, digit map, etc.).
- The activation of each feature remains in effect until it is deactivated (i.e., not deactivated after a call).

The following procedure describes how to configure some of the keypad features through the Web interface. For a description of all the keypad parameters, see [Telephone Keypad Key Sequence Parameters](#) on page 2042.

➤ **To configure key sequences:**

1. Open the Keypad Features page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Keypad Features**).

FORWARD		HOTLINE	
Forward Unconditional	<input type="text"/>	Hot-line Activate	<input type="text"/>
Forward No Answer	<input type="text"/>	Hot-line Deactivate	<input type="text"/>
Forward On Busy	<input type="text"/>		
Forward On Busy or No Answer	<input type="text"/>		
Do Not Disturb	<input type="text"/>		
Forward Deactivate	<input type="text"/>		
CALLER ID RESTRICTION		CALL WAITING	
Restricted Caller ID Activate	<input type="text"/>	Call Waiting Activate	<input type="text"/>
Restricted Caller ID Deactivate	<input type="text"/>	Call Waiting Deactivate	<input type="text"/>
		REJECT ANONYMOUS CALL	
		Reject Anonymous Call Activate	<input type="text"/>
		Reject Anonymous Call Deactivate	<input type="text"/>

2. Configure the key sequence for each required call feature.

3. Click **Apply**.

## Configuring Metering Tones

The FXS interfaces can generate 12/16 KHz metering pulses toward the Tel side (e.g., for connection to a pay phone or private meter). Tariff pulse rate is according to the device's Charge Codes table. This capability enables users to define different tariffs according to the source/destination numbers and the time-of-day. The tariff rate includes the time interval between the generated pulses and the number of pulses generated on answer.

- The Metering Tones page is applicable only to FXS interfaces.
- Charge Code rules can be assigned to routing rules in the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946). When a new call is established, the Tel-to-IP Routing table is searched for the destination IP address. Once a route is located, the Charge Code (configured for that route) is used to associate the route with an entry in the Charge Codes table.

### ➤ To configure metering tone type:

1. Open the Analog Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Analog Settings**).

Analog TTX Voltage Level	<input type="text" value="0.5V"/>	
Analog Metering Type	<input type="text" value="16 kHz sinusoidal bursts"/>	

2. From the 'Analog Metering Type' drop-down list (MeteringType), select the metering pulse generated toward the Tel side.

3. In the 'Analog TTX Voltage Level' field (AnalogTTXVoltageLevel), configure the metering signal/pulse voltage level.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Configuring FXO Settings

The FXO Settings page lets you configure the device's specific FXO parameters. For a description of these parameters, see [Configuration Parameters Reference](#) on page 1701.

The FXO Settings page is applicable only to FXO interfaces.

### ➤ To configure the FXO parameters:

1. Open the FXO Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **FXO Settings**).

GENERAL	ADVANCED
Dialing Mode	Disconnect Call on Busy Tone Detection (CAS)
Waiting for Dial Tone	Disconnect On Dial Tone
Time to Wait before Dialing [msec]	Guard Time Between Calls
Ring Detection Timeout [sec]	FXO Double Answer
Reorder Tone Duration [sec]	FXO AutoDial Play BusyTone
Rings before Detecting Caller ID	
Send Metering Message to IP	

2. Configure the parameters as required.
3. Click **Apply**.

## Configuring Authentication

The Authentication table lets you configure an authentication username and password per analog port.

- The feature is applicable only to the Gateway application - FXS and FXO interfaces.
- If authentication is configured for the entire device, configuration in the table is ignored.
- If the username or password is not configured in the table, the port's phone number (configured in the Trunk Groups table) and global password (configured by the global parameter, Password) are used instead for authentication of the port.
- After you click **Apply**, the password is displayed as an asterisk (\*).

The following procedure describes how to configure authentication per port through the Web interface. You can also configure it through ini file [Authentication] or CLI (`configure voip > gateway analog authentication`).

➤ **To configure authentication credentials per port:**

1. Configure the device to authenticate per endpoint. You can configure this globally for all endpoints or for endpoints belonging to a specific Trunk Group:
  - For all endpoints: Open the Proxy & Registration page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Proxy & Registration**), and then configure the 'Registration Mode' [AuthenticationMode] parameter to **Per Endpoint**:

## GATEWAY AUTHENTICATION

Registration Mode

• **Per Endpoint** ▼

- Endpoints per Trunk Group: Open the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937), and then for the required Trunk Group ID, configure the 'Registration Mode' parameter to **Per Endpoint**.
2. Open the Authentication table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Authentication**).
  3. Select the row corresponding to the port that you want to configure, and then click **Edit**; the following dialog box appears:

GENERAL		CREDENTIALS	
Index	0	User Name	
Module	1	Password	
Port	1		
Port Type	FXS		

4. Configure the authentication username and password per port according to the parameters described in the table below.
5. Click **Apply**.

Table 29-1: Authentication Table Parameter Descriptions

Parameter	Description
<b>General</b>	
'Index' [Index]	(Read-only) Displays the index number of the table row.
'Module' port-type [Module]	(Read-only) Displays the module number on which the port is located.
'Port' port [Port]	(Read-only) Displays the port number.
'Port Type' [PortType]	(Read-only) Displays the port type (FXS or FXO).
<b>Credentials</b>	
'User Name' user-name [UserId]	Defines the username for authenticating the port. The valid value is a string of up to 60 characters. By default, no value is defined.
'Password' password [UserPassword]	Defines the password for authenticating the port. <b>Note:</b> The password cannot be configured with wide characters.

## Configuring Automatic Dialing

The Automatic Dialing table lets you configure telephone numbers that are automatically dialed when analog ports go off-hook. The dialing can be done immediately upon off-hook or after a user-defined interval after off-hook, referred to as *Hotline* dialing. For example, you can configure Hotline automatic dialing where if Port #1 remains off-hooked for over 15 seconds, the device automatically dials 911.

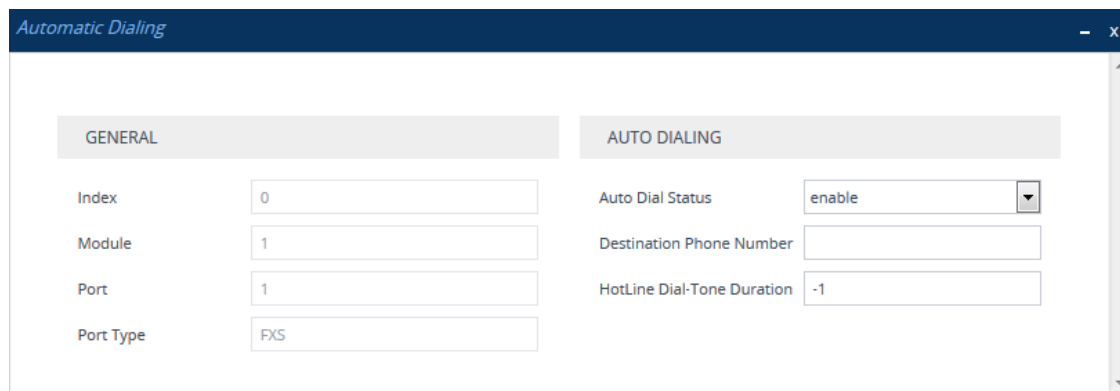

The feature is applicable only to FXS and FXO interfaces.

The following procedure describes how to configure automatic dialing upon off-hook through the Web interface. You can also configure it through ini file [TargetOfChannel] or CLI (configure voip > gateway analog automatic-dialing).

➤ **To configure automatic dialing per port:**

1. Open the Automatic Dialing table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Automatic Dialing**).
2. Select the row corresponding to the port that you want to configure, and then click **Edit**; the following dialog box appears:

The screenshot shows the 'Automatic Dialing' dialog box with two tabs: 'GENERAL' and 'AUTO DIALING'. The 'GENERAL' tab is selected, displaying the following fields:

- Index:** 0
- Module:** 1
- Port:** 1
- Port Type:** FXS

The 'AUTO DIALING' tab is also visible, displaying the following fields:

- Auto Dial Status:** enable (dropdown menu)
- Destination Phone Number:** (empty text field)
- HotLine Dial-Tone Duration:** -1

3. Configure automatic dialing per port according to the parameters described in the table below.
4. Click **Apply**.

**Table 29-2: Automatic Dialing Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	(Read-only) Displays the index number of the table row.
'Module' [Module]	(Read-only) Displays the module number on which the port is located.
'Port' port [Port]	(Read-only) Displays the port number.
'Port Type' [PortType]	(Read-only) Displays the port type (FXS or FXO).
'Destination Phone Number' dst-number [Destination]	Defines the destination telephone number to automatically dial.
'Auto Dial Status' auto-dial-status	Enables automatic dialing.

Parameter	Description
[Type]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Automatic dialing for the specific port is disabled.</li> <li>■ [1] <b>Enable</b> = (Default) Automatic dialing is enabled and the phone number configured in the 'Destination Phone Number' field is automatically dialed if the following occurs: <ul style="list-style-type: none"> <li>✓ FXS interfaces: The phone is off-hooked</li> <li>✓ FXO interfaces: A ring signal (from a PBX/PSTN switch) is detected on the FXO line. The device initiates a call to the destination without seizing the FXO line. The line is seized only after the SIP call is answered.</li> </ul> </li> <li>■ [2] <b>Hotline</b> = Automatic dialing is done after an interval configured by the 'Hotline Dial Tone Duration' parameter: <ul style="list-style-type: none"> <li>✓ FXS interfaces: When the phone is off-hooked and no digit is dialed within a user-defined time, the configured destination number is automatically dialed.</li> <li>✓ FXO interfaces: If a ring signal is detected, the device seizes the FXO line, plays a dial tone, and then waits for DTMF digits. If no digits are detected within a user-defined time, the configured destination number is automatically dialed by sending a SIP INVITE message with this number.</li> </ul> </li> </ul>
'Hotline Dial Tone Duration' hotline-dial-tone-duration [HotLineToneDuration]	<p>Defines the duration (in seconds) after which the destination phone number is automatically dialed. This is applicable only if the port has been configured for Hotline (i.e., 'Auto Dial Status' is set to <b>Hotline</b>).</p> <p>The valid value is 0 to 60. The default is 16.</p> <p><b>Note:</b> You can configure this Hotline interval for all ports, using the global parameter [HotLineToneDuration].</p>

## Configuring Caller Display Information

The Caller Display Information table lets you configure caller identification strings (caller ID) per analog port. The table also lets you enable the device to send the caller ID to the IP side for Tel-to-IP calls. The device includes the caller ID in the From header of the outgoing SIP INVITE message. For more information on Caller ID restriction according to destination/source prefixes, see [Configuring Source-Destination Number Manipulation Rules](#) on page 983.

- The feature is applicable to FXS and FXO interfaces.
- If an FXS port receives 'private' or 'anonymous' strings in the SIP From header, the calling name or number is not sent to the Caller ID display.
- If the device detects Caller ID on an FXO line (EnableCallerID = 1), it uses this Caller ID instead of the Caller ID configured in the Caller Display Information table.

The following procedure describes how to configure caller ID through the Web interface. You can also configure it through ini file [CallerDisplayInfo] or CLI (`configure voip > gateway analog caller-display-info`).

➤ **To configure caller ID:**

1. Open the Caller Display Information table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Caller Display Information**).
2. Select the row corresponding to the port that you want to configure, and then click **Edit**; the following dialog box appears:

3. Configure caller ID per port according to the parameters described in the table below.
4. Click **Apply**.

**Table 29-3: Caller Display Information Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	(Read-only) Displays the index number of the table row.
'Module' [Module]	(Read-only) Displays the module number on which the port is located.

Parameter	Description
'Port' [Port]	(Read-only) Displays the port number.
'Port Type' [PortType]	(Read-only) Displays the port type (FXS or FXO).
<b>Caller Display</b>	
'Display String' display-string [DisplayString]	<p>Defines the caller ID.</p> <p>The valid value is a string of up to 18 characters.</p> <p><b>Note:</b> If you configure the parameter to "Private" or "Anonymous" (without quotation marks), caller ID is restricted and the settings of the 'Presentation' parameter (see below) is ignored.</p>
'Presentation' presentation [IsCidRestricted]	<p>Enables the device to send the caller ID string to the IP side.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Allowed</b> = Caller ID is sent when a Tel-to-IP call is made.</li> <li>■ [1] <b>Restricted</b> = Caller ID is not sent. The caller ID is sent to the remote side using only the SIP P-Asserted-Identity or P-Preferred-Identity headers, according to the [AssertedIdMode] parameter.</li> </ul> <p><b>Note:</b> The parameter is overridden by the 'Presentation' parameter in the Source Number Manipulation table (see <a href="#">Configuring Source-Destination Number Manipulation Rules</a> on page 983).</p>

## Configuring Call Forward

The Call Forward table lets you configure call forwarding per analog port for IP-to-Tel calls. Call forwarding redirects calls, using a SIP 302 response, initially destined to a specific port to a different port on the device or to an IP destination. You can configure the reason upon which the call is forwarded:

- Immediate: incoming call is forwarded immediately and unconditionally.
- Busy: incoming call is forwarded if the endpoint is busy.
- No Reply: incoming call is forwarded if it isn't answered for a specified time.
- On Busy or No Reply: incoming call is forwarded if the port is busy or when calls are not answered after a specified time.
- Do Not Disturb: immediately reject incoming calls. Upon receiving a call for a Do Not Disturb, the SIP 603 (Decline) response code is sent.

- The feature is applicable only to FXS and FXO interfaces.
- To enable call forwarding, see [Enabling Call Forwarding](#) on page 1043.

The following procedure describes how to configure call forwarding per port through the Web interface. You can also configure it through ini file [FwdInfo] or CLI (`configure voip > gateway analog call-forward`).

➤ **To configure call forwarding per port:**

1. Open the Call Forward table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Call Forward**).
2. Select the row corresponding to the port that you want to configure, and then click **Edit**; the following dialog box appears:

3. Configure call forwarding per port according to the parameters described in the table below.
4. Click **Apply**.

**Table 29-4: Call Forward Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	(Read-only) Displays the index number of the table row.
'Module' [Module]	(Read-only) Displays the module number on which the port is located.
'Port'	(Read-only) Displays the port number.

Parameter	Description
[Port]	
'Port Type' [PortType]	(Read-only) Displays the port type (FXS or FXO).
'Type' type [Type]	<p>Defines the condition upon which the call is forwarded.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Deactivate</b> = (Default) Don't forward incoming calls.</li> <li>■ [1] <b>On Busy</b> = Forward incoming calls when the port is busy.</li> <li>■ [2] <b>Unconditional</b> = Always forward incoming calls.</li> <li>■ [3] <b>No Answer</b> = Forward incoming calls that are not answered within the time specified in the 'No Reply Time' field.</li> <li>■ [4] <b>On Busy or No Answer</b> = Forward incoming calls when the port is busy or when calls are not answered within the time specified in the 'No Reply Time' field.</li> <li>■ [5] <b>Don't Disturb</b> = Immediately reject incoming calls.</li> </ul>
<b>Call Forward</b>	
'Forward Destination' destination [Destination]	<p>Defines the telephone number or URI (&lt;number&gt;@&lt;IP address&gt;) to where the call is forwarded.</p> <p><b>Note:</b> If the parameter is configured with only a telephone number and a Proxy isn't used, this forwarded-to phone number must be specified in the Tel-to-IP Routing table (see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946).</p>
'No Reply Time' no-reply-time [NoReplyTime]	<p>If you have set the 'Type' parameter for this port to <b>No Answer</b> or <b>On Busy or No Answer</b>, then configure the number of seconds the device waits before forwarding the call to the specified phone number.</p> <p><b>Note:</b> If you deactivate an active call forwarding rule (i.e., 'Type' parameter changed to <b>Deactivate</b>), the configured value in the 'No Reply Time' parameter is maintained and the value in the 'Forward Destination' parameter is deleted.</p>

## Configuring Caller ID Permissions

The Caller ID Permissions table lets you enable caller ID generation per FXS port for IP-to-Tel calls and detection per FXO port.

- The feature is applicable only to analog interfaces (FXS and FXO ).
- For ports that are not configured in the table, Caller ID is according to the global parameter, as described in [Enabling Caller ID Generation and Detection on Tel Side](#) on page 1053.

The following procedure describes how to configure Caller ID permissions through the Web interface. You can also configure it through ini file [EnableCallerID] or CLI (`configure voip > gateway analog enable-caller-id`).

➤ **To configure Caller ID permissions per port:**

1. Open the Caller ID Permissions table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Caller ID Permissions**).
2. Select the row corresponding to the port that you want to configure, and then click **Edit**; the following dialog box appears:

3. Configure a Caller ID permission per port according to the parameters described in the table below.
4. Click **Apply**.

**Table 29-5: Caller ID Permissions Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Module' [Module]	(Read-only) Displays the module number on which the port is located.
'Port'	(Read-only) Displays the port number.

Parameter	Description
[Port]	
'Port Type' [PortType]	(Read-only) Displays the port type (e.g., FXS).
Caller ID	
'Caller ID' caller-id [IsEnabled]	<p>Enables Caller ID generation (FXS) or detection (FXO) for the port.</p> <ul style="list-style-type: none"> <li>■ 0] <b>Disable</b></li> <li>■ [1] <b>Enable</b></li> </ul>

## Configuring Call Waiting

The Call Waiting table lets you enable call waiting per FXS port. When call waiting is enabled for a port and the device receives a call for the port, if the port is busy (i.e., currently in another call):

1. The device responds to the caller with a SIP 182 response (instead of a 486 busy).
2. The device plays a call waiting indication signal to the busy port.
3. When the device detects a hook-flash from the port, the device switches to the waiting call.
4. The device plays a call waiting ringback tone to the calling party after a 182 response is received.

- The feature is applicable only to FXS interfaces.
- For ports that are not configured in the table, call waiting is according to the global parameter, as described in [Enabling Call Waiting](#) on page 1050.
- In the installed CPT file, you must include the "Call Waiting Ringback" (#17) tone (heard by the calling party) and "Call Waiting" (#9) tone (heard by the called party, for FXS interfaces only). For more information, see [Call Progress Tones File](#) on page 1351.
- For call waiting support, you must enable call hold for the calling and called parties, as described in [Enabling Call Waiting](#) on page 1050.
- For additional call waiting configuration, see [Enabling Call Waiting](#) on page 1050.

The following procedure describes how to configure call waiting per port through the Web interface. You can also configure it through ini file [CallWaitingPerPort] or CLI (`configure voip > gateway analog call-waiting`).

### ➤ To enable call waiting per port:

1. Open the Call Waiting table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Call Waiting**).

2. Select the row corresponding to the port that you want to configure, and then click **Edit**; the following dialog box appears:

The screenshot shows a 'Call Waiting' dialog box with two tabs: 'GENERAL' and 'CALLER WAITING'. The 'GENERAL' tab is active, showing four input fields: 'Index' (0), 'Module' (1), 'Port' (1), and 'Port Type' (FXS). The 'CALLER WAITING' tab is visible but not active, showing a dropdown menu for 'Enable Call Waiting'.

3. Configure call waiting per port according to the parameters described in the table below.
4. Click **Apply**.

**Table 29-6: Call Waiting Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Module' [Module]	(Read-only) Displays the module number on which the port is located.
'Port' [Port]	(Read-only) Displays the port number.
'Port Type' [PortType]	(Read-only) Displays the port type (e.g., FXS).
Caller Waiting	
'Enable Call Waiting' enable-call-waiting [IsEnabled]	Enables call waiting for the port.  <div> <input type="checkbox"/> [0] <b>Disable</b> </div> <div> <input type="checkbox"/> [1] <b>Enable</b> </div>

## Rejecting Anonymous Calls

The device can reject anonymous calls received from the IP and destined to an FXS port. To configure the functionality, use the ini file parameter, `RejectAnonymousCallPerPort`. If configured for a specific port and the port receives an anonymous call, the device rejects the call and responds with a SIP 433 (Anonymity Disallowed) response. For a description of the parameter see [Caller ID Parameters](#) on page 1949.

The feature is applicable only to FXS interfaces.

## Configuring FXS Distinctive Ringing and Call Waiting Tones per Source/Destination Number

The Tone Index table lets you configure up to 50 rules, which define distinctive ringing tones and call waiting tones per calling (source) and called (destination) number (or prefix) for IP-to-Tel calls. You can configure the feature per FXS port or for a range of FXS ports. Therefore, different tones can be played per FXS port, depending on the source or destination number of the received call. You can also configure multiple entries with different source or destination prefixes and tones for the same FXS port.

Typically, the played ring tone or call waiting tone is indicated in the SIP Alert-Info header of the received INVITE message. However, if the header is not present, the feature is used and the tone played is according to the settings in this table.

- The feature is applicable only to FXS interfaces.
- To enable call waiting, see [Configuring Call Waiting](#) on page 1103.

The following procedure describes how to configure tones per FXS port through the Web interface. You can also configure it through ini file [ToneIndex] or CLI (`configure voip > gateway analog tone-index`).

### ➤ To configure distinctive ringing and call waiting tones per FXS port:

1. Open the Tone Index table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Tone Index**).
2. Click **New**; the following dialog box appears:

**Tone Index**

**GENERAL**

Index: 0

FXS Port First: 1

FXS Port Last: 4

Source Prefix: 2

Destination Prefix:

Priority Index: 1

The figure above shows a configuration example for using distinctive ringing and call waiting tones of Index #9 ('Priority Index' 1) in the CPT file for FXS endpoints 1 through 4 when a call is received from a calling (source) number with prefix 2.

3. Configure distinctive ringing and call waiting tones per port according to the parameters described in the table below.
4. Click **Apply**.

**Table 29-7: Tone index Table Parameter Description**

Parameter	Description
'Index'	Defines the table index entry.
'FXS Port First' fxs-port-first [ToneIndex_ FXSPort_First]	Defines the first port in the FXS port range.
'FXS Port Last' fxs-port-last [ToneIndex_ FXSPort_Last]	Defines the last port in the FXS port range.
'Source Prefix' src-pattern [ToneIndex_ SourcePrefix]	Defines the prefix of the calling number.
'Destination Prefix' dst-pattern	Defines the prefix of the called number.

Parameter	Description
[ToneIndex_ DestinationPrefix]	
'Priority Index' priority [ToneIndex_ PriorityIndex]	<p>Defines the index of the distinctive ringing and call waiting tones. The call waiting tone index is equal to the value of the 'Priority Index' parameter plus the value of the FirstCallWaitingToneID parameter (which defines the index of the first call waiting tone in the CPT file). For example, if you want to use the call waiting tone in the CPT file that is defined at Index #9, you need to configure the 'Priority Index' parameter to "1" and the FirstCallWaitingToneID parameter to "8". The summation of these values is 9 (1 + 8).</p> <p>The default is 0.</p> <p>To configure the CPT file, see <a href="#">Call Progress Tones File</a> on page 1351.</p>

## Analog Coefficient Types

The device can use the following analog Coefficient types:

### ■ FXS:

- USA line type: 600 ohm AC impedance and 40 V RMS ringing voltage for ringer equivalence number (REN) of 3
- European standard (TBR21)

### ■ FXO:

- REN: 0.5
- USA line type: 600 ohm AC impedance
- European standard (TBR21)

The Coefficient types increase return loss and trans-hybrid loss performance for two telephony line type interfaces (US or European). The adaptation is performed by modifying the telephony interface characteristics. This means, for example, that changing impedance matching or hybrid balance doesn't require hardware modifications, so that a single device is able to meet requirements for different markets. The digital design of the filters and gain stages also ensures high reliability, no drifts (over temperature or time) and simple variations between different line types.

The FXS Coefficient types provide best termination and transmission quality adaptation for two FXS line type interfaces. The parameter affects the following AC and DC interface parameters:

- DC (battery) feed characteristics
- AC impedance matching

- Transmit gain
- Receive gain
- Hybrid balance
- Frequency response in transmit and receive direction
- Hook thresholds
- Ringing generation and detection parameters

➤ **To select the Coefficient types:**

1. Open the Analog Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Analog Gateway** > **Analog Settings**).

COEFFICIENT

FXS Coefficient Type USA

FXO Coefficient Type • USA

2. From the 'FXS Coefficient Type' drop-down list (FXSCountryCoefficients), select the required FXS Coefficient type.
3. From the 'FXO Coefficient Type' drop-down list (FXOCountryCoefficients), select the required FXO Coefficient type.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## FXO Operating Modes

This section provides a description of the device's FXO operating modes:

- For IP-to-Tel calls (see [FXO Operations for IP-to-Tel Calls](#) below)
- For Tel-to-IP calls (see [FXO Operations for Tel-to-IP Calls](#) on page 1111)
- Call termination on FXO devices (see [Call Termination on FXO Devices](#) on page 1113)

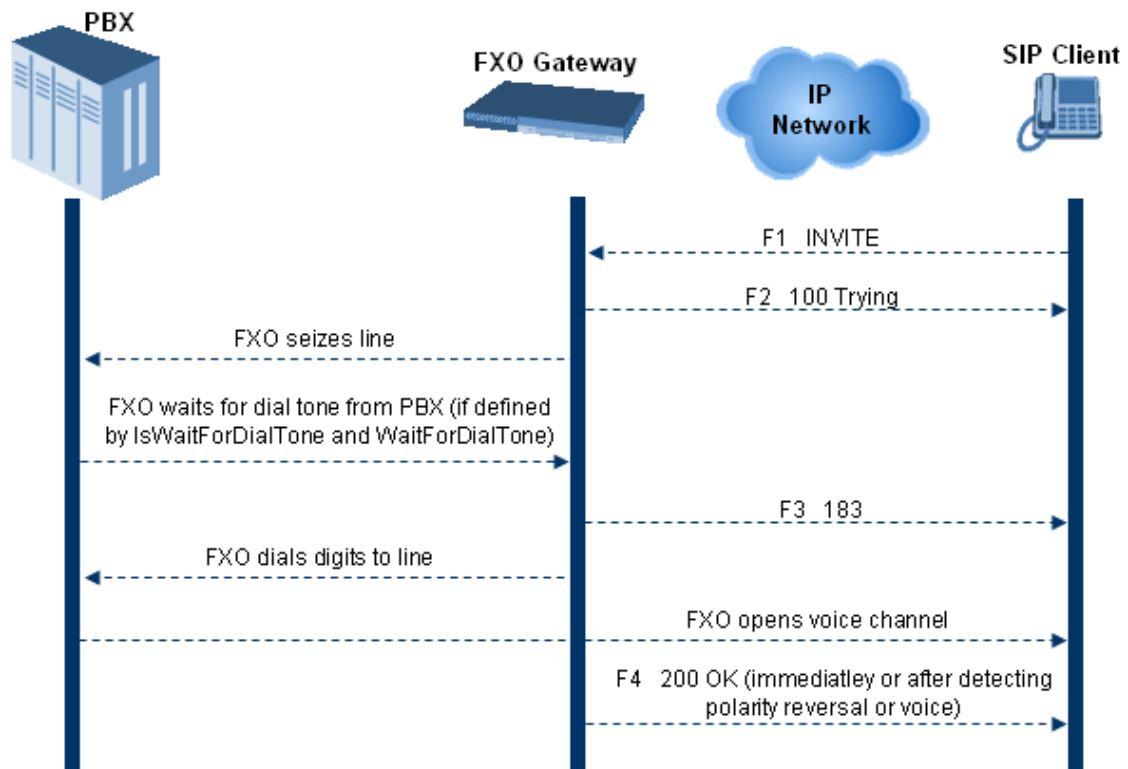

### FXO Operations for IP-to-Tel Calls

The FXO device provides the following operating modes for IP-to-Tel calls:

- One-stage dialing (see [One-Stage Dialing](#) on the next page)
  - Waiting for dial tone (see [Two-Stage Dialing](#) on page 1110)
  - Time to wait before dialing
  - Answer supervision
- Two-stage dialing (see [Two-Stage Dialing](#) on page 1110)
- Dialing time: DID wink (see [DID Wink](#) on page 1110)

## One-Stage Dialing

One-stage dialing is when the FXO device receives an IP-to-Tel call, off-hooks the PBX line connected to the telephone, and then immediately dials the destination telephone number. In other words, the IP caller doesn't dial the PSTN number upon hearing a dial tone.

One-stage dialing incorporates the following FXO functionality:

- **Waiting for Dial Tone:** Enables the device to dial the digits to the Tel side only after detecting a dial tone from the PBX line. The *ini* file parameter `IsWaitForDialTone` is used to configure this operation.
- **Time to Wait Before Dialing:** Defines the time (in msec) between seizing the FXO line and starting to dial the digits. The *ini* file parameter `WaitForDialTime` is used to configure this operation.

The *ini* file parameter `IsWaitForDialTone` must be disabled for this mode.

- **Answer Supervision:** The Answer Supervision feature enables the FXO device to determine when a call is connected, by using one of the following methods:
  - **Polarity Reversal:** the device sends a 200 OK in response to an INVITE only when it detects a polarity reversal.
  - **Voice Detection:** the device sends a 200 OK in response to an INVITE only when it detects the start of speech (fax or modem answer tone) from the Tel side. Note that the IPM detectors must be enabled.

## Two-Stage Dialing

Two-stage dialing is when the IP caller is required to dial twice. The caller initially dials to the FXO device and only after receiving a dial tone from the PBX (via the FXO device), dials the destination telephone number.

Two-stage dialing implements the Dialing Time feature. Dialing Time allows you to define the time that each digit can be separately dialed. By default, the overall dialing time per digit is 200 msec. The longer the telephone number, the greater the dialing time.

The relevant parameters for configuring Dialing Time include the following:

- **DTMFDigitLength** (100 msec): time for generating DTMF tones to the PSTN (PBX) side
- **DTMFInterDigitInterval** (100 msec): time between generated DTMF digits to PSTN (PBX) side

## DID Wink

The device's FXO ports support Direct Inward Dialing (DID). DID is a service offered by telephone companies that enables callers to dial directly to an extension on a PBX without the assistance of an operator or automated call attendant. This service makes use of DID trunks, which forward only the last three to five digits of a phone number to the PBX. If, for example, a company has a PBX with extensions 555-1000 to 555-1999, and a caller dials 555-1234, the local central office (CO) would forward, for example, only 234 to the PBX. The PBX would then ring extension 234.

DID wink enables the originating end to seize the line by going off-hook. It waits for acknowledgment from the other end before sending digits. This serves as an integrity check

that identifies a malfunctioning trunk and allows the network to send a re-order tone to the calling party.

The "start dial" signal is a wink from the PBX to the FXO device. The FXO then sends the last four to five DTMF digits of the called number. The PBX uses these digits to complete the routing directly to an internal station (telephone or equivalent).

- DID Wink can be used for connection to EIA/TIA-464B DID Loop Start lines.
- DID service for FXS interfaces is also supported.

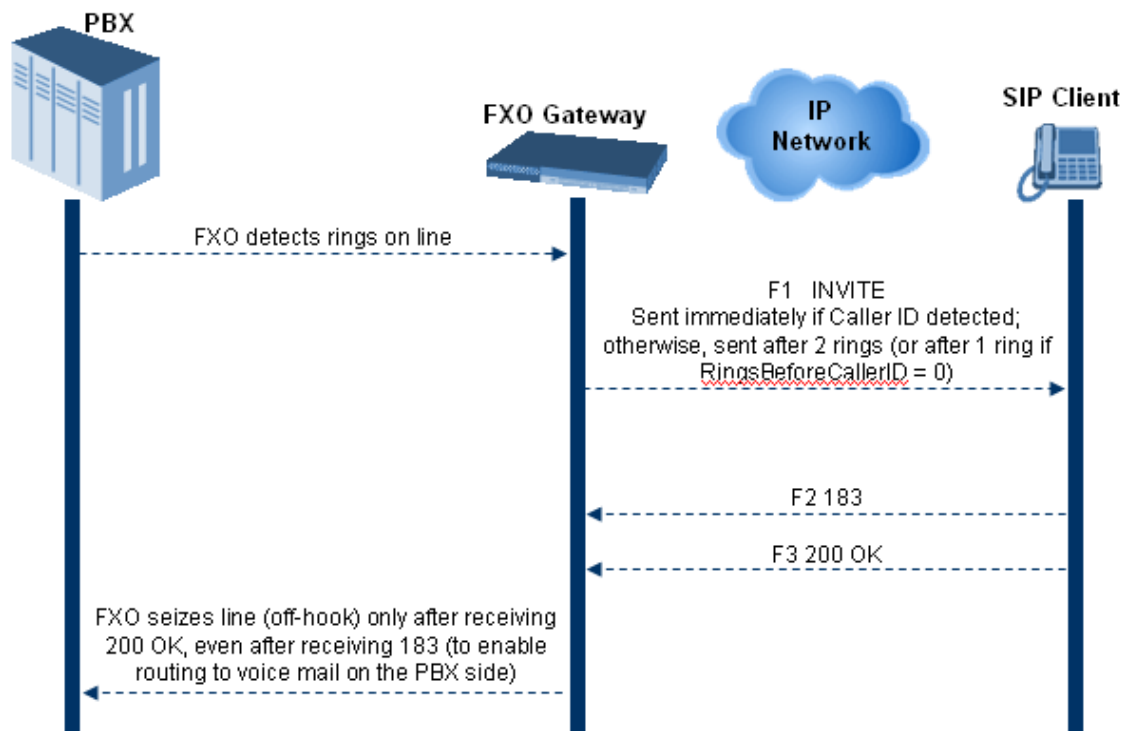

## FXO Operations for Tel-to-IP Calls

The FXO device provides the following FXO operating modes for Tel-to-IP calls:

- Automatic Dialing (see [Automatic Dialing](#) below)
- Collecting Digits Mode (see [Collecting Digits Mode](#) on the next page)
- FXO Supplementary Services (see [FXO Supplementary Services](#) on the next page)
  - Hold/Transfer Toward the Tel side
  - Hold/Transfer Toward the IP side
  - Blind Transfer to the Tel side

### Automatic Dialing

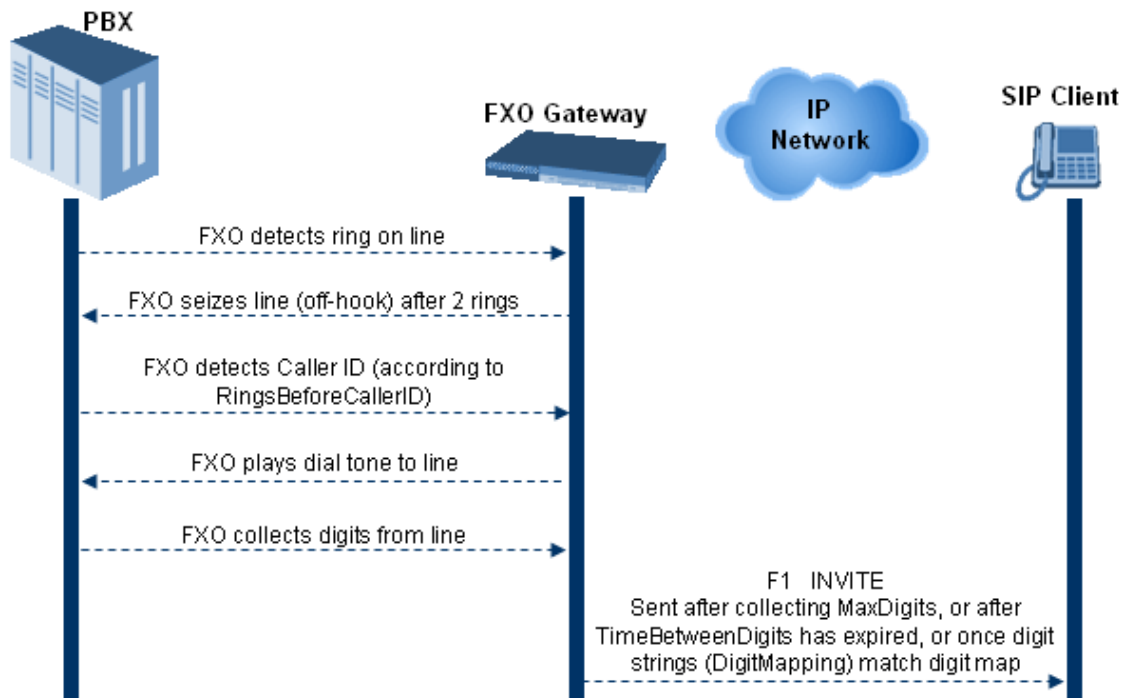

The SIP call flow diagram below illustrates Automatic Dialing:

To configure Automatic dialing, see [Configuring Automatic Dialing](#) on page 1095).

### Collecting Digits Mode

When automatic dialing is not configured, the device collects the digits. The SIP call flow diagram below illustrates the Collecting Digits Mode.

### FXO Supplementary Services

The FXO supplementary services include the following:

- **Hold / Transfer toward the Tel side:** The *ini* file parameter `LineTransferMode` must be set to 0 (default). If the FXO receives a hook-flash from the IP side (using out-of-band or RFC 2833), the device sends the hook-flash to the Tel side by performing one of the following:

- Performing a hook flash (i.e., on-hook and off-hook)
- Sending a hook-flash code (defined by the *ini* file parameter `HookFlashCode`)

The PBX may generate a dial tone that is sent to the IP, and the IP side may dial digits of a new destination.

- **Blind Transfer to the Tel side:** A blind transfer is one in which the transferring phone connects the caller to a destination line before ringback begins. The *ini* file parameter `LineTransferMode` must be set to 1.

The blind transfer call process is as follows:

- FXO receives a REFER request from the IP side

- FXO sends a hook-flash to the PBX, dials the digits (that are received in the Refer-To header), and then drops the line (on-hook). Note that the time between flash to dial is according to the WaitForDialTime parameter.
  - PBX performs the transfer internally
- **Hold / Transfer toward the IP side:** The FXO device doesn't initiate hold / transfer as a response to input from the Tel side. If the FXO receives a REFER request (with or without replaces), it generates a new INVITE according to the Refer-To header.

## Call Termination on FXO Devices

This section describes the device's call termination capabilities for its FXO interfaces:

- Calls terminated by a PBX (see [Calls Termination by PBX](#) below)
- Calls terminated before call establishment (see [Call Termination before Call Establishment](#) on the next page)
- Ring detection timeout (see [Ring Detection Timeout](#) on the next page)

### Calls Termination by PBX

The FXO device supports various methods for identifying when a call has been terminated by the PBX.

The PBX doesn't disconnect calls, but instead signals to the device that the call has been disconnected using one of the following methods:

- **Detection of polarity reversal/current disconnect:** The call is immediately disconnected after polarity reversal or current disconnect is detected on the Tel side (assuming the PBX/CO generates this signal). This is the recommended method.

Relevant parameters: [EnableReversalPolarity], [EnableCurrentDisconnect], [CurrentDisconnectDuration], [CurrentDisconnectDefaultThreshold], and [TimeToSampleAnalogLineVoltage].

- **Detection of Reorder, Busy, Dial, and Special Information Tone (SIT) tones:** The call is immediately disconnected after a Reorder, Busy, Dial, or SIT tone is detected on the Tel side (assuming the PBX / CO generates this tone). This method requires the correct tone frequencies and cadence to be defined in the Call Progress Tones file. If these frequencies are unknown, define them in the CPT file. The tone produced by the PBX / CO must be recorded and its frequencies analyzed. This method is slightly less reliable than the previous one.

Relevant parameters: [DisconnectOnBusyTone] and [DisconnectOnDialTone].

- **Special DTMF code:** A digit pattern that when received from the Tel side, indicates to the device to disconnect the call.

Relevant parameter: [TelDisconnectCode].

- **Interruption of RTP stream:** Relevant parameters: [BrokenConnectionEventTimeout] and [DisconnectOnBrokenConnection].

This method operates correctly only if silence suppression is not used.

- **Protocol-based termination of the call from the IP side**

Note: The implemented disconnect method must be supported by the CO or PBX.

## Call Termination before Call Establishment

The device supports the following call termination methods before a call is established:

- **Call termination upon receipt of SIP error response (in Automatic Dialing mode):** By default, when the FXO device operates in Automatic Dialing mode, there is no method to inform the PBX if a Tel-to-IP call has failed (SIP error response - 4xx, 5xx or 6xx - is received). The reason is that the FXO device doesn't seize the line until a SIP 200 OK response is received. Use the [FXOAutoDialPlayBusyTone] parameter to allow the device to play a busy / reorder tone to the PSTN line if a SIP error response is received. The FXO device seizes the line (off-hook) for the duration defined by the [TimeForReorderTone] parameter. After playing the tone, the line is released (on-hook).
- **Call termination after caller (PBX) on-hooks phone (Ring Detection Timeout feature):** This method operates in one of the following manners:
  - **Automatic Dialing is enabled:** if the remote IP party doesn't answer the call and the ringing signal (from the PBX) stops for a user-defined time (configured by the parameter FXOBetweenRingTime), the FXO device releases the IP call.
  - **No automatic dialing and Caller ID is enabled:** the device seizes the line after detection of the second ring signal (allowing detection of caller ID sent between the first and the second rings). If the second ring signal is not received within this timeout, the device doesn't initiate a call to IP.

This feature is applicable only to FXO interfaces.

## Ring Detection Timeout

The operation of Ring Detection Timeout depends on the following:

- **Automatic dialing is disabled and Caller ID is enabled:** if the second ring signal is not received for a user-defined time (using the parameter FXOBetweenRingTime), the FXO device doesn't initiate a call to the IP.
- **Automatic dialing is enabled:** if the remote party doesn't answer the call and the ringing signal stops for a user-defined time (using the parameter FXOBetweenRingTime), the FXO device releases the IP call.

Ring Detection Timeout supports full ring cycle of ring on and ring off (from ring start to ring start).

## Remote PBX Extension between FXO and FXS Devices

Remote PBX extension offers a company the capability of extending the "power" of its local PBX by allowing remote phones (remote offices) to connect to the company's PBX over the IP network (instead of via PSTN). This is as if the remote office is located in the head office (where the PBX is installed). PBX extensions are connected through FXO ports to the IP network, instead of being connected to individual telephone stations. At the remote office, FXS units connect analog phones to the same IP network. To produce full transparency, each FXO port is mapped to an FXS port (i.e., one-to-one mapping). This allows individual extensions to be extended to remote locations. To call a remote office worker, a PBX user or a PSTN caller simply dials the PBX extension that is mapped to the remote FXS port.

This section provides an example on how to implement a remote telephone extension through the IP network, using FXO and FXS interfaces. In this configuration, the FXO device routes calls received from the PBX to the 'Remote PBX Extension' connected to the FXS device. The routing is transparent as if the telephone connected to the FXS device is directly connected to the PBX.

The following is required:

- FXO interfaces with ports connected directly to the PBX lines (shown in the figure below)
- FXS interfaces for the 'remote PBX extension'
- Analog phones (POTS)
- PBX (one or more PBX loop start lines)
- LAN network

## Dialing from Remote Extension (Phone at FXS)

The following procedure describes how to dial from the 'remote PBX extension' (i.e., phone connected to the FXS interface).

### ➤ To make a call from the FXS interface:

1. Off-hook the phone and wait for the dial tone from the PBX. This is as if the phone is connected directly to the PBX. The FXS and FXO interfaces establish a voice path connection from the phone to the PBX immediately after the phone is off-hooked.
2. Dial the destination number (e.g., phone number 201). The DTMF digits are sent over IP directly to the PBX. All the audible tones are generated from the PBX (such as ringback, busy, or fast busy tones). One-to-one mapping occurs between the FXS ports and PBX lines.
3. The call disconnects when the phone connected to the FXS goes on-hook.

## Dialing from PBX Line or PSTN

The following procedure describes how to dial from a PBX line (i.e., from a telephone directly connected to the PBX) or from the PSTN to the 'remote PBX extension' (i.e., telephone connected to the FXS interface).

### ➤ To dial from a telephone directly connected to the PBX or from the PSTN:

- Dial the PBX subscriber number (e.g., phone number 101) in the same way as if the user's phone was connected directly to the PBX. As soon as the PBX rings the FXO device, the ring signal is 'sent' to the phone connected to the FXS device. Once the phone connected to the FXS device is off-hooked, the FXO device seizes the PBX line and the voice path is established between the phone and PBX.

There is one-to-one mapping between PBX lines and FXS device ports. Each PBX line is routed to the same phone (connected to the FXS device). The call disconnects when the phone connected to the FXS device is on-hooked.

## Message Waiting Indication for Remote Extensions

The device supports the relaying of Message Waiting Indications (MWI) for remote extensions (and voice mail applications). Instead of subscribing to an MWI server to receive notifications of pending messages, the FXO device receives subscriptions from the remote FXS device and notifies the appropriate extension when messages (and the number of messages) are pending.

The FXO device detects an MWI message from the Tel (PBX) side using any one of the following methods:

- 100 VDC (sent by the PBX to activate the phone's lamp)
- Stutter dial tone from the PBX
- MWI display signal (according to the parameter CallerIDType)

Upon detection of an MWI message, the FXO device sends a SIP NOTIFY message to the IP side. When receiving this NOTIFY message, the remote FXS device generates an MWI signal toward its Tel side.

### Call Waiting for Remote Extensions

When the FXO device detects a Call Waiting indication (FSK data of the Caller Id - CallerIDType2) from the PBX, it sends a proprietary INFO message, which includes the caller identification to the FXS device. Once the FXS device receives this INFO message, it plays a call waiting tone and sends the caller ID to the relevant port for display. The remote extension connected to the FXS device can toggle between calls using the Hook Flash button.

### FXS Gateway Configuration

The following procedure describes how to configure the FXS interface (at the 'remote PBX extension').

#### ➤ To configure the FXS interface:

1. In the Trunk Groups table (see [Configuring Trunk Groups](#)), assign the phone numbers 100 to 104 to the device's FXS ports.

Group Index	Module	From Trunk	To Trunk	Channels	Phone Number	Trunk Group ID	Tel Profile Name
1	Module 5 FXS			1-4	100		None

2. In the Automatic Dialing table (see [Configuring Automatic Dialing](#) on page 1095), configure automatic dialing for the FXS ports to dial the FXO endpoints, as shown in the figure below.

For example, when the phone connected to FXS Port #1 off-hooks, the device automatically dials the number "200".

INDEX	MODULE	PORT	PORT TYPE	AUTO DIAL STATUS	DESTINATION PHONE NUMBER
0	2	1	FXS	enable	200
1	2	2	FXS	enable	201
2	2	3	FXS	enable	202
3	2	4	FXS	enable	203

- In the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946), enter 20 for the destination phone prefix and 10.1.10.2 for the IP address of the FXO device.

INDEX	NAME	SOURCE TRUNK GROUP ID	SOURCE PHONE PREFIX	DESTINATION PHONE PREFIX	DESTINATION IP GROUP	SIP INTERFACE	DESTINATION IP ADDRESS	FORKING GROUP	CONNECTIVITY STATUS
0	FXS Routing	-1	*	20	--	--	10.1.10.2	-1	Not Available

For the transfer to function in remote PBX extensions, Hold must be disabled at the FXS device (i.e., Enable Hold = 0) and hook-flash must be transferred from the FXS to the FXO (HookFlashOption = 4).

## FXO Gateway Configuration

The following procedure describes how to configure the FXO interface (to which the PBX is directly connected).

### ➤ To configure the FXO interface:

- In the Trunk Groups table page (see [Configuring Trunk Groups](#) on page 934, assign the phone numbers 200 to 204 to the device's FXO endpoints.

Group Index	Module	From Trunk	To Trunk	Channels	Phone Number	Trunk Group ID	Tel Profile Name
1	Module 3 FXO			1-4	200		None

- In the Automatic Dialing table, enter the phone numbers of the FXS device in the 'Destination Phone Number' fields. When a ringing signal is detected at Port #1, the FXO device automatically dials the number "100".

INDEX	MODULE	PORT	PORT TYPE	AUTO DIAL STATUS	DESTINATION PHONE NUMBER
0	2	1	FXO	enable	100
1	2	2	FXO	enable	101
2	2	3	FXO	enable	102
3	2	4	FXO	enable	103

- In the Tel-to-IP Routing table, enter 10 in the 'Destination Phone Prefix' field, and the IP address of the FXS device (10.1.10.3) in the field 'IP Address'.

INDEX	NAME	SOURCE TRUNK GROUP ID	SOURCE PHONE PREFIX	DESTINATION PHONE PREFIX	DESTINATION IP GROUP	SIP INTERFACE	DESTINATION IP ADDRESS	FORKING GROUP	CONNECTIVITY STATUS
0		-1	*	10	--	--	10.1.10.3	-1	Not Available

4. In the FXO Settings page (see [Configuring FXO Settings](#) on page 1093), set the parameter 'Dialing Mode' to **Two Stages** (IsTwoStageDial = 1).

# **Part VI**

## **Session Border Controller Application**

## 30 Overview

This section provides an overview of the device's SBC application.

- For guidelines on how to deploy your SBC device, refer to the *SBC Design Guide* document.
- The SBC feature is available only if the device is installed with a License Key that includes this feature. For installing a License Key, see [License Key](#) on page 1362.
- For the maximum number of supported SBC sessions, and SBC users than can be registered in the device's registration database, see [Technical Specifications](#) on page 2155.

### Feature List

The SBC application supports the following main features:

- NAT traversal: The device supports NAT traversal, allowing, for example, communication with ITSPs with globally unique IP addresses and with far-end users located behind NAT on the WAN. The device supports this by:
  - Continually registering far-end users with its users registration database.
  - Maintaining remote NAT binding state by frequent registrations and thereby, off-loading far-end registrations from the LAN IP PBX.
  - Using Symmetric RTP (RFC 4961) to overcome bearer NAT traversal.
- VoIP firewall and security for signaling and media:
  - SIP signaling:
    - ◆ Deep and stateful inspection of all SIP signaling packets.
    - ◆ SIP dialog initiations may be rejected based on values of incoming SIP INVITE message and other Layer-3 characteristics.
    - ◆ Packets not belonging to an authorized SIP dialog are discarded.
  - RTP:
    - ◆ Deep packet inspection of all RTP packets.
    - ◆ Late rogue detection - if a SIP session was gracefully terminated and someone tries to "ride on it" with rogue traffic from the already terminated RTP and SIP context, the VoIP Firewall prevents this from occurring.
    - ◆ Disconnects call (after user-defined time) if RTP connection is broken.
    - ◆ Black/White lists for both Layer-3 firewall and SIP classification.

- **Stateful Proxy Operation Mode:** The device can act as a Stateful Proxy by enabling SIP messages to traverse it transparently (with minimal interference) between the inbound and outbound legs.
- **B2BUA and Topology Hiding:** The device intrinsically supports topology hiding, limiting the amount of topology information displayed to external parties. For example, IP addresses of ITSPs' equipment (e.g. proxies, gateways, and application servers) can be hidden from outside parties. The device's topology hiding is provided by implementing back-to-back user agent (B2BUA) leg routing:
  - Strips all incoming SIP Via header fields and creates a new Via value for the outgoing message.
  - Each leg has its own Route/Record Route set.
  - User-defined manipulation of SIP To, From, and Request-URI host names.
  - Generates a new SIP Call-ID header value (different between legs).
  - Changes the SIP Contact header and sets it to the device's address.
  - Layer-3 topology hiding by modifying source IP address in the SIP IP header.
- **SIP normalization:** The device supports SIP normalization, whereby the SBC application can overcome interoperability problems between SIP user agents. This is achieved by the following:
  - Manipulation of SIP URI user and host parts.
  - Connection to ITSP SIP trunks on behalf of an IP-PBX - the device can register and utilize user and password to authenticate for the IP-PBX.
- **Survivability:**
  - Routing calls to alternative routes such as the PSTN.
  - Routing calls between user agents in the local network using a dynamic database (built according to registrations of SIP user agents).
- **Routing:**
  - IP-to-IP routing translations of SIP, UDP, TCP, TLS (when extensive transcoding is not required).
  - Load balancing and redundancy of SIP servers.
  - Routing according to Request-URI\Specific IP address\Proxy\FQDN.
  - Alternative routing.
  - Routing between different Layer-3 networks (e.g., LAN and WAN).
- **Load balancing\redundancy of SIP servers.**
- **ITSP accounts.**
- **SIP URI user and host name manipulations.**

- **Coder transcoding.**

## B2BUA and Stateful Proxy Operating Modes

The device can operate in one or both of the following SBC modes:

- **Back-to-Back User Agent (B2BUA):** Maintains independent sessions toward the endpoints, processing an incoming request as a user agent server (UAS) on the inbound leg, and processing the outgoing request as a user agent client (UAC) on the outbound leg. SIP messages are modified regarding headers between the legs and all the device's interworking features may be applied.
- **Stateful Proxy Server:** SIP messages traverse the device transparently (with minimal interference) between the inbound and outbound legs, for connecting SIP endpoints.

By default, the device's B2BUA mode changes SIP dialog identifiers and topology data in SIP messages traversing through it:

- **Call identifiers:** Replaces the From-header tag and Call-ID header so that they are different for each leg (inbound and outbound).
- **Routing headers:**
  - Removes all Via headers in incoming requests and sends the outgoing message with its own Via header.
  - Doesn't forward any Record-Route headers from the inbound to outbound leg, and vice versa.
  - Replaces the address of the Contact header in the incoming message with its own address in the outgoing message.
- Replaces the User-Agent/ Server header value in the outgoing message, and replaces the original value with itself in the incoming message.

In contrast, when the device operates in Stateful Proxy mode, the device by default forwards SIP messages transparently (unchanged) between SIP endpoints (from inbound to outbound legs). The device retains the SIP dialog identifiers and topology headers received in the incoming message and sends them as is in the outgoing message. The device handles the above mentioned headers transparently (i.e., they remain unchanged) or according to configuration (enabling partial transparency), and only adds itself as the top-most Via header and optionally, to the Record-Route list. To configure the handling of these headers for partial transparency, use the following IP Profile parameters (see [Configuring IP Profiles](#) on page 674):

- 'Remote Representation Mode': Contact and Record-Route headers
- 'Keep Incoming Via Headers': Via headers
- 'Keep User-Agent Header': User-Agent headers
- 'Keep Incoming Routing Headers': Record-Route headers
- 'Remote Multiple Early Dialogs': To-header tags

Thus, the Stateful Proxy mode provides full SIP transparency (no topology hiding) or asymmetric topology hiding. Below is an example of a SIP dialog-initiating request when operating in Stateful Proxy mode for full transparency, showing all the incoming SIP headers retained in the outgoing INVITE message.

Incoming INVITE	Outgoing INVITE
<pre> INVITE sip:bob@domain.com SIP/2.0 To: Bob &lt;sip:bob@domain.com&gt; From: Alice &lt;sip:alice@caller.com&gt;;tag=100 Call-ID: callid1@caller.com Contact: &lt;sip:alice@pc1.caller.com&gt; Via: SIP/2.0/UDP pc2.com;branch=branch2 Via: SIP/2.0/UDP pc1.com;branch=branch1 Record-Route: &lt;pc2.com;lr&gt; Record-Route: &lt;pc1.com;lr&gt; CSeq: 666 INVITE User-Agent: IPPv3.1 Max-Forwards: 70 Content-Type: application/sdp Content-Length: 142  v=0 ... </pre>	<pre> INVITE sip:bob@domain.com SIP/2.0 To: Bob &lt;sip:bob@domain.com&gt; From: Alice &lt;sip:alice@caller.com&gt;;tag=100 Call-ID: callid1@caller.com Contact: &lt;sip:alice@pc1.caller.com&gt; Via: SIP/2.0/UDP Proxy-IP;branch=branch3 Via: SIP/2.0/UDP pc2.com;branch=branch2 Via: SIP/2.0/UDP pc1.com;branch=branch1 Record-Route: &lt;Proxy-IP;lr&gt; Record-Route: &lt;pc2.com;lr&gt; Record-Route: &lt;pc1.com;lr&gt; CSeq: 666 INVITE User-Agent: IPPv3.1 Max-Forwards: 70 Content-Type: application/sdp Content-Length: 142  v=0 ... </pre>

Some of the reasons for implementing Stateful Proxy mode include:

- B2BUA typically hides certain SIP headers for topology hiding. In specific setups, some SIP servers require the inclusion of these headers to know the history of the SIP request. In such setups, the requirement may be asymmetric topology hiding, whereby SIP traffic toward the SIP server must expose these headers whereas SIP traffic toward the users must not expose these headers.
- B2BUA changes the call identifiers between the inbound and outbound SBC legs and therefore, call parties may indicate call identifiers that are not relayed to the other leg. Some SIP functionalities are achieved by conveying the SIP call identifiers either in SIP specific headers (e.g., Replaces) or in the message bodies (e.g. Dialog Info in an XML body).
- In some setups, the SIP client authenticates using a hash that is performed on one or more of the headers that B2BUA changes (removes). Therefore, implementing B2BUA would cause authentication to fail.
- For facilitating debugging procedures, some administrators require that the value in the Call-ID header remains unchanged between the inbound and outbound SBC legs. As B2BUA changes the Call-ID header, such debugging requirements would fail.

The operating mode can be configured per the following configuration entities:

- SRDs in the SRDs table (see [Configuring SRDs](#) on page 558)
- IP Groups in the IP Groups table (see [Configuring IP Groups](#) on page 591)

If the operation mode is configured in both tables, the operation mode of the IP Group is applied. Once configured, the device uses default settings in the IP Profiles table for handling the SIP headers, as mentioned previously. However, you can change the default settings to enable partial transparency.

- The To-header tag remains the same for inbound and outbound legs of the dialog, regardless of operation mode.
- If the Operation Mode of the SRD\IP Group of one leg of the dialog is set to 'Call Stateful Proxy', the device also operates in this mode on the other leg with regards to the dialog identifiers (Call-ID header, tags, CSeq header).
- It is recommended to implement the B2BUA mode, unless one of the reasons mentioned previously is required. B2BUA supports all the device's feature-rich offerings, while Stateful Proxy may offer only limited support. The following features are not supported when in Stateful Proxy mode:
  - ✓ Alternative routing
  - ✓ Call forking
  - ✓ Terminating REFER/3xx
- If Stateful Proxy mode is enabled and any one of the unsupported features is enabled, the device disables the Stateful Proxy mode and operates in B2BUA mode.
- You can configure the device to operate in both B2BUA and Stateful Proxy modes for the same users. This is typically implemented when users need to communicate with different SIP entities (IP Groups). For example, B2BUA mode for calls destined to a SIP Trunk and Stateful Proxy mode for calls destined to an IP PBX. The configuration is done using IP Groups and SRDs.
- If Stateful Proxy mode is used only due to the debugging benefits, it is recommended to configure the device to only forward the Call-ID header unchanged

## Call Processing of SIP Dialog Requests

The device processes incoming SIP dialog requests (SIP methods) such as INVITE, SUBSCRIBE, OPTIONS, REFER, INFO, UNSOLICITED NOTIFY, MESSAGE, and REGISTER. The process is summarized in the following figure and subsequently described:

The first stage of the SIP dialog-initiating process is **determining source and destination URLs**. The SIP protocol has more than one URL in a dialog-initiating request that may represent the source and destination URLs. The device obtains the source and destination URLs from certain SIP headers. Once the URLs are determined, the user and host parts of the URLs can be used as matching rule characteristics for classification, message manipulation, and call routing.

■ **All SIP requests (e.g., INVITE) except REGISTER:**

- Source URL: Obtained from the From header. If the From header contains the value 'Anonymous', the source URL is obtained from the P-Preferred-Identity header. If the P-Preferred-Identity header doesn't exist, the source URL is obtained from the P-Asserted-Identity header.
- Destination URL: Obtained from the Request-URI.

#### ■ REGISTER dialogs:

- Source URL: Obtained from the To header.
- Destination URL: Obtained from the Request-URI.

You can specify the SIP header from where you want the device to obtain the source URL in the incoming dialog request. This is configured in the IP Groups table using the 'Source URI Input' parameter (see [Configuring IP Groups](#) on page 591).

The next stages of the SIP dialog-initiating process is as follows:

1. **Determining the SIP Interface:** The device checks the SIP Interface on which the SIP dialog is received. The SIP Interface defines the local SIP "listening" port and IP network interface. For more information, see [Configuring SIP Interfaces](#) on page 570.
2. **Applying Pre-parsing SIP Message Manipulation:** If configured, the device can apply SIP message manipulation to the incoming SIP message before it is parsed by the device. This type of manipulation is called Pre-Parsing Manipulation, which is configured in the Pre-Parsing Manipulation Sets table (see [Configuring Pre-Parsing Manipulation Rules](#) on page 870) and is assigned to the SIP Interface.
3. **Applying Pre-classification SIP Message Manipulation:** If configured, the device can apply SIP message manipulation to the incoming SIP message before it is classified to a source IP Group. This manipulation is configured in the SIP Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856 and is assigned to the SIP Interface.
4. **Classifying to a Source IP Group using Tags:** If configured, the device can classify the incoming SIP message to a source IP Group, based on a source tag that is determined by running a Call Setup Rule. The Call Setup Rule is configured in the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809) and is assigned to the SIP Interface. For more information on tag-based classification, see [Configuring Classification Based on Tags](#) on page 1183.
5. **Classifying to a Source IP Group:** Classification identifies the incoming SIP dialog request as belonging to a specific IP Group (i.e., from where the SIP dialog request originated). The classification process is based on the SRD to which the dialog belongs (the SRD is determined according to the SIP Interface). For more information, see [Configuring Classification Rules](#) on page 1171.
6. **Applying Inbound Manipulation:** Depending on configuration, the device can apply an Inbound Manipulation rule to the incoming dialog. This manipulates the user part of the SIP URI for source (e.g., in the SIP From header) and destination (e.g., in the Request-URI line). The manipulation rule is associated with the incoming dialog, by configuring the rule with incoming matching characteristics such as source IP Group and destination host name. The manipulation rules are also assigned a Routing Policy, which in turn, is assigned to IP-to-IP routing rules. As most deployments require only one Routing Policy, the default Routing Policy is automatically assigned to manipulation and routing rules. For more information, see [Configuring IP-to-IP Inbound Manipulations](#) on page 1231.

- 7. Applying a Dial Plan to Determine Tag:** If configured, the device can run a Dial Plan rule based on the source (or destination) number of the incoming SIP message to determine its' tag. The tag can later be used in the routing and manipulation stages. Dial Plan rules are configured in the Dial Plan table (see [Configuring Dial Plans](#) on page 825) and assigned to the IP Group.
- 8. Applying Call Setup Rules for Various Functions:** If configured, the device can run Call Setup Rules to apply various functions to the call, for example, querying an LDAP server. The Call Setup Rule is configured in the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809) and is assigned to the IP Group.
- 9. SBC IP-to-IP Routing:** The device searches the IP-to-IP Routing table for a routing rule that matches the characteristics of the incoming call. If found, the device routes the call to the configured destination which can be, for example, an IP Group, the Request-URI if the user is registered with the device, and a specified IP address. For more information, see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186.
- 10. Applying Call Setup Rules for Various Functions:** If configured, the device can run Call Setup Rules to apply various functions to the call. The Call Setup Rule is configured in the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809) and is assigned to the IP-to-IP Routing table.
- 11. Applying Inbound SIP Message Manipulation:** Depending on configuration, the device can apply a SIP message manipulation rule (assigned to the IP Group) on the incoming dialog. For more information, see Stage 3.
- 12. Applying Outbound Manipulation:** Depending on configuration, the device can apply an Outbound Manipulation rule to the outbound dialog. This manipulates the user part of the Request-URI for source (e.g., in the SIP From header) or destination (e.g., in the SIP To header) or calling name in the outbound SIP dialog. The manipulation rule is associated with the dialog, by configuring the rule with incoming matching characteristics such as source IP Group and destination host name. The manipulation rules are also assigned a Routing Policy, which in turn, is assigned to IP-to-IP routing rules. As most deployments require only one Routing Policy, the default Routing Policy is automatically assigned to manipulation rules and routing rules. For more information, see [Configuring IP-to-IP Outbound Manipulations](#) on page 1236.
- 13. Applying Outbound SIP Message Manipulation:** Depending on configuration, the device can apply a SIP message manipulation rule (assigned to the IP Group) on the outbound dialog. For more information, see Stage 3.
- 14.** The call is sent to the configured destination.

## User Registration

The device provides a registration database for registering users. Only users belonging to a User-type IP Group can register with the device. User-type IP Groups represent a group of SIP user agents that share the following characteristics:

- Perform registrations and share the same serving proxy\registrar

- Same SIP and media behavior
- Same IP Profile
- Same SIP handling configuration
- Same Call Admission Control (CAC)

Typically, the device is configured as the user's outbound proxy, routing requests (using the IP-to-IP Routing table) from the user's User-type IP Group to the serving proxy, and vice versa. Survivability can be achieved using the alternative routing feature.

The device forwards registration requests (REGISTER messages) from a Server-type IP Group, but doesn't save the registration binding in its' registration database.

## Initial Registration Request Processing

A summary of the device's handling of registration requests (REGISTER messages) is as follows:

- The URL in the SIP To header of the REGISTER message constitutes the primary Address of Record (AOR) for registration (according to SIP standards). If the To header's URL includes the "user=phone" parameter, then only the user part of the URL constitutes the AOR. If the To header's URL doesn't include the "user=phone" parameter, then both the user part and host part of the URL constitutes the AOR.
- The device can save other AORs in its registration database as well. When the device searches for a user in its' registration database, any of the user's AORs can result in a match.
- The device's Classification process for initial REGISTER messages is slightly different than for other SIP messages. Unlike other requests, initial REGISTER requests can't be classified according to the registration database.
- If registration succeeds (replied with 200 OK by the destination server), the device adds a record to its' registration database, which identifies the specific contact of the specific user (AOR). The device uses this record to route subsequent SIP requests to the specific user (in normal or survivability modes).
- The records in the device's registration database include the Contact header. The device adds every REGISTER request to the registration database before manipulation, allowing correct user identification in the Classification process for the next received request.
- You can configure Call Admission Control (CAC) rules for incoming and outgoing REGISTER messages. For example, you can limit REGISTER requests from a specific IP Group or SRD. Note that this applies only to concurrent REGISTER dialogs and not concurrent registrations in the device's registration database.

The device provides a dynamic registration database that it updates according to registration requests traversing it. Each database entry for a user represents a binding between an AOR (obtained from the SIP To header), optional additional AORs, and one or more contacts (obtained from the SIP Contact headers). Database bindings are added upon successful

registration responses from the proxy server (SIP 200 OK). The device removes database bindings in the following cases:

- Successful de-registration responses (REGISTER with Expires header that equals zero).
- Registration failure responses.
- Timeout of the Expires header value (in scenarios where the UA did not send a refresh registration request).

- The same contact cannot belong to more than one AOR.
- Contacts with identical URIs and different ports and transport types are not supported (same key is created).
- Multiple contacts in a single REGISTER message is not supported.
- One database is shared between all User-type IP Groups.

## Classification and Routing of Registered Users

The device can classify incoming SIP dialog requests (e.g., INVITE) from registered users to an IP Group, by searching for the sender's details in the registration database. The device uses the AOR from the From header and the URL in the Contact header of the request to locate a matching registration binding. The found registration binding contains information regarding the registered user, including the IP Group to which it belongs. (Upon initial registration, the Classification table is used to classify the user to a User-type IP Group and this information is then added with the user in the registration database.)

The destination of a dialog request can be a registered user and the device thus uses its registration database to route the call. This can be achieved by various ways such as configuring a rule in the IP-to-IP Routing table where the destination is a User-type IP Group or any matching user registered in the database ('Destination Type' is configured to **All Users**). The device searches the registration database for a user that matches the incoming Request-URI (listed in chronological order):

- Unique Contact generated by the device and sent in the initial registration request to the serving proxy.
- AOR. The AOR is originally obtained from the incoming REGISTER request and must either match both user part and host part (user@host) of the Request-URI, or only user part.
- Contact. The Contact is originally obtained from the incoming REGISTER request.

If registrations are destined to the database (using the above rules), the device doesn't attempt to find a database match, but instead replies with a SIP 200 OK (used for Survivability). Once a match is found, the request is routed either to the contact received in the initial registration or (if the device identifies that the user agent is behind a NAT) to the source IP address of the initial registration.

You can configure (using the [SBCDBRoutingSearchMode] parameter) for which part of the destination Request-URI in the INVITE message the device must search in the registration database:

- Only by entire Request-URI (user@host), for example, "4709@joe.company.com".
- By entire Request-URI, but if not found, by the user part of the Request-URI, for example, "4709".

When an incoming INVITE is received for routing to a user and the user is located in the registration database, the device sends the call to the user's corresponding contact address specified in the database.

If the Request-URI contains the "tel:" URI or "user=phone" parameter, the device searches only for the user part.

You can also configure which URI parameters are excluded when the device compares the URIs of two incoming dialog-initiating SIP requests (e.g., INVITEs) to determine if they were sent from a user that is registered in the device's registration database. For example, you can configure the parameter to exclude ports from the comparison. For more information, see the description of the [SBCURIComparisonExcludedParams] parameter.

## General Registration Request Processing

The device's general handling of registration requests (REGISTER messages) for unregistered users is as follows:

- The device routes REGISTER requests according to the IP-to-IP Routing table. If the destination is a User-type IP Group, the device doesn't forward the registration; instead, it accepts (replies with a SIP 200 OK response) or rejects (replies with a SIP 4xx) the request according to the user's IP Group configuration.
- Alternative routing can be configured for REGISTER requests in the IP-to-IP Routing table.
- By default, the SIP Expires header has the same value in incoming and outgoing REGISTER messages. However, you can modify the its value using the following parameters: [SBCUserRegistrationTime], [SBCProxyRegistrationTime], [SBCRandomizeExpires], and [SBCSurvivabilityRegistrationTime]. You can also modify the Expires value of REGISTER requests received from users located behind NAT, using the IP Profile parameters 'NAT UDP Registration Time' and 'NAT TCP Registration Time'.
- By default, the SIP Contact header in the outgoing REGISTER message is different than the Contact header in the incoming REGISTER. The user part of the Contact header is populated with a unique contact generated by the device and associated with the specific registration. The IP address in the host part is changed to the address of the device. Alternatively, the original user can be retained in the Contact header and used in the outgoing REGISTER request, using the [SBCKeepContactUserinRegister] parameter.

## Registration Refreshes

Registration refreshes are incoming REGISTER requests from users that are registered in the device's registration database. The device sends these refreshes to the serving proxy only if the serving proxy's Expires time is about to expire; otherwise, the device responds with a 200 OK to

the user without routing the REGISTER. Each such refresh also refreshes the internal timer set on the device for this specific registration.

The device automatically notifies SIP proxy / registrar servers of users that are registered in its registration database and whose registration timeout has expired. When a user's registration timer expires, the device removes the user's record from the database and sends an un-register notification (REGISTER message with the Expires header set to 0) to the proxy/registrar. This occurs only if a REGISTER message is sent to an IP Group destination type (in the IP-to-IP Routing table).

You can also apply a graceful period to unregistered requests, using the 'User Registration Grace Time' parameter ([SBCUserRegistrationGraceTime]):

- You can configure the device to add extra time (grace period) to the expiration timer of registered users in the database. If you configure this grace period, the device keeps the user in the database (and doesn't send an unregister to the registrar server), allowing the user to send a "late" re-registration to the device. The device removes the user from the database only when this additional time expires.
- The graceful period is also used before removing a user from the registration database when the device receives a successful unregister response (200 OK) from the registrar/proxy server. This is useful in scenarios, for example, in which users (SIP user agents) such as IP Phones erroneously send unregister requests. Instead of immediately removing the user from the registration database upon receipt of a successful unregister response, the device waits until it receives a successful unregister response from the registrar server, waits the user-defined graceful time and if no register refresh request is received from the user agent, removes the contact (or AOR) from the database.

The device keeps registered users in its' registration database even if connectivity with the proxy is lost (i.e., proxy doesn't respond to users' registration refresh requests). The device removes users from the database only when their registration expiry time is reached (with the additional grace period, if configured).

## Registration Restriction Control

The device provides flexibility in controlling user registrations:

- **Limiting Number of Registrations:** You can limit the number of users that can register with the device per IP Group, SIP Interface, and/or SRD, in the IP Group, SIP Interface and SRDs tables respectively. By default, no limitation exists.
- **Blocking Incoming Calls from Unregistered Users:** You can block incoming calls (INVITE requests) from unregistered users belonging to User-type IP Groups. By default, calls from unregistered users are not blocked. This is configured per SIP Interface or SRD. When the call is rejected, the device sends a SIP 500 (Server Internal Error) response to the remote end.

## Deleting Registered Users

You can remove registered users from the device's registration database through CLI:

- To delete a specific registered user:

```
# clear voip register db sbc user <AOR of user - user part or user@host>
```

For example:

```
# clear voip register db sbc user John@10.33.2.22  
# clear voip register db sbc user John
```

- To delete all registered users belonging to a specific IP Group:

```
# clear voip register db sbc ip-group <ID or name>
```

## Media Handling

Media behavior includes anything related to the establishment, management and termination of media sessions within the SIP protocol. Media sessions are created using the SIP offer-answer mechanism. If successful, the result is a bi-directional media (RTP) flow (e.g. audio, fax, modem, DTMF). Each offer-answer may create multiple media sessions of different types (e.g. audio and fax). In a SIP dialog, multiple offer-answer transactions may occur and each may change the media session characteristics (e.g. IP address, port, coders, media types, and RTP mode).

The media capabilities exchanged in an offer-answer transaction include the following:

- Media types (e.g., audio, secure audio, video, fax, and text).
- IP addresses and ports of the media flow.
- Media flow mode (send receive, receive only, send only, inactive).
- Media coders (coders and their characteristics used in each media flow).
- Other (standard or proprietary) media and session characteristics.

Typically, the device doesn't change the negotiated media capabilities (mainly performed by the remote user agents). However, it does examine and may take an active role in the SDP offer-answer mechanism. This is done mainly to anchor the media to the device (default) and also to change the negotiated media type, if configured. Some of the media handling features, which are described later in this section, include the following:

- Media anchoring (default).
- Direct media (see [Direct Media Calls](#) on page 1135).
- Audio coders restrictions.
- Audio coders transcoding.
- RTP-SRTP transcoding.
- DTMF translations.

- Fax translations and detection.
- Early media and ringback tone handling.
- Call hold translations and held tone generation.
- NAT traversal.
- RTP broken connections.
- Media firewall:
  - RTP pin holes - only RTP packets related to a successful offer-answer negotiation traverse the device: When the device initializes, there are no RTP pin holes opened. This means that each RTP\RTCP packets destined to the device are discarded. Once an offer-answer transaction ends successfully, an RTP pin hole is opened and RTP\RTCP flows between the two remote user agents. Once a pin hole is opened, the payload type and RTP header version is validated for each packet. RTP pin holes close if one of the associated SIP dialogs is closed (may also be due to broken connection).
  - Late rogue detection - once a dialog is disconnected, the related pin holes also disconnect.
  - Deep Packet inspection of the RTP that flows through the opened pin holes.

## Media Anchoring

By default, the device anchors the media (RTP) traffic. In other words, the media between SIP endpoints traverses the device. You can change this default mode by enabling direct media between SIP endpoints. Media anchoring may be required, for example, to resolve NAT problems, enforce media security policies, perform media transcoding, and media monitoring.

To enforce RTP traffic to flow through the device, the device modifies all IP address fields in the SDP:

- Origin: IP address, session and version id
- Session connection attribute ('c=' field)
- Media connection attribute ('c=' field)
- Media port number
- RTCP media attribute IP address and port

The device uses different local ports (e.g., for RTP, RTCP and fax) for each leg (inbound and outbound). The local ports are allocated from the Media Realm associated with each leg. The Media Realm assigned to the leg's IP Group (in the IP Groups table) is used. If not assigned to the IP Group, the Media Realm assigned to the leg's SIP Interface (in the SIP Interfaces table) is used. The following figure provides an example of SDP handling for a call between a LAN IP Phone 10.2.2.6 and a remote IP Phone 212.179.1.13 on the WAN.

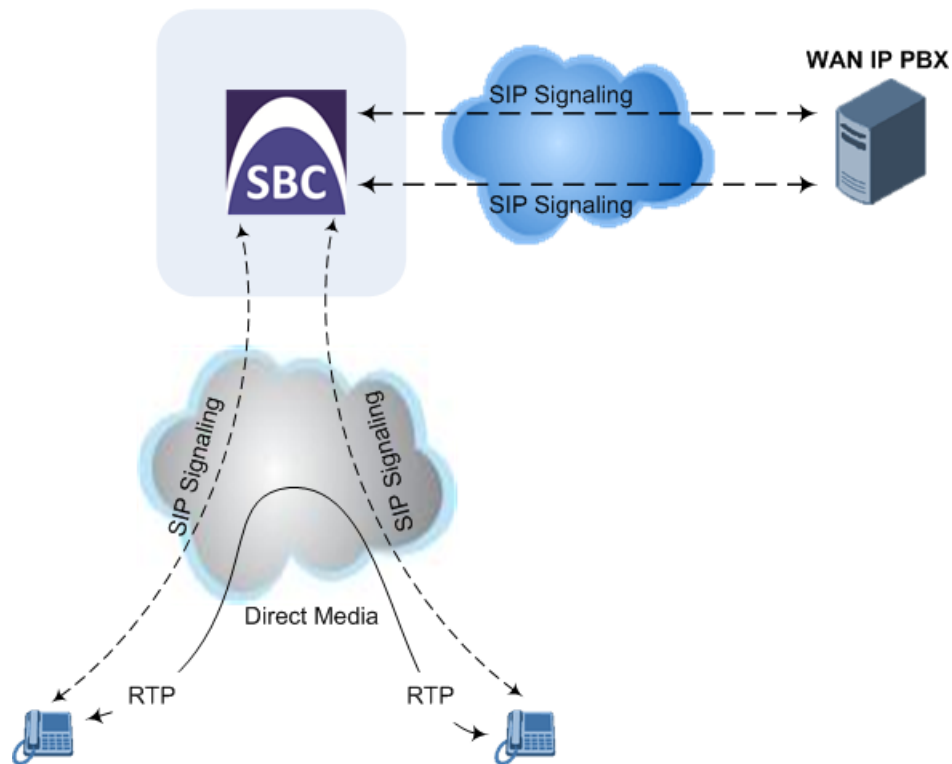

## Direct Media Calls

You can configure the device to allow the media (RTP/SRTP) session to flow directly between the SIP endpoints without traversing the device. This is referred to as No Media Anchoring (also known as Anti-Tromboning or Direct Media). SIP signaling continues to traverse the device with minimal intermediation and involvement to enable certain SBC capabilities such as routing. By default, the device employs media anchoring, whereby the media session traverses the device, as described in [Media Anchoring](#) on the previous page.

Direct media offers the following benefits:

- Saves network bandwidth
- Reduces the device's CPU usage (as there is no media handling)
- Avoids interference in SDP negotiation and header manipulation on RTP/SRTP

Direct media is typically implemented for calls between users located in the same LAN or domain, and where NAT traversal is not required and other media handling features such as media transcoding is not required. The following figure provides an example of direct media between LAN IP phones, while SIP signaling continues to traverse the device between LAN IP phones and the hosted WAN IP-PBX.

➤ **To enable direct media:**

- **For all calls:** Use the global parameter [SBCDirectMedia], which **overrides** all other direct media configuration.
- **For specific calls:**
  - SIP Interface: You can enable direct media per SIP Interface (in the SIP Interfaces table), whereby calls (source and destination) associated with **this same** SIP Interface are handled as direct media calls. The SIP Interface can also enable direct media for users located behind the same NAT. For more information, see [Configuring SIP Interfaces](#) on page 570.
  - Direct Media Tag: You can enable direct media between users that are configured with the same Direct Media tag value. The tag is configured by the IP Profile parameter 'Direct Media Tag' (see [Configuring IP Profiles](#) on page 674).

Regardless of the device's settings for direct media (mentioned in this section), the device always handles calls whose incoming SIP dialog-initiating request (e.g., INVITE message) contains the proprietary SIP header 'X-AC-Action' with the value 'direct-media' (i.e., 'X-AC-Action: direct-media'), as direct media calls. These calls remain as direct media calls until they end. The device doesn't open voice channels and doesn't allocate any resources (media ports) for these calls.

The device employs direct media between endpoints under the following configuration conditions (listed in chronological order):

1. Direct media is enabled by the global parameter [SBCDirectMedia].

2. IP Groups of the endpoints are associated with IP Profiles whose 'Direct Media Tag' parameter has the same value (non-empty value).
3. IP Groups of the endpoints have the 'SBC Operation Mode' parameter set to **Microsoft Server** (direct media is required in the Skype for Business environment). For more information, see [Configuring IP Groups](#) on page 591.
4. IP Groups of the endpoints use the same SIP Interface and the SIP Interface's 'SBC Direct Media' parameter is set to **Enable**.
5. IP Groups of the endpoints use the same SIP Interface and the SIP Interface's 'SBC Direct Media' parameter is set to **Enable When Single NAT**, and the endpoints are located behind the same NAT.

- **Direct Media configured for all calls (i.e., using the [SBCDirectMedia] parameter):** The device doesn't open voice channels and doesn't allocate media ports for these calls, because the media always bypasses the device.
- **Direct Media configured for specific calls (i.e., using the IP Profile's 'Direct Media Tag' parameter or SIP Interface's 'Direct Media' parameter):** The device always allocates ports for these calls, because these ports may be required at some stage during the call if it changes to a **non-direct media** call for mid-call services such as early media, call forwarding, call transfer, or playing on-hold tones. Therefore, make sure that you have allocated sufficient media ports (Media Realm) for these calls.
- The following features are not supported for Direct Media calls:
  - ✓ Manipulation of SDP data (offer-answer transaction) such as ports, IP address, coders
  - ✓ Forced transcoding
  - ✓ Extension Coders
  - ✓ Extension of RFC 2833 / out-of-band DTMF / in-band DTMF
  - ✓ Extension of SRTP/RTP
  - ✓ All restriction features (Allowed Coders, restrict SRTP/RTP, and restrict RFC 2833)
  - ✓ All media-related parameters in the IP Profiles table are not applicable to Direct Media calls
- The device doesn't fully support call transfer (SIP REFER) terminations for direct media calls. One of the SIP User Agents (UA) in the call must support re-INVITE messages without SDP for the device to synchronize the media.
- For two users belonging to the same SIP Interface that is enabled for direct media and one of the users is defined as a foreign user (example, "follow me service") located in the WAN while the other is located in the LAN: calls between these two users cannot be established until direct media is disabled for the SIP Interface. The reason for this is that the device doesn't interfere in the SIP signaling. In other words, parameters such as IP addresses are not manipulated for calls between LAN and WAN (although required).
- If you have configured a SIP Recording rule (see [SIPREC SIP-based Media Recording](#) on page 339) for calls that have also been configured for direct media, using a SIP Interface ('Direct Media' parameter) or an IP Profile ('Direct Media Tag' parameter), the device automatically disables direct media for these calls (during their SIP signaling setup). This ensures that the media passes through the device so that it can be recorded and sent to the SRS. However, if you enable direct media using the [SBCDirectMedia] parameter (i.e., for all calls), direct media is always enforced and calls will not be recorded.

## Restricting Audio Coders

You can configure a list of permitted (allowed) voice coders that can be used for a specific SIP entity (leg). In other words, you can enforce the use of specific coders. If the SDP offer in the incoming SIP message doesn't contain any coder that is configured as an allowed coder, the device rejects the calls (unless transcoding is implemented whereby Extension coders are added to the SDP, as described in [Coder Transcoding](#) on the next page). If the SDP offer contains some coders that are configured as allowed coders, the device manipulates the SDP offer by

removing the coders that are not configured as allowed coders, before routing the SIP message to its destination. The device also re-orders (prioritizes) the coder list in the SDP according to the listed order of configured allowed coders.

For example, assume the following:

- The SDP offer in the incoming SIP message contains the G.729, G.711, and G.723 coders.
- The allowed coders configured for the SIP entity include G.711 and G.729.

The device removes the G.723 coder from the SDP offer, re-orders the coder list so that G.711 is listed first, and sends the SIP message containing only the G.711 and G.729 coders in the SDP.

The allowed coders are configured in the Allowed Audio Coders Groups table. For more information, see [Configuring Allowed Audio Coder Groups](#) on page 669.

If you assign the SIP entity an Allowed Audio Coders Group for coder restriction and a Coders Group for extension coders (i.e., voice transcoding), the allowed coders take precedence over the extension coders. In other words, if an extension coder is not listed as an allowed coder, the device doesn't add the extension coder to the SDP offer.

## Coder Transcoding

By default, the device forwards media packets transparently (i.e., no media negotiation) between the SIP endpoints. However, when there are no common coders between two SIP entities that need to establish voice communication (i.e., the SDP answer from one SIP entity doesn't include any coder included in the SDP offer previously sent by the other), you can configure the device to perform audio coder transcoding between the inbound and outbound legs in order to enable media flow between them.

Transcoding may also be performed in scenarios where the same coder has been chosen between the legs, but where coder transrating is required. For example, the coders may use different coder settings such as rate and packetization time (G.729 at 20 ms to G.729 at 30 ms).

The coders that the device adds to the SDP offer on the outbound leg is referred to as *extension coders*. The extension coders are configured using Coder Groups (see [Configuring Coder Groups](#) on page 661), which you need to then assign to the IP Profile associated with the SIP entity.

The figure below illustrates transcoding between two SIP entities (IP Groups) where one uses G.711 (LAN IP phone) and the other G.729 (WAN IP phone). The initial SDP offer received on the inbound leg from the LAN IP phone includes coder G.711 as the supported coder. In the outgoing SDP offer on the outbound leg to the WAN IP phone, the device adds extension coder G.729 to the SDP, which is supported by the WAN IP phone. The subsequent incoming SDP answer from the WAN IP phone includes the G.729 coder as the chosen coder. Since this coder was not included in the original incoming SDP offer from the LAN IP phone, the device performs G.729-G.711 transcoding between the inbound and outbound legs.

- If you assign a SIP entity an Allowed Audio Coders Group for coder restriction (allowed coders) and a Coders Group for extension coders, the allowed coders take precedence over the extension coders. In other words, if an extension coder is not listed as an allowed coder, the device doesn't add the extension coder to the SDP offer.
- If none of the coders in the incoming SDP offer on the inbound leg appear in the associated Allowed Audio Coders Group for coder restriction, the device rejects the call (sends a SIP 488 to the SIP entity that initiated the SDP offer).
- If none of the coders (including extension coders) in the outgoing SDP offer on the outbound leg appear in the associated Allowed Audio Coders Group for coder restriction, the device rejects the call (sends a SIP 488 to the SIP entity that initiated the SDP offer).
- For coder transcoding, the following prerequisites must be met (otherwise, the extension coders are not added to the SDP offer):
  - ✓ The device must support at least one of the coders listed in the incoming SDP offer.
  - ✓ The device must have available DSPs for both legs (inbound and outbound).
  - ✓ The incoming SDP offer must have at least one media line that is audio ('m=audio').
- The device adds the extension coders below the coder list received in the original SDP offer. This increases the chance of media flow without requiring transcoding.
- The device doesn't add extension coders that also appear in the original SDP offer.
- You can view the number of currently active transcoding sessions, using the CLI command `show voip calls statistics sbc media`.

As an example for using allowed and extension coders, assume the following:

#### ■ Inbound leg:

- Incoming SDP offer includes the G.729, G.711, and G.723 coders.

```
m=audio 6050 RTP/AVP 18 0 8 4 96
a=rtpmap:18 G729/8000
a=rtpmap:0 PCMU/8000
a=rtpmap:8 PCMA/8000
a=rtpmap:4 G723/8000
a=fmtp:4 annexa=no
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
a=ptime:20
a=sendrecv
```

The SDP "m=audio 6010 RTP/AVP 18 0 8 4 96" line shows the coder priority, where "18" (G.729) is highest and "4" (G.723) is lowest.

- Allowed Audio Coders Group for coder restriction includes the G.711 and G.729 coders (listed in order of appearance).

#### ■ Outbound leg:

- Allowed Audio Coders Group for coder restriction includes the G.723, G.726, and G.729 coders (listed in order of appearance).
  - Allowed Audio Coders Group for coder extension (transcoding) includes the G.726 coder.
1. On the inbound leg for the incoming SDP offer: The device allows and keeps the coders in the SDP that also appear in the Allowed Audio Coders Group for coder restriction (i.e., G.711 and G.729). It changes the order of listed coders in the SDP so that G.711 is listed first. The device removes the coders (i.e., G.723) from the SDP that do not appear in the Allowed Audio Coders Group for coder restriction.

```
m=audio 6050 RTP/AVP 0 8 18 96
a=rtpmap:0 PCMU/8000
a=rtpmap:8 PCMA/8000
a=rtpmap:18 G729/8000
a=fmtp:4 annexa=no
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
a=ptime:20
a=sendrecv
```

2. On the outbound leg for the outgoing SDP offer: The SDP offer now includes only the G.711 and G.729 coders due to the coder restriction process on the incoming SDP offer (see Step 1).

- a. The device adds the extension coder to the SDP offer and therefore, the SDP offer now includes the G.711, G.729 and G.726 coders.

```
m=audio 6050 RTP/AVP 0 8 18 96 96
a=rtpmap:0 PCMU/8000
a=rtpmap:8 PCMA/8000
a=rtpmap:18 G729/8000
a=rtpmap:96 G726-32/8000
a=fmtp:4 annexa=no
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
a=ptime:20
a=sendrecv
```

- b. The device applies coder restriction to the SDP offer. As the Allowed Audio Coders Group for coder restriction includes the G.723, G.726, and G.729 coders, the device allows and keeps the G.729 and G.726, but removes the G.711 coder as it doesn't appear in the Allowed Audio Coders Group for coder restriction.

```
m=audio 6050 RTP/AVP 18 96 96
a=rtpmap:18 G729/8000
a=rtpmap:96 G726-32/8000
a=fmtp:4 annexa=no
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
a=ptime:20
a=sendrecv
```

3. The device includes only the G.729 and G.726 coders in the SDP offer that it sends from the outgoing leg to the outbound SIP entity. The G.729 is listed first as the Allowed Audio Coders Group for coder restriction takes precedence over the extension coder.

➤ **To configure coder transcoding:**

1. In the Coders Groups table, configure a Coders Group for extension coders. For more information, see [Configuring Coders Groups](#) on page 661.
2. In the IP Profiles table, configure the IP Profile associated with the SIP entity:
  - a. Assign the Coders Group to the IP Profile, using the 'Extension Coders Group' parameter (SBCExtensionCodersGroupName).
  - b. Enable extension coders by configuring the 'Allowed Coders Mode' parameter to **Restriction** or **Restriction and Preference**.

- The device's License Key (see [License Key](#) on page 1362) specifies transcoding capabilities:
  - ✓ 'DSP Channels' - maximum number of DSP resources.
  - ✓ 'Transcoding Sessions' - maximum number of transcoding sessions.
- Each transcoding session uses two DSP resources.
- You can configure the transcoding mode globally, using the [TranscodingMode] parameter, or for specific calls using the IP Profile parameter 'Mediation Mode'.

## Transcoding Mode

By default, the device performs transcoding only when necessary. This refers to all types of transcoding (interworking) that require the use of the device's DSP resources, for example, voice coder transcoding, DTMF negotiations, and fax negotiations. Transcoding is required, for example, when two SIP entities use different coders. In such a scenario, the device can be configured to use a different coder for each leg (inbound and outbound), using IP Profiles. If the SIP entities use the same coder, the device doesn't perform transcoding.

Alternatively, you can configure the device to always perform transcoding, regardless of whether it is required or not. This is referred to as *forced* transcoding. For example, if the SIP entities use the same coder, the device performs transcoding of the same coder (e.g., G.711 and G.711) between the two legs.

To configure the transcoding mode, use the global parameter [TranscodingMode] or the IP Profile parameter 'Mediation Mode'.

If the transcoding mode is configured to **Force Transcoding** (i.e., always perform transcoding) for an IP Profile associated with a specific SIP entity, the device also applies forced transcoding for the SIP entity communicating with this SIP entity, regardless of its IP Profile settings.

## Prioritizing Coder List in SDP Offer

In addition to restricting the use of coders using Allowed Audio Coders Groups (see [Configuring Allowed Audio Coder Groups](#) on page 669), you can also prioritize the coders listed in the SDP offer. This feature is referred to as *Coder Preference* and applies to both SBC legs:

- **Incoming SDP offer:** The device arranges the coder list in the incoming SDP offer according to the order of appearance of the Allowed Audio Coders Group that is associated with the incoming dialog. The coders listed higher up in the group take preference over ones listed lower down. To configure this, configure the 'Allowed Coders Mode' parameter in the associated IP Profile to **Preference** or **Restriction and Preference**. If you configure the parameter to **Preference**, the coders in the SDP offer that also appear in the Allowed Audio Coders Group are listed first in the SDP offer, and the coders in the SDP offer that do not appear in the Allowed Audio Coders Group are listed after the Allowed coders in the SDP offer. Therefore, this setting doesn't restrict coder use to Allowed coders, but uses (prefers) the Allowed coders whenever possible.

- **Outgoing SDP offer:** If only Allowed coders are used, the device arranges the coders in the SDP offer as described above. However, if Extension coders are also used, the coder list is arranged according to the SBCPreferencesMode parameter. Depending on the parameter's settings, the Extension coders are added after the Allowed coders according to their order in the Allowed Audio Coders Group, or the Allowed and Extension coders are arranged according to their position in the Allowed Audio Coders Group.

## Allocating DSPs on SDP Offer or Answer

By default, the device allocates DSP resources for a call at the SDP Offer stage. If DSP resources are available at this stage, the device reserves DSPs for the call just in case call setup succeeds with the SDP Answer and DSPs are required (e.g., for transcoding). If there are no free DSP resources at the SDP Offer stage, no DSP resources are allocated for the call, at any stage of the SDP Offer-Answer exchange, and if DSPs are required (based on the SDP Answer), the device rejects the call.

However, this default behavior may cause call failure for a call requiring DSPs even when the device has sufficient DSP resources. For example, assume the device is licensed for 10 concurrent transcoding calls and is currently handling the establishment of 10 calls where only half require transcoding (DSPs). For all these calls, the device allocates DSPs during the SDP Offer stage (even if some of these calls may not require DSPs, based on the SDP Answer). If during this time the device starts processing an 11<sup>th</sup> call that requires transcoding (DSPs), since it has already allocated all of its DSP resources, it doesn't allocate any DSPs to this call and as a result, the device rejects the call.

To avoid such scenarios, you can configure the device to allocate DSPs only at the SDP Answer stage (SIP 200 OK or 180), when it can determine if DSPs are required or not for the call. If DSPs are required and DSP resources are available, the device allocates DSPs. If DSPs are required but there are no available DSPs, the device rejects the call.

### ➤ To disable reserving DSPs on SDP Offer:

1. Open the Media Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Settings**).
2. Clear the 'Reserve DSP on SDP Offer' check box:

Reserve DSP on SDP Offer ☐

3. Click **Apply**.

## SRTP-RTP and SRTP-SRTP Transcoding

The device supports transcoding between SRTP and RTP. The device can also enforce specific SBC legs to use SRTP and/or RTP. The device's handling of SRTP/RTP is configured using the IP Profile parameter [SBCMediaSecurityBehaviour], which provides the following options:

- SBC passes the media as is, regardless of whether it's RTP or SRTP (default).

- SBC legs negotiate only SRTP media lines (m=); RTP media lines are removed from the incoming SDP offer-answer.
- SBC legs negotiate only RTP media lines; SRTP media lines are removed from the incoming offer-answer.
- Each SDP offer-answer is extended (if not already) to two media lines for RTP and SRTP.

If after SDP offer-answer negotiation, an SBC leg uses RTP while the other uses SRTP, the device performs RTP- SRTP transcoding. To translate between RTP and SRTP, the following prerequisites must be met:

- At least one supported SDP "crypto" attribute.
- SRTP must be enabled - [EnableMediaSecurity] parameter configured to [1].

Transcoding where both legs are configured for SRTP is typically required to trans-encrypt and trans-decrypt. This is relevant when the MKI and Symmetric MKI parameters are enabled. In other words, both sides need to both encrypt and decrypt the outgoing and incoming SRTP packets, respectively.

DSP resources are not required for RTP-SRTP transcoding.

## Multiple RTP Media Streams per Call Session

The device's SBC application supports multiple RTP media streams per SBC call session. It supports the negotiation of up to five media streams ('m=' line) in the SDP offer/answer model per session. The media can include a combination of any of the following types:

- Audio, indicated in the SDP as 'm=audio'
- Video, indicated in the SDP as 'm=video'
- Text, indicated in the SDP as 'm=text'
- Fax, indicated in the SDP as 'm=image'
- Binary Floor Control Protocol (BFCP), indicated in the SDP as 'm=application <port> UDP/BFCP'

Therefore, the device supports transcoding of various attributes in the SDP offer-answer (e.g., codec, port, and packetization time) per media type. If the device is unable to perform transcoding (e.g., doesn't support the coder), it relays the SBC dialog transparently.

The device transparently forwards Binary Floor Control Protocol (BFCP) signaling over UDP between IP entities (RFC 4582). BFCP is a signaling protocol used by some third-party conferencing servers to share content (such as video conferencing, presentations or documents) between conference participants (SIP clients supporting BFCP). The SDP offer/answer exchange model is used to establish (negotiate) BFCP streams between clients. The BFCP stream is identified in the SDP as 'm=application <port> UDP/BFCP' and a dedicated UDP port is used for the BFCP streams.

## Interworking Miscellaneous Media Handling

This section describes various interworking features relating to media handling.

### Interworking DTMF Methods

The device supports interworking between various DTMF methods such as RFC 2833, In-Band DTMF's, and SIP INFO (Cisco\Nortel\Korea). By default, the device allows the remote user agents to negotiate (in case of RFC 2833) and passes DTMF without intervention. However, if two user agents (UA) support different DTMF methods, the device can interwork these different DTMF methods at each leg.

This DTMF interworking feature is enabled using IP Profiles (*ini* file parameter IPProfile):

- SBCRFC2833Behavior - affects the RFC 2833 SDP offer-answer negotiation:
  - [0]: (default) the device doesn't intervene in the RFC 2833 negotiation.
  - [1]: each outgoing offer-answer includes RFC 2833 in the offered SDP (the device adds RFC 2833 only if the incoming offer doesn't include RFC 2833).
  - [2]: the device removes RFC 2833 from the incoming offer.
- SBCAlternativeDTMFMethod – the device's first priority for DTMF method at each leg is RFC 2833. Therefore, if a specific leg negotiates RFC 2833 successfully, then the chosen DTMF method for this leg is RFC 2833. For legs where RFC 2833 is not negotiated successfully, the device uses the parameter to determine the DTMF method for the leg.

The chosen DTMF method determines (for each leg) which DTMF method is used for sending DTMF's. If the device interworks between different DTMF methods and one of the methods is In-band\RFC 2833, detection and generation of DTMF methods requires DSP resources.

### Interworking RTP Redundancy

The device supports interworking of RTP redundancy (according to RFC 2198) between SIP entities. Employing IP Profiles, you can configure RTP redundancy handling per SIP entity:

- Generate RFC 2198 redundant packets, using the 'RTP Redundancy Depth' parameter.
- Determine RTP redundancy support in the RTP redundancy negotiation in SDP offer/answer, using the 'RTP Redundancy Mode' parameter. If not supported, the device discards RTP redundancy packets (if present) received from or sent to the SIP entity.

For more information, see the above parameters in [Configuring IP Profiles](#) on page 674.

### Interworking RTP-RTCP Multiplexing

The device supports interworking of RTP-RTCP multiplexing onto a single, local UDP port (according to RFC 5761) between SIP entities. Employing IP Profiles, you can configure RTP multiplexing per SIP entity, using the 'RTCP Mux' parameter (see [Configuring IP Profiles](#) on page 674).

### Interworking RTCP Attribute in SDP

The device supports interworking the RTCP attribute 'a=rtcp' in the SDP between SIP entities. Employing IP Profiles, you can configure RTCP attribute handling (add, remove or transparent) per SIP entity, using the 'SDP Handle RTCP' parameter (see [Configuring IP Profiles](#) on page 674).

### Interworking Crypto Lifetime Field

The device supports interworking the lifetime field in the 'a=crypto' attribute of the SDP, between SIP entities. Employing IP Profiles, you can configure the lifetime field handling (remove or retain) per SIP entity, using the IP Profile parameter 'SBC Remove Crypto Lifetime in SDP' (see [Configuring IP Profiles](#) on page 674).

### Interworking Media Security Protocols

The device supports interworking media security protocols for SRTP, between SIP entities. Employing IP Profiles, you can configure the security protocol (SDS and DTLS) per SIP entity, using the 'SBC Media Security Method' parameter (see [Configuring IP Profiles](#) on page 674). For more information on SDS and DTLS, see [Configuring SRTP](#) on page 320.

### Interworking ICE for NAT Traversal

The device supports interworking ICE for NAT traversal, between SIP entities. Employing IP Profiles, you can enable ICE per SIP entity, using the 'ICE Mode' parameter (see [Configuring IP Profiles](#) on page 674).

## Fax Negotiation and Transcoding

The device can allow fax transmissions to traverse transparently without transcoding or it can handle the fax as follows:

- Allow interoperability between different fax machines, supporting fax transcoding if required.
- Restrict usage of specific fax coders to save bandwidth, enhance performance, or comply with supported coders. These coders include G.711 (A-Law or Mu-Law), VBD (G.711 A-Law or G.711 Mu-Law), and T38.

Fax configuration is done in the Coders Groups table and IP Profiles table. The Coders Groups table defines the supported coders, which is assigned to the IP Profile associated with the SIP entity. The IP Profiles table also defines the negotiation method used between the incoming and outgoing fax legs, using the following fax-related parameters:

- 'Fax Mode': Defines the offer negotiation method - pass fax transparently, negotiate fax according to fax settings in IP Profile, or enforce remote UA to first establish a voice channel before fax negotiation.
- 'Fax Coders Group': Defines the supported fax coders (from the Coders Groups table).
- 'Fax Offer Mode': Defines the fax coders sent in the outgoing SDP offer.

- 'Fax Answer Mode': Defines the fax coders sent in the outgoing SDP answer.
- 'Remote Renegotiate on Fax Detection': You can also configure the device to detect for faxes (CNG tone) immediately after the establishment of a voice channel (i.e., after 200 OK) and within a user-defined interval. If detected, it can then handle the subsequent fax renegotiation by sending re-INVITE messages to both SIP entities (originating and terminating faxes). For more information, see the parameter in [Configuring IP Profiles](#) on page 674.

The voice-related coder configuration (Allowed and Extension coders) is independent of the fax-related coder configuration, with the exception of the G.711 coder. If the G.711 coder is restricted by the Allowed Audio Coders Groups table, it is not used for fax processing even if it is listed in the Coders Groups table for faxes. However, support for G.711 coders for voice is not dependent upon which fax coders are listed in the Coders Groups table.

## SBC Authentication

The device can authenticate SIP servers and SBC users (clients). The different authentication methods are described in the subsequent subsections.

### SIP Authentication Server Functionality

The device can function as an Authentication server for authenticating incoming SIP message requests, based on HTTP authentication Digest with MD5 or SHA-256 (configured by [SIPServerDigestAlgorithm]). Alternatively, such requests can be authenticated by an external, third-party server.

When functioning as an Authentication server, the device can authenticate the following SIP entities:

- **SIP servers:** This is applicable to Server-type IP Groups. This provides protection from rogue SIP servers, preventing unauthorized usage of device resources and functionality. To authenticate remote servers, the device challenges the server with a user-defined username and password that is shared with the remote server. When the device receives an INVITE request from the remote server, it challenges the server by replying with a SIP 401 Unauthorized response containing the WWW-Authenticate header. The remote server then re-sends the INVITE containing an Authorization header with authentication information based on this username-password combination to confirm its identity. The device uses the username and password to authenticate the message prior to processing it.
- **SIP clients:** These are clients belonging to a User-type IP Group. This support prevents unauthorized usage of the device's resources by rogue SIP clients. When the device receives an INVITE or REGISTER request from a client (e.g., SIP phone) for SIP message authorization, the device processes the authorization as follows:

- a. The device challenges the received SIP message only if it is configured as a SIP method (e.g., INVITE) for authorization. This is configured in the IP Groups table, using the 'Authentication Method List' parameter.
- b. If the message is received without a SIP Authorization header, the device "challenges" the client by sending a SIP 401 or 407 response. The client then resends the request with an Authorization header (containing the username and password).
- c. The device validates the SIP message according to the AuthNonceDuration, AuthChallengeMethod and AuthQOP parameters.
  - ◆ If validation fails, the device rejects the message and sends a 403 (Forbidden) response to the client.
  - ◆ If validation succeeds, the device verifies client identification. It checks that the username and password received from the client is the same username and password in the device's SBC User Information table / database (see [Configuring SBC User Information](#) on page 802). If no username and password is configured in the SBC User Information table, the device authenticates the users based on the username and password configured for the relevant IP Group in the IP Groups table ('Username As Server' and 'Password As Server' parameters). If the client is not successfully authenticated after three attempts, the device sends a SIP 403 (Forbidden) response to the client. If the user is successfully identified, the device accepts the SIP message request.

The device's Authentication server functionality is configured per IP Group, using the 'Authentication Mode' parameter in the IP Groups table (see [Configuring IP Groups](#) on page 591).

## RADIUS-based Authentication of SIP User Agents

The device can authenticate SIP clients (users) using a remote RADIUS server. The device supports the RADIUS extension for digest authentication of SIP clients, according to draft-sterman-aaa-sip-01. Based on this standard, the device generates the nonce (in contrast to RFC 5090, where it is done by the RADIUS server).

RADIUS based on draft-sterman-aaa-sip-01 operates as follows:

1. The device receives a SIP request without an Authorization header from the SIP client.
2. The device generates the nonce and sends it to the client in a SIP 407 (Proxy Authentication Required) response.
3. The SIP client sends the SIP request with the Authorization header to the device.
4. The device sends an Access-Request message to the RADIUS server.
5. The RADIUS server verifies the client's credentials and sends an Access-Accept (or Access-Reject) response to the device.
6. The device accepts the SIP client's request (sends a SIP 200 OK or forwards the authenticated request) or rejects it (sends another SIP 407 to the SIP client).

To configure this feature, set the SBCServerAuthMode ini file parameter to 2.

## Interworking SIP Signaling

The device supports interworking of SIP signaling messages to ensure interoperability between communicating SIP UAs or entities. This is critical in network environments where the UAs on opposing SBC legs have different SIP signaling support. For example, some UAs may support different versions of a SIP method while others may not even support a specific SIP method. The configuration method for assigning specific SIP message handling modes to UAs, includes configuring an IP Profile with the required interworking mode, and then assigning the IP Profile to the relevant IP Group.

This section describes some of the device's support for handling SIP methods to ensure interoperability.

## Interworking SIP 3xx Redirect Responses

The device supports interworking of SIP 3xx redirect responses. By default, the device's handling of SIP 3xx responses is to send the Contact header unchanged. However, some SIP UAs may support different versions of the SIP 3xx standard while others may not even support SIP 3xx.

The handling of SIP 3xx can be configured for all calls, using the global parameter SBC3xxBehavior. To configure different SIP 3xx handling options for different UAs (i.e., per IP Group), use the IP Profiles table parameter, 'SBC Remote 3xx Mode'.

## Resultant INVITE Traversing Device

The device can handle SIP 3xx responses so that the new INVITE message sent as a result of the 3xx traverses the device. The reasons for enforcing resultant INVITEs to traverse the device may vary:

- The user that receives the 3xx is unable to route to the 3xx contact (i.e., the user is on the LAN and the new contact is on the WAN). In such a scenario, the device enables the user to reach the WAN contact and overcome NAT problems.
- Enforce certain SBC policies (e.g., call admission control, header manipulation, and transcoding) on the resultant INVITE.

The device enforces this by modifying each Contact in the 3xx response as follows:

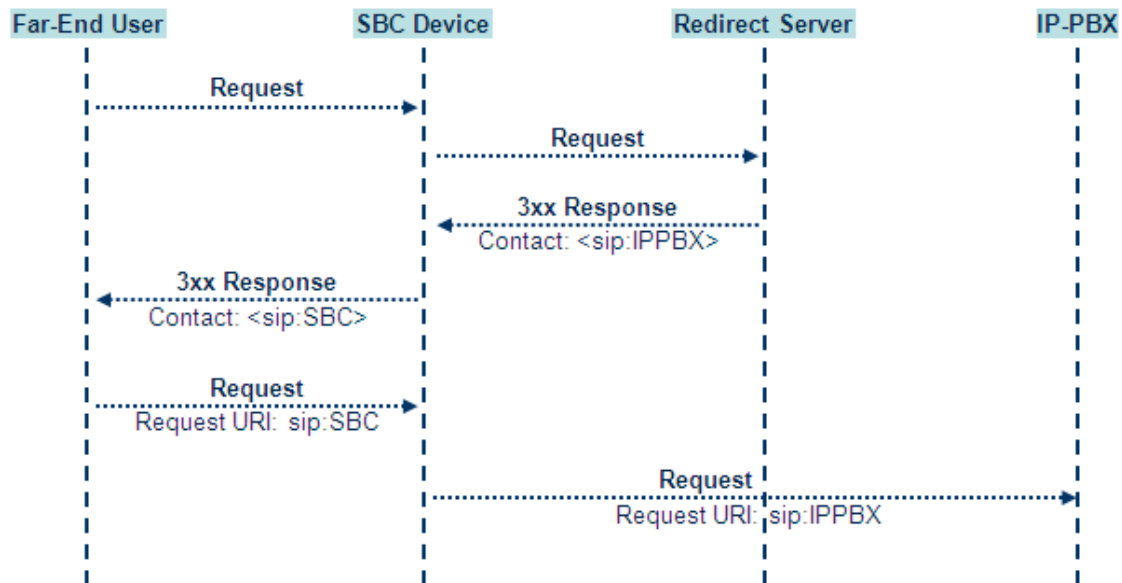

- Changes the host part to the device's IP address – this change causes the remote user agent to send the INVITE to the device.
- Adds a special prefix ("T~&R\_") to the Contact user part – to identify the new INVITE as a 3xx resultant INVITE.

The SBC handling for the 3xx resultant INVITE is as follows:

1. The incoming INVITE is identified as a 3xx resultant INVITE according to the special prefix.

2. The device automatically replaces the SBC host part (in the Request-URI) with the host from the 3xx Contact.
3. The prefix ("T~&R\_") remains in the user part for the classification, manipulation, and routing mechanisms.
4. The classification, manipulation, and routing processes are done exactly like any other INVITE handling. The special prefix can be used for specific routing rules for 3xx resultant INVITES.
5. The prefix is removed before the resultant INVITE is sent to the destination.

The process of this feature is described using an example:

1. The device receives the Redirect server's SIP 3xx response (e.g., Contact: <sip:User@IPPBX:5060;transport=tcp;param=a;q=0.5>).
2. The device replaces the Contact header value with the special prefix and database key value as user part, and with the device's URL as host part (e.g., Contact: <sip:Prefix\_Key\_User@SBC:5070;transport=udp;q=0.5>).
3. The device sends this manipulated SIP 3xx response to the Far-End User (FEU).
4. The FEU sends a new request with the Request-URI set to the value of the received 3xx response's Contact header (e.g., RequestURI: sip:Prefix\_Key\_User@SBC:5070;transport=udp).
5. Upon receipt of the new request from the FEU, the device replaces the Request-URI with the new destination address (e.g., RequestURI: sip:Prefix\_Key\_User@IPPBX:5070;transport=tcp;param=a).
6. The device removes the user prefix from the Request-URI, and then sends this Request-URI to the new destination (e.g., RequestURI: sip:User@IPPBX:5070;transport=tcp;param=a).

## Local Handling of SIP 3xx

The device can handle SIP 3xx responses on behalf of the dialog-initiating UA and retry the request (e.g., INVITE) using one or more alternative URIs included in the 3xx response. The new request includes SIP headers from the initial request such as Diversion, History-Info, P-Asserted-Id, and Priority. The source and destination URIs can be manipulated using the regular manipulation mechanism.

The device sends the new request to the alternative destination according to the IP-to-IP Routing table rules. (where the 'Call Trigger' field is set to **3xx**). It is also possible to specify the IP Group that sent the 3xx request as matching criteria for the re-routing rule in this table ('ReRoute IP Group ID' field).

## Interworking SIP Diversion and History-Info Headers

This device can be configured to interwork between the SIP Diversion and History-Info headers. This is important, for example, to networks that support the Diversion header but not the History-Info header, or vice versa. Therefore, mapping between these headers is crucial for preserving the information in the SIP dialog regarding how and why (e.g., call redirection) the call arrived at a certain SIP UA. If the Diversion header is used, you can specify the URI type (e.g., "tel:") to use in the header, using the SBCEdiversionUriType parameter.

This feature is configured in the IP Profiles table using the following parameters:

- 'Diversion Header Mode' - defines the device's handling of the Diversion header
- 'History-Info Header Mode' - defines the device's handling of the History-Info header

The handling of the SIP Diversion and History-Info headers is described in the table below:

**Table 30-1: Handling of SIP Diversion and History-Info Headers**

Parameter Value	SIP Header Present in incoming SIP Message		Device Action	IP Header Present in outgoing SIP Message	
	Diversion	History-Info		Diversion	History-Info
'Diversion Header Mode' = <b>Add</b> 'History-Info Header Mode' = <b>Add</b>	Not present	Present	Diversion added from History-Info	Present	Present
'Diversion Header Mode' = <b>Add</b>	Present	Not present	History-Info added from Diversion	Present	Present

Parameter Value	SIP Header Present in incoming SIP Message		Device Action	IP Header Present in outgoing SIP Message	
'History-Info Header Mode' = <b>Add</b>					
'Diversion Header Mode' = <b>Add</b> 'History-Info Header Mode' = <b>Add</b>	Present	Present	Diversion replaced and added from History-Info History-Info replaced and added from Diversion	Present	Present
'Diversion Header Mode' = * 'History-Info Header Mode' = *	Not present	Not present	As no headers are present on incoming message, nothing is added	Not present	Not present
'Diversion Header Mode' = <b>Add</b> 'History-Info Header Mode' = <b>As Is</b>	Not present	Present	Diversion added from History-Info	Present	Present
'Diversion Header Mode' = <b>As Is</b> 'History-Info Header Mode' = <b>Add</b>	Present	Not present	History-Info added from Diversion	Present	Present
'Diversion Header Mode' = <b>Add</b> 'History-Info Header Mode' = <b>Remove</b>	Not present	Present	Diversion added from History-Info History-Info removed	Present	Not present

Parameter Value	SIP Header Present in incoming SIP Message		Device Action	IP Header Present in outgoing SIP Message	
'Diversion Header Mode' = <b>Remove</b> 'History-Info Header Mode' = <b>Add</b>	Present	Not present	History-Info added from Diversion Diversion removed	Not present	Present
'Diversion Header Mode' = <b>Remove</b> 'History-Info Header Mode' = <b>Remove</b>	Present	Present	Both removed	Not present	Not present

## Interworking SIP REFER Messages

The device supports interworking of SIP REFER messages. SIP UAs may support different versions of the REFER standard while others may not even support REFER.

This feature supports the following:

- Attended, unattended, and semi-attended call transfers
- Sending INVITE, REFER-notifications, BYE, PRACK and Session Timer on behalf of peer PBXs
- Advanced routing rules for the new, initiated INVITE
- Forwarding early media after REFER while attempting to avoid transcoding (by sending session update)
- Interoperate with environments where different SIP UAs lack basic SIP functionality such as re-INVITE, UPDATE, PRACK, Delayed Offer, re-INVITE without SDP
- Session updates after connect to avoid transcoding

The handling of REFER can be configured for all calls, using the global parameter [SBCReferBehavior]. To configure different REFER handling options for different UAs (i.e., IP Groups), use the IP Profiles table parameter, 'Remote REFER Mode'.

- Local handling of REFER: This option is used for UAs that do not support REFER. Upon receipt of a REFER request, instead of forwarding it to the IP Group, the device handles it locally. It generates a new INVITE to the alternative destination according to the rules in the IP-to-IP Routing table (where the 'Call Trigger' field is set to **REFER**). It is also possible to

specify the IP Group that sent the REFER request, as matching criteria for the re-routing rule in this table ('ReRoute IP Group ID' field).

- **Transparent handling:** The device forwards the REFER with the Refer-To header unchanged.
- **Re-routing through SBC:** The device changes the Refer-To header so that the re-routed INVITE is sent through the SBC application.
- **IP Group Name:** The device sets the host part in the REFER message to the name configured for the IP Group in the IP Groups table.

## Interworking SIP PRACK Messages

The device supports interworking of SIP Provisional Response ACKnowledgement (PRACK) messages (18x). While some UAs may not support PRACK (RFC 3262) others may require it. The device can be configured to resolve this interoperable issue and enable sessions between such endpoints. SIP PRACK handling is configured using the IP Profile parameter, 'SBC Prack Mode':

- **Optional:** PRACK is optional for these UAs. If required, the device performs the PRACK process on behalf of the destination UA.
- **Mandatory:** PRACK is required for these UAs. Calls from UAs that do not support PRACK are rejected. Calls destined to these UAs are also required to support PRACK.
- **Transparent (default):** The device doesn't intervene with the PRACK process and forwards the request as is.

## Interworking SIP Session Timer

The device supports interworking of the SIP signaling keep-alive mechanism. The SIP standard provides a signaling keep-alive mechanism using re-INVITE and UPDATE messages. In certain setups, keep-alive may be required by some SIP UAs while for others it may not be supported. The device can resolve this mismatch by performing the keep-alive process on behalf of SIP UAs that do not support it.

To configure the handling of session expires, use the IP Profile parameter, 'SBC Session Expires Mode'.

## Interworking SIP Early Media

The device supports early media. Early media is when the media flow starts before the SIP call is established (i.e., before the 200 OK response). This occurs when the first SDP offer-answer transaction completes. The offer-answer options can be included in the following SIP messages:

- Offer in first INVITE, answer on 180, and no or same answer in the 200 OK
- Offer in first INVITE, answer on 180, and a different answer in the 200 OK (not standard)
- INVITE without SDP, offer in 180, and answer in PRACK
- PRACK and UPDATE transactions can also be used for initiating subsequent offer-answer transactions before the INVITE 200 OK response.

- In a SIP dialog life time, media characteristics after originally determined by the first offer-answer transaction can be changed by using subsequent offer-answer transactions. These transactions may be carried either in UPDATE or re-INVITE transactions. The media handling is similar to the original offer-answer handling. If the offer is rejected by the remote party, no media changes occur (e.g., INVITE without SDP, then 200 OK and ACK, offer-answer within an offer-answer, and Hold re-INVITE with IP address of 0.0.0.0 - IP address is unchanged).

The device supports various interworking modes for early media between SIP UAs (i.e., IP Groups):

- **Early Media Enabling:** The device supports the interworking of early media between SIP UAs that support early media and those that do not support receipt of early media. Early media can arrive in provisional responses to an INVITE request. The device forwards the request of early media for IP Groups that support this capability; otherwise, the device terminates it. Provisional responses whose SDP are suppressed are changed to a SIP 180 response. This feature is also supported for delayed offers. This is configured using the IP Profile parameter, 'SBC Remote Early Media Support'. The device refers to the parameter also for features that require early media such as playing ringback tone.
- **Early Media Response Type:** The device supports the interworking of different SIP provisional response types between UAs for forwarding the early media to the caller. This can support all early media response types (default), SIP 180 only, or SIP 183 only, and is configured by the IP Profile parameter, 'SBC Remote Early Media Response Type'.
- **Multiple 18x:** The device supports the interworking of different support for multiple 18x responses (including 180 Ringing, 181 Call is Being Forwarded, 182 Call Queued, and 183 Session Progress) that are forwarded to the caller. The UA can be configured as supporting only receipt of the first 18x response (i.e., the device forwards only this response to the caller), or receipt of multiple 18x responses (default). This is configured by the IP Profile parameter, 'SBC Remote Multiple 18x Support'.
- **Early Media RTP:** The device supports the interworking with remote clients that send 18x responses with early media and whose subsequent RTP is delayed, and with remote clients that do not support this and require RTP to immediately follow the 18x response. Some clients do not support 18x with early media, while others require 18x with early media (i.e., they cannot play ringback tone locally). These various interworking capabilities are configured by the IP Profile parameters, 'Remote Early Media RTP Detection Mode', 'SBC Remote Supports RFC 3960', and 'SBC Remote Can Play Ringback'. See the flowcharts below for the device's handling of such scenarios:

**Figure 30-1: SBC Early Media RTP - 18x without SDP**

**Figure 30-2: SBC Early Media RTP - 18x with SDP**

## Interworking SIP re-INVITE Messages

The device supports interworking of SIP re-INVITE messages. This enables communication between endpoints that generate re-INVITE requests and those that do not support the receipt of re-INVITES. The device doesn't forward re-INVITE requests to IP Groups that do not support it. Instead, it sends a SIP response to the re-INVITE request, which can either be a success or a failure, depending on whether the device can bridge the media between the endpoints. The device can also handle re-INVITES with or without an SDP body, enabling communication between endpoints that do not support re-INVITE requests without SDP, and those that require SDP. The device generates an SDP offer and adds it to the incoming re-INVITE request if it doesn't contain an SDP and only then forwards it to the destination endpoint. This interworking support is configured by the IP Profile parameter, 'SBC Remote Reinvite Support'.

## Interworking SIP UPDATE Messages

The device supports interworking of the SIP UPDATED message. This enables communication between UAs that generate UPDATE requests and those that do not support the receipt of UPDATE requests. The device doesn't forward UPDATE requests to IP Groups that do not

support it. Instead, it sends a SIP response to the UPDATE request which can either be a success or a failure, depending on whether the device can bridge the media between the endpoints. The handling of UPDATE messages is configured by the IP Profile parameter 'SIP UPDATE Support'.

## Interworking SIP re-INVITE to UPDATE

The device enables communication between endpoints (IP Groups) that do not support re-INVITE requests but support the UPDATE method, and vice versa. The device translates the re-INVITE request to the UPDATE request, and vice versa. Note that if a re-INVITE request arrives without SDP, the device generates the SDP and adds it to the outgoing UPDATE request. To enable this feature, each IP Group needs to be configured with its unique capabilities by associating it with a relevant IP Profile. For example, an IP Group that supports UPDATE requests but not re-INVITES would be configured as follows:

- SBCRemoteUpdateSupport = 2 (Supported)
- SBCRemoteReinviteSupport = 0 (Not Supported)

If a re-INVITE request needs to be forwarded to this IP Group, it is translated to an UPDATE request.

## Interworking Delayed Offer

The device supports interworking of INVITE messages with and without SDP between SIP entities. The device enables sessions between endpoints (IP Groups) that send INVITES without SDP (i.e., delayed media) and those that do not support the receipt of INVITES without SDP. The device creates an SDP and adds it to INVITES that arrive without SDP. Delayed offer is also supported when early media is present.

Employing IP Profiles, you can configure this interworking feature per SIP entity, using the 'SBC Remote Delayed Offer Support' parameter (see [Configuring IP Profiles](#) on page 674).

- The above mentioned intervention in the SDP offer-answer process may require transcoding.
- For SIP entities that do not support delayed offer, you must assign extension coders to its IP Profile (using the 'Extension Coders' parameter).

## Interworking Call Hold

The device supports the interworking of call hold / retrieve requests between SIP entities supporting different call hold capabilities:

- Interworking SDP call hold formats. This is configured by the IP Profile parameter, 'SBC Remote Hold Format'.
- Interworking the play of the held tone for IP entities that cannot play held tones locally. This is configured by the IP Profile parameter, 'Play Held Tone'.

- Interworking generation of held tone where the device generates the tone to the held party instead of the call hold initiator. This is configured by the IP Profile parameter, 'SBC Reliable Held Tone Source'.

To configure IP Profiles, see [Configuring IP Profiles](#) on page 674.

## Interworking SIP Via Headers

The device supports the interworking of SIP Via headers between SIP entities. For the outgoing message sent to a SIP entity, the device can remove or retain all the Via headers received in the incoming SIP request from the other side. Employing IP Profiles, you can configure this interworking feature per SIP entity, using the 'Keep Incoming Via Headers' parameter (see [Configuring IP Profiles](#) on page 674).

## Interworking SIP User-Agent Headers

The device supports the interworking of SIP User-Agent headers between SIP entities. For the outgoing message sent to a SIP entity, the device can remove or retain all the User-Agent headers received in the incoming SIP request/response from the other side. Employing IP Profiles, you can configure this interworking feature per SIP entity, using the 'Keep User-Agent Header' parameter (see [Configuring IP Profiles](#) on page 674).

## Interworking SIP Record-Route Headers

The device supports the interworking of SIP Record-Route headers between IP entities. For the outgoing message sent to a SIP entity, the device can remove or retain all the Record-Route headers received in the incoming SIP request/response from the other side. Employing IP Profiles, you can configure this interworking feature per SIP entity, using the 'Keep Incoming Routing Headers' parameter (see [Configuring IP Profiles](#) on page 674).

## Interworking SIP To-Header Tags in Multiple SDP Answers

The device supports the interworking of SIP To-header tags in call forking responses (i.e., multiple SDP answers) between IP entities. The device can either use the same To-header tag value for all SDP answers sent to the SIP entity, or send each SDP answer with its original tag. Employing IP Profiles, you can configure this interworking feature per SIP entity, using the 'Remote Multiple Early Dialogs' parameter (see [Configuring IP Profiles](#) on page 674).

## Interworking In-dialog SIP Contact and Record-Route Headers

The device supports the interworking of in-dialog, SIP Contact and Record-Route headers between SIP entities. Employing IP Profiles, you can configure this interworking feature per SIP entity, using the 'Remote Representation Mode' parameter (see [Configuring IP Profiles](#) on page 674).

## 31 Utilizing Gateway Channel Resources for SBC

The device can utilize resources of non-configured Gateway channels (analog and digital) for SBC sessions, regardless of whether the device is licensed for SBC functionality. This feature, in essence, allows "call" resources to be migrated from the Gateway application to the SBC application, allowing you to migrate your Gateway deployment to an all IP-based voice network with only a simple configuration change. One of the main advantages of the feature is that if you purchased the device for deploying it initially as a Gateway for PSTN calls, you can at any stage easily use the device for SBC calls without having to purchase an SBC license.

A Gateway channel is considered "not configured" if it is not associated with any Trunk Group (see [Configuring Trunk Groups](#) on page 934). If all Gateway channels are configured, resources from these channels cannot be used for SBC sessions. If the resources of a currently active SBC call is obtained from a Gateway channel and you configure all Gateway channels during the call, the device maintains the SBC call until it is terminated by the call parties, but obtaining resources from Gateway channels for new SBC calls will not be made possible.

For every non-configured Gateway channel, one SBC session can be processed. For example:

A License Key licensing 1 E1 and 4 FXS and 1 BRI can support up to 37 SBC sessions (31 channels for E1 + 4 channels for FXS + 2 channels for 1 BRI port) if all the Gateway channels are not configured. If the License Key also provides a license for 5 SBC sessions, up to 42 SBC sessions (31 channels for E1 + 4 channels for FXS + 2 channels for 1 BRI port + 5 sessions for SBC) can be supported.

The number of SBC sessions that can be derived from using resources from Gateway channels that are not configured is displayed in the Web interface's License Key page (see [Viewing the License Key](#) on page 1362), in the 'TDM-to-SBC Sessions' field.

- To support the feature, the License Key installed on your device must include the "TDM-to-SBC" (TDM2SBC) feature key; otherwise, to purchase the feature, contact the sales representative of your purchased device to upgrade your License Key.
- The maximum number of SBC sessions that can be supported is according to the device's maximum SBC capacity (see [Capacity for Signaling, Media and User Registrations](#) on page 2154).

## 32 Configuring General SBC Settings

This section describes configuration of various SBC features.

### Interworking Dialog Information in SIP NOTIFY Messages

You can enable the device to interwork dialog information (XML body) received in SIP NOTIFY messages from a remote (WAN) application server. The NOTIFY message is sent by application servers to notify a SIP client, subscribed to a service and located behind the device (LAN), of the status of another SIP client in the LAN. For example, user B can subscribe to an application server for call pick-up service, whereby if user A's phone rings, the application server notifies user B. User B can then press a pre-configured key sequence to answer the call.

The NOTIFY message contains the XML body with call identifiers (call-id and tags). However, as the application server is located in the external network WAN and the SIP clients behind the device, the call dialog information sent by the application server reflects only the dialog between the device and itself; not that of the involved SIP clients. This is due to, for example, the device's topology hiding (e.g., IP address) of its LAN elements. The device resolves this by replacing the call identifiers received from the application server with the correct call identifiers (e.g., user A and user B). Thus, users subscribed to the service can receive relevant NOTIFY messages from the device and use the service.

#### ➤ To enable the feature:

- Configure the 'SBC Dialog-Info Interworking' (EnableSBCDialogInfoInterworking) parameter to **Enable**.

When the feature is disabled, the device forwards the NOTIFY message as is, without modifying its XML body.

Below is an example of an XML body where the call-id, tags, and URIs have been replaced by the device:

```
<?xml version="1.0"?>
<dialog-info xmlns="urn:ietf:params:xml:ns:dialog-info"
```

```
version="10" state="partial"
entity="sip:alice@example.com">
<dialog id="zxcvbnm3" call-id="67402270@10.132.10.150"

```

## 33 Configuring Call Admission Control

You can implement Call Admission Control (CAC) to regulate the volume of voice traffic handled by the device.

Call Admission Control applies the **same** maximum concurrent call limit to all users associated with it. If you want to apply a different maximum concurrent call limit to each user, you need to use tags in Call Setup Rules and Dial Plans, as described in [Configuring Maximum Concurrent Calls per Specific User](#) on page 1297.

CAC configuration is done using two tables with parent-child type relationship:

- Call Admission Control Profile table: This is the parent table, which defines a name for the CAC profile.
- Call Admission Control Rule table: This is the child table, which defines the actual CAC rules for the profile.

You can configure up to 102 CAC profiles and up to 102 CAC rules. In addition, a CAC profile can be configured with up to 8 CAC rules.

Once you have configured a CAC profile with CAC rules, you need to assign it to any of the following SIP configuration entities (using the 'CAC Profile' parameter):

- IP Group (see [Configuring IP Groups](#) on page 591)
- SIP Interface (see [Configuring SIP Interfaces](#) on page 570)
- SRD (see [Configuring SRDs](#) on page 558)

CAC rules define the maximum number of allowed concurrent calls (SIP dialog-initiating requests) for the assigned SIP entity (listed above) and per registered user belonging to the SIP entity. This can also include the maximum number of allowed concurrent SIP dialogs per second (*rate*). The CAC rule can be defined for a specific SIP message type (e.g., only INVITEs) as well as for a specific call direction (e.g., only outbound calls).

- **Token Bucket:** This scheme is a SIP-dialog rate control using the token-bucket mechanism. Token bucket is a control mechanism that determines the rate of SIP dialog processing based on the presence of tokens in the bucket. Tokens in the bucket are removed ("cached in") for the ability to process each dialog. If there are no tokens, the device rejects the dialog request with a SIP 480 (Temporarily Unavailable). Configuration of the token-bucket mechanism involves the following:

- Configuring the number of tokens that are added to the bucket per second. This is referred to as *rate*. To process (allow) a SIP dialog, the device needs a token from the bucket.
- Configuring the maximum number of tokens that the bucket can hold and thus, the maximum number of tokens that can be used for processing SIP dialogs that are received at one time. This is referred to as *burst*.

For example, assume that the rate is configured to 1 and the burst to 4:

- One token is added to the bucket every second.
- The maximum number of tokens that the bucket can hold is four.
- If SIP dialogs have never been received by the device, the bucket is filled to its maximum, which is four tokens (i.e., burst), regardless of the number of seconds that have passed.
- If four SIP dialogs are received at the same time (i.e., burst), the device uses the four tokens to process the dialogs. The bucket is now left with no tokens at that given moment, but after a second, a new token is added to the bucket (due to the rate). If there are no calls for the next three seconds, the bucket fills up again to four tokens (and no more).
- If the bucket contains four tokens (i.e., full) and five SIP dialogs are received at the same time, the device uses the four tokens to process four of the dialogs and rejects one.
- If the bucket has one token and SIP dialogs are then received every second, the device uses the token to process the first dialog, adds a token to the bucket after a second and processes the second dialog, and so on.

Your CAC rule can also define a guaranteed number of concurrent calls (reserved capacity) for the assigned SIP entity (see above) . Reserved capacity is especially useful when the device operates with multiple entities. For example, if the total call capacity supported by the device is 200, a scenario may arise where a SIP entity may reach 200 call sessions, leaving no available call resources for the other SIP entities. If the reserved call capacity of a SIP entity is threatened by a new call for a different SIP entity, the device rejects the call to safeguard the reserved capacity.

Requests that reach the user-defined call limit (maximum concurrent calls or call rate) are sent to an alternative route, if configured (in the IP-to-IP Routing table). If no alternative routing rule exists, the device rejects the SIP request with a SIP 480 "Temporarily Unavailable" response.

- If the device rejects an incoming SIP dialog request due to CAC, it sends a SIP 480 "Temporarily Unavailable" response.
- The device applies the CAC rule for the incoming leg immediately after the Classification process. If the call / request is rejected at this stage, no routing is performed. The enforcement for the outgoing leg is performed within each alternative route iteration. This is accessed from two places - during initial classification / routing and during alternative routing.
- CAC doesn't apply to Test Calls (see [Configuring Basic Incoming Test Calls](#) on page 1688).

The following procedure describes how to configure CAC profiles through the Web interface. You can also configure them through other management interfaces:

- Call Admission Control Profile table: ini file [SBCAdmissionProfile] or CLI (`configure voip > sbc cac-profile`)

- Call Admission Control Rule table: ini file [SBCAdmissionRule] or CLI (`configure voip > sbc cac-rule`)

➤ **To configure a CAC profile:**

1. Open the Call Admission Control Profile table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Call Admission Control Profile**).
2. Click **New**; the following dialog box appears:

Call Admission Control Profile

GENERAL

Index: 0

Name:

3. Configure a CAC profile according to the parameters described in the table below.
4. Click **Apply**.

**Table 33-1: Call Admission Control Profile Table Parameter Description**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. By default, no value is defined. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>

5. In the Call Admission Control Profile table, select the required row, and then click the **Call Admission Control Rule** link located below the table; the Call Admission Control Rule table appears.
6. Click **New**; the following dialog box appears:

Call Admission Control Rule

MATCH

Index: 0

Request Type: All

Request Direction: Both

ACTION

Limit: -1

Limit per User: -1

Rate: 0

Maximum Burst: 0

Rate Per User: 0

Maximum Burst Per User: 0

Reserved Capacity: 0

7. Configure a CAC rule according to the parameters described in the table below.
8. Click **Apply**.

**Table 33-2: Call Admission Control Rule Table Parameter Description**

Parameter	Description
<b>Match</b>	
'Index' sbc-admission-rule- <Index>/<Index> [SBCAdmissionRule_RuleIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Request Type' request-type [SBCAdmissionRule_ RequestType]	Defines the type of SIP dialog-initiating request to which you want to apply the rule (not to subsequent requests, which can be of different type and direction). <ul style="list-style-type: none"> <li>■ [0] <b>All</b> (default)</li> <li>■ [1] <b>INVITE</b></li> <li>■ [2] <b>SUBSCRIBE</b></li> <li>■ [3] <b>Other</b> = All SIP request types except INVITEs and SUBSCRIBEs (e.g., REGISTER).</li> </ul>
'Request Direction' request-direction [SBCAdmissionRule_ RequestDirection]	Defines the call direction of the SIP request to which the rule applies. <ul style="list-style-type: none"> <li>■ [0] <b>Both</b> = (Default) Rule applies to inbound and outbound SIP dialogs.</li> <li>■ [1] <b>Inbound</b> = Rule applies only to inbound SIP dialogs.</li> <li>■ [2] <b>Outbound</b> = Rule applies only to outbound SIP dialogs.</li> </ul>
<b>Action</b>	
'Limit' limit [SBCAdmissionRule_Limit]	Defines the maximum allowed number of concurrent SIP dialogs. You can also use the following special values: <ul style="list-style-type: none"> <li>■ [-1] <b>-1</b> = (Default) Unlimited number of concurrent SIP dialogs.</li> <li>■ [0] <b>0</b> = Blocks all the SIP dialog types specified in the 'Request Type' parameter (above).</li> </ul> <b>Note:</b> The parameter is not related to the rate-limiting algorithms.

Parameter	Description
'Limit per User' limit-per-user [SBCAdmissionRule_LimitPerUser]	<p>Defines the maximum number of allowed concurrent SIP dialogs per user.</p> <p>You can also use the following special values:</p> <ul style="list-style-type: none"> <li>■ [-1] -1 = (Default) Unlimited number of concurrent SIP dialogs per user.</li> <li>■ [0] 0 = Blocks all the SIP dialog types specified in the 'Request Type' parameter (above).</li> </ul> <p><b>Note:</b> The parameter is not related to the rate-limiting algorithms.</p>
'Rate' rate [SBCAdmissionRule_Rate]	<ul style="list-style-type: none"> <li>■ <b>Token Bucket algorithm:</b> Defines the number of tokens added to the token "bucket" per second, where a token "buys" a SIP dialog. For example, if you configure the parameter to 1, one token is added to the bucket every second. If there are no calls for five seconds, the bucket would have accumulated 5 tokens.</li> </ul> <p>The valid value is 0 to 65,535. The default is 0 (i.e., unlimited rate).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter, you <b>must</b> also configure the 'Maximum Burst' parameter to a non-zero value.</li> </ul>
'Maximum Burst' max-burst [SBCAdmissionRule_MaxBurst]	<p>Defines the maximum number of SIP dialogs that can be processed at any given time.</p> <p>Token Bucket algorithm: In other words, it defines the maximum number of tokens that the "bucket" can hold. The device only accepts a SIP dialog if a token exists in the "bucket". Once the SIP dialog is accepted, a token is removed from the "bucket". If a SIP dialog is received by the device and the token "bucket" is empty, the device rejects the SIP dialog. Alternatively, if the "bucket" is full, for example, 100 tokens, and 101 SIP dialogs arrive (before another token is added to the "bucket", i.e., faster than that configured in the 'Rate' parameter), the device accepts the first 100 SIP dialogs and rejects the last one. Dropped requests are not counted in the "bucket".</p> <p>The valid value is 0 to 65,535. The default is 0 (i.e.,</p>

Parameter	Description
	<p>unlimited SIP dialogs).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter functions together with the 'Rate' parameter (see above). Therefore, the parameter must be configured.</li> <li>■ The parameter's value cannot be greater than 10 times (x) the value of the 'Rate' parameter. For example, if you configured the 'Rate' parameter to 2, you can configure the 'Maximum Burst' parameter to any value less than or equal to 20 (i.e., 10 x 2).</li> <li>■ The token bucket feature is per SIP request type and SIP request direction.</li> </ul>
'Rate Per User' <code>rate-per-user</code> [SBCAdmissionRule_ RatePerUser]	<p>Defines the maximum allowed number of concurrent SIP dialogs per registered user that can be handled per second.</p> <p>The valid value is 0 to 65,535. The default is 0 (i.e., unlimited rate).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure this parameter, you must also configure the 'Maximum Burst per User' parameter to a non-zero value (see below).</li> </ul>
'Maximum Burst Per User' <code>max-burst-per-user</code> [SBCAdmissionRule_ MaxBurstPerUser]	<p>Defines the maximum number of tokens (SIP dialogs) per user that the bucket can hold (see the 'Maximum Burst' parameter for a detailed description).</p> <p>The valid value is 0 to 65,535. The default is 0 (i.e., unlimited SIP dialogs).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter functions together with the 'Rate Per User' parameter (see above).</li> </ul>
'Reserved Capacity' <code>reservation</code> [SBCAdmissionRule_ Reservation]	<p>Defines the guaranteed (minimum) call capacity.</p> <p>The default is 0 (i.e., no reserved capacity).</p> <p>If you configure reserved call capacity for an SRD and each of its associated IP Groups, the SRD's reserved call capacity must be greater or equal to the summation of the reserved call capacity of all these IP Groups. In other words, the SRD serves as the "parent" reserved call capacity. If the SRD's reserved call capacity is greater, the</p>

Parameter	Description
	<p>extra call capacity can be used as a shared pool between the IP Groups for unreserved calls when they exceed their reserved capacity. For example, assume that the reserved capacity for an SRD and its associated IP Groups are as follows:</p> <ul style="list-style-type: none"> <li>■ SRD reserved call capacity: 40</li> <li>■ IP Group ID 1 reserved call capacity: 10</li> <li>■ IP Group ID 2 reserved call capacity: 20</li> </ul> <p>In this setup, the SRD offers a shared pool for unreserved call capacity of 10 [i.e., <math>40 - (10 + 20)</math>]. If IP Group ID 1 needs to handle 15 calls, it is guaranteed 10 calls and the remaining 5 is provided from the SRD's shared pool. If the SDR's shared pool is currently empty and resources for new calls are required, the quota is taken from the device's total capacity, if available. For example, if IP Group ID 1 needs to handle 21 calls, it's guaranteed 10, the SRD's shared pool provides another 10, and the last call is provided from the device's total call capacity support (e.g., of 200).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is not related to the rate-limiting algorithms.</li> <li>■ Reserved call capacity is applicable only to IP Groups and SRDs.</li> <li>■ Reserved call capacity is applicable only to INVITE and SUBSCRIBE messages.</li> <li>■ Reserved call capacity must be less than the maximum capacity (limit) configured for the CAC rule (see the 'Limit' parameter).</li> <li>■ The total reserved call capacity configured for all CAC rules must be within the device's total call capacity support.</li> </ul>

## 34 Routing SBC

This section describes configuration of call routing for the SBC application.

### Configuring Classification Rules

The Classification table lets you configure up to 102 Classification rules. A Classification rule classifies incoming SIP dialog-initiating requests (e.g., INVITE messages) to a "source" IP Group. The source IP Group is the SIP entity that sent the SIP dialog request. Once classified, the device uses the IP Group to process the call (manipulation and routing).

You can also use the Classification table for employing SIP-level access control for successfully classified calls, by configuring Classification rules with whitelist and blacklist settings. If a Classification rule is configured as a whitelist ("Allow"), the device accepts the SIP dialog and processes the call. If the Classification rule is configured as a blacklist ("Deny"), the device rejects the SIP dialog.

Configuration of Classification rules includes two areas:

- **Match:** Defines the matching characteristics of the incoming IP call (e.g., source SIP Interface and IP address). Classification is primarily based on the SIP Interface as the matching characteristics on which the incoming dialog is received. As Classification rules must first be assigned an SRD, the SIP Interface is one that belongs to the SRD. Therefore, Classification rules are configured per SRD, where multiple SIP Interfaces can be used as matching characteristics. However, as multiple SRDs are relevant only for multi-tenant deployments, for most deployments only a single SRD is required. As the device provides a default SRD ("Default\_SRD"), where only one SRD is required, the device automatically assigns it to the Classification rule.
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (i.e., classifies the call to the specified IP Group).

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it classifies the call to the IP Group configured for that rule. If you are using source tags to classify incoming calls to IP Groups, then once the device locates a matching rule (including a match for the source tag), the device searches the IP Groups table for an IP Group with the matching tag. For more information on classification based on tags, see [Configuring Classification Based on Tags](#) on page 1183.

Configure stricter classification rules higher up in the table than less strict rules to ensure incoming dialogs are classified to the desired IP Group. *Strict* refers to the number of matching characteristics configured for the rule. For example, a rule configured with source host name and destination host name as matching characteristics is stricter than a rule configured with only source host name. If the rule configured with only source host name appears higher up in the table, the device ("erroneously") uses the rule to classify incoming dialogs matching this source host name (even if they also match the rule appearing lower down in the table configured with the destination host name as well).

If the device doesn't find a matching rule (i.e., classification fails), the device rejects or allows the call depending on configuration. For more information, see [Configuring Action for Classification Failure](#) on page 1185.

The Classification table is used to classify incoming SIP dialog-initiating requests **only** if the following classification stages **fail**:

1. **Classification Stage 1 - Classification by Users Registration Database:** The device searches its users registration database to check whether the incoming SIP dialog-initiating request arrived from a registered user. The device searches the database for a user that matches the address-of-record (AOR) and Contact of the incoming SIP message:

- Compares the SIP Contact header to the contact value in the database.
- Compares the URL in the SIP P-Asserted-Identity/From header to the registered AOR in the database.

If the device finds a matching registered user, it classifies the user to the IP Group that is associated with the user in the database.

If this classification stage fails, the device proceeds to classification by Proxy Set (see below).

You can enable or disable classification by the device's users registration database per SIP Interface. For more information, see the 'Classify By Registration DB' parameter in the SIP Interfaces table, as described in [Configuring SIP Interfaces](#) on page 570.

2. **Classification Stage 2 - Classification by Proxy Set:** If classification of the incoming SIP dialog-initiating request by users registration database fails (see above), the device performs classification based on Proxy Set. This classification is applicable only to Server-type IP Groups and is done only if you've enabled classification by Proxy Set ('Classify By Proxy Set' parameter in the IP Groups table, as described in [Configuring IP Groups](#) on page 591).

By default, the device checks if the **source IP address** (ISO Layer 3) of the incoming SIP dialog message (e.g., INVITE) matches an IP address in the Proxy Set that is associated with the IP Group (assigned in the IP Groups table). If the Proxy Set is configured with a host name, the device checks if the source IP address matches one of the dynamically DNS-

resolved IP addresses. If such a Proxy Set exists, the device classifies the SIP dialog to the IP Group associated with the Proxy Set.

You can also configure Classification by Proxy Set whereby the device checks if the IP address in the **SIP Contact header** of the incoming SIP dialog matches an IP address in the Proxy Set that is associated with the IP Group. If the header contains a SIP URI that has an IP address (not hostname) in the host part and it matches an IP address in the Proxy Set, the call is classified to the IP Group. This mode is useful, for example, when the source IP address is an internal address.

The IP address to use (source IP address or IP address in Contact header) of the incoming SIP dialog for classification by Proxy Set is configured by the global parameter, 'Classify By Proxy Set Mode' (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**), as shown below. When configured to **Both**, the device first checks if the source IP address matches an IP address in the Proxy Set. Only if there is no match, does it check if the IP address in the SIP Contact header matches an IP address in the Proxy Set.

#### Classify By Proxy Set Mode

IP address ▼

If more than one Proxy Set is configured with the same IP address and associated with the same SIP Interface, the device may classify and route the SIP dialog to an incorrect IP Group. In such a scenario, a warning is generated in the syslog message. However, if some Proxy Sets are configured with the same IP address but different ports (e.g., 10.1.1.1:5060 and 10.1.1.1:5070) and the 'Classification Input' parameter is configured to **IP Address, Port & Transport Type**, classification (based on IP address and port combination) to the correct IP Group is achieved. Therefore, when classification is by Proxy Set, pay attention to the configured IP addresses and the 'Classification Input' parameter of your Proxy Sets. When more than one Proxy Set is configured with the same IP address, the device selects the matching Proxy Set in the following precedence order:

- a. Selects the Proxy Set whose IP address, port, and transport type match the source of the incoming dialog.
- b. If no match is found for a), it selects the Proxy Set whose IP address and transport type match the source of the incoming dialog (if the 'Classification Input' parameter is configured to **IP Address Only**).
- c. If no match is found for b), it selects the Proxy Set whose IP address match the source of the incoming dialog (if the 'Classification Input' parameter is configured to **IP Address Only**).

If classification by Proxy Set fails (or classification by Proxy Set is disabled), the device proceeds to classification by the Classification table, as described in this section

- For security, it is recommended to classify SIP dialogs based on Proxy Set only if the IP address of the Server-type IP Group is **unknown**. In other words, if the Proxy Set associated with the IP Group is configured with an FQDN. In such cases, the device classifies incoming SIP dialogs to the IP Group based on the DNS-resolved IP address. If the IP address is known, it is recommended to use a Classification rule instead (and disable the Classify by Proxy Set feature), where the rule is configured with not only the **IP address, but also with SIP message characteristics** to increase the strictness of the classification process. The reason for preferring classification based on Proxy Set when the IP address is unknown is that IP address forgery (commonly known as IP spoofing) is more difficult than malicious SIP message tampering and therefore, using a Classification rule without an IP address offers a weaker form of security. When classification is based on Proxy Set, the Classification table for the specific IP Group is ignored.
- If multiple IP Groups are associated with the same Proxy Set, use Classification rules to classify the incoming dialogs to the IP Groups (do **not** use the Classify by Proxy Set feature).
- When using the Classification table for classification instead of by Proxy Set, it's recommended to enable the 'Validate Source IP' parameter in the IP Groups table. This setting verifies that the request was sent from one of the IP addresses (including DNS-resolved IP addresses) of the associated Proxy Set.
- The device saves incoming SIP REGISTER messages in its registration database. If the REGISTER message is received from a User-type IP Group, the device sends the message to the configured destination.

The flowchart below illustrates the classification process:

The following procedure describes how to configure Classification rules through the Web interface. You can also configure it through ini file [Classification] or CLI (`configure voip > sbc classification`).

➤ **To configure a Classification rule:**

1. Open the Classification table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Classification Table**).
2. Click **New**; the following dialog box appears (cropped for convenience):

3. Configure the Classification rule according to the parameters described in the table below.

4. Click **Apply**.

**Table 34-1: Classification Table Parameter Descriptions**

Parameter	Description
'SRD' srd-name [SRDName]	<p>Assigns an SRD to the rule as a matching characteristic for the incoming SIP dialog.</p> <p>If only one SRD is configured in the SRDs table, the SRD is assigned to the rule by default. If multiple SRDs are configured in the SRDs table, no value is assigned.</p> <p>To configure SRDs, see <a href="#">Configuring SRDs</a> on page 558.</p> <p><b>Note:</b> The parameter is mandatory.</p>
<b>Match</b>	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Name' classification-name [ClassificationName]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no name is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Source SIP Interface' src-sip-interface-name [SrcSIPInterfaceName]	<p>Assigns a SIP Interface to the rule as a matching characteristic for the incoming SIP dialog.</p> <p>The default is <b>Any</b> (i.e., all SIP Interfaces belonging to the SRD assigned to the rule).</p> <p><b>Note:</b> The SIP Interface must belong to the SRD assigned to</p>

Parameter	Description
	the rule (see the 'SRD' parameter in the table).
'Source IP Address' src-ip-address [SrcAddress]	<p>Defines a source IP address as a matching characteristic for the incoming SIP dialog.</p> <p>The valid value is an IP address in dotted-decimal notation. In addition, the following wildcards can be used:</p> <ul style="list-style-type: none"> <li>■ "x" wildcard: represents single digits. For example, 10.8.8.xx represents all addresses between 10.8.8.10 and 10.8.8.99.</li> <li>■ Asterisk (*) wildcard: represents any number between 0 and 255. For example, 10.8.8.* represents all addresses between 10.8.8.0 and 10.8.8.255.</li> </ul> <p>By default, no value is defined (i.e., any source IP address is accepted).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to Server-type IP Groups.</li> <li>■ If the IP address is unknown (i.e., configured for the associated Proxy Set as an FQDN), it is recommended to classify incoming dialogs based on Proxy Set (instead of using a Classification rule). For more information on classification by Proxy Set or by Classification rule, see the note bulletin in the beginning of this section.</li> </ul>
'Source Transport Type' src-transport-type [SrcTransportType]	<p>Defines the source transport type as a matching characteristic for the incoming SIP dialog.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Any</b> = (Default) All transport types</li> <li>■ [0] <b>UDP</b></li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS</b></li> <li>■ [3] <b>SCTP</b></li> </ul>
'Source Port' src-port [SrcPort]	<p>Defines the source port number as a matching characteristic for the incoming SIP dialog.</p> <p>By default, no value is defined.</p>
'Source Username Pattern' src-user-name-	<p>Defines the source URI user part as a matching characteristic for the incoming SIP dialog. The URI is</p>

Parameter	Description
<p>pattern</p> <p>[SrcUsernamePrefix]</p>	<p>typically located in the SIP From header. However, you can configure the SIP header from where the device obtains the source URI, in the IP Groups table ('Source URI Input' parameter). For more information on how the device obtains the URI, see <a href="#">Call Processing of SIP Dialog Requests</a> on page 1125.</p> <p>You can use special patterns (notations) to denote the user part. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)", without the quotation marks. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The valid value is a string of up to 60 characters. The default is the asterisk (*) symbol, meaning any source user part.</p> <p><b>Note:</b> For REGISTER requests, the source URI is obtained from the To header.</p>
<p>'Source Host'</p> <p>src-host</p> <p>[SrcHost]</p>	<p>Defines the prefix of the source URI host name as a matching characteristic for the incoming SIP dialog.</p> <p>The URI is typically located in the SIP From header. However, you can configure the SIP header from where the device obtains the source URI, in the IP Groups table ('Source URI Input' parameter). For more information on how the device obtains this URI, see <a href="#">Call Processing of SIP Dialog Requests</a> on page 1125.</p> <p>The default is the asterisk (*) symbol, which represents any source host prefix.</p> <p><b>Note:</b> For REGISTER requests, the source URI is obtained from the To header.</p>
<p>'Destination Username Pattern'</p> <p>dst-user-name-pattern</p> <p>[DestUsernamePrefix]</p>	<p>Defines the destination Request-URI user part as a matching characteristic for the incoming SIP dialog.</p> <p>You can use special patterns (notations) to denote the user part. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)", without the quotation marks. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The valid value is a string of up to 60 characters. The</p>

Parameter	Description
	default is the asterisk (*) symbol, meaning any destination user part.
'Destination Host' dst-host [DestHost]	<p>Defines the prefix of the destination Request-URI host name as a matching characteristic for the incoming SIP dialog.</p> <p>The default is the asterisk (*) symbol, which represents any destination host prefix.</p>
'Message Condition' message-condition-name [MessageConditionName]	<p>Assigns a Message Condition rule to the Classification rule as a matching characteristic for the incoming SIP dialog.</p> <p>By default, no value is defined.</p> <p>To configure Message Condition rules, see <a href="#">Configuring Message Condition Rules</a> on page 865.</p>
'TLS Remote Subject Name' tls-remote-subject-name [TLSRemoteSubjectName]	<p>Defines the Subject Name of the TLS certificate used for the TLS connection upon which the SIP dialog message is received, as a matching characteristic for the incoming SIP dialog.</p> <p>If there is no match and the SAN is marked as "critical", classification to the specific rule fails. If there is no match but the Subject Alternative Name (SAN) isn't marked as "critical", the device checks if the configured value matches the certificate's Common Name (CN).</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For classification of incoming SIP dialogs by TLS certificate Subject Name, make sure that you also do the following: <ul style="list-style-type: none"> <li>✓ Enable TLS mutual authentication globally using the 'TLS Mutual Authentication' parameter [SIPSRequireClientCertificate], or per SIP Interface using the 'TLS Mutual Authentication' parameter.</li> <li>✓ Configure the Proxy Set's 'Peer Host Name Verification Mode' parameter to <b>Disable</b> (prevents TLS connections closing before the Classification stage).</li> </ul> </li> <li>■ If you are classifying incoming SIP dialogs by Proxy Set (configured by the 'Classify By Proxy Set' parameter in the IP Groups table), classification by certificate Subject Name isn't supported and therefore, this parameter</li> </ul>

Parameter	Description
	<p>isn't applicable. For classification by Proxy Set, enable the Proxy Set's 'Peer Host Name Verification Mode' parameter (see <a href="#">Configuring Proxy Sets</a> on page 632).</p> <ul style="list-style-type: none"> <li>■ A certificate may include multiple SAN types (e.g., Email, DNS, URI, and IP). The only SAN types that the device compares for matching are DNS and IP.</li> </ul>
Action	
'Action Type' action-type [ActionType]	<p>Defines a whitelist or blacklist for the matched incoming SIP dialog.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Deny</b> = Blocks incoming SIP dialogs that match the characteristics of the rule (blacklist).</li> <li>■ [1] <b>Allow</b> = (Default) Allows incoming SIP dialogs that match the characteristics of the rule (whitelist) and assigns it to the associated IP Group.</li> </ul>
'Destination Routing Policy' dest-routing-policy [DestRoutingPolicy]	<p>Assigns a Routing Policy to the matched incoming SIP dialog.</p> <p>The assigned Routing Policy overrides the Routing Policy assigned to the SRD (in the SRDs table). The option to assign Routing Policies to Classification rules is useful in deployments requiring different routing and manipulation rules for specific calls pertaining to the <b>same</b> SRD. In such scenarios, you need to configure multiple Classification rules for the same SRD, where for some rules no Routing Policy is assigned (i.e., the SRD's assigned Routing Policy is used) while for others a different Routing Policy is specified to override the SRD's assigned Routing Policy.</p> <p>By default, no value is defined.</p> <p>To configure Routing Policies, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p>
'IP Group Selection' ip-group-selection [IPGroupSelection]	<p>Defines how the incoming SIP dialog is classified to an IP Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Source IP Group</b> = (Default) The SIP dialog is classified to the IP Group that is specified in the 'Source IP Group' parameter (see below).</li> <li>■ [1] <b>Tagged IP Group</b> = The SIP dialog is classified to an IP Group based on source tag, which is specified in the 'IP Group Tag Name' parameter (see below). For more</li> </ul>

Parameter	Description
	information on Classification of incoming SIP dialogs to IP Groups using tags, see <a href="#">Configuring Classification Based on Tags</a> on page 1183.
'Source IP Group' src-ip-group-name [SrcIPGroupName]	<p>Assigns an IP Group to the matched incoming SIP dialog. By default, no value is defined.</p> <p>To configure IP Groups, see <a href="#">Configuring IP Groups</a> on page 591.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the 'IP Group Selection' parameter to <b>Source IP Group</b>.</li> <li>■ The IP Group must be associated with the assigned SRD (see the 'SRD' parameter in the table).</li> </ul>
'IP Group Tag Name' ip-group-tag-name [IpGroupTagName]	<p>Defines the source tag of the incoming SIP dialog. The tag is used for classifying the SIP dialog to an IP Group. The tag is obtained from the Call Setup Rule that is associated with the SIP Interface on which the dialog is received.</p> <p>The valid value is a string of up to 70 characters. The default value is "default" (without quotation marks), which must be used when the resultant tag from the Call Setup Rule is only a value (e.g., "Ireland"). If the resultant tag is a name=value (e.g., "Country=Ireland"), then configure the parameter with the <b>name</b> only (e.g., "Country"). Only <b>one</b> tag name can be configured.</p> <p>For more information on Classification of incoming SIP dialogs to IP Groups using tags, see <a href="#">Configuring Classification Based on Tags</a> on page 1183.</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'IP Group Selection' parameter to <b>Tagged IP Group</b>.</p>
'IP Profile' ip-profile-id [IpProfileName]	<p>Assigns an IP Profile to the matched incoming SIP dialog. The assigned IP Profile overrides the IP Profile assigned to the IP Group (in the IP Groups table) to which the SIP dialog is classified. Therefore, assigning an IP Profile during classification allows you to assign different IP Profiles to specific users (calls) that belong to the same IP Group (User or Server type).</p> <p>For example, you can configure two Classification rules to classify incoming calls to the same IP Group. However, one Classification rule is a regular rule that doesn't specify any</p>

Parameter	Description
	<p>IP Profile (IP Profile assigned to IP Group is used), while the second rule is configured with an additional matching characteristic for the source hostname prefix (e.g., "abcd.com") and with an additional action that assigns a different IP Profile.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> For User-type IP Groups, if a user is already registered with the device (from a previous, initial classification process), the device classifies subsequent INVITE requests from the user according to the device's users database instead of the Classification table. In such a scenario, the same IP Profile that was previously assigned to the user by the Classification table is also used (in other words, the device's users database stores the associated IP Profile).</p>

### Classification Based on URI of Selected Header Example

The following example describes how to configure classification of incoming calls to IP Groups, based on source URI in a specific SIP header. The example assumes the following incoming INVITE message:

```

INVITE sip:8000@10.33.4.226 SIP/2.0
Via: SIP/2.0/UDP 10.33.4.226;branch=z9hG4bKVEBTDHSAHSUYRTEXEDEGJY
From: <sip:100@10.33.4.226>;tag=YSQQKXXREVDPYPTNFMWG
To: <sip:8000@10.33.4.226>
Call-ID: FKPNOYRNKROIMEGBSSKS@10.33.4.226
CSeq: 1 INVITE
Contact: <sip:100@10.33.4.226>
Route: <sip:2000@10.10.10.10>,<sip:300@10.10.10.30>
Supported: em,100rel,timer,replaces
P-Caller-Party-ID: <sip:1111@10.33.38.1>
User-Agent: Sip Message Generator V1.0.0.5
Content-Length: 0

```

1. In the Classification table, add the following classification rules:

Index	Source Username Pattern	Destination Username Pattern	Destination Host	Source IP Group
0	333	-	-	1
1	1111	2000	10.10.10.10	2

2. In the IP Groups table, add the following IP Groups:

Index	Source URI Input	Destination URI Input
1	-	-
2	P-Called-Party-ID	Route

In the example, a match exists only for Classification Rule #1. This is because the source (1111) and destination (2000) username prefixes match those in the INVITE's P-Called-Party-ID header (i.e., "<sip:1111@10.33.38.1>") and Route header (i.e., "<sip:2000@10.10.10.10>"), respectively. These SIP headers were determined in IP Group 2.

## Configuring Classification Based on Tags

You can classify incoming SIP dialogs to IP Groups, using tags (source tags) that are obtained from Call Setup Rules associated with the SIP Interfaces on which dialogs are received. Using tags can significantly reduce the number of required Classification rules. In some scenarios, a single Classification rule may suffice.

Classification based on tags includes the following stages:

1. The device determines the tag of the incoming SIP dialog by running a Call Setup Rule that is associated with the SIP Interface on which the dialog is received. The Call Setup Rule on SIP Interfaces can be based on synchronous or asynchronous queries. For example, the Call Setup Rule can send an asynchronous query to an external HTTP server (AudioCodes ARM) for a source tag, which can then be used to classify the incoming SIP dialog to a source IP Group. Alternatively, you can configure the Call Setup Rule to generate a tag with a name and value (e.g., "Country=Ireland") or only a value (e.g., "Ireland").
2. The device searches the Classification table for a matching rule based on the SIP Interface (and optionally, any other existing matching properties) as well as the tag. The tag can be a name (e.g., "Country"), or "default" if the tag only has a value (e.g., "Ireland").
3. The device searches the IP Groups table for an IP Group that is configured with the tag from the Call Setup Rule (name=value or value only) and if found, classifies the dialog to that IP Group.

- Classification based on tags is done only if classification based on user registration and Proxy Set fail.
- The IP Group Set table is not used for classification (i.e., ignores tags).

The following procedure describes how to configure incoming SIP dialog classification based on tags. The procedure is based on an example that uses Dial Plan tags to classify calls to three different IP Groups:

- Calls with source number (user) 410 are classified to IP Group-1
- Calls with source number (user) 420 are classified to IP Group-2

- Calls with source number (user) 430 are classified to IP Group-3

➤ **To configure Classification based on tags:**

1. Open the Dial Plan table (see [Configuring Dial Plans](#) on page 825), and then configure Dial Plan tags. In our example, the following Dial Plan rules are configured for Dial Plan "ITSP":

Name	Prefix	Tag
Rule1	410	Country=Ireland
Rule2	420	Country=Scotland
Rule3	430	Country=England

2. Open the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809), and then configure Call Setup Rules for obtaining source tags of incoming SIP dialogs. In our example, the following Call Setup Rule is configured:

General	
'Rules Set ID'	1
'Request Type'	Dial Plan
'Request Target'	ITSP
'Request Key'	Param.Call.Src.User
'Condition '	DialPlan.Found exists
Action	
'Action Subject'	SrcTags
'Action Type'	Modify
'Action Value'	DialPlan.Result

3. Open the SIP Interfaces table (see [Configuring SIP Interfaces](#) on page 570), and then configure a SIP Interface with the 'Call Setup Rules Set ID' parameter set to the 'Rules Set ID' value of your Call Setup Rules. In our example, the SIP Interface is named "SIPIfx-Tags" and the parameter is configured to 1.
4. Open the Classification table, and then configure a rule with the following:

Match	
'Source SIP	SIPIfx-Tags (or select Any)

Match	
Interface'	
Action	
'IP Group Selection'	<b>Tagged IP Group</b>
'IP Group Tag Name'	<b>Country</b> <b>Note:</b> Enter the tag's name only. If the tag only has a value, then enter "default" (without quotation marks).

5. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then configure IP Groups with the 'Tags' parameter set to the appropriate tag. If the source tag has a name and value, then configure the parameter as name=value (e.g., "Country=Ireland"). If it only has a value, then configure it with the value. In our example, the following IP Groups are configured:

Name	Tags
IPGroup-1	Country=Ireland
IPGroup-2	Country=Scotland
IPGroup-3	Country=England

## Configuring Action for Classification Failure

If the device doesn't find a matching rule in the Classification table for the incoming SIP dialog-initiating request (i.e., classification fails), you can configure the device to reject or allow the call.

### ➤ To configure action for unclassified calls:

1. Open the SBC General Settings (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
2. From the 'Unclassified Calls' drop-down list, select one of the following:
  - **Reject:** The device rejects the call.
  - **Allow:** The device accepts the call and classifies it to an IP Group as follows:
    - i. The device determines the SIP listening port (e.g., 5061) on which the incoming SIP dialog request was received and then determines the SIP Interface that is configured with this same port (in the SIP Interfaces table).

- ii. The device determines the SRD associated with the SIP Interface, and then classifies the SIP dialog to the first IP Group in the IP Groups table that is associated with this specific SRD. For example, if IP Groups #3 and #4 belong to the same SRD, the device classifies the call to IP Group #3.

Unclassified Calls

Reject

3. Click **Apply**.

## Configuring SBC IP-to-IP Routing Rules

The IP-to-IP Routing table lets you configure up to 615 SBC IP-to-IP routing rules.

Configuration of IP-to-IP routing rules includes two areas:

- **Match:** Defines the characteristics of the incoming SIP dialog message (e.g., IP Group from which the message is received).
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (i.e., routes the call to the specified destination).

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it sends the call to the destination configured for that rule. If it doesn't find a matching rule, it rejects the call.

Configure stricter rules higher up in the table than less strict rules to ensure the desired rule is used to route the call. *Strict* refers to the number of matching characteristics configured for the rule. For example, a rule configured with source host name and source IP Group as matching characteristics is stricter than a rule configured with only source host name. If the rule configured with only source host name appears higher up in the table, the device ("erroneously") uses the rule to route calls matching this source host name (even if they also match the rule appearing lower down in the table configured with the source IP Group as well).

The IP-to-IP Routing table lets you route incoming SIP dialog messages (e.g., INVITE) to any of the following IP destinations:

- According to registered user Contact listed in the device's registration database (only for User-type IP Groups).
- IP Group - the destination is the address configured for the Proxy Set associated with the IP Group.
- IP Group Set - the destination can be based on multiple IP Groups for load balancing, where each call may be sent to a different IP Group within the IP Group Set depending on the IP Group Set's definition.
- Routing tag - the device sends the call to an IP Group (or IP Group Set) based on a destination tag (determined by Dial Plans or Call Setup Rules).

- IP address in dotted-decimal notation or FQDN. Routing to a host name can be resolved using NAPTR/SRV/A-Record.
- Request-URI of incoming SIP dialog-initiating requests.
- Any registered user in the registration database. If the Request-URI of the incoming INVITE exists in the database, the call is sent to the corresponding contact address specified in the database.
- According to result of an ENUM query.
- Hunt Group - used for call survivability of call centers (see [Configuring Call Survivability for Call Centers](#) on page 1286).
- According to result of LDAP query (for more information on LDAP-based routing, see [LDAP-based Services](#) on page 378).
- ARM, which determines the destination (next hop) of the call (IP Group). The IP Group represents the next device in the routing path to the final destination. For more information on routing by ARM, see [Centralized Routing by ARM \(AudioCodes Routing Manager\)](#) on page 451.
- Tel destination (Gateway application). The rule redirects the call to the IP-to-Tel Routing table where the device searches for a matching IP-to-Tel routing rule. This feature can also be done for alternative routing. If an IP-to-IP routing rule fails and it is configured with a "Gateway" routing rule as an alternative route, the device uses the IP-to-Tel Routing table to send the call to the Tel. The device identifies (internally) calls re-directed for alternative Gateway routing, by appending a user-defined string to the prefix destination Request-URI user part (by default, "acgateway-<prefix destination>", for example, acgateway-200). The device removes this prefix before sending it to the Tel side. To configure this prefix string, use the [GWDirectRoutePrefix] parameter.
- Back to the sender of the incoming message, where the reply can be a SIP response code or a 3xx redirection response (with an optional Contact field to where the sender must re-send the message).

The following figure summarizes the destination types:

To configure and apply an IP-to-IP Routing rule, the rule must be associated with a Routing Policy. The Routing Policy associates the routing rule with an SRD(s). Therefore, the Routing Policy lets you configure routing rules for calls belonging to specific SRD(s). However, as multiple Routing Policies are relevant only for multi-tenant deployments (if needed), for most deployments, only a single Routing Policy is required. As the device provides a default Routing Policy ("Default\_SBCRoutingPolicy"), when only one Routing Policy is required, the device automatically assigns the default Routing Policy to the routing rule. If you are implementing LDAP-based routing (with or without Call Setup Rules) and/or Least Cost Routing (LCR), you need to configure these settings for the Routing Policy (regardless of the number of Routing Policies employed). For more information on Routing Policies, see [Configuring SBC Routing Policies](#) on page 1218.

The IP-to-IP Routing table also provides the following features:

■ **Alternative Routing:** In addition to the alternative routing/load balancing provided by the Proxy Set associated with the destination IP Group, the table allows the configuration of alternative routes where if a route fails, the next adjacent (below) rule in the table that is configured to **Alt Route Ignore/Consider Inputs** are used. The alternative routing rules can be set to enforce the input matching criteria or to ignore any matching criteria. Alternative routing occurs upon one of the following conditions:

- A request sent by the device is responded with one of the following:
  - ◆ SIP response code (e.g., 4xx, 5xx, and 6xx) that is also configured for an Alternative Reasons Set (see [Configuring SIP Response Codes for Alternative Routing Reasons](#))

on page 1214) assigned to the IP Group ('SBC Alternative Routing Reasons Set' parameter).

- ◆ SIP 408 Timeout or no response (after timeout).
- The DNS resolution includes IP addresses that the device has yet to try (for the current call).

Messages are re-routed with the same SIP Call-ID and CSeq header fields (increased by 1).

If the Proxy Set (see [Configuring Proxy Sets](#) on page 632) associated with the destination of the call is configured with multiple IP addresses, the device first attempts to route the call to one of these IP addresses, starting with the first listed address. Only when the call cannot be routed to any of the Proxy Set's IP addresses does the device search the IP-to-IP Routing table for an alternative routing rule for the call.

- **Load Balancing:** You can implement load balancing of calls, belonging to the same source, between a set of destination IP Groups known as an *IP Group Set*. The IP Group Set can include up to five IP Groups (Server-type and/or Gateway-type only) and the chosen IP Group depends on the configured load-balancing policy (e.g., Round Robin). To configure the feature, you need to first configure an IP Group Set (see [Configuring IP Group Sets](#) on page 1223), and then assign it to a routing rule with 'Destination Type' configured to **IP Group Set**.
- **Re-routing SIP Requests:** This table enables you to configure "re-routing" rules of requests (e.g., INVITEs) that the device sends upon receipt of SIP 3xx responses or REFER messages. These rules are configured for destinations that do not support receipt of 3xx or REFER and where the device handles the requests locally (instead of forwarding the 3xx or REFER to the destination).
- **Least Cost Routing (LCR):** If the LCR feature is enabled, the device searches the routing table for matching routing rules and then selects the one with the lowest call cost. The call cost of the routing rule is done by assigning it a Cost Group. To configure Cost Groups, see [Least Cost Routing](#) on page 461. If two routing rules have identical costs, then the rule appearing higher up in the table (i.e., first-matched rule) is used. If a selected route is unavailable, the device uses the next least-cost routing rule. However, even if a matched rule is not assigned a Cost Group, the device can select it as the preferred route over other matched routing rules that are assigned Cost Groups, according to the default LCR settings configured for the assigned Routing Policy (see [Configuring SBC Routing Policies](#) on page 1218).
- **Call Forking:** The IP-to-IP Routing table can be configured to route an incoming IP call to multiple destinations (call forking). The incoming call can be routed to multiple destinations of any type such as an IP Group or IP address. The device forks the call by sending simultaneous INVITE messages to all the specified destinations. It handles the multiple SIP dialogs until one of the calls is answered and then terminates the other SIP dialogs.

Call forking is configured by creating a Forking group. A Forking group consists of a main routing rule ('Alternative Route Options' set to **Route Row**) whose 'Group Policy' is set to

**Forking**, and one or more associated routing rules ('Alternative Route Options' set to **Group Member Ignore Inputs** or **Group Member Consider Inputs**). The group members must be configured in contiguous table rows to the main routing rule. If an incoming call matches the input characteristics of the main routing rule, the device routes the call to its destination and all those of the group members.

An alternative routing rule can also be configured for the Forking group. The alternative route is used if the call fails for the Forking group (i.e., main route and all its group members). The alternative routing rule must be configured in the table row immediately below the last member of the Forking group. The 'Alternative Route Options' of this alternative route must be set to **Alt Route Ignore Inputs** or **Alt Route Consider Inputs**. The alternative route can also be configured with its own forking group members, where if the device uses the alternative route, the call is also sent to its group members. In this case, instead of setting the alternative route's 'Group Policy' to **None**, you must set it to **Forking**. The group members of the alternative route must be configured in the rows immediately below it.

The LCR feature can also be employed with call forking. The device calculates a maximum call cost for each Forking group and routes the call to the Forking group with the lowest cost. Thus, even if the call can successfully be routed to the main routing rule, a different routing rule can be chosen (even an alternative route, if configured) based on LCR. If routing to one Forking group fails, the device tries to route the call to the Forking group with the next lowest cost (main or alternative route), and so on. The prerequisite for this functionality is that the incoming call must successfully match the input characteristics of the main routing rule.

- **Tags Representing Source / Destination Numbers:** If your deployment includes calls of many different called (source URI user part) and/or calling (destination URI user part) numbers that need to be routed to the same destination, you can employ user-defined tags to represent these numbers. Therefore, instead of configuring many routing rules, you can configure only one routing rule using the tag(s) as the source or destination number matching characteristics, and a destination for the calls. Tags can be obtained using Dial Plans (see [Using Dial Plan Tags for Matching Routing Rules](#) on page 841) or Call Setup Rules ([Configuring Call Setup Rules](#) on page 809).
- **Destination Tags for Determining Destination IP Group:** Instead of configuring multiple routing rules, you can configure a single routing rule with a destination tag. The tag can be determined using Dial Plans or Call Setup Rules. The device uses the tag to search the IP Groups table for a destination IP Group that matches the tag ('Tags' parameter). For more information on tag-based routing, see [Using Destination Tags for Choosing Routing Destinations](#) on page 842.
- **Fax Rerouting:** You can configure the device to reroute incoming calls that it identifies as fax calls to a new IP destination. For more information, see [Configuring Rerouting of Calls to Fax Destinations](#) on page 1206.

Call forking is not applicable to LDAP-based routing.

The following procedure describes how to configure IP-to-IP routing rules through the Web interface. You can also configure it through ini file [IP2IPRouting] or CLI (`configure voip > sbc routing ip2ip-routing`).

➤ **To configure an IP-to-IP routing rule:**

1. Open the IP-to-IP Routing table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Routing** > **IP-to-IP Routing**).
2. Click **New**; the following dialog box appears:

3. From the 'Routing Policy' drop-down list, select a Routing Policy (configured in [Configuring SBC Routing Policies](#) on page 1218).
4. Configure an IP-to-IP routing rule according to the parameters described in the table below.
5. Click **Apply**.

**Table 34-2: IP-to-IP Routing Table Parameter Descriptions**

Parameter	Description
'Routing Policy' sbc- routing- policy-name [RoutingPolicyName]	<p>Assigns a Routing Policy to the rule. The Routing Policy associates the rule with an SRD(s). The Routing Policy also defines default LCR settings as well as the LDAP servers used if the routing rule is based on LDAP routing (and Call Setup Rules).</p> <p>If only one Routing Policy is configured in the Routing Policies table, the Routing Policy is automatically assigned. If multiple Routing Policies are configured, no value is assigned.</p> <p>To configure Routing Policies, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p> <p><b>Note:</b> The parameter is mandatory.</p>
<b>General</b>	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Name'	Defines a descriptive name, which is used when associating the row in

Parameter	Description
route-name [RouteName]	<p>other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter value can't be configured with the character string "any" (upper or lower case).</p>
'Alternative Route Options' alt-route-options [AltRouteOptions]	<p>Determines whether this routing rule is the main routing rule or an alternative routing rule (to the rule defined directly above it in the table).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Route Row</b> = (Default) Main routing rule - the device first attempts to route the call to this route if the incoming SIP dialog's input characteristics matches this rule.</li> <li>■ [1] <b>Alternative Route Ignore Inputs</b> = If the call cannot be routed to the main route (Route Row), the call is routed to this alternative route regardless of the incoming SIP dialog's input characteristics.</li> <li>■ [2] <b>Alternative Route Consider Inputs</b> = If the call cannot be routed to the main route (Route Row), the call is routed to this alternative route only if the incoming SIP dialog matches this routing rule's input characteristics.</li> <li>■ [3] <b>Group Member Ignore Inputs</b> = This routing rule is a member of the Forking routing rule. The incoming call is also forked to the destination of this routing rule. The matching input characteristics of the routing rule are ignored.</li> <li>■ [4] <b>Group Member Consider Inputs</b> = This routing rule is a member of the Forking routing rule. The incoming call is also forked to the destination of this routing rule only if the incoming call matches this rule's input characteristics.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The alternative routing entry ([1] or [2]) must be defined in the next consecutive table entry index to the Route Row entry (i.e., directly below it). For example, if Index 4 is configured as a Route Row, Index 5 must be configured as the alternative route.</li> <li>■ The Forking Group members must be configured in a table row that is immediately below the main Forking routing rule, or below an alternative routing rule for the main rule, if configured.</li> <li>■ For IP-to-IP alternative routing, configure alternative routing based on the receipt of specific SIP responses (see <a href="#">Configuring SIP Response Codes for Alternative Routing Reasons</a> on page 1214). However, if no response, ICMP, or a SIP 408 response is received,</li> </ul>

Parameter	Description
	<p>the device attempts to use the alternative route even if you haven't configured any SIP responses for alternative routing.</p> <ul style="list-style-type: none"> <li>Multiple alternative route entries can be configured (e.g., Index 1 is the main route - Route Row - and indices 2 through 4 are configured as alternative routes).</li> </ul>
Match	
'Source IP Group' src-ip-group-name [SrcIPGroupName]	<p>Defines the IP Group from where the IP call is received (i.e., the IP Group that sent the SIP dialog). Typically, the IP Group of an incoming SIP dialog is determined (or classified) using the Classification table (see <a href="#">Configuring Classification Rules</a> on page 1171).</p> <p>The default is <b>Any</b> (i.e., any IP Group).</p> <p><b>Note:</b> The selectable IP Group for the parameter depends on the assigned Routing Policy (in the 'Routing Policy' parameter in this table). For more information, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p>
'Request Type' request-type [RequestType]	<p>Defines the SIP dialog request type (SIP Method) of the incoming SIP dialog.</p> <ul style="list-style-type: none"> <li>[0] <b>ALL</b> (default)</li> <li>[1] <b>INVITE</b></li> <li>[2] <b>REGISTER</b></li> <li>[3] <b>SUBSCRIBE</b></li> <li>[4] <b>INVITE and REGISTER</b></li> <li>[5] <b>INVITE and SUBSCRIBE</b></li> <li>[6] <b>OPTIONS</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>For User-type IP Groups, if you also need to send REGISTER messages received from this IP Group, then it's recommended that the configured destination of the routing rule is a Server-type IP Group and <b>not</b> an IP address (configured by the 'Destination Type' parameter). If you need to send non-REGISTER messages (e.g., INVITE) to a destination that is configured as an IP address, then you need to configure two IP-to-IP Routing rules for this User-type IP Group -- one for routing REGISTER messages and one for routing non-REGISTER messages.</li> <li>If the device receives a REFER message, it searches again for a</li> </ul>

Parameter	Description
	matching routing rule in the IP-to-IP Routing table and then forwards the message to the destination configured of the matched rule.
'Source Username Pattern' src-user-name-pattern [SrcUsernamePrefix]	<p>Defines the user part of the incoming SIP dialog's source URI (usually the From URI).</p> <p>You can use special patterns (notations) to denote the user part. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". To denote calls without a user part in the URI, use the dollar (\$) sign. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The valid value is a string of up to 60 characters. The default is the asterisk (*) symbol (i.e., any user part).</p> <p>If this rule is not required, leave this field empty.</p> <p><b>Note:</b> If you need to route calls of many different source URI user names to the same destination, you can use tags (see 'Source Tags' parameter below) instead of this parameter.</p>
'Source Host' src-host [SrcHost]	<p>Defines the host part of the incoming SIP dialog's source URI (usually the From URI).</p> <p>The default is the asterisk (*) symbol (i.e., any host name). If this rule is not required, leave this field empty.</p>
'Source Tags' src-tags [SrcTags]	<p>Defines a source tag(s) for matching this routing rule.</p> <p>The source tag can be obtained using a Dial Plan (assigned to the source IP Group or SRD) or Call Setup Rules (assigned to the source IP Group or SIP Interface).</p> <p>The valid value is:</p> <ul style="list-style-type: none"> <li>■ A string of up to 70 characters.</li> <li>■ Up to eight tags, where each tag is separated by a semicolon (;).</li> <li>■ Up to seven tags containing a name with a value (e.g., Country=Ireland). If you are configuring multiple tags in the name=value format, the names of each tag must be unique (e.g., <b>Country</b>=Ireland;<b>Land</b>=Scotland).</li> <li>■ Only <b>one</b> tag containing a value only (e.g., USA).</li> </ul> <p>By default, no value is defined.</p> <p>The following example configures the maximum number of tags (i.e., seven name=value tags and one value-only tag):</p> <p>Country=Ireland;Country2=Scotland;Country3=RSA;Country4=Canada;</p>

Parameter	Description
	<p>Country5=UK;Country6=France;Country7=Germany;USA.</p> <p>To configure Dial Plans, see <a href="#">Configuring Dial Plans</a> on page 825. To configure tags using Call Setup Rules (i.e., using the SrcTags attribute), see <a href="#">Configuring Call Setup Rules</a> on page 809.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The tag is case insensitive.</li> <li>■ Instead of using tags and configuring the parameter, you can use the 'Source Username Pattern' parameter to configure a specific URI source user part (or all source users).</li> </ul>
'Destination Username Pattern' dst-user-name-pattern [DestUsernamePrefix]	<p>Defines the incoming SIP dialog's destination URI (usually the Request URI) user part.</p> <p>You can use special patterns (notations) to denote the user part. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". To denote calls without a user part in the URI, use the dollar (\$) sign. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The valid value is a string of up to 60 characters. The default is the asterisk (*) symbol (i.e., any user part). If this rule is not required, leave this field empty.</p> <p><b>Note:</b> If you need to route calls of many different destination URI user names to the same destination, you can use tags (see 'Source Tags' parameter below) instead of this parameter.</p>
'Destination Host' dst-host [DestHost]	<p>Defines the host part of the incoming SIP dialog's destination URI (usually the Request-URI).</p> <p>The default is the asterisk (*) symbol (i.e., any destination host). If this rule is not required, leave this field empty.</p>
'Destination Tags' dest-tags [DestTags]	<p>Defines a destination tag(s) for matching this routing rule.</p> <p>The destination tag can be obtained using a Dial Plan (assigned to the source IP Group or SRD) or Call Setup Rules (assigned to the source IP Group or SIP Interface).</p> <p>The valid value is:</p> <ul style="list-style-type: none"> <li>■ A string of up to 70 characters.</li> <li>■ Up to eight tags, where each tag is separated by a semicolon (;).</li> <li>■ Up to seven tags containing a name with a value (e.g., Country=Ireland). If you are configuring multiple tags in the name=value format, the names of each tag must be unique (e.g.,</li> </ul>

Parameter	Description
	<p><b>Country=Ireland;Land=Scotland).</b></p> <ul style="list-style-type: none"> <li>Only <b>one</b> tag containing a value only (e.g., USA).</li> </ul> <p>By default, no value is defined.</p> <p>The following example configures the maximum number of tags (i.e., seven name=value tags and one value-only tag):</p> <p>Country=Ireland;Country2=Scotland;Country3=RSA;Country4=Canada;Country5=UK;Country6=France;Country7=Germany;USA.</p> <p>To configure Dial Plans, see <a href="#">Configuring Dial Plans</a> on page 825. To configure tags using Call Setup Rules (i.e., using the DstTags attribute), see <a href="#">Configuring Call Setup Rules</a> on page 809.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The tag is case insensitive.</li> <li>Instead of using tags and configuring the parameter, you can use the 'Destination Username Pattern' parameter to configure a specific URI destination user (or all destinations users).</li> </ul>
'Message Condition' message-condition-name [MessageConditionName]	<p>Assigns a SIP Message Condition rule to the IP-to-IP Routing rule.</p> <p>To configure Message Condition rules, see <a href="#">Configuring Message Condition Rules</a> on page 865.</p>
'Call Trigger' trigger [Trigger]	<p>Defines the reason (i.e., trigger) for re-routing (i.e., alternative routing) the SIP request.</p> <ul style="list-style-type: none"> <li>[0] <b>Any</b> = (Default) This routing rule is used for all scenarios (re-routes and non-re-routes).</li> <li>[1] <b>3xx</b> = Re-routes the request if it was triggered as a result of a SIP 3xx response.</li> <li>[2] <b>REFER</b> = Re-routes the INVITE if it was triggered as a result of a REFER request.</li> <li>[3] <b>3xx or REFER</b> = Applies to optional values <b>3xx</b> and <b>REFER</b>.</li> <li>[4] <b>Initial only</b> = This routing rule is used for regular requests that the device forwards to the destination. This rule is not used for re-routing of requests triggered by the receipt of REFER or 3xx.</li> <li>[5] <b>Broken Connection</b> = If the device detects a broken RTP or</li> </ul>

Parameter	Description
	<p>MSRP connection (no packets received for a user-defined timeout) during the call and the Broken RTP/MSRP Connection feature is enabled (IP Profile parameter 'Broken Connection Mode' configured to <b>Reroute</b> or <b>Reroute with Original SIP Headers</b>), you can use this option as an explicit matching characteristics to route the call to an alternative destination. Therefore, for alternative routing upon broken RTP or MSRP detection, position the routing rule configured with this option above the regular routing rule associated with the call. Such configuration ensures that the device uses this alternative routing rule only when RTP or MSRP broken connection is detected.</p> <ul style="list-style-type: none"> <li>■ <b>[6] Fax Rerouting</b> = Reroutes the INVITE to a fax destination (different IP Group) if it is identified as a fax call. For more information, see <a href="#">Configuring Rerouting of Calls to Fax Destinations</a> on page 1206.</li> </ul>
'ReRoute IP Group' re-route-ip-group-id  [ReRouteIPGroup Name]	<p>Defines the IP Group that initiated (sent) the SIP redirect response (e.g., 3xx) or REFER message. This parameter is typically used for rerouting requests (e.g., INVITEs) when interworking is required for SIP 3xx redirect responses or REFER messages. For more information, see <a href="#">Interworking SIP 3xx Redirect Responses</a> on page 1150 and <a href="#">Interworking SIP REFER Messages</a> on page 1154, respectively. The parameter functions together with the 'Call Trigger' parameter (in the table).</p> <p>The default is <b>Any</b> (i.e., any IP Group).</p> <p><b>Note:</b> The selectable IP Group for the parameter depends on the assigned Routing Policy (in the 'Routing Policy' parameter in this table). For more information, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p>
Action	
'Destination Type' dst-type [DestType]	<p>Defines the type of destination to where the device sends the outgoing SIP dialog.</p> <ul style="list-style-type: none"> <li>■ <b>[0] IP Group</b> = (Default) The device sends the SIP dialog to the IP Group as configured in the 'Destination IP Group' parameter. For more information on the actual address, see the 'Destination IP Group' parameter.</li> <li>■ <b>[1] Dest Address</b> = The device sends the SIP dialog to the address that is configured by the following parameters: 'Destination Address', 'Destination Port', and 'Destination Transport Type'.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>Request URI</b> = The device sends the SIP dialog to the address indicated in the incoming SIP Request-URI. If you have configured the 'Destination Port' and 'Destination Transport Type' parameters, the device overrides the parameters of the incoming Request-URI and these parameters take precedence.</li> <li>■ [3] <b>ENUM</b> = The device sends an ENUM query to include the destination address. If you have configured the 'Destination Port' and 'Destination Transport Type' parameters, the device overrides the parameters of the incoming Request-URI and these parameters take precedence.</li> <li>■ [4] <b>Hunt Group</b> = This option is used for call center survivability (see <a href="#">Configuring Call Survivability for Call Centers</a> on page 1286).</li> <li>■ [5] <b>Dial Plan</b> = (<b>For Backward Compatibility Only - see Note below</b>) The IP destination is determined by a Dial Plan index of the loaded Dial Plan file. The syntax of the Dial Plan index in the Dial Plan file is as follows: &lt;destination / called prefix number&gt;,0,&lt;IP destination&gt;  Note that the second parameter "0" is ignored. An example of a configured Dial Plan (# 6) in the Dial Plan file is shown below:   <pre>[ PLAN6 ] 200,0,10.33.8.52    ; called prefix 200 is routed to destination 10.33.8.52 201,0,10.33.8.52 300,0,itsp.com     ; called prefix 300 is routed to destination itsp.com</pre> <p>Once the Dial Plan is defined, you need to assign it (0 to 7) to the routing rule as the destination in the 'Destination Address' parameter, where "0" denotes [PLAN1], "1" denotes [PLAN2], and so on.</p> </li> <li>■ [7] <b>LDAP</b> = This option does LDAP-based routing. Make sure that the Routing Policy assigned to the routing rule is configured with the LDAP Server Group for defining the LDAP server(s) to query.</li> <li>■ [8] <b>Gateway</b> = The device sends the SBC call to the Tel side (Gateway call) using an IP-to-Tel routing rule in the IP-to-Tel Routing table (see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960). The IP-to-Tel routing rule must be configured with the same call matching characteristics as this SBC IP-to-IP routing rule. This option is also used for alternative routing of an IP-to-IP route</li> </ul>

Parameter	Description
	<p>to the PSTN. In such a case, the IP-to-Tel routing rule must also be configured with the same call matching characteristics as this SBC IP-to-IP routing rule.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>✓ If you configure the parameter to <b>Gateway</b> for a rule that is used for alternative routing (i.e., 'Alternative Route Options' parameter is configured to any value other than <b>Route Row</b>), the device uses two DSP session resources. One session resource is for the new Gateway route and one for the initial SBC session used for the incoming leg.</li> <li>✓ When the device uses this rule that is configured to <b>Gateway</b> and the 'Alternative Route Options' parameter is configured to <b>Route Row</b>, it ignores all other matching rules listed below this rule in the IP-to-IP Routing table.</li> </ul> <ul style="list-style-type: none"> <li>■ [9] <b>Routing Server</b> = The device sends a request to ARM for an appropriate destination (next hop) for the matching call. For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</li> <li>■ [10] <b>All Users</b> = The device checks if the SIP Request-URI (i.e., destination user) in the incoming INVITE is registered in its' users database. If registered, the device sends the INVITE to the address of the corresponding contact that is specified in the database. If the Request-URI is not registered, the call is rejected.</li> </ul> <p>If the incoming SIP dialog is a REGISTER message, the device acts as a registrar and only responds to the sender of the request (200 OK) without sending the REGISTER message to a destination (i.e., termination of REGISTER messages).</p> <ul style="list-style-type: none"> <li>■ [11] <b>IP Group Set</b> = The device employs load balancing and sends the call to an IP Group in the IP Group Set that you assigned using the 'IP Group Set' parameter (below).</li> <li>■ [12] <b>Destination Tag</b> = The device sends the call to an IP Group that is matched by destination tag. For more information on tag-based routing, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</li> </ul> <p><b>Note:</b> For tag-based routing, you also need to configure the 'Routing Tag Name' parameter (below).</p> <ul style="list-style-type: none"> <li>■ [13] <b>Internal</b> = Instead of sending the incoming SIP dialog to another destination, the device replies to the sender of the dialog</li> </ul>

Parameter	Description
	<p>with a SIP response code or a redirection response, configured by the 'Internal Action' parameter below.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Use the <b>Dial Plan</b> option only for backward compatibility purposes; otherwise, use prefix tags as described in <a href="#">Configuring Dial Plans</a> on page 825.</li> <li>■ If you configure the parameter to <b>Dest Address, Request URI, ENUM, Dial Plan</b> or <b>LDAP</b>, you must specify a destination IP Group using the 'Destination IP Group' parameter, even though these calls are <b>not</b> sent to the specified IP Group (i.e., its associated Proxy Set). This allows you to associate other configuration entities (such as an IP Profile) that are assigned to the IP Group, with the destination of these calls. If you do not specify a destination IP Group, the device uses its own logic in choosing a destination IP Group (and thus its associated configuration entities) for the routing rule.</li> <li>■ You can configure up to 20 IP-to-IP Routing rules whose 'Destination Type' is <b>Internal</b>.</li> </ul>
'Destination IP Group' dst-ip-group-name [DestIPGroupName]	<p>Defines the IP Group to where you want to route the call. The actual destination of the SIP dialog message depends on the IP Group type (as defined in the 'Type' parameter):</p> <ul style="list-style-type: none"> <li>■ Server-type IP Group: The SIP dialog is sent to the IP address configured for the Proxy Set that is associated with the IP Group.</li> <li>■ User-type IP Group: The device checks if the SIP dialog is from a registered user, by searching for a match between the Request-URI of the received SIP dialog and an AOR registration record in the device's database. If found, the device sends the SIP dialog to the IP address specified in the database for the registered contact.</li> </ul> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the 'Destination Type' parameter is configured to <b>IP Group</b>. However, you also need to specify this parameter if the 'Destination Type' parameter is configured to <b>Dest Address, Request URI, ENUM, Dial Plan</b> or <b>LDAP</b> (even though these calls are <b>not</b> sent to the specified IP Group). For these cases, it allows you to associate other configuration entities (such as an IP Profile) that are assigned to the IP Group, with the destination of these calls.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>The selectable IP Group for the parameter depends on the assigned Routing Policy (in the 'Routing Policy' parameter in this table). For more information, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</li> </ul>
'Destination SIP Interface' <code>dest-sip-interface-name</code> [DestSIPInterfaceName]	<p>Defines the destination SIP Interface to where the call is sent. By default, no value is defined.</p> <p>To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable <b>only</b> if the 'Destination Type' parameter is configured to any value other than <b>IP Group</b>. If the 'Destination Type' parameter is configured to <b>IP Group</b>, the following SIP Interface is used:               <ul style="list-style-type: none"> <li>✓ Server-type IP Groups: SIP Interface that is assigned to the Proxy Set associated with the IP Group.</li> <li>✓ User-type IP Groups: SIP Interface is determined during user registration with the device.</li> </ul> </li> <li>For multi-tenancy, if the assigned Routing Policy is not shared (i.e., the Routing Policy is associated with an Isolated SRD), the SIP Interface must be one that is associated with the Routing Policy or with a shared Routing Policy (i.e., the Routing Policy is associated with one or more Shared SRDs). If the Routing Policy is shared, the SIP Interface can be one that is associated with any SRD or Routing Policy (but it's recommended that it belong to the same SRD/Routing Policy or to shared SRD/Routing Policy to avoid "bleeding").</li> </ul>
'Destination Address' <code>dst-address</code> [DestAddress]	<p>Defines the destination address to where the call is sent.</p> <p>The valid value is an IP address in dotted-decimal notation or an FQDN (domain name, e.g., domain.com).</p> <p>If ENUM-based routing is used (i.e., the 'Destination Type' parameter is set to <b>ENUM</b>) the parameter configures the address of the ENUM service, for example, e164.arpa, e164.customer.net or NRENum.net. The device sends the ENUM query containing the destination phone number to an external DNS server, configured in the IP Interfaces table. The ENUM reply includes a SIP URI (user@host) which is used as the destination Request-URI in this routing table.</p> <p>The valid value is a string of up to 50 characters (IP address or FQDN). By default, no value is defined.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only if the 'Destination Type' parameter is configured to <b>Dest Address</b> [1] or <b>ENUM</b> [3]; otherwise, the parameter is ignored.</li> <li>■ When using domain names, enter the DNS server's IP address or alternatively, define these names in the Internal DNS table (see <a href="#">Configuring the Internal SRV Table</a> on page 201).</li> <li>■ To terminate SIP OPTIONS messages at the device (i.e., to handle them locally), set the parameter to "internal".</li> </ul>
'Destination Port' dst-port [DestPort]	Defines the destination port to where the call is sent.
'Destination Transport Type' dst-transport-type [DestTransportType]	<p>Defines the transport layer type for sending the call.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured. The transport type is determined by the [SIPTransportType] global parameter.</li> <li>■ [0] <b>UDP</b></li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS</b></li> <li>■ [3] <b>SCTP</b></li> </ul>
'IP Group Set' ipgroupset-name [IPGroupSetName]	<p>Assigns an IP Group Set to the routing rule. The device routes the call to one of the IP Groups in the IP Group Set according to the load-balancing policy configured for the IP Group Set. For more information, see <a href="#">Configuring IP Group Sets</a> on page 1223.</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'Destination Type' parameter to <b>IP Group Set</b> (above).</p>
'Pre Route Call Setup Rules Set ID' pre-route-call-setup-rules-set-id [PreRouteCallSetupRulesSetId]	<p>Assigns a Call Setup Rule Set ID to the routing rule. The device runs this Call Setup Rules Set if the incoming call matches the characteristics of this routing rule. The device routes the call to the destination according to the routing rule's configured action, only after it has run the Call Setup rules.</p> <p>To configure Call Setup rules, see <a href="#">Configuring Call Setup Rules</a> on page 809.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you have assigned a Call Setup Rules Set using both the 'Pre Route Call Setup Rules Set ID' and 'Call Setup Rules Set ID'</li> </ul>

Parameter	Description
	<p>parameters, the device first runs the Call Setup Rules Set of the 'Pre Route Call Setup Rules Set ID' parameter.</p> <ul style="list-style-type: none"> <li>■ For tag-based routing during the routing stage (IP-to-IP Routing table): <ul style="list-style-type: none"> <li>✓ Assign the Call Setup Rules Set that determines the tag name, using the 'Pre Route Call Setup Rules Set ID' parameter (not 'Call Setup Rules Set ID' parameter). This tag <b>overrides</b> tags of any previously run Call Setup Rules Sets (of SIP Interfaces, source IP Groups, or Dial Plans).</li> <li>✓ Configure the 'Destination Type' parameter to <b>Destination Tag</b> (see above).</li> <li>✓ Configure the tag name in the 'Routing Tag Name' parameter (see below).</li> <li>✓ The device uses the resultant tag name to find a matching destination IP Group (i.e., in 'Tags' parameter) in the IP Groups table.</li> <li>✓ For alternative routing, you can assign a different Call Setup Rules Set to each alternative routing rule so that they each use a different destination tag and therefore, a different destination IP Group.</li> <li>✓ For more information on tag-based routing, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</li> </ul> </li> </ul>
'Call Setup Rules Set ID' call-setup-rules-set-id [CallSetupRulesSetId]	<p>Assigns a Call Setup Rule Set ID to the routing rule. The device runs the Call Setup rules of this Set ID if the incoming call matches the characteristics of this routing rule. The device routes the call to the destination according to the routing rule's configured action, only after it has run the Call Setup rules.</p> <p>To configure Call Setup rules, see <a href="#">Configuring Call Setup Rules</a> on page 809.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you have assigned a Call Setup Rules Set using both the 'Pre Route Call Setup Rules Set ID' and 'Call Setup Rules Set ID' parameters, the device first runs the Call Setup Rules Set of the 'Pre Route Call Setup Rules Set ID' parameter.</li> <li>■ If you want to use Call Setup Rules to determine the destination tag, assign the Call Setup Rule Set using the 'Pre Route Call Setup Rules Set ID' parameter (instead of 'Call Setup Rules Set ID').</li> </ul>

Parameter	Description
'Group Policy' group-policy [GroupPolicy]	<p>Defines if the routing rule includes call forking.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) Call uses only this route (even if Forking Group members are configured in the rows below it).</li> <li>■ [1] <b>Forking</b> = Call uses this route and the routes of Forking Group members, if configured (in the rows below it).</li> </ul> <p><b>Note:</b> Each Forking Group can contain up to 20 members. In other words, up to 20 routing rules can be configured for the same Forking Group.</p>
'Cost Group' cost-group [CostGroup]	<p>Assigns a Cost Group to the routing rule for determining the cost of the call.</p> <p>By default, no value is defined.</p> <p>To configure Cost Groups, see <a href="#">Configuring Cost Groups</a> on page 464.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To implement LCR and its Cost Groups, you must enable LCR for the Routing Policy assigned to the routing rule (see <a href="#">Configuring SBC Routing Policies</a> on page 1218). If LCR is disabled, the device ignores the parameter.</li> <li>■ The Routing Policy also determines whether matched routing rules that are <b>not</b> assigned Cost Groups are considered as a higher or lower cost route compared to matching routing rules that are assigned Cost Groups. For example, if the 'Default Call Cost' parameter in the Routing Policy is configured to <b>Lowest Cost</b>, even if the device locates matching routing rules that are assigned Cost Groups, the first-matched routing rule without an assigned Cost Group is considered as the lowest cost route and thus, chosen as the preferred route.</li> </ul>
'Routing Tag Name' routing-tag-name [RoutingTagName]	<p>Defines the destination tag name, which is used to determine the destination IP Group. The device searches the IP Groups table for an IP Group whose 'Tags' parameter value matches this tag name (and value).</p> <p>The valid value:</p> <ul style="list-style-type: none"> <li>■ A string of up to 70 characters.</li> <li>■ Only <b>one</b> tag can be configured.</li> <li>■ Only the tag <b>name</b> (not value, if exists) can be configured. For example, if the tag in the Dial Plan rule is "Country=England", configure the parameter to "Country".</li> <li>■ The tag is case insensitive.</li> </ul>

Parameter	Description
	<p>The default value is "default", meaning that the device uses the first tag name that is configured without a value. For example, if the Dial Plan rule is configured with tags "Country=England;City=London;Essex", the default tag is "Essex".</p> <p>An example of configuring this parameter when Call Setup Rules (assigned to the 'Pre Route Call Setup Rules Set ID' parameter above) are used to obtain the tag name: If you configure the parameter to "IPGroupName" (i.e., tag name) and the Call Setup Rule's 'Action Subject' parameter is "DstTags.IPGroupName" which results in the value "Teams" (i.e., tag value), the device searches the IP Groups table for a destination IP Group whose 'Tags' parameter is configured to "ipGroupName=Teams".</p> <p>For more information on tag-based routing, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the 'Destination Type' parameter is configured to <b>Destination Tag</b> (see above).</li> <li>■ If you're using a Call Setup Rule to determine the tag during the device's routing stage, assign the Call Setup Rules Set to the 'Pre Route Call Setup Rules Set ID' parameter (see above).</li> </ul>
'Internal Action' internal-action [InternalAction]	<p>Defines a SIP response code (e.g., 200 OK) or a redirection response (with an optional Contact field indicating to where the sender must re-send the message) that the device sends to the sender of the incoming SIP dialog (instead of sending the call to another destination). The parameter is applicable only when the 'Destination Type' parameter in this table is configured to <b>Internal</b> (see above).</p> <p>The valid value syntax (case-insensitive) is:</p> <ul style="list-style-type: none"> <li>■ For SIP response codes: <pre>reply(response='&lt;code&gt;')</pre> <p>The following example sends a SIP 200:</p> <pre>reply(response='200')</pre> </li> <li>■ For redirection responses: <pre>redirect(response='&lt;code&gt;',contact='sip:'+....)</pre> </li> </ul>

Parameter	Description
	<div>redirect(contact='...',response='&lt;code&gt;')</div> <div>redirect(contact='sip:user@host')</div> <p>Examples:</p> <ul style="list-style-type: none"> <li>✓ The device responds to the dialog with a SIP 300 redirect response that includes a contact value:</li> </ul> <div>redirect(response='300',contact='sip:102@host')</div> <ul style="list-style-type: none"> <li>✓ The device redirects the call from the sender to a SIP Recording Server (SRS):</li> </ul> <div>           redirect            (response='302',contact='sip:'+header.to.url.user+'@siprecording.com')         </div> <p>You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter can be used for normal and alternative routing.</li> <li>■ The response code for redirect messages can only be 3xx.</li> </ul>
'Modified Destination User Name' modified-dest-user-name [ModifiedDestUserName]	<p>Defines the user part of the Request-URI in the outgoing SIP dialog message.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter is currently used only when the device communicates with VoiceAI Connect.</p>

## Configuring Rerouting of Calls to Fax Destinations

You can configure the device to reroute incoming SBC calls identified as fax calls to a new IP destination. The device identifies a fax call if it detects, within a user-defined interval, a calling (CNG) tone on the originator side (incoming IP leg). If the device detects a fax call, it terminates the call and reroutes it using a new INVITE to the new fax destination (new IP Group). If the

initial INVITE that was used to establish the voice call was already sent, the device sends a CANCEL (if not connected yet) or a BYE (if already connected) to release the call (with the internal disconnect reason RELEASE\_BECAUSE\_FAX\_REROUTING, translated to Q.850 reason GWAPP\_NORMAL\_UNSPECIFIED 31).

- You must configure the originating fax to use the G.711 coder.
- If the remote side replies with T.38 or G.711 VBD, fax rerouting is not done.
- If both fax rerouting and fax re-INVITE are configured, only fax rerouting is done.

The following provides a basic example on how to configure fax rerouting.

➤ **To configure fax rerouting:**

1. Open the Fax/Modem/CID Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Fax/Modem/CID Settings**).
  - a. In the 'Fax Detection Timeout' field [SBCFaxDetectionTimeout], enter the duration (in seconds) for which the device attempts to detect fax (CNG tone):

Fax Detection Timeout [sec]

10

- b. From the 'CNG Detector Mode' drop-down list [CNGDetectorMode], select **Event Only**.
2. Upload an ini file to the device through the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348) with the following parameter setting, which enables in-band network detection related to fax:

EnableFaxModemInbandNetworkDetection = 1

3. In the IP Groups table (see [Configuring IP Groups](#) on page 591), configure the following IP Groups:
  - IP Group #0 "HQ": This is the source IP Group, sending voice calls and fax calls.
  - IP Group #1 "Voice": This is the destination for voice calls sent from IP Group #0.
  - IP Group #2 "Fax": This is the destination for fax calls sent from IP Group #0.
4. For the fax destination (IP Group #2), do the following:
  - a. In the Coders Groups table (see [Configuring Coders Groups](#) on page 661), configure a Coder Group with T.38 to enable fax transmission over IP.
  - b. In the IP Profiles table (see [Configuring IP Profiles](#) on page 674), configure an IP Profile:
    - i. From the 'Fax Coders Group' drop-down list, select the Coder Group that you configured above.
    - ii. From the 'Fax Mode' drop-down list, select **Handle always**.

- c. In the IP Groups table, edit IP Group #2, and then from the 'IP Profile' drop-down list, select the IP Profile that you configured above.
5. For the voice destination (IP Group #1), do the following:
- a. In the IP Profiles table, configure an IP Profile - from the 'Fax Rerouting Mode' drop-down list, select **Rerouting without delay**:

Fax Rerouting Mode      • Rerouting without delay ▼

- b. In the IP Groups table, edit IP Group #1, and then from the 'IP Profile' drop-down list, select the IP Profile that you configured above.
6. In the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), configure the following adjacent rows of IP-to-IP Routing rules:
- IP-to-IP Routing Rule #0 to route voice calls from IP Group #0 to IP Group #1:

Match	
Source IP Group	HQ (IP Group #0)
Call Trigger	Initial Only
ReRoute IP Group	Voice (IP Group #1)
Action	
Destination Type	IP Group
Destination IP Group	Voice (IP Group #1)

- IP-to-IP Routing Rule #1 to route fax calls from IP Group #0 to IP Group #2:

Match	
Source IP Group	HQ (IP Group #0)
Call Trigger	Fax Rerouting
Action	
Destination Type	IP Group
Destination IP Group	Fax (IP Group #2)

## Configuring Specific UDP Ports using Tag-based Routing

You can configure the device to use a specific local UDP port for each SIP entity (e.g., PBX) communicating with a common proxy server (e.g., ITSP). The figure below illustrates an

example scenario of such an implementation, whereby the device uses a specific local UDP port (e.g., 6001, 6002, and 6003) for each IP PBX, on the leg interfacing with the proxy server:

For each IP PBX, the device sends SIP messages to the proxy server using the specific local, UDP port on the leg interfacing with the proxy server. For SIP messages received from the proxy server, the device routes the messages to the appropriate IP PBX according to the local UDP port on which the message was received. On the leg interfacing with the IP PBXs, the device uses the same local UDP port (e.g., 5060) for all IP PBXs (send and receive).

To configure this feature, you need to configure the SIP Interface of the proxy server with a special UDP port range, and use tag-based routing with Call Setup Rules to specify the exact UDP port you want assigned to each SIP entity (IP PBX), from the SIP Interface port range. The following procedure describes how to configure the device to use a specific local UDP port per SIP entity on the leg interfacing with a proxy server that is common to all the SIP entities. To facilitate understanding, the procedure is based on the previous example.

➤ **To configure specific UDP ports for SIP entities communicating with common proxy server:**

1. Open the SIP Interfaces table (see [Configuring SIP Interfaces](#) on page 570), and then configure the following SIP Interfaces:
  - SIP Interface for leg interfacing with IP PBXs (local UDP port 5060 is used):

General	
Index	<b>1</b>
Name	<b>PBX</b>
Network Interface	<b>WAN</b>
UDP Port	<b>5060</b>

- SIP Interface for leg interfacing with proxy server (specific local UDP ports are later taken from this port range):

General	
Index	<b>2</b>
Name	<b>ITSP</b>
Network Interface	<b>LAN</b>
UDP Port	<b>5060</b>
Additional UDP Ports	<b>6000-7000</b>

For guidelines on configuring the 'Additional UDP Ports' parameter, see [Configuring SIP Interfaces](#) on page 570.

- Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then configure the following IP Groups:
  - IP Group for the first IP PBX ("Type" and "Port" tags are later used to identify the IP PBX and assign it a local UDP port 6001 on the leg interfacing with the proxy server):

General	
Index	<b>1</b>
Name	<b>PBX-1</b>
Type	<b>Server</b>
SBC Advanced	
Call Setup Rules Set ID	<b>1</b>
Tags	<b>Type=PBX;Port=6001</b>

- IP Group for the second IP PBX ("Type" and "Port" tags are later used to identify the IP PBX and assign it a local UDP port 6002 on the leg interfacing with the proxy server):

General	
Index	<b>2</b>
Name	<b>PBX-2</b>
Type	<b>Server</b>
SBC Advanced	

General	
Call Setup Rules Set ID	<b>1</b>
Tags	<b>Type=PBX;Port=6002</b>

- IP Group for the third IP PBX ("Type" and "Port" tags are later used to identify the IP PBX and assign it a local UDP port 6003 on the leg interfacing with the proxy server):

General	
Index	<b>3</b>
Name	<b>PBX-3</b>
Type	<b>Server</b>
SBC Advanced	
Call Setup Rules Set ID	<b>1</b>
Tags	<b>Type=PBX;Port=6003</b>

- IP Group for the proxy server ("Type" tag is later used to identify proxy server):

General	
Index	<b>4</b>
Name	<b>ITSP</b>
Type	<b>Server</b>
SBC Advanced	
Call Setup Rules Set ID	<b>1</b>
Tags	<b>Type=ITSP</b>

3. Open the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809), and then configure the following Call Setup rules:
  - Uses the value of the "Type" tag name, configured in the IP Group's 'Tags' parameter, as the source tag:

General	
Index	<b>1</b>

General	
Rule Set ID	<b>1</b>
<b>Action</b>	
Action Subject	<b>srctags.Type</b>
Action Type	<b>Modify</b>
Action Value	<b>param.ipg.src.tags.Type</b>

- If the source tag name "Type" equals "PBX" (i.e., SIP message from an IP Group belonging to one of the IP PBXs), then use the value of the "Port" tag name, configured in the 'Tags' parameter of the classified IP Group, as the local UDP port on the leg interfacing with the proxy server for messages sent to the proxy server:

General	
Index	<b>2</b>
Rule Set ID	<b>1</b>
Condition	<b>srctags.Type=='PBX'</b>
<b>Action</b>	
Action Subject	<b>message.outgoing.local-port</b>
Action Type	<b>Modify</b>
Action Value	<b>param.ipg.src.tags.Port</b>

- If the source tag name "Type" equals "ITSP" (i.e., SIP message from the ITSP), then use the value (port number) of the local port on which the incoming message from the proxy server is received by the device, as the value of the destination tag name "Port". In other words, the value could either be "6001", "6002", or "6003". This value is then used by the IP-to-IP Routing table to determine to which IP PBX to send the message. For example, if the destination tag value is "6001", the device identifies the destination as "PBX-1":

General	
Index	<b>3</b>
Rule Set ID	<b>1</b>

General	
Condition	<b>srctags.Type=='ITSP'</b>
<b>Action</b>	
Action Subject	<b>dsttags.Port</b>
Action Type	<b>Modify</b>
Action Value	<b>message.incoming.local-port</b>

4. Open the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), and then configure the following IP-to-IP Routing rules:
- Routes calls from the IP PBXs (identified by the source tag name-value "Type=PBX") to the ITSP (identified as an IP Group):

General	
Index	<b>1</b>
Name	<b>PBX-to-ITSP</b>
<b>Match</b>	
Source Tag	<b>Type=PBX</b>
<b>Action</b>	
Destination Type	<b>IP Group</b>
Destination IP Group	<b>ITSP</b>

- Routes calls from the ITSP (identified by the source tag name-value "Type=ITSP") to the IP PBXs (identified by the specific port assigned to the IP PBX by the value of the destination tag name "Port"):

General	
Index	<b>2</b>
Name	<b>ITSP-to-PBX</b>
<b>Match</b>	
Source Tag	<b>Type=ITSP</b>
<b>Action</b>	

General	
Destination Type	Destination Tag
Routing Tag Name	Port

## Configuring a Routing Response Timeout

If you have routing rules in the IP-to-IP Routing table that need to query external servers (e.g., LDAP server, ENUM server, or HTTP GET method requests) on whose responses the device uses to determine where to route the SBC calls, you can configure a timeout for the responses. If the timeout expires before the device receives a response, the device sends a routing failure message (SIP 500) to the caller or uses an alternative routing rule (if configured).

### ➤ To configure a timeout for routing query responses:

1. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
2. In the 'Routing Timeout' [SbcRoutingTimeout] field, enter the maximum duration (in seconds) that the device is prepared to wait for a response from external servers.

Routing Timeout [sec]

10

3. Click **Apply**.

## Configuring SIP Response Codes for Alternative Routing Reasons

The Alternative Reasons Set table lets you configure groups of SIP response codes for SBC call release (termination) reasons that trigger alternative routing. This feature works together with the Proxy Hot Swap feature, which is configured in the Proxy Sets table.

Alternative routing based on SIP responses is configured using two tables with "parent-child" relationship:

- **Alternative Reasons Set table ("parent"):** Defines the name of the Alternative Reasons Set. You can configure up to 10 Alternative Reasons Sets.
- **Alternative Reasons Rules table ("child"):** Defines SIP response codes per Alternative Reasons Set. You can configure up to 200 Alternative Reasons Rules in total, where each Alternative Reasons Set can include up to 20 Alternative Reasons Rules.

To apply your configured alternative routing reason rules, you need to assign the Alternative Reasons Set for which you configured the rules, to the relevant IP Group in the IP Groups table, using the 'SBC Alternative Routing Reasons Set' parameter.

In addition to configuring the response codes described in this section, you need to configure the following:

- A Proxy Set with one or more addresses (proxy servers) and whose 'Proxy Hot Swap Mode' parameter is configured to **Enable** (see [Configuring Proxy Sets](#) on page 632).
- An IP-to-IP Routing rule 1) whose 'Destination IP Group' parameter is a Server-type IP Group that is associated with the above Proxy Set (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186) and 2) that is assigned the relevant Alternative Reasons Set (using the 'SBC Alternative Routing Reasons Set' parameter).
- An alternative IP-to-IP Routing rule for the above rule.

Alternative routing based on SIP response codes functions as follows:

1. The device sends (outgoing) a SIP dialog-initiating message (e.g., INVITE, OPTIONS, and SUBSCRIBE) to one of the online proxy servers (addresses) configured for the Proxy Set that is associated with the destination IP Group of the matched IP-to-IP Routing rule.
2. If there is no response to the sent SIP message, or a "reject" (release) response is received (e.g., SIP 406) that is also configured for the Alternative Reasons Set assigned to the destination IP Group, the device tries to route the SIP message again (re-transmission) to the same proxy for a user-defined number of times, configured by the [HotSwapRtx] parameter. If still unsuccessful, the device tries to send the message to a different online proxy of the Proxy Set and if unsuccessful, it tries another online proxy, and so on (up to four online proxies are attempted). The order of attempted online proxies is according to the Proxy Set's configuration.

The following can then occur depending on received response codes or no responses:

- If any attempted proxy sends a response code that you have not configured for the assigned Alternative Reasons Set, the routing of the SIP message fails and the device **doesn't** make any further attempts to route the message.
- If the device has tried all the online proxies of the Proxy Set and no response has been received or responses have been received that you have also configured for the assigned Alternative Reasons Set, the device searches the IP-to-IP Routing table for a matching alternative routing rule and if found, sends the SIP message to the destination configured for that alternative routing rule (repeating steps 1 through 2 above, if needed).

You can also configure alternative routing for the following proprietary response codes (if configured in the table) that are issued by the device itself:

- **806 Media Limits Exceeded:** The device generates the response code when the call is terminated due to crossed user-defined thresholds of QoE metrics such as MOS, packet delay, and packet loss (see [Configuring Quality of Experience Profiles](#) on page 528) and/or media bandwidth (see [Configuring Bandwidth Profiles](#) on page 535). When this occurs, the device sends a SIP 480 (Temporarily Unavailable) response to the SIP entity (IP Group). This is configured by 1) assigning an IP Group a QoE and/or Bandwidth profile that rejects calls if

the threshold is crossed, 2) configuring 806 for an Alternative Reasons Set that is assigned to the IP Group and 3) configuring an alternative routing rule.

The device also generates the response code when it rejects a call based on Quality of Service rules due to crossed Voice Quality and Bandwidth thresholds (see [Configuring Quality of Service Rules](#) on page 540). If the response code is configured in the table and the device rejects a call due to threshold crossing, it searches in the IP-to-IP Routing table for an alternative routing rule.

- **850 Signalling Limits Exceeded:** The device generates the response code when it rejects a call based on Quality of Service rules due to crossed ASR, NER or ACD thresholds (see [Configuring Quality of Service Rules](#) on page 540). If the response code is configured for an Alternative Reasons Set that is assigned to the IP Group and the device rejects a call due to threshold crossing, it searches in the IP-to-IP Routing table for an alternative routing rule.

- This section is applicable only to the SBC application.
- The device issues itself the SIP response code 408 when no response is received from a sent SIP message.
- If the device receives a SIP 408 response, an ICMP message, or no response, it still does alternative routing even if you have not configured this code for an Alternative Reasons Set.
- SIP requests belonging to an SRD or IP Group that have reached the call limit (maximum concurrent calls and/or call rate), configured in the Call Admission Control Profile table are sent to an alternative route (if configured in the IP-to-IP Routing table for the SRD or IP Group). If no alternative routing rule is found, the device automatically rejects the SIP request with a SIP 480 (Temporarily Unavailable) response.
- If due to an INVITE message the device receives from the proxy a SIP 18x response (e.g., 180 or 183) followed by any failure response (e.g., 400 Not Found), the device doesn't do alternative routing, but instead terminates the call. This occurs even if the failure response is configured in the associated Alternative Reasons Set.

The following procedure describes how to configure Alternative Reasons sets through the Web interface. You can also configure it through other management platforms:

- Alternative Reasons Set table: ini file [SBCAltRoutingReasonsSet] or CLI (`configure voip > sbc routing alt-route-reasons-set`)
- Alternative Reasons Rules table: ini file [SBCAltRoutingReasonsList] or CLI (`configure voip > sbc routing alt-route-reasons-set < alt-route-reasons-rules`)

#### ➤ To configure SIP reason codes for alternative IP routing:

1. Open the Alternative Reasons Set table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Routing** > **Alternative Reasons Set**).
2. Click **New**; the following dialog box appears:

**Alternative Reasons Set**

GENERAL

Index: 1

Name:

Description:

3. Configure an Alternative Reasons Set according to the parameters described in the table below.
4. Click **Apply**.

**Table 34-3: Alternative Reasons Set Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines an arbitrary name to easily identify the row. The valid value is a string of up to 40 characters. <b>Note:</b> Configure each row with a unique name.
'Description' description [Description]	Defines a description for the Alternative Reasons Set. The valid value is a string of up to 99 characters. By default, no value is defined.

5. Select the index row of the Alternative Reasons Set that you added, and then click the **Alternative Reasons Rules** link located at the bottom of the page; the Alternative Reasons Rules table opens.
6. Click **New**; the following dialog box appears:

**Alternative Reasons Rules**

GENERAL

Index: 0

Release Cause Code: 408 Request Timeout

7. Configure Alternative Reasons rules according to the parameters described in the table below.

8. Click **Apply**.**Table 34-4: Alternative Reasons Rules Table Parameter Descriptions**

Parameter	Description
'Index' alt-route-reasons-rules [SBCAltRoutingReasonsList_ SBCAltRouteIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Release Cause Code' rel-cause-code [SBCAltRoutingReasonsList_ ReleaseCauseCode]	Defines a SIP response code that triggers the device's alternative routing mechanism. [4] <b>4xx</b> ; [5] <b>5xx</b> ; [6] <b>6xx</b> ; [400] <b>400 Bad Request</b> ; [402] <b>402 Payment Required</b> ; [403] <b>403 Forbidden</b> ; [404] <b>404 Not Found</b> ; [405] <b>405 Method Not Allowed</b> ; [406] <b>406 Not Acceptable</b> ; [408] <b>408 Request Timeout</b> (Default); [409] <b>409 Conflict</b> ; [410] <b>410 Gone</b> ; [413] <b>413 Request Too Large</b> ; [414] <b>414 Request URI Too Long</b> ; [415] <b>415 Unsupported Media</b> ; [420] <b>420 Bad Extension</b> ; [421] <b>421 Extension Required</b> ; [423] <b>423 Session Interval Too Small</b> ; [480] <b>480 Unavailable</b> ; [481] <b>481 Transaction Not Exist</b> ; [482] <b>482 Loop Detected</b> ; [483] <b>483 Too Many Hops</b> ; [484] <b>484 Address Incomplete</b> ; [485] <b>485 Ambiguous</b> ; [486] <b>486 Busy</b> ; [487] <b>487 Request Terminated</b> ; [488] <b>488 Not Acceptable Here</b> ; [491] <b>491 Request Pending</b> ; [493] <b>493 Undecipherable</b> ; [500] <b>500 Internal Error</b> ; [501] <b>501 Not Implemented</b> ; [502] <b>502 Bad Gateway</b> ; [503] <b>503 Service Unavailable</b> ; [504] <b>504 Server Timeout</b> ; [505] <b>505 Version Not Supported</b> ; [513] <b>513 Message Too Large</b> ; [600] <b>600 Busy Everywhere</b> ; [603] <b>603 Decline</b> ; [604] <b>604 Does Not Exist Anywhere</b> ; [606] <b>606 Not Acceptable</b> ; [806] <b>806 Media Limits Exceeded</b> ; [850] <b>850 Signalling Limits Exceeded</b> .

## Configuring SBC Routing Policies

The Routing Policies table lets you configure up to 20 Routing Policy rules. A Routing Policy determines the routing and manipulation (inbound and outbound) rules per SRD in a multiple SRD configuration topology. The Routing Policy also configures the following:

- Enables Least Cost Routing (LCR), and configures default call cost (highest or lowest) and average call duration for routing rules that are not assigned LCR Cost Groups. The default call cost determines whether matched routing rules that are not assigned Cost Groups are considered as a higher or lower cost route compared to other matching routing rules that

are assigned Cost Groups. If you disable LCR, the device ignores the Cost Groups assigned to the routing rules in the IP-to-IP Routing table.

- Assigns LDAP servers (LDAP Server Group) for LDAP-based routing. IP-to-IP routing rules configured for LDAP or CSR (Call Setup Rules) queries use the LDAP server(s) that is assigned to the routing rule's associated Routing Policy. You can configure a Routing Policy per SRD or alternatively, configure a single Routing Policy that is shared between all SRDs.

The implementation of Routing Policies is intended for the following deployments **only**:

- Deployments requiring LCR and/or LDAP-based routing.
- Multi-tenant deployments that require multiple, logical routing tables where each tenant has its own dedicated ("separated") routing (and manipulation) table. In such scenarios, each SRD (tenant) is configured as an Isolated SRD and assigned its own unique Routing Policy, implementing an almost isolated, non-bleeding routing configuration topology.

For all other deployment scenarios, the Routing Policy is irrelevant and the handling of the configuration entity is not required as a default Routing Policy ("Default\_SBCRoutingPolicy" at Index 0) is provided. When only one Routing Policy is required, the device automatically associates the default Routing Policy with newly added configuration entities that can be associated with the Routing Policy (as mentioned later in this section, except for Classification rules). This facilitates configuration, eliminating the need to handle the Routing Policy configuration entity (except if you need to enable LCR and/or assign an LDAP server to the Routing Policy). In such a setup, where only one Routing Policy is used, single routing and manipulation tables are employed for all SRDs.

If possible, it is recommended to use only **one** Routing Policy for all SRDs (tenants), unless deployment requires otherwise (i.e., a dedicated Routing Policy per SRD).

Once configured, you need to associate the Routing Policy with an SRD(s) in the SRDs table. To determine the routing and manipulation rules for the SRD, you need to assign the Routing Policy to routing and manipulation rules. The figure below shows the configuration entities to which Routing Policies can be assigned:

Typically, assigning a Routing Policy to a Classification rule is not required, as when an incoming call is classified it uses the Routing Policy associated with the SRD to which it belongs. However, if a Routing Policy is assigned to a Classification rule, it overrides the Routing Policy assigned to the SRD. The option to assign Routing Policies to Classification rules is useful in deployments requiring different routing and manipulation rules for specific calls pertaining to the **same** SRD.

In such scenarios, you need to configure multiple Classification rules for the same SRD, where for some rules no Routing Policy is assigned (i.e., the SRD's assigned Routing Policy is used) while for others a different Routing Policy is specified to override the SRD's assigned Routing Policy.

In multi-tenant environments employing multiple SRDs and Routing Policies, the IP Groups that can be used in routing rules (in the IP-to-IP Routing table) are as follows:

- If the Routing Policy is assigned to only one SRD and the SRD is an Isolated SRD, the routing rules of the Routing Policy can be configured with IP Groups belonging to the Isolated SRD and IP Groups belonging to all Shared SRDs.
- If the Routing Policy is assigned to a Shared SRD, the routing rules of the Routing Policy can be configured with any IP Group (i.e., belonging to Shared and Isolated SRDs). In effect, the Routing Policy can include routing rules for call routing between Isolated SRDs.
- If the Routing Policy is assigned to multiple SRDs (Shared and/or Isolated), the routing rules of the Routing Policy can be configured with IP Groups belonging to all Shared SRDs as well as IP Groups belonging to Isolated SRDs that are assigned the Routing Policy.

To facilitate the configuration of routing rules in the IP-to-IP Routing table through the Web interface, only the permitted IP Groups (according to the above) are displayed as optional values.

The general flow for processing the call for multi-tenant deployments and Routing Policies is as follows:

1. Using the Classification table, the device classifies the incoming call to an IP Group, based on the SIP Interface on which the call is received. Based on the SIP Interface, the device associates the call to the SRD that is assigned to the SIP Interface.
2. Once the call has been successfully classified to an IP Group, the Routing Policy assigned to the associated SRD is used. However, if a Routing Policy is configured in the Classification table, it overrides the Routing Policy assigned to the SRD.
3. The regular manipulation (inbound and outbound) and routing processes are done according to the associated Routing Policy.

- The Classification table is used only if classification by registered user in the device's users registration database or by Proxy Set fails.
- If the device receives incoming calls (e.g., INVITE) from users that have already been classified and registered in the device's registration database, the device ignores the Classification table and uses the Routing Policy that was determined for the user during the initial classification process.

The following procedure describes how to configure Routing Policies rules through the Web interface. You can also configure it through ini file [SBCRoutingPolicy] or CLI (`configure voip > sbc routing sbc-routing-policy`).

➤ **To configure a Routing Policy rule:**

1. Open the Routing Policies table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Routing** > **Routing Policies**).
2. Click **New**; the following dialog box appears:

**Routing Policies**

**GENERAL**

Index: 1

Name:

LDAP Servers Group Name: -- [View](#)

**LEAST COST ROUTING**

LCR Feature: Disable

Default Call Cost: Lowest Cost

LCR Call Duration [min]: 1

3. Configure the Routing Policy rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 34-5: Routing Policies table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index'	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [SBCRoutingPolicy_Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. By default, no name is defined. If you don't configure a name, the device automatically assigns a name in the following format: "SBCRoutingPolicy_<Index>", for example, "SBCRoutingPolicy_2". <b>Note:</b> ■ Configure each row with a unique name.

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'LDAP Servers Group Name' ldap-srv-group-name [SBCRoutingPolicy_ LdapServersGroupName]	<p>Assigns an LDAP Server Group to the Routing Policy. Routing rules in the IP-to-IP Routing table that are associated with the Routing Policy and that are configured with LDAP and/or Call Setup Rules, use the LDAP server(s) configured for this LDAP Server Group.</p> <p>By default, no value is defined.</p> <p>For more information on LDAP Server Groups, see <a href="#">Configuring LDAP Server Groups</a> on page 382.</p> <p><b>Note:</b> The default Routing Policy is assigned the default LDAP Server Group ("DefaultCTRLServersGroup").</p>
Least Cost Routing	
'LCR Feature' lcr-enable [SBCRoutingPolicy_ LCREnable]	<p>Enables the Least Cost Routing (LCR) feature for the Routing Policy.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information on LCR, see <a href="#">Least Cost Routing</a> on page 461.</p>
'Default Call Cost' lcr-default-cost [SBCRoutingPolicy_ LCRDefaultCost]	<p>Defines whether routing rules in the IP-to-IP Routing table that are not assigned a Cost Group are considered a higher cost or lower cost route compared to other matched routing rules that are assigned Cost Groups.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Lowest Cost</b> = (Default) The device considers a matched routing rule (belonging to the Routing Policy) that is not assigned a Cost Group as the lowest cost route. Therefore, it uses the routing rule.</li> <li>■ [1] <b>Highest Cost</b> = The device considers a matched routing rule (belonging to the Routing Policy) that is not assigned a Cost Group as the highest cost route. Therefore, it is only used if the other matched routing rules that are assigned Cost Groups are unavailable.</li> </ul> <p><b>Note:</b> If multiple matched routing rules without an assigned Cost Group exist, the device selects the first matched rule in the table.</p>

Parameter	Description
'LCR Call Duration' lcr-call-length [SBCRoutingPolicy_ LCRAverageCallLength]	<p>Defines the average call duration (in minutes) and is used to calculate the variable portion of the call cost. This is useful, for example, when the average call duration spans over multiple time bands. The LCR is calculated as follows: cost = call connect cost + (minute cost * average call duration). The valid value is 0-65533. The default is 1.</p> <p>For example, assume the following Cost Groups:</p> <ul style="list-style-type: none"> <li>■ "Weekend A": call connection cost is 1 and charge per minute is 6. Therefore, a call of 1 minute cost 7 units.</li> <li>■ "Weekend B": call connection cost is 6 and charge per minute is 1. Therefore, a call of 1 minute cost 7 units.</li> </ul> <p>Therefore, for calls under one minute, "Weekend A" carries the lower cost. However, if the average call duration is more than one minute, "Weekend B" carries the lower cost.</p>

## Configuring IP Group Sets

The IP Group Set table lets you configure up to 51 IP Group Sets. An IP Group Set is a group of IP Groups used for load balancing of calls, belonging to the same source, to a call destination (i.e., IP Group). Each IP Group Set can include up to five IP Groups (Server-type and Gateway-type only). The chosen destination IP Group for each call depends on the configured load-balancing policy, which can be Round Robin, Random Weights, or Homing (for more information, see the table's description, later in this section).

IP Group Sets are applicable only to the SBC application.

Alternative routing within the IP Group Set is also supported. If a chosen destination IP Group responds with a reject response that is configured for an Alternative Reasons Set (see [Configuring SIP Response Codes for Alternative Routing Reasons](#) on page 1214) that is assigned to the IP Group ('SBC Alternative Routing Reasons Set' parameter), or doesn't respond at all (i.e., keep-alive with its' associated Proxy Set fails), the device attempts to send the call to another IP Group in the IP Group Set (according to the load-balancing policy). For enabling Proxy Set keep-alive, see [Configuring Proxy Sets](#) on page 632.

An example of round-robin load-balancing and alternative routing: The first call is sent to IP Group #1 in the IP Group Set, the second call to IP Group #2, and the third call to IP Group #3. If the call sent to IP Group #1 is rejected, the device employs alternative routing and sends it to IP Group #4.

Once you have configured your IP Group Set, to implement call load-balancing by IP Groups, do one of the following:

- In the IP-to-IP Routing table, configure the routing rule's 'Destination Type' parameter to **IP Group Set**, and then assign it the IP Group Set in the 'IP Group Set' parameter.
- If you are routing to IP Groups based on Dial Plan tags:
  - In the IP Group Set table (see below), specify the tag name.
  - In the IP-to-IP Routing table, configure the routing rule's 'Destination Type' parameter to **Destination Tag**, and then specify the tag name in the 'Routing Tag Name' parameter.

For more information on IP-to-IP Routing rules, see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186. For more information on routing based on destination Dial Plan tags, see [Using Destination Tags for Choosing Routing Destinations](#) on page 842.

IP Group Sets are configured using two tables with parent-child type relationship:

- **Parent table:** IP Group Set table, which defines the name and load-balancing policy of the IP Group Set.
- **Child table:** IP Group Set Member table, which assigns IP Groups to IP Group Sets. You can assign up to five IP Groups per IP Group Set.

The following procedure describes how to configure IP Group Sets through the Web interface. You can also configure it through other management platforms:

- **IP Group Set Table:** *ini* file [IPGroupSet] or CLI (`configure voip > sbc routing ip-group-set`)
- **IP Group Set Member Table:** *ini* file [IPGroupSetMember] or CLI (`configure voip > sbc routing ip-group-set-member`)

➤ **To configure an IP Group Set:**

1. Open the IP Group Set table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Routing** > **IP Group Set**).
2. Click **New**; the following dialog box appears:

The screenshot shows a web-based configuration window titled "IP Group Set". It features a "GENERAL" tab. Below the tab, there are four configuration fields: "Index" (text input with "0"), "Name" (text input), "Policy" (dropdown menu with "Round-Robin" selected), and "Tags" (text input). The window has standard minimize and close buttons in the top right corner.

3. Configure the IP Group Set according to the parameters described in the table below.

4. Click **Apply**.**Table 34-6: IP Group Set Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Name' name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
'Policy' policy [Policy]	<p>Defines the load-balancing policy.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Round-Robin</b> = (Default) The device selects the next consecutive, available IP Group for each call. The device selects the first IP Group in the table (i.e., lowest index) for the first call and the next consecutive IP Groups for the next calls. For example, first call to IP Group at Index 0, second call to IP Group at Index 2, third call to IP Group at Index 3, and so on. If an IP Group is offline, the device selects the next consecutive IP Group. Once the last IP Group in the IP Group Set list is selected for a call, the device goes to the beginning of the list and sends the next call to the first IP Group, and so on.</li> <li>■ [1] <b>Random Weight</b> = The device selects IP Groups at random and their weights determine their probability of getting chosen over others. The higher the weight, the more chance of the IP Group being chosen.</li> <li>■ [2] <b>Homing</b> = The device always attempts to send all calls to the first IP Group in the table (i.e., lowest index). If unavailable, it sends the calls to the next consecutive, available IP Group. However, if the first IP Group comes online again, the device selects it.</li> </ul> <p><b>Note:</b> For the <b>Random Weight</b> optional value, use the 'Weight' parameter in the IP Group Set Member table (below) to configure weight value per IP Group.</p>
'Tags' tags [Tags]	<p>Assigns a Dial Plan tag that is used to determine whether the incoming SIP dialog is sent to IP Groups belonging to this IP Group Set. The parameter is used when IP-to-IP Routing rules are configured for destination based on tags (i.e., 'Destination Type' parameter configured to Destination Tag). For more information on routing based on destination tags, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</p>

Parameter	Description
	<p>The valid value is a string of up to 70 characters. By default, no value is defined. You can configure the parameter with up to five tags, where each tag is separated by a semicolon (;). However, you can configure only up to four tags containing a name and value (e.g., Country=Ireland), and <b>one</b> tag containing a value only (e.g., Ireland). You can also configure multiple tags with the same name (e.g., Country=Ireland;Country=Scotland). The following example configures the maximum number of tags (i.e., four name=value tags and one value-only tag):</p> <p>Country=Ireland;Country=Scotland;Country=RSA;Country=Canada;USA.</p> <p><b>Note:</b> If the IP Groups belonging to the IP Group Set are also configured with Dial Plan tags, the Dial Plan tag configured for the parameter takes precedence. If the same Dial Plan tag is also configured for other IP Groups in the IP Groups table, the IP Group Set takes precedence and the device sends the SIP dialog to the IP Group(s) belonging to the IP Group Set.</p>

- Select the IP Group Set row for which you want to assign IP Groups, and then click the **IP Group Set Member** link located below the table; the IP Group Set Member table appears.
- Click **New**; the following dialog box appears:

- Configure IP Group Set members according to the parameters described in the table below.
- Click **Apply**, and then save your settings to flash memory.

**Table 34-7: IP Group Set Member Table Parameter Descriptions**

Parameter	Description
'Index' index [IPGroupSetMember_ IPGroupSetMemberIndex]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>

Parameter	Description
'IP Group' ip-group-name [IPGroupSetMember_ IPGroupName]	Assigns an IP Group to the IP Group Set. To configure IP Groups, see <a href="#">Configuring IP Groups</a> on page 591. <b>Note:</b> The IP Group can only be a Server-type or Gateway-type.
'Weight' weight [IPGroupSetMember_ Weight]	Defines the weight of the IP Group. The higher the weight, the more chance of the IP Group being selected as the destination of the call. The valid value is 1 to 9. The default is 1. <b>Note:</b> The parameter is applicable only if you configure the 'Policy' parameter to <b>Random Weight</b> .

## 35 SBC Manipulations

This section describes the configuration of the manipulation rules for the SBC application.

For additional manipulation features, see the following:

- [Configuring SIP Message Policy Rules](#) on page 867
- [Configuring SIP Message Manipulation](#) on page 856

The device supports SIP URI user part (source and destination) manipulations for inbound and outbound routing. These manipulations can be applied to a source IP group, source and destination host and user prefixes, and/or user-defined SIP request (e.g., INVITE, OPTIONS, SUBSCRIBE, and/or REGISTER). Since outbound manipulations are performed after routing, the outbound manipulation rule matching can also be done by destination IP Group. Manipulated destination user and host are performed on the following SIP headers: Request-URI, To, and Remote-Party-ID (if exists). Manipulated source user and host are performed on the following SIP headers: From, P-Asserted (if exists), P-Preferred (if exists), and Remote-Party-ID (if exists).

You can also restrict source user identity in outgoing SIP dialogs in the Outbound Manipulation table (using the column PrivacyRestrictionMode). The device identifies an incoming user as restricted if one of the following exists:

- From header user is 'anonymous'.
- P-Asserted-Identity and Privacy headers contain the value 'id'.

All restriction logic is done after the user number has been manipulated.

Host name (source and destination) manipulations are simply host name substitutions with the names defined for the source and destination IP Groups respectively (if any, in the IP Groups table).

Below is an example of a call flow and consequent SIP URI manipulations:

### ■ Incoming INVITE from LAN:

```
INVITE sip:1000@10.2.2.3;user=phone;x=y;z=a SIP/2.0
Via: SIP/2.0/UDP 10.2.2.6;branch=z9hGLLLLLan
```

```

The SIP message manipulations in the example above (contributing to typical topology hiding) are as follows:

- Inbound source SIP URI user name from "7000" to "97000":

```
From:<sip:7000@10.2.2.6;user=phone;x=y;z=a>;tag=OILAN;paramer1=abe
```

to

```
From: <sip:97000@IP_PBX;user=phone;x=y;z=a>;tag=OWan;paramer1=abe
```

- Source IP Group name (i.e., SIP URI host name) from "10.2.2.6" to "IP\_PBX":

```
From:<sip:7000@10.2.2.6;user=phone;x=y;z=a>;tag=OILAN;paramer1=abe
```

to

```
From: <sip:97000@IP_PBX;user=phone;x=y;z=a>;tag=OWan;paramer1=abe
```

- Inbound destination SIP URI user name from "1000" to 9721000":

```
INVITE sip:1000@10.2.2.3;user=phone;x=y;z=a SIP/2.0  
To: <sip:1000@10.2.2.3;user=phone>
```

to

```
INVITE sip:9721000@ITSP;user=phone;x=y;z=a SIP/2.0  
To: <sip:9721000@ITSP;user=phone>
```

- Destination IP Group name (SIP URI host name) from "10.2.2.3" to "ITSP":

```
INVITE sip:1000@10.2.2.3;user=phone;x=y;z=a SIP/2.0  
To: <sip:1000@10.2.2.3;user=phone>
```

to

```
INVITE sip:9721000@ITSP;user=phone;x=y;z=a SIP/2.0  
To: <sip:9721000@ITSP;user=phone>
```

## Configuring IP-to-IP Inbound Manipulations

The Inbound Manipulations table lets you configure up to 205 IP-to-IP Inbound Manipulation rules. An Inbound Manipulation rule defines a manipulation sequence for the source or destination SIP URI user part of inbound SIP dialog requests. You can apply these manipulations to different SIP dialog message types (e.g., INVITE or REGISTER) and SIP headers as follows:

- Manipulated **destination URI user part** are done on the following SIP headers: Request-URI and To
- Manipulated **source URI user part** are done on the following SIP headers: From, P-Asserted-Identity (if exists), P-Preferred-Identity (if exists), and Remote-Party-ID (if exists)

Manipulated URI user part of the SIP From and Request-URI headers overwrite the user part of other headers.

Configuration of Inbound Manipulation rules includes two areas:

- **Match:** Defines the matching characteristics of an incoming SIP dialog (e.g., source host name).
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule. In other words, the device manipulates the source or destination SIP URI user part of the SIP dialog (e.g., removes a user-defined number of characters from the left of the SIP URI user part).

Configure stricter classification rules higher up in the table than less strict rules to ensure the desired rule is used to manipulate the incoming dialog. *Strict* refers to the number of matching characteristics configured for the rule. For example, a rule configured with source host name and source IP Group as matching characteristics is stricter than a rule configured with only source host name. If the rule configured with only source host name appears higher up in the table, the device ("erroneously") uses the rule to manipulate incoming dialogs matching this source host name (even if they also match the rule appearing lower down in the table configured with the source IP Group as well).

To configure and apply an Inbound Manipulation rule, the rule must be associated with a Routing Policy. The Routing Policy associates the rule with an SRD(s). Therefore, the Routing Policy lets you configure manipulation rules for calls belonging to specific SRD(s). However, as multiple Routing Policies are relevant only for multi-tenant deployments (if needed), for most deployments, only a single Routing Policy is required. As the device provides a default Routing Policy ("Default\_SBCRoutingPolicy"), when only one Routing Policy is required, the device automatically assigns the default Routing Policy to the routing rule. If you are implementing LDAP-based routing (with or without Call Setup Rules) and/or Least Cost Routing (LCR), you need to configure these settings for the Routing Policy (regardless of the number of Routing Policies employed). For more information on Routing Policies, see [Configuring SBC Routing Policies](#) on page 1218.

The IP Groups table can be used to configure a host name that overwrites the received host name. This manipulation can be done for source and destination IP Groups (see [Configuring IP Groups](#) on page 591).

If you have configured call routing from the device's SBC application (IP-to-IP routing) to the device's Gateway application for IP-to-Tel routing, the device uses the initial SIP message as if it's a new call. Therefore, if any manipulations were done on the SIP message by the SBC application, the device ignores them.

The following procedure describes how to configure Inbound Manipulation rules through the Web interface. You can also configure it through ini file [IPInboundManipulation] or CLI (configure voip > sbc manipulation ip-inbound-manipulation).

➤ **To configure an Inbound Manipulation rule:**

1. Open the Inbound Manipulations table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Manipulation** > **Inbound Manipulations**).
2. Click **New**; the following dialog box appears:

3. Configure the Inbound Manipulation rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 35-1: Inbound Manipulations Table Parameter Descriptions**

Parameter	Description
'Routing Policy' routing-policy-name [RoutingPolicyName]	<p>Assigns an Routing Policy to the rule. The Routing Policy associates the rule with an SRD(s). The Routing Policy also defines default LCR settings as well as the LDAP servers if the routing rule is based on LDAP routing (and Call Setup Rules).</p> <p>If only one Routing Policy is configured in the Routing Policies table, the Routing Policy is automatically assigned. If multiple Routing Policies are configured, no value is</p>

Parameter	Description
	<p>assigned.</p> <p>To configure Routing Policies, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p> <p><b>Note:</b> The parameter is mandatory.</p>
<b>General</b>	
<p>'Index'</p> <p>[Index]</p>	<p>Defines an index number for the new table record.</p> <p><b>Note:</b> Each table row must be configured with a unique index.</p>
<p>'Name'</p> <p>manipulation-name</p> <p>[ManipulationName]</p>	<p>Defines an arbitrary name to easily identify the manipulation rule.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter value can't be configured with the character string "any" (upper or lower case).</p>
<p>'Additional Manipulation'</p> <p>is-additional-manipulation</p> <p>[IsAdditionalManipulation]</p>	<p>Determines whether additional SIP URI user part manipulation is done for the table entry rule listed directly above it.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Regular manipulation rule (not done in addition to the rule above it).</li> <li>■ [1] <b>Yes</b> = If the above row entry rule matched the call, consider this row entry as a match as well and perform the manipulation specified by this rule.</li> </ul> <p><b>Note:</b> Additional manipulation can only be done on a different SIP URI, source or destination, to the rule configured in the row above as configured by the 'Manipulated URI' parameter (see below).</p>
<p>'Manipulation Purpose'</p> <p>purpose</p> <p>[ManipulationPurpose]</p>	<p>Defines the purpose of the manipulation.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Normal</b> = (Default) Inbound manipulations affect the routing input and source and/or destination number.</li> <li>■ [1] <b>Routing input only</b> = Inbound manipulations affect the routing input only, retaining the original source and destination number.</li> <li>■ [2] <b>Shared Line</b> = Used for the Shared-Line Appearance feature. This manipulation is for registration requests</li> </ul>

Parameter	Description
	to change the destination number of the secondary extension numbers to the primary extension. For more information, see <a href="#">Configuring BroadSoft's Shared Phone Line Call Appearance for Survivability</a> on page 1284.
<b>Match</b>	
'Request Type' request-type [RequestType]	<p>Defines the SIP request type to which the manipulation rule is applied.</p> <ul style="list-style-type: none"> <li>■ [0] <b>All</b> = (Default) All SIP messages.</li> <li>■ [1] <b>INVITE</b> = All SIP messages except REGISTER and SUBSCRIBE.</li> <li>■ [2] <b>REGISTER</b> = Only REGISTER messages.</li> <li>■ [3] <b>SUBSCRIBE</b> = Only SUBSCRIBE messages.</li> <li>■ [4] <b>INVITE and REGISTER</b> = All SIP messages except SUBSCRIBE.</li> <li>■ [5] <b>INVITE and SUBSCRIBE</b> = All SIP messages except REGISTER.</li> </ul>
'Source IP Group' src-ip-group-name [SrcIpGroupName]	<p>Defines the IP Group from where the incoming INVITE is received.</p> <p>The default is <b>Any</b> (i.e., any IP Group).</p>
'Source Username Pattern' src-user-name-pattern [SrcUsernamePrefix]	<p>Defines the source SIP URI user name (usually in the From header).</p> <p>The default is the asterisk (*) symbol (i.e., any source user name). You can use special pattern notations to denote the user part. For available notations, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p><b>Note:</b> You can only use a comma (,) as a separator in the pattern and not as a special comma character.</p>
'Source Host' src-host [SrcHost]	<p>Defines the source SIP URI host name - full name (usually in the From header).</p> <p>The default is the asterisk (*) symbol (i.e., any host name).</p>
'Destination Username Pattern' dst-user-name-pattern	<p>Defines the destination SIP URI user name, typically located in the Request-URI and To headers.</p> <p>The default is the asterisk (*) symbol (i.e., any destination user name). You can use special pattern notations to</p>

Parameter	Description
[DestUsernamePrefix]	denote the user part. For available notations, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697. <b>Note:</b> You can only use a comma (,) as a separator in the pattern and not as a special comma character.
'Destination Host' dst-host [DestHost]	Defines the destination SIP URI host name - full name, typically located in the Request URI and To headers. The default is the asterisk (*) symbol (i.e., any destination host name).
<b>Operation Rule - Action</b>	
'Manipulated Item' manipulated-uri [ManipulatedURI]	Determines whether the source or destination SIP URI user part is manipulated.  ■ [0] <b>Source</b> = (Default) Manipulation is done on the source SIP URI user part.  ■ [1] <b>Destination</b> = Manipulation is done on the destination SIP URI user part.
'Remove From Left' remove-from-left [RemoveFromLeft]	Defines the number of digits to remove from the left of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "n".
'Remove From Right' remove-from-right [RemoveFromRight]	Defines the number of digits to remove from the right of the user name prefix. For example, if you enter 3 and the user name is "john", the new user name is "j". <b>Note:</b> If both 'Remove From Right' and 'Leave From Right' parameters are configured, the 'Remove From Right' setting is applied first.
'Leave From Right' leave-from-right [LeaveFromRight]	Defines the number of characters that you want retained from the right of the user name. <b>Note:</b> If both 'Remove From Right' and 'Leave From Right' parameters are configured, the 'Remove From Right' setting is applied first.
'Prefix to Add' prefix-to-add [Prefix2Add]	Defines the number or string that you want added to the front of the user name. For example, if you enter 'user' and the user name is "john", the new user name is "userjohn".
'Suffix to Add' suffix-to-add	Defines the number or string that you want added to the end of the user name. For example, if you enter '01' and

Parameter	Description
[Suffix2Add]	the user name is "john", the new user name is "john01".

## Configuring IP-to-IP Outbound Manipulations

The Outbound Manipulations table lets you configure up to 205 IP-to-IP Outbound Manipulation rules. An Outbound Manipulation rule defines a manipulation action for the SIP Request-URI user part (source or destination) or calling name of outbound SIP dialog requests. You can apply these manipulations to different SIP request types (e.g., INVITE) and SIP headers as follows:

- Manipulated **destination URI user part** are done on the following SIP headers: Request URI and To
- Manipulated **source URI user part** are done on the following SIP headers: From, P-Asserted (if exists), P-Preferred (if exists), and Remote-Party-ID (if exists)

Manipulated URI user part of the SIP From and Request-URI headers overwrite the user part of other headers.

Configuration of Outbound Manipulation rules includes two areas:

- **Match:** Defines the matching characteristics of an incoming SIP dialog (e.g., source host name). As the device performs outbound manipulations only after the routing process, destination IP Groups can also be used as matching characteristics.
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule. In other words, the device manipulates the source or destination SIP URI user part or calling name of the SIP dialog (e.g., removes a user-defined number of characters from the left of the SIP URI user part).

- Configure stricter classification rules higher up in the table than less strict rules to ensure the desired rule is used to manipulate the outbound dialog. *Strict* refers to the number of matching characteristics configured for the rule. For example, a rule configured with source host name and source IP Group as matching characteristics is stricter than a rule configured with only source host name. If the rule configured with only source host name appears higher up in the table, the device ("erroneously") uses the rule to manipulate outbound dialogs matching this source host name (even if they also match the rule appearing lower down in the table configured with the source IP Group as well).
- SIP URI host name (source and destination) manipulations can also be configured in the IP Groups table (see [Configuring IP Groups](#) on page 591). These manipulations are simply host name substitutions with the names configured for the source and destination IP Groups, respectively.
- If you have configured call routing from the device's SBC application (IP-to-IP routing) to the device's Gateway application for IP-to-Tel routing, the device uses the initial SIP message as if it's a new call. Therefore, if any manipulations were done on the SIP message by the SBC application, the device ignores them.

The following procedure describes how to configure Outbound Manipulations rules through the Web interface. You can also configure it through ini file [IPOutboundManipulation] or CLI (configure voip > sbc manipulation ip-outbound-manipulation).

➤ **To configure Outbound Manipulation rules:**

1. Open the Outbound Manipulations table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Manipulation** > **Outbound Manipulations**).
2. Click **New**; the following dialog box appears:

3. Configure an Outbound Manipulation rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 35-2: Outbound Manipulations Table Parameter Description**

Parameter	Description
'Routing Policy'	Assigns a Routing Policy to the rule. The Routing Policy associates the

Parameter	Description
routing-policy-name [RoutingPolicy Name]	<p>rule with an SRD(s). The Routing Policy also defines default LCR settings as well as the LDAP servers if the routing rule is based on LDAP routing (and Call Setup Rules).</p> <p>If only one Routing Policy is configured in the Routing Policies table, the Routing Policy is automatically assigned. If multiple Routing Policies are configured, no value is assigned.</p> <p>To configure Routing Policies, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p> <p><b>Note:</b> The parameter is mandatory.</p>
<b>General</b>	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Name' manipulation-name [Manipulation Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter value can't be configured with the character string "any" (upper or lower case).</p>
'Additional Manipulation' is-additional-manipulation [IsAdditionalManipulation]	<p>Determines whether additional manipulation is done for the table entry rule listed directly above it.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Regular manipulation rule - not done in addition to the rule above it.</li> <li>■ [1] <b>Yes</b> = If the previous table row entry rule matched the call, consider this row entry as a match as well and perform the manipulation specified by this rule.</li> </ul> <p><b>Note:</b> Additional manipulation can only be done on a different item (source URI, destination URI, or calling name) to the rule configured in the row above (configured by the 'Manipulated URI' parameter).</p>
'Call Trigger' trigger [Trigger]	<p>Defines the reason (i.e., trigger) for re-routing the SIP request.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Any</b> = (Default) Re-routed for all scenarios (re-routes and non-re-routes).</li> <li>■ [1] <b>3xx</b> = Re-routed if triggered as a result of a SIP 3xx response.</li> <li>■ [2] <b>REFER</b> = Re-routed if triggered as a result of a REFER request.</li> <li>■ [3] <b>3xx or REFER</b> = Applies to optional values <b>3xx</b> and <b>REFER</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [4] <b>Initial only</b> = Regular requests that the device forwards to a destination. In other words, re-routing of requests triggered by the receipt of REFER or 3xx doesn't apply.</li> </ul>
<b>Match</b>	
'Request Type' request-type [RequestType]	Defines the SIP request type to which the manipulation rule is applied. <ul style="list-style-type: none"> <li>■ [0] <b>All</b> = (Default) all SIP messages.</li> <li>■ [1] <b>INVITE</b> = All SIP messages except REGISTER and SUBSCRIBE.</li> <li>■ [2] <b>REGISTER</b> = Only SIP REGISTER messages.</li> <li>■ [3] <b>SUBSCRIBE</b> = Only SIP SUBSCRIBE messages.</li> <li>■ [4] <b>INVITE and REGISTER</b> = All SIP messages except SUBSCRIBE.</li> <li>■ [5] <b>INVITE and SUBSCRIBE</b> = All SIP messages except REGISTER.</li> </ul>
'Source IP Group' src-ip-group-name  [SrcIPGroupName]	Defines the IP Group from where the INVITE is received. The default value is <b>Any</b> (i.e., any IP Group).
'Destination IP Group' dst-ip-group-name  [DestIPGroupName]	Defines the IP Group to where the INVITE is to be sent. The default value is <b>Any</b> (i.e., any IP Group).
'Source Username Pattern' src-user-name-pattern [SrcUsernamePrefix]	Defines the source SIP URI user name (typically used in the SIP From header). You can use special patterns (notations) to denote the user part. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697. The valid value is a string of up to 60 characters. The default value is the asterisk (*) symbol, meaning any source user part. <b>Note:</b>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If you need to manipulate calls of many different source URI user parts, you can use tags (see 'Source Tags' parameter below) instead of this parameter.</li> <li>■ You can only use a comma (,) as a separator in the pattern and not as a special comma character.</li> </ul>
'Source Host' src-host [SrcHost]	<p>Defines the source SIP URI host name - full name, typically in the From header.</p> <p>The default value is the asterisk (*) symbol (i.e., any source host name).</p>
'Source Tags' src-tags [SrcTags]	<p>Assigns a prefix tag to denote source URI user names corresponding to the tag configured in the associated Dial Plan.</p> <p>The valid value is a string of up to 70 characters. The tag is case insensitive. By default, no value is defined. You can configure the parameter with up to five tags, where each tag is separated by a semicolon (;). However, you can configure only up to seven tags containing a name and value (e.g., Country=Ireland), and <b>one</b> tag containing a value only (e.g., Ireland). If you are configuring multiple tags in the name=value format, the names of each tag must be unique (e.g., <b>Country</b>=Ireland;<b>Land</b>=Scotland). The following example configures the maximum number of tags (i.e., seven name=value tags and one value-only tag):</p> <p>Country=Ireland;Country2=Scotland;Country3=RSA;Country4=Canada;Country5=UK;Country6=France;Country7=Germany;USA.</p> <p>To configure prefix tags, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Make sure that you assign the Dial Plan in which you have configured the prefix tag, to the related IP Group or SRD.</li> <li>■ Instead of using tags and configuring the parameter, you can use the 'Source Username Pattern' parameter to specify a specific URI source user or all source users.</li> </ul>
'Destination Username Pattern' dst-user-name-pattern [DestUsernamePrefix]	<p>Defines the destination SIP URI user part (typically located in the Request-URI and To headers).</p> <p>You can use special patterns (notations) to denote the user part. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The valid value is a string of up to 60 characters. The default value is the asterisk (*) symbol, meaning any destination user part.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you need to manipulate calls of many different destination URI user names, you can use tags (see 'Destination Tags' parameter below) instead of this parameter.</li> <li>■ You can only use a comma (,) as a separator in the pattern and not as a special comma character.</li> </ul>
'Destination Host' dst-host [DestHost]	<p>Defines the destination SIP URI host name - full name, typically located in the Request-URI and To headers.</p> <p>The default value is the asterisk (*) symbol (i.e., any destination host name).</p>
'Destination Tags' dest-tags [DestTags]	<p>Assigns a prefix tag to denote destination URI user names corresponding to the tag configured in the associated Dial Plan.</p> <p>The valid value is a string of up to 70 characters. The tag is case insensitive. By default, no value is defined. You can configure the parameter with up to five tags, where each tag is separated by a semicolon (;). However, you can configure only up to seven tags containing a name and value (e.g., Country=Ireland), and <b>one</b> tag containing a value only (e.g., Ireland). If you are configuring multiple tags in the name=value format, the names of each tag must be unique (e.g., <b>Country</b>=Ireland;<b>Land</b>=Scotland). The following example configures the maximum number of tags (i.e., seven name=value tags and one value-only tag):</p> <p>Country=Ireland;Country2=Scotland;Country3=RSA;Country4=Canada;Country5=UK;Country6=France;Country7=Germany;USA.</p> <p>To configure prefix tags, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Make sure that you assign the Dial Plan in which you have configured the prefix tag, to the related IP Group or SRD.</li> <li>■ Instead of using tags and configuring the parameter, you can use the 'Destination Username Pattern' parameter to specify a specific URI destination user or all destinations users.</li> </ul>
'Calling Name Pattern' calling-name-pattern [CallingNamePrefix]	<p>Defines the calling name (caller ID). The calling name appears in the SIP From header.</p> <p>The valid value is a string of up to 37 characters. By default, no calling name is defined. You can use special patterns (notations) to denote the calling name. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p>

Parameter	Description
'Message Condition' message-condition-name [MessageConditionName]	<p>Assigns a Message Condition rule as a matching characteristic. Message Condition rules define required SIP message formats.</p> <p>To configure Message Condition rules, see <a href="#">Configuring Message Condition Rules</a> on page 865.</p>
'ReRoute IP Group' re-route-ip-group-name [ReRouteIPGroupUpName]	<p>Defines the IP Group that initiated (sent) the SIP redirect response (e.g., 3xx) or REFER message. The parameter is typically used for re-routing requests (e.g., INVITEs) when interworking is required for SIP 3xx redirect responses or REFER messages.</p> <p>The default is <b>Any</b> (i.e., any IP Group).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter functions together with the 'Call Trigger' parameter (see below).</li> <li>■ For more information on interworking of SIP 3xx redirect responses or REFER messages, see <a href="#">Interworking SIP 3xx Redirect Responses</a> on page 1150 and <a href="#">Interworking SIP REFER Messages</a> on page 1154, respectively.</li> </ul>
<b>Action</b>	
'Manipulated Item' manipulated-uri [IsAdditionalManipulation]	<p>Defines the element in the SIP message that you want manipulated.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Source URI</b> = (Default) Manipulates the source SIP Request-URI user part.</li> <li>■ [1] <b>Destination URI</b> = Manipulates the destination SIP Request-URI user part.</li> <li>■ [2] <b>Calling Name</b> = Manipulates the calling name in the SIP message.</li> </ul>
'Remove From Left' remove-from-left [RemoveFromLeft]	<p>Defines the number of digits to remove from the left of the manipulated item prefix. For example, if you enter 3 and the user name is "john", the new user name is "n".</p>
'Remove From Right' remove-from-right	<p>Defines the number of digits to remove from the right of the manipulated item prefix. For example, if you enter 3 and the user name is "john", the new user name is "j".</p>

Parameter	Description
[RemoveFromRight]	
'Leave From Right' leave-from-right [LeaveFromRight]	Defines the number of digits to keep from the right of the manipulated item.
'Prefix to Add' prefix-to-add [Prefix2Add]	<p>Defines the number or string to add in the front of the manipulated item. For example, if you enter 'user' and the user name is "john", the new user name is "userjohn".</p> <p>If you set the 'Manipulated Item' parameter to <b>Source URI</b> or <b>Destination URI</b>, you can configure the parameter to a string of up to 49 characters. If you set the 'Manipulated Item' parameter to <b>Calling Name</b>, you can configure the parameter to a string of up to 36 characters.</p>
'Suffix to Add' suffix-to-add [Suffix2Add]	<p>Defines the number or string to add at the end of the manipulated item. For example, if you enter '01' and the user name is "john", the new user name is "john01".</p> <p>If you set the 'Manipulated Item' parameter to <b>Source URI</b> or <b>Destination URI</b>, you can configure the parameter to a string of up to 49 characters. If you set the 'Manipulated Item' parameter to <b>Calling Name</b>, you can configure the parameter to a string of up to 36 characters.</p>
'Privacy Restriction Mode' privacy-restriction-mode [PrivacyRestrictionMode]	<p>Defines user privacy handling (i.e., restricting source user identity in outgoing SIP dialogs).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) No intervention in SIP privacy.</li> <li>■ [1] <b>Don't change privacy</b> = The user identity remains the same as in the incoming SIP dialog. If a restricted number exists, the restricted presentation is normalized as follows: <ul style="list-style-type: none"> <li>✓ From URL header: "anonymous@anonymous.invalid"</li> <li>✓ If a P-Asserted-Identity header exists (either in the incoming SIP dialog or added by the device), a Privacy header is added with the value "id".</li> </ul> </li> <li>■ [2] <b>Restrict</b> = The user identity is restricted. The restriction is as follows:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ From URL header: "anonymous@anonymous.invalid"</li> <li>✓ If a P-Asserted-Identity header exists (either in the incoming SIP dialog or added by the device), a Privacy header is added with the value "id".</li> <li>■ [3] <b>Remove Restriction</b> = The device attempts to reveal the user identity by setting user values in the From header and removing the privacy "id" value if the Privacy header exists. If the From header user is "anonymous", the value is taken from the P-Preferred-Identity, P-Asserted-Identity, or Remote-Party-ID header (if exists).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Restriction is done only after user number manipulation, if any.</li> <li>■ The device identifies an incoming user as restricted if one of the following exists: <ul style="list-style-type: none"> <li>✓ From header user is "anonymous".</li> <li>✓ P-Asserted-Identity and Privacy headers contain the value "id".</li> </ul> </li> </ul>

## Using Proprietary SIP X-AC-Action Header

You can use AudioCodes proprietary SIP header *X-AC-Action* in Message Manipulation rules to trigger certain actions. These actions can be used to support, for example, interworking of SIP-I and SIP endpoints for the ISUP SPIROU variant (see [Enabling Interworking of SIP and SIP-I Endpoints](#) on page 1262).

The following actions are supported by the X-AC-Action header:

■ **To disconnect a call (optionally, after a user-defined time):**

X-AC-Action: 'disconnect'

X-AC-Action: 'disconnect;delay=<time in ms>'

■ **To resume a previously suspended call:**

X-AC-Action: 'abort-disconnect'

■ **To automatically reply to a message without forwarding the response to the other side:**

X-AC-Action: 'reply'

- To automatically reply to a message with a specific SIP response without forwarding the response to the other side:

```
X-AC-Action: 'reply;response=<response code, e.g., 200>'
```

- To override device's handling of SIP REFER messages for SBC calls, which is configured by the **'Remote REFER Mode' parameter**. The X-AC-Action header can be added to the incoming SIP REFER request using Message Manipulation rules. This is useful if you don't want the settings of this parameter to apply to all calls that are associated with the IP Profile. For example, if you configure the 'Remote REFER Mode' parameter to **Handle Locally**, all incoming SIP REFER requests associated with the IP Profile are terminated at the device. However, you can configure a Message Manipulation rule with the proprietary header to override this parameter setting and allow the device to forward the REFER requests as is for calls with a specific URI, for example. You can configure Message Manipulation rules to add this X-AC-Action header for REFER handling, with one of the following values:

- To allow the device to forward the REFER as is, regardless of the 'Remote REFER Mode' parameter settings:

```
X-AC-Action: 'use-config;refer-behavior=regular'
```

- To allow the device to handle (terminate) the REFER request regardless of the 'Remote REFER Mode' parameter settings:

```
X-AC-Action: 'use-config;refer-behavior= handle-locally'
```

- To switch to a different IP Profile for the call (re-INVITE only), as defined in the IP Group:

```
X-AC-Action: 'switch-profile;profile-name=<IP Profile Name>'
```

```
X-AC-Action: 'switch-profile;profile-name=<IP Profile  
Name>;reason=<PoorInVoiceQuality or PoorInVoiceQualityFailure>'
```

If the IP Profile name contains one or more spaces (e.g., "ITSP NET"), enclose the name in double quotation marks, for example:

```
X-AC-Action: 'switch-profile;profile-name="ITSP NET"'
```

The X-AC-Action header for triggering the actions *disconnect*, *abort-disconnect*, and *reply* is supported only for the following SIP messages (methods):

- re-INVITE
- UPDATE
- INFO
- REFER

For example, to use the X-AC-Action header to switch IP Profiles from "ITSP-Profile-1" to "ITSP-Profile-2" during a call for an IP Group (e.g., IP PBX) if the negotiated media port changes to 7550, perform the following configuration:

1. In the IP Profiles table, configure two IP Profiles ("ITSP-Profile-1" and "ITSP-Profile-2").
2. In the IP Groups table, assign the main IP Profile ("ITSP-Profile-1") to the IP Group using the 'IP Profile' parameter.
3. In the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856), configure the following manipulation rule:
  - Manipulation Set ID: **1**
  - Message Type: **reinvite.request**
  - Condition: **body.sdp regex (.\*)(m=audio 7550 RTP/AVP)(.\*)**
  - Action Subject: **header.X-AC-Action**
  - Action Type: **Add**
  - Action Value: **'switch-profile;profile-name=ITSP-Profile-2'**
4. In the IP Groups table, assign the Message Manipulation rule to the IP Group, using the 'Inbound Message Manipulation Set' parameter.

In the above example, if the device receives from the IP Group a re-INVITE message whose media port value is 7550, the device adds the SIP header "X-AC-Action: switch-profile;profile-name=ITSP-Profile-2" to the incoming re-INVITE message. As a result of receiving this manipulated message, the device starts using IP Profile "ITSP-Profile-2" instead of "ITSP-Profile-1", for the IP Group.

## 36 Configuring Malicious Signatures

The Malicious Signature table lets you configure up to 20 Malicious Signature patterns. Malicious Signatures are signature patterns that identify SIP user agents (UA) who perform malicious attacks on SIP servers by SIP scanning. Malicious Signatures allow you to protect SBC calls handled by the device from such malicious activities, thereby increasing your SIP security. The Malicious Signature patterns identify specific scanning tools used by attackers to search for SIP servers in the network. The feature identifies and protects against SIP (Layer 5) threats by examining new inbound SIP dialog messages. Once the device identifies an attack based on the configured malicious signature pattern, it marks the SIP message as invalid and discards it or alternatively, rejects it with a SIP response (by default, 400), configured in the Message Policies table (see [Configuring SIP Message Policy Rules](#) on page 867). Protection applies only to new dialogs (e.g., INVITE and REGISTER messages) and unauthenticated dialogs.

Malicious signatures can also be used with the Intrusion Detection System (IDS) feature (see [Configuring IDS Policies](#) on page 264). You can configure an IDS Policy that is activated if the device detects a malicious signature (when the 'Reason' parameter is configured to **Dialog establishment failure**).

Malicious signature patterns are typically based on the value of SIP User-Agent headers, which attackers use as their identification string (e.g., "User-Agent: VaxSIPUserAgent"). However, you can configure signature patterns based on any SIP header. To configure signature patterns, use the same syntax as that used for configuring Conditions in the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856). Below are configured signature patterns based on the User-Agent header:

- Malicious signature for the VaxSIPUserAgent malicious UA:

```
header.user-agent prefix 'VaxSIPUserAgent'
```

- Malicious signature for the scanning tool "sip-scan":

```
header.user-agent prefix 'sip-scan'
```

By default, the table provides preconfigured malicious signatures of known, common attackers.

- Malicious Signatures do not apply to the following:
  - ✓ Calls from IP Groups where Classification is by Proxy Set.
  - ✓ In-dialog SIP sessions (e.g., refresh REGISTER requests and re-INVITEs).
  - ✓ Calls from users that are registered with the device.
- If you delete all the entries in the table, when you next restart the device, the table is populated again with all the default signatures.

You can export / import Malicious Signatures in CSV file format to / from a remote server through HTTP, HTTPS, or TFTP. To do this, use the following CLI commands:

```
(config-voip)# sbc malicious-signature-database <export-csv-to | import-csv-from>
<URL>
```

To apply malicious signatures to calls, you need to enable the use of malicious signatures for a Message Policy and then assign the Message Policy to the SIP Interface associated with the calls (i.e., IP Group). To configure Message Policies, see [Configuring SIP Message Policy Rules](#) on page 867.

The following procedure describes how to configure Malicious Signatures through the Web interface. You can also configure it through ini file [MaliciousSignatureDB] or CLI (`configure voip > sbc malicious-signature-database`).

➤ **To configure a Malicious Signature:**

1. Open the Malicious Signature table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **Malicious Signature**).
2. Click **New**; the following dialog box appears:

3. Configure a Malicious Signature according to the parameters described in the table below.
4. Click **Apply**.

**Table 36-1: Malicious Signature Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [MaliciousSignatureDB_ Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 30 characters. <b>Note:</b> Configure each row with a unique name.
'Pattern' pattern [MaliciousSignatureDB_ Pattern]	Defines the signature pattern. The valid value is a string of up to 60 characters. You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions. <b>Note:</b> The parameter is mandatory.

## 37 Advanced SBC Features

This section describes configuration of advanced SBC features.

### Configuring Call Preemption for SBC Emergency Calls

The device supports emergency call preemption for SBC calls by prioritizing emergency calls over regular calls. If the device receives an incoming emergency call when there are unavailable resources to process the call, the device preempts one of the regular calls to free up resources for sending the emergency call to its' destination (i.e., emergency service provider), instead of rejecting it. The device may preempt more than one active call in order to provide sufficient resources for processing the emergency call. Available resources depends on the number of INVITE messages currently processed by the device.

If the device preempts a call, it disconnects the call as follows:

- If the call is being setup (not yet established), it sends a SIP 488 response to the incoming leg and a SIP CANCEL message to the outgoing leg.
- If the call is already established, it sends a SIP BYE message to each leg. The device includes in the SIP BYE message, the Reason header describing the cause as "preemption".

Once the device terminates the regular call, it immediately sends the INVITE message of the emergency call to its' destination without waiting for any response from the remote sides (e.g., 200 OK after BYE). If the device is unable to preempt a call for the emergency call, it rejects the emergency call with a SIP 503 "Emergency Call Failed" (instead of "Service Unavailable") response.

For the device to identify incoming calls as emergency calls, you need to configure a Message Condition rule in the Message Conditions table. Below are examples of Message Condition rules for identifying emergency calls:

**Table 37-1: Examples of Message Condition Rules for Emergency Calls**

Index	Name	Condition
0	Emergency1 - RP header	header.resource-priority contains 'emergency'
1	Emergency2 - RP header	header.resource-priority contains 'esnet'
2	Emergency1 - user with providers address	header.to.url.user=='911'
3	Emergency2 - user with providers address	header.to.url.user=='100'    header.to.url.user=='101'    header.to.url.user=='102'

Index	Name	Condition
4	Emergency3 - user with providers address	header.request.uri contains 'urn:service:sos'

- Indices 0 and 1: SIP Resource-Priority header contains a string indicating an emergency call.
- Indices 2 to 4: Destination user-part contains the emergency provider's address.

The device applies the Message Condition rule only after call classification (but, before inbound manipulation).

The device doesn't preempt established emergency calls.

➤ **To configure SBC emergency call preemption:**

1. In the Message Conditions table (see [Configuring Message Condition Rules](#) on page 865), configure a Message Condition rule to identify incoming emergency calls. See above for examples.
2. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Priority and Emergency**), and then scroll down to the below group of fields:

Preemption Mode	<input checked="" type="checkbox"/>
Emergency Message Condition	<input type="text" value="0"/>
Emergency RTP DiffServ	<input type="text" value="46"/>
Emergency Signaling DiffServ	<input type="text" value="40"/>

3. Select the 'Preemption Mode' check box (SBCPreemptionMode) to enable call preemption.
4. In the 'Emergency Message Condition' field, enter the row index of the Message Condition rule that you configured in Step 1.
5. (Optional) Assign DiffServ levels (markings) to packets belonging to emergency calls:
  - In the 'Emergency RTP DiffServ' field (SBCEmergencyRTPDiffServ), enter the QoS level for RTP packets.
  - In the 'Emergency Signaling DiffServ' field (SBCEmergencySignalingDiffServ), enter the QoS level for SIP signaling packets.
6. Click **Apply**.

The call preemption feature uses only total licensed SBC signaling (SIP) resources and/or the Call Admission Control feature (see [Configuring Call Admission Control](#) on page 1164), and not the number of configured available media (RTP) ports for determining an out-of-resources scenario. Therefore, it's highly recommended that you configure the number of media session legs in the Media Realm table with at least twice the number of SBC signaling resources.

## Configuring Message Session Relay Protocol

The device supports Message Session Relay Protocol (MSRP), which is a text-based protocol for exchanging a series of related instant messages (IM) across an IP network (TCP or TLS only) in the context of a session. The protocol can also be used to transfer large files or images, or share remote desktops or whiteboards. MSRP is typically required for Next Generation 911 (NG911) services, allowing 911 callers to not only access 911 services through voice calls, but also through text messages with Public Safety Answering Points (PSAPs). The device's MSRP support is in accordance with RFC 4975 (The Message Session Relay Protocol (MSRP)) and RFC 6135 (An Alternative Connection Model for the Message Session Relay Protocol (MSRP)). The device also supports secure MSRP sessions (MSRPS), using TLS certificates (TLS Context).

MSRP is applicable only to the SBC application.

The device establishes MSRP sessions using the SDP offer/answer negotiation model over SIP. The MSRP session starts with a SIP INVITE and ends with a SIP BYE message. As a B2BUA, the device interoperates between the MSRP endpoints, terminating the incoming MSRP message on the inbound leg and then generating a new MSRP message on the outbound leg. Before sending the INVITE, the device manipulates the SDP body (e.g., 'a=path', 'c=', 'm=', 'a=setup' and 'a=fingerprint' lines). The device can perform optional message manipulation and other translations such as resolving NAT traversal when the endpoints or device are located behind NAT.

An example of an SDP body with the fields for MSRP negotiation in the INVITE message is shown below:

```
INVITE sip:alice@atlanta.example.com SIP/2.0
To: <sip:bob@biloxi.example.com>
From: <sip:alice@atlanta.example.com>;tag=786
Call-ID: 3413an89KU
Content-Type: application/sdp

c=IN IP4 atlanta.example.com
m=message 7654 TCP/MSRP *
a=accept-types:text/plain
a=path:msrp://atlanta.example.com:7654/jshA7weztas;tcp
a=setup:active
```

Where,

- 'c=' line ignores IP address and port
- 'm=' line indicates an MSRP message
- 'a=accept-types:' line lists allowed content types
- 'a=path:msrp:' line indicates the URI to where the messages are to be sent
- 'a=setup' line indicates the MSRP role (active UA initiates connection; passive UA listens on port)

If secured MSRP (MSRPS) is required (i.e., incoming SDP contains 'm=' line with 'TCP/TLS/MSRP' value, 'a=path' with 'msrps', and 'a=fingerprint'), during MSRP session establishment, the device enforces the validity of the fingerprint from the TLS handshake (public key) with the fingerprint in the received SDP. When the device establishes a secured MSRP session, the offered fingerprint is obtained from the TLS Context, which is assigned to the IP Profile of the endpoint.

The device handles MSRP sessions as follows:

1. When the device receives an INVITE message with the MSRP offer, it initiates an SDP offer to the destination endpoint on the outgoing leg. Before sending the INVITE message, the device does the following:
  - Uses the configured MSRP TCP or MSRP TLS port (SIP Interface) in the SDP 'm=' line.
  - Uses the IP address (SDP 'c=' line) of the associated IP Interface (SIP Interface).
  - Sets the 'a=setup' line to the configured preferred MSRP role of the device.
2. When the device receives the MSRP answer from the destination endpoint, it sends an SDP answer to the dialog-initiating endpoint. Before sending the INVITE message, the device does the following:
  - If the device has chosen a TCP server role, it selects the listening port configured for MSRP in the associated SIP Interface. The port number is included in the media line of the SDP.
  - The device includes the IP address of the associated IP Interface in the 'c=' line of the SDP.
  - Sets the 'a=setup' line to the device's negotiated role.

Once SDP negotiation between the UAs is complete and the MSRP session is being established, the device initiates a TCP/TLS connection (or waits to be initiated) on each leg, depending on SDP negotiation. Once a TCP/TLS connection is established, the endpoints can start sending MSRP messages using MSRP SEND requests, as shown in the following example:

```
MSRP a786hjs2 SEND
To-Path: msrp://biloxi.example.com:12763/kjhd37s2s20w2a;tcp
From-Path: msrp://atlanta.example.com:7654/jshA7weztas;tcp
Message-ID: 87652491
Byte-Range: 1-25/25
```

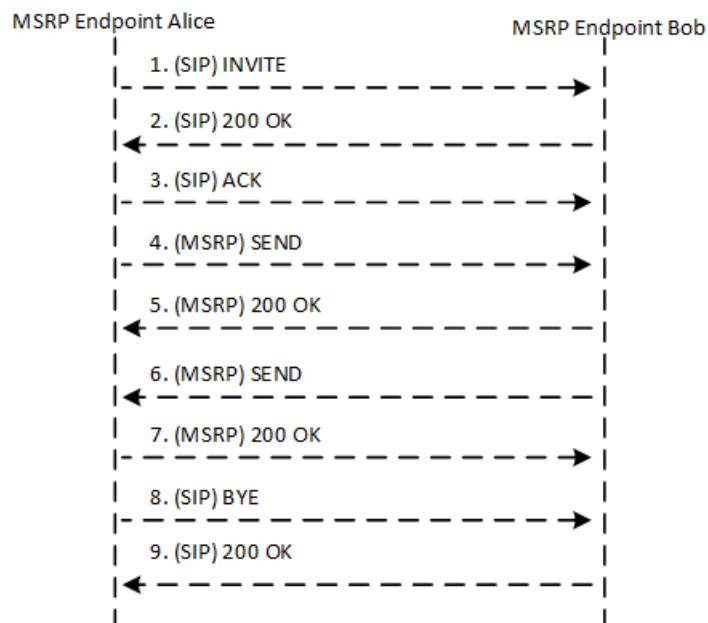

Content-Type: text/plain

Hey Bob, are you there?  
-----a786hjs2\$

The MSRP payload or content (i.e., the actual message) follows the Content-Type header. Finally, the SEND request is closed with an end-line of seven hyphens, the Transaction ID, and one of the following symbols:

- **\$**: The request contains the final part of the message (end).
- **+**: The request doesn't contain the final part of the message (\$), but is only part of a series of messages.
- **#**: The sender is aborting an incomplete message and intends to send no further chunks in that message (message should be discarded).

An example of a basic MSRP flow is shown below:

- When the device operates in HA mode, MSRP sessions are terminated during an HA switchover. MSRP endpoints are expected to re-initiate failed sessions.
- MSRP is not supported with other media types (i.e., voice) in the same SDP session.
- MSRP is supported on IPv4 and IPv6 networks.
- The Call Admission Control (CAC) mechanism handles MSRP sessions as regular media sessions (i.e., they are not calculated and monitored separately from regular media calls).
- CDRs generated by the device for MSRP calls include the value "msrp" in the Media List CDR field.

The following procedure provides the basic steps for configuring MSRP.

➤ **To configure MSRP:**

1. Enable MSRP functionality:

- a. Open the Media Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Settings**).
- b. Select the 'Enable MSRP' check box:

Enable MSRP

- c. Click **Apply**, and then restart the device with a burn-to-flash for your settings to take effect.
2. Configure the MSRP endpoint's IP Profile:
- a. Open the IP Profiles table (see [Configuring IP Profiles](#) on page 674).
  - b. Configure the following (in addition to other IP Profile settings):
    - ◆ From the 'SBC Media Security Mode' drop-down list, select the transport protocol for the outgoing leg - **Secured** or **Both** for MSRPS (example below); **Not Secured** for MSRP.

SBC Media Security Mode

Secured

- ◆ From the 'MSRP Offer Setup Role' drop-down list, select the MSRP role mode in SDP negotiations ('a=setup' line). The device's role is according to the response: If 'a=setup passive', it's the "active" role; if 'a=setup active', it's the "passive" role. If no 'a=setup' in the response, it's the "active" role.

MSRP Offer Setup Role

ActPass

- ◆ In the 'Data DiffServ' field, configure the DiffServ value of MSRP traffic ('m=message').

Data DiffServ

5

- ◆ From the 'MSRP re-INVITE/UPDATE' drop-down list, select if the destination MSRP endpoint supports the receipt of re-INVITE requests and UPDATE messages.

MSRP re-INVITE/UPDATE

Supported

- ◆ From the 'MSRP Empty Message Format' drop-down list, select if the device must add a Content-Type header to empty MSRP messages that are used to initiate the connection.

**MSRP Empty Message Format**

With Content Type

- ◆ If you want to implement alternative routing if the MSRP endpoints don't establish an MSRP connection within a specific timeout (configured by the 'Timeout to Establish MSRP Connection' global parameter) or if the MSRP socket is closed after the call was established, then from the 'Broken Connection Mode' drop-down list, select **Reroute** or **Reroute with Original SIP Headers**:

**Broken Connection Mode**

Reroute

For more information on the Broken Connection feature, see the description of the 'Broken Connection Mode' parameter in [Configuring IP Profiles](#) on page 674.

- c. Click **Apply**.
3. Configure the SIP Interface for the MSRP endpoint:
- a. Open the SIP Interfaces table (see [Configuring SIP Interfaces](#) on page 570).
  - b. In the 'MSRP TCP Port' field and 'MSRP TLS Port' field, configure a single TCP and/or TLS port number, respectively. The port number is used in the SDP's 'a=path' line.

MSRP TCP Port

4000

MSRP TLS Port

4060

- c. Click **Apply**.

- For secured MSRP (MSRPS), the TLS Context assigned to the SIP Interface ('TLS Context Name' field) is used.
- The IP Interface assigned to the SIP Interface is used for the MSRP sessions.

4. Configure the timeout for establishing the MSRP connection through the MSRP port. If the timeout expires and the connection has yet to be established, the device ends the SIP session.
- a. Open the Media Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Settings**).
  - b. In the 'Timeout to Establish MSRP Connection' field, enter the timeout:

**Timeout to Establish MSRP Connection**

1009

- c. Click **Apply**.

5. For NAT traversal of MSRP sessions when the device is located behind NAT, use the NAT Translation table (see [Configuring NAT per IP Interface](#) on page 181). The target IP address:port (public) is used in the SDP's 'a=path' line.

## Emergency Call Routing using LDAP to Obtain ELIN

The device can route emergency calls (e.g., 911) for INVITE messages that are received without an ELIN number. This is in contrast to when the device is deployed in a Microsoft Teams / Skype for Business environment, whereby the received INVITE messages contain ELIN numbers. For a detailed explanation on ELIN numbers and handling of emergency calls by emergency server providers, see [E9-1-1 Support for Microsoft Teams and Skype for Business](#) on page 498.

To obtain an ELIN number for emergency calls received without ELINs, you can configure the device to query an LDAP server for the 911 caller's ELIN number. The device adds the resultant ELIN number and a Content-Type header for the PIDF XML message body to the outgoing INVITE message, for example:

```
Content-Type: application/pidf+xml
<ELIN>1234567890</ELIN>
```

### ➤ To enable emergency call routing using LDAP to obtain ELIN:

1. Configure a Call Setup rule in the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809). The following example shows a Call Setup rule that queries an Active Directory (AD) server for the attribute "telephoneNumber" whose value is the E9-1-1 caller's number (source), and then retrieves the user's ELIN number from the attribute "numberELIN":

The screenshot shows the 'Call Setup Rules' configuration window for a rule named 'ELIN from LDAP'. The window is divided into two main sections: 'GENERAL' and 'ACTION'.

**GENERAL Section:**

- Index:** 1
- Name:** ELIN from LDAP
- Rules Set ID:** 1
- Request Type:** LDAP
- Request Target:** (empty)
- Request Key:** telephoneNumber=Param.Call.Src.User
- Attributes To Get:** numberELIN
- Row Role:** Use Current Condition
- Condition:** LDAP.Attr.numberELIN exists

**ACTION Section:**

- Action Subject:** Body:application/pidf+xml
- Action Type:** Add
- Action Value:** <ELIN>{ldap.attr.numberELIN}</ELIN>

2. Enable the E9-1-1 feature, by configuring the 'PSAP Mode' parameter to **PSAP Server** in the IP Groups table for the IP Group of the PSAP server (see [Enabling the E9-1-1 Feature](#) on page 510).
3. Configure routing rules in the IP-to-IP Routing table for routing between the emergency callers' IP Group and the PSAP server's IP Group. The only special configuration required for the routing rule from emergency callers to the PSAP server:
  - Configure the emergency number (e.g., 911) in the 'Destination Username Pattern' field.

- Assign the Call Setup rule that you configured for obtaining the ELIN number from the AD (see Step 1) in the 'Call Setup Rules Set ID' field (see [Configuring SBC IP-to-IP Routing Rule for E9-1-1](#) on page 512).

## Configuring Dual Registration for SIP Entity

Some SIP entities (e.g., IP Phones) are setup to register with two registrar/proxy servers (primary and secondary). The reason for this is to provide call redundancy for the SIP entity in case one of the proxy servers fail. When the SIP entity registers with the proxy servers, it sends two identical REGISTER messages - one to the primary proxy and one to the secondary proxy. When the device is located between the SIP entity and the two proxy servers, it needs to differentiate between these two REGISTER messages even though they are identical. This is crucial to ensure that the device forwards the two registrations to the proxy servers and that the device performs correct call routing between the SIP entity and the two proxy servers.

To differentiate between these REGISTER messages, a unique SIP Interface needs to be used for each REGISTER message. Each REGISTER message is registered in the registration database using a unique "ac-int=<value>" string identifying the SIP Interface for the Contact user. In addition, for SIP requests (e.g., INVITE) from the proxy servers, the device needs to search its registration database for the contact user so that it can forward it to the user. In normal registration, the host part of the Request-URI contains the IP address of the device and therefore, there is no way of knowing which registered user the INVITE is intended for. To overcome this issue, you can configure the device to use a special string with a unique value, "ac-feu=<value>" for each registration, allowing the device to differentiate between two registrations from the same user (identical REGISTER requests). Each REGISTER message is registered in the registration database using the unique "ac-feu=" string identifier for the Contact user.

A summary of how the device registers the two REGISTER messages in its registration database is as follows:

1. The addresses of the proxy servers that are configured on the SIP entity (IP Phone) must be the device's IP address with a different SIP local port for each one, for example:
  - Primary Proxy Server: 172.17.0.1:5060
  - Secondary Proxy Server: 172.17.0.1:5080
2. When the device receives two identical REGISTER messages from the SIP entity, it differentiates them by the SIP port on which they are received. The port allows the device to associate them with a SIP Interface (5060 for "Interface-1" and 5080 for "Interface-2").
3. The device performs SIP message manipulation (Pre-classification Manipulation) on the REGISTER messages to add a special parameter ("ac-int=<value>") to the Contact header to identify the SIP Interface on which each message is received. For example:
  - REGISTER for Primary Proxy received on SIP Interface "Interface-1":

**REGISTER**

To: &lt;sip:100@example.com&gt;

Contact: &lt;sip:100@172.17.100.20;ac-int=1&gt;

- REGISTER for Secondary Proxy received on SIP Interface "Interface-2":

**REGISTER**

To: &lt;sip:100@example.com&gt;

Contact: &lt;sip:100@172.17.100.20;ac-int=2&gt;

4. The device adds to the Contact header a special string with a unique value, "ac-feu=<value>" for each registration (e.g., "Contact: <sip:100@172.17.100.20;ac-int=1;ac-feu=x>").
5. The device saves the two contacts (100@172.17.100.20;ac-int=1;ac-feu=x and 100@172.17.100.20;ac-int=2;ac-feu=y) under the **same AOR** (100@example.com) in its user registration database.

The SIP call flow for dual registration is shown below:

The basic SIP call flow for INVITEs to and from the registered user is shown below:

➤ **To configure support for dual registration:**

1. On the SIP entity (IP Phone), configure the primary and secondary proxy server addresses as the IP address of the device and where each address has a different SIP port number.
2. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**), and then from the 'Keep Original User in Register' drop-down list, select **Keep user; add unique identifier as URI parameter**.
3. In the Message Manipulations table, configure the following rules:
  - Index 0:
    - ◆ Manipulation Set ID: **1**
    - ◆ Action Subject: **header.contact.url.ac-int**
    - ◆ Action Type: **Modify**
    - ◆ Action Value: **'1'**
  - Index 1:
    - ◆ Manipulation Set ID: **2**
    - ◆ Action Subject: **header.contact.url.ac-int**
    - ◆ Action Type: **Modify**
    - ◆ Action Value: **'2'**
4. In the SIP Interfaces table, configure the following SIP Interfaces:
  - Index 0 (SIP Interface for IP Phone A):
    - ◆ Name: **Interface-1**
    - ◆ UDP Port: **5060**
    - ◆ Pre-classification Manipulation Set ID: **1**
  - Index 1 (SIP Interface for IP Phone B):
    - ◆ Name: **Interface-2**
    - ◆ UDP Port: **5080**

- ◆ Pre-classification Manipulation Set ID: **2**
5. In the Proxy Sets table, configure a Proxy Set for each proxy server (primary and secondary):
- Index 0:
    - ◆ Proxy Name: **Primary**
    - ◆ SBC IPv4 SIP Interface: **Interface-1**
    - ◆ Proxy Address: **200.10.10.1**
  - Index 1:
    - ◆ Proxy Name: **Secondary**
    - ◆ SBC IPv4 SIP Interface: **Interface-2**
    - ◆ Proxy Address: **200.10.10.2**
6. In the IP Groups table, configure the following IP Groups:
- Index 0:
    - ◆ Type: **Server**
    - ◆ Name: **Primary-Proxy**
    - ◆ Proxy Set: **Primary**
    - ◆ Classify By Proxy Set: **Enable**
  - Index 1:
    - ◆ Type: **Server**
    - ◆ Name: **Sec-Proxy**
    - ◆ Proxy Set: **Secondary**
    - ◆ Classify By Proxy Set: **Enable**
  - Index 2:
    - ◆ Type: **User**
    - ◆ Name: **IP-Phone-A**
  - Index 3:
    - ◆ Type: **User**
    - ◆ Name: **IP-Phone-B**
7. In the Classification table, configure rules to classify calls from the IP Phones based on SIP Interface:
- Index 0:
    - ◆ Source SIP Interface: **Interface-1**

- ◆ Source IP Group: **IP-Phone-A**
- Index 1:
  - ◆ Source SIP Interface: **Interface-2**
  - ◆ Source IP Group: **IP-Phone-B**
- 8. In the IP-to-IP Routing table, configure the routing rules:
  - Index 0:
    - ◆ Source IP Group: **IP-Phone-A**
    - ◆ Destination IP Group: **Primary-Proxy**
  - Index 1:
    - ◆ Source IP Group: **Primary-Proxy**
    - ◆ Destination IP Group: **IP-Phone-A**
  - Index 2:
    - ◆ Source IP Group: **IP-Phone-B**
    - ◆ Destination IP Group: **Sec-Proxy**
  - Index 3:
    - ◆ Source IP Group: **Sec-Proxy**
    - ◆ Destination IP Group: **IP-Phone-B**

## Handling Registered AORs with Same Contact URIs

The device can handle registration and call routing in cases where user registration includes AORs with the same Contact header URIs, as shown in the example below. Such a scenario typically occurs when two SIP endpoints reside in separate private networks and both are assigned the same local IP address.

### ■ User 1 Registration:

```
REGISTER sip:300@10.33.4.140;user=phone SIP/2.0
```

```
Via: SIP/2.0/UDP 10.33.2.40;branch=OTGHREPCXDBIWECOCPIK
```

```
From: <sip:300@domain1;user=phone>;tag=ULYEYCGXHXMBPSOCXVWH
```

```
To: <sip:300@domain1;user=phone>
```

```
Call-ID: XDRXGAAWNVTBFHBMQCKE@10.33.2.38
```

```
CSeq: 1 REGISTER
```

```
Contact: <sip:300@10.33.2.40>
```

■ User 2 Registration:

```
REGISTER sip:300@10.33.4.140;user=phone SIP/2.0
```

```
Via: SIP/2.0/UDP 10.33.2.40;branch=YHDWUJRMMOEIJRXVYKHD
```

```
From: <sip:300@domain2;user=phone>;tag=CVYTCHLIVMPBCGNGRTUA
```

```
To: <sip:300@domain2;user=phone>
```

```
Call-ID: INRNGFCHFHE TRXAQNAIT@10.33.2.38
```

```
CSeq: 1 REGISTER
```

```
Contact: <sip:300@10.33.2.40>
```

For two such user registrations as shown in the example above, the device adds two AORs ("300@domain1" and "300@domain2") to its registration database, where each AOR is assigned the same Contact URI ("300@10.33.2.40"). To route a call to the correct user, the device needs to search the database for the full URI (user@host parts). To enable this support, perform the following configuration steps:

➤ **To enable handling of multiple AORs with identical Contact URIs:**

1. Open the Proxy & Registration page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Proxy & Registration**).
2. From the 'DB Routing Search Mode' drop-down list (SBCDBRoutingSearchMode), select **Dest URI dependant**, and then click **Apply**.

## Enabling Interworking of SIP and SIP-I Endpoints

The device can interwork between SIP and SIP-I endpoints for SBC calls. SIP-I endpoints are entities that are connected to the SS7 PSTN network, referred to as the ISDN User Part (ISUP) domain. The device supports the SIP-I Application-layer signaling protocol, which is the standard for encapsulating a complete copy of the SS7 ISUP message in SIP messages, according to ITU-T Q.1912.5, Interworking between Session Initiation Protocol (SIP) and Bearer

Independent Call Control protocol or ISDN User Part. In other words, SIP-I is SIP encapsulated with ISUP and the interworking is between SIP signaling and ISUP signaling. This allows you to deploy the device in a SIP environment where part of the call path involves the PSTN.

The SIP-I sends calls, originating from the SS7 network, to the SIP network by adding ISUP messaging in the SIP INVITE message body. The device can receive such a message from the SIP-I and remove the ISUP information before forwarding the call to the SIP endpoint. In the other direction, the device can receive a SIP INVITE message that has no ISUP information and before forwarding it to the SIP-I endpoint, create a SIP-I message by adding ISUP information in the SIP body. For SIP-I to SIP-I calls, the device can pass ISUP data transparently between the endpoints.

For the interworking process, the device maps between ISUP data (including cause codes) and SIP headers. For example, the E.164 number in the Request-URI of the outgoing SIP INVITE is mapped to the Called Party Number parameter of the IAM message, and the From header of the outgoing INVITE is mapped to the Calling Party Number parameter of the IAM message.

The ISUP data is included in SIP messages using the Multipurpose Internet Mail Extensions (MIME) body part, for example (some headers have been removed for simplicity):

```
INVITE sip:1774567@172.20.1.177;user=phone SIP/2.0
Via: SIP/2.0/UDP 172.20.73.230:5060;branch=z9hG4bK.il
```

...

```
Accept: application/sdp, application/isup, applicatio
Content-Type: multipart/mixed; boundary=unique-bounda
MIME-Version: 1.0
Content-Length: 350
```

...

```
Content-Type: application/isup; version=FTSSURI; base
Content-Disposition: signal; handling=required
01 00 40 01 0a 02 02 08 06 83 10 71 47 65 07 08
01 00 00
--unique-boundary-1--
```

```

D6 SIP-T ISUP/IAM (Initial address message)
(-- ) len:-- >> Nature of connection indicators
Oct 1 : ---0---- Echo ctrl = Half echo not included
----00-- Cont. check = Not required
-----00 Satellite = No circuit
(-- ) len:-- >> Forward call indicators
Oct 1 : 01----- ISUP pref. = Not req. all the way
--0----- ISUP indic. = Not used all the way
---0---- End-end inf = Not available
----0--- Interwork. = Not encountered
-----00- Method. ind = No method available
-----0 Call indic. = as National call
Oct 2 : -----00- SCCP method = No indication

```

ISUP data, received in the MIME body of the incoming SIP message is parsed according to the ISUP variant (SPIROU itu or ansi), indicated in the SIP Content-Type header. The device supports the following ISUP variants (configured by the 'ISUP Variant' parameter in the IP Profile table):

- French (France) specification, SPIROU (Système Pour l'Interconnexion des Réseaux OUverts), which regulates Telecommunication equipment that interconnect with networks in France. For SPIROU, the device sets the value of the SIP Content-Type header to "version=spirou; base=itu-t92+".
- ITU-92, where the device sets the value of the SIP Content-Type header to "version=itu-t92+; base=itu-t92+".

To configure interworking of SIP and SIP-I endpoints, using the IP Profile parameter 'ISUP Body Handling' (see [Configuring IP Profiles](#) on page 674).

You can manipulate ISUP data, by configuring manipulation rules for the SIP Content-Type and Content-Disposition header values, in the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856). For a complete description of the ISUP manipulation syntax, refer to the document *Syntax for SIP Message Manipulation Reference Guide*. In addition, you can use the AudioCodes proprietary SIP header X-AC-Action in Message Manipulation rules to support the various call actions (e.g., SIP-I SUS and RES messages) for the ISUP SPIROU variant. For more information, see [Using Proprietary SIP X-AC-Action Header](#) on page 1244.

## Configuring SBC MoH from External Media Source

The External Media Source table lets you configure an external media (audio) source (streamer). The device can play Music-on-Hold (MoH) audio originating from this external media source, to SBC call parties that are placed on hold. Implementing an external media source offers flexibility in the type of audio that you want played as MoH (e.g., radio, adverts, or music). If you are not using an external media source, the device plays its' local default hold tone or a hold tone from an installed PRT file (depending on your configuration).

When a user (A) initiates call on-hold (i.e., sends a re-INVITE with SDP 'a=sendonly' or 'a=inactive' to the device), the device sends a new re-INVITE with SDP 'a=sendonly' to place the user (B) on hold. Once the user (B) responds with a SIP 200 OK, the device forwards the RTP audio stream for MoH from the external media source to the held party. When the user (A) retrieves the call (i.e., sends a re-INVITE with SDP 'a=sendrecv') to the held user (B), which then responds with a 200 OK, the device disconnects the held party from the external media source.

- Only one external media source can be connected to the device.
- The device can play MoH from an external media source to a maximum of 20 concurrent call sessions (on-hold parties).
- If you have configured an external media source and connection between the media source and the device is established, and you then modify configuration in this table, the device disconnects from the media source and then reconnects with it.
- If the connection with the media source is lost for any reason other than reconfiguration (e.g., receives a SIP BYE from the media source or RTP broken connection occurs), the device waits three seconds before attempting to re-establish the session by sending a new INVITE to the media source. This is repeated until the media source is reconnected or you disable the feature.

The following procedure describes how to configure an external media source through the Web interface. You can also configure it through ini file [ExternalMediaSource] or CLI (`configure voip > sbc external-media-source`).

➤ **To configure an external media source:**

1. Open the External Media Source table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **External Media Source**).
2. Click **New**; the following dialog box appears:

3. Configure the external media source according to the parameters described in the table below.
4. Click **Apply**; the device sends a SIP INVITE to the external media source and when SDP negotiation (e.g., for the offered coder) is complete and the device receives a SIP 200 OK response, connection is established and audio is continuously sent by the external media source to the device.

You can refresh the connection between the device and the external media source (mainly needed if you have modified configuration). When you do this, the device disconnects from the external media source and then reconnects with a new session.

➤ **To refresh connectivity:**

- On the table's toolbar, from the **Action** drop-down list, choose **Re-establish**.

**Table 37-2: External Media Source Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row.
'IP Group' ip-group-name [IPGroupName]	Assigns an IP Group from the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591). This is the IP Group that represents the external audio streamer. <b>Note:</b> The parameter is mandatory.
'Source URI' src-uri [SourceURI]	Defines the source URI (user@host) of the SIP From header contained in the INVITE message that the device sends to the external media source. If you do not configure this parameter, the device sets the URI to the local IP address of the IP Interface on which the device sends the message.
'Destination URI' dst-uri [DestinationURI]	Defines the destination URI (user@host) of the SIP To header contained in the INVITE message that the device sends to the external media source. If you do not configure this parameter, the device sets the URI to the value of the IP Group's 'SIP Group Name' parameter.

Configuration of MoH from an external media source includes the following basic settings:

- Configuring an IP Profile (namely, the 'Extension Coders Group' parameter) and IP Group (namely, the 'IP Profile' parameter) for the media source
- Designating the media source IP Group as the external media source (in the External Media Source table, as described above)
- Configuring IP Profiles (namely, the 'Reliable Held Tone Source' and 'Play Held Tone' parameters) and IP Groups for the users

However, specific configuration may differ based on your implementation of this MoH feature. For example, you may implement this feature in one of the following architectures:

- A company with an on-site external media source for playing all MoH to branch users.

- A company with an on-site external media source that only plays MoH to branch users when connectivity with the remote media source is down

A configuration example of an on-site external media source that is always used to play MoH to its branch users is shown below and subsequently described.

1. Open the Coders Groups table (see [Configuring Coders Groups](#) on page 661), and then configure a Coders Group (e.g., AudioCodersGroups\_0) with the coder(s) to use for communication between the device and the media source.
2. Open the IP Profiles table (see [Configuring IP Profiles](#) on page 674), and then configure two IP Profiles:
  - External Media Source:
    - ◆ 'Extension Coders Group': Assign the Coders Group configured in Step 1 (above).
  - Branch Users:
    - ◆ 'Reliable Held Tone Source': **No**
    - ◆ 'Play Held Tone': **External**
3. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then configure two IP Groups:
  - External Media Source:
    - ◆ 'IP Profile': Assign the IP Profile configured for the external media source in Step 2 (above)
  - Branch Users:
    - ◆ 'IP Profile': Assign the IP Profile configured for the branch users in Step 2 (above)
4. Open the External Media Source table (see the beginning of this section), and then configure an External Media Source entity and associate it with the IP Group that you configured for the external media source in Step 3 (above).

## Configuring Background Tones for SBC Calls

You can configure the device to play a background tone (defined in the PRT file) to the call parties in an SBC call. The tone can be played to one or both of the call parties (caller and/or callee). When played to both parties, the tone is played simultaneously. The device can play the tone after call establishment or during early media.

For playing background tones, you need to configure a Message Manipulation rule (see [Configuring SIP Message Manipulation](#) on page 856) with the following special options:

- 'Action Subject' field: `Var.Call.Dst|Src.PlayBackgroundTone` - enables background tone on the configured side (Dst) or peer side (Src)
- 'Action Value' field: `<side>,<tone ID>,<time between play>`, where:
  - `<side>` defines the call party to which the device plays the tone – **both** (caller and callee) or **single** (only on side according to `Var.Call.Dst|Src.PlayBackgroundTone`).
  - `<tone ID>` defines the user-defined tone to play, by index in the PRT file (`acUserDefineTone<ID>`). For an explanation on the PRT file, see [Uploading a Prerecorded Tones File](#) on page 1357.
  - `<time between play>` defines the duration (1 to 600,000 msec) of no tone play between each play of tone. For example, you can use this option to play a beep every 3 seconds (periodically). Alternatively, if you want the device to play the tone continuously, don't configure this option.

For example:

- The value "both,5,3000" means that the device plays the `acUserDefineTone5` tone (in the PRT file) every 3000 msec to both caller and callee.
- The value "single,5" means that the device plays the `acUserDefineTone5` tone (in the PRT file) continuously to the configured party only.

- If you want the device to play the tone only once, make sure that when you're converting the recorded tone to a file (PRT) that's loadable to the device using the DConvert utility, that you configure the 'Default' field to a non-zero value:

- For devices in HA, the device resumes playing the tone after a switchover.
- This feature is applicable only to the SBC application.

## WebRTC

The device supports interworking of Web Real-Time Communication (WebRTC) and SIP-based VoIP communication. The device interworks WebRTC calls made from a Web browser (WebRTC client) and the SIP destination. The device provides the media interface to WebRTC.

WebRTC is a browser-based real-time communication protocol. WebRTC is an open source, client-side API definition (based on JavaScript) drafted by the World Wide Web Consortium (W3C) that supports browser-to-browser applications for voice calling (video chat, and P2P file sharing) without plugins. Currently, the device's WebRTC feature is supported only by Mozilla Firefox and Google Chrome Web browsers other browsers are still not fully compatible with WebRTC). Though the WebRTC standard has obvious implications for changing the nature of peer-to-peer communication, it is also an ideal solution for customer-care solutions to allow direct access to the contact center. An example of a WebRTC application is a click-to-call button on a consumer Web site (see following figure). After clicking the button, the customer can start a voice and/or video call with a customer service personnel directly from the browser without having to download any additional software plugins. The figure below displays an example of a click-to-call application from a customer Web page, where the client needs to enter credentials (username and password) before placing the call.

- The WebRTC feature is applicable only to the SBC application.
- The WebRTC feature is a license-based feature. For more information, see [Prerequisites for WebRTC](#) on page 1274.
- For maximum concurrent WebRTC sessions (signaling-over-secure WebSocket and media-over-DTLS), refer to the device's *Release Notes*, which can be downloaded from AudioCodes [website](#).

The WebRTC standard requires the following mandatory components, which are supported by the device:

- **Voice coders:** Narrowband G.711 and wideband Opus (Version 1.0.3, per RFC 6176).
- **Video coders:** VP8 video coder. The device transparently forwards the video stream, encoded with the VP8 coder, between the endpoints.
- **ICE (per RFCs 5389/5245):** Resolves NAT traversal problems, using STUN and TURN protocols to connect peers. For more information, see [Implementing ICE for Media Sessions](#) on page 186.
- **DTLS-SRTP (RFCs 5763/5764):** Media channels must be encrypted (secured) through Datagram Transport Layer Security (DTLS) for SRTP key exchange. For more information, see [SRTP using DTLS Protocol](#) on page 324.
- **SRTP (RFC 3711):** Secures media channels by SRTP.
- **RTP Multiplexing (RFC 5761):** Multiplexing RTP data packets and RTCP control packets onto a single port for each RTP session. For more information, see [Interworking RTP-RTCP Multiplexing](#) on page 1146.
- **Secure RTCP with Feedback (i.e., RTP/SAVPF format in the SDP - RFC 5124):** Combines secured voice (SRTP) with immediate feedback (RTCP) to improve session quality. The SRTP profile is called SAVPF and must be in the SDP offer/answer (e.g., "m=audio 11050 RTP/SAVPF 103"). For more information, see the IP Profile parameter 'RTCP Feedback' (see [Configuring IP Profiles](#) on page 674).

- **WebSocket:** WebSocket is a signaling (SIP messaging) transport protocol, providing full-duplex communication channels over a single TCP connection for Web browsers and clients. SIP messages are sent to the device over the WebSocket session. For more information, see [SIP over WebSocket](#) on the next page.

For more information on WebRTC, visit the [WebRTC website](#).

Below shows a summary of the WebRTC components and the device's interworking of these components between the WebRTC client and the SIP user agent:

The call flow process for interworking WebRTC with SIP endpoints by the device is illustrated below and subsequently described:

1. The WebRTC client uses a Web browser to visit the Web site page.
2. The Web page receives Web page elements and JavaScript code for WebRTC from the Web hosting server. The JavaScript code runs locally on the Web browser.
3. When the client clicks the Call button or call link, the browser runs the JavaScript code which sends the HTTP upgrade request for WebSocket in order to establish a WebSocket

session with the device. The address of the device is typically included in the JavaScript code.

4. A WebSocket session is established between the WebRTC client and the device in order for the WebRTC client to register with the device. This is done using a SIP REGISTER message sent over the WebSocket session (SIP over WebSocket). Registration can be initiated when the client enters credentials (username and password) on the Web page or it can be done automatically when the client initially browses to the page. This depends on the design of the Web application (JavaScript). On the WebRTC client, the WebSocket connection is established for registration when the Web page is loaded; for click-to-call applications, registration is not needed and the WebSocket connection is established when the button for calling is clicked.
5. Once registered with the device, the client can receive or make calls, depending on the Web application.
6. To make a call, the client clicks the call button or link on the Web page.
7. Negotiation of a workable IP address between the WebRTC client and the device is done through ICE.
8. Negotiation of SRTP keys using DTLS is done between WebRTC and the client on the media.
9. Media flows between the WebRTC client and the SIP client located behind the device.

## SIP over WebSocket

The device supports the transmission of SIP signaling over WebSocket. WebSocket is a protocol providing real-time, full-duplex (two-way) communication over a single TCP connection (socket) between a Web browser or page (client) and a remote host (server). This is used for browser-based applications such as click-to-call from a Web page. As WebSocket has been defined by the WebRTC standard as mandatory, its support by the device is important for deployments implementing WebRTC.

If you use WebSocket tunneling, the IP address **169.254.0.1** must not be configured for any IP Interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).

A WebSocket connection starts as an HTTP connection between the Web client and the server, guaranteeing full backward compatibility with the pre-WebSocket world. The protocol switch from HTTP to WebSocket is referred to as the WebSocket handshake, which is done over the same underlying TCP/IP connection. A WebSocket connection is established using a handshake between the Web browser (WebSocket client) and the server (i.e., the device). The browser sends a request to the server, indicating that it wants to switch protocols from HTTP to WebSocket. The client expresses its' desire through the Upgrade header (i.e., upgrade from HTTP to WebSocket protocol) in an HTTP GET request, for example:

```
GET /chat HTTP/1.1
Upgrade: websocket
```

```

Connection: Upgrade
Host: <IP address:port of SBC device>
Sec-WebSocket-Protocol: SIP
Sec-WebSocket-Key: dGhllHNhbXBsZSBub25jZQ==
Origin: <server that provided JavaScript code to browser, e.g., http://domain.com>
Sec-WebSocket-Version: 13

```

If the server understands the WebSocket protocol, it agrees to the protocol switch through the Upgrade header in an HTTP 101 response, for example:

```

HTTP/1.1 101 Switching Protocols
Upgrade: WebSocket
Connection: Upgrade
Sec-WebSocket-Accept: rLHCkw/SKsO9GAH/ZSFhBATDKrU=
Sec-WebSocket-Protocol: SIP
Server: SBC

```

At this stage, the HTTP connection breaks down and is replaced by a WebSocket connection over the same underlying TCP/IP connection. By default, the WebSocket connection uses the same ports as HTTP (80) and HTTPS (443).

Once a WebSocket connection is established, the SIP messages are sent over the WebSocket session. The device, as a "WebSocket gateway" or server can interwork WebSocket browser originated traffic to SIP over UDP, TCP or TLS, as illustrated below:

The SIP messages over WebSocket are indicated by the "ws" value, as shown in the example below of a SIP REGISTER request received from a client:

```

REGISTER sip:10.132.10.144 SIP/2.0
Via: SIP/2.0/WS v6iqlt8lne5c.invalid;branch=z9hG4bK7785666
Max-Forwards: 69
To: <sip:101@10.132.10.144>
From: "joe" <sip:101@10.132.10.144>;tag=ub50pqjgpr
Call-ID: fhddgc3kc3hhu32h01fghl
CSeq: 81 REGISTER
Contact: <sip:0bfr9fd5@v6iqlt8lne5c.invalid;transport=ws>;reg-

```

```
id=1;+sip.instance="<urn:uuid:4405bbe2-cf06-4c27-9c59-6caf83af9b00>";expires=600
Allow: ACK,CANCEL,BYE,OPTIONS,INVITE,MESSAGE
Supported: path, outbound, gruu
User-Agent: JsSIP 0.3.7
Content-Length: 0
```

To keep a WebSocket session alive, it is sometimes necessary to send regular messages to indicate that the channel is still being used. Some servers, browsers or proxies may close an idle connection. Ping-Pong WebSocket messages are designed to send non-application level traffic that prevents the channel from being prematurely closed. You can configure how often the device pings the WebSocket client, using the [WebSocketProtocolKeepAlivePeriod] parameter (see [Configuring WebRTC](#) below). The device always replies to ping control messages with a pong message. The WebSocket protocol supports keep-alive using special frames, however it is used only on the server side; for the Web client, a special ping (CRLF) request is used which the device answers.

In this way the client can detect connection failures

When the device operates in High-Availability (HA) mode, if a WebSocket connection has been established and a switchover subsequently occurs, the WebSocket session is not copied to the redundant device. As Chrome doesn't renew the WebSocket connection with the device, WebRTC calls remain open indefinitely; the Chrome side will stop the call, but the device will keep all of the call's resources open and the other side will have an active call with no voice. To prevent this, for the IP Profile associated with the WebRTC clients, configure the 'Broken Connection Mode' parameter to **Disconnect**.

## Prerequisites for WebRTC

Before you can configure the device for WebRTC, make sure that the device's installed License Key (see [Viewing the License Key](#) on page 1362) includes the following licenses:

- "WebRTC Sessions" (under the VoIP Capacity group) - defines the maximum number of WebRTC sessions
- "Media Encryption" (under the Security Features group) - enables media security (SRTP)

- Without these licenses, the device rejects WebRTC calls.
- For ordering these licenses, contact your AudioCodes sales representative.

## Configuring WebRTC

To support WebRTC, you need to perform special configuration settings for the device's SBC leg interfacing with the WebRTC client (i.e., Web browser).

For the WebRTC deployment environment, you need to install a signed certificate by a Certificate Authority (CA) on you Web server machine (hosting the WebRTC JavaScript) and on your AudioCodes SBC device (i.e., WebSocket server).

- The WebRTC feature is applicable only to the SBC application.
- Google announced a security policy change that impacts new versions of the Chrome Web browser. Any Web site that has integrated WebRTC, geolocation technology, screen-sharing and more, now requires to be served from a secure (HTTPS) site, including WebRTC-based WebSocket servers (WSS instead of WS). The configuration described below accommodates for this basic requirement.
- If you configure WebRTC (which implements WebSocket tunneling), the IP address **169.254.0.1** must not be configured for any IP Interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
- WebRTC JavaScript configuration is beyond the scope of this document.
- The device's WebRTC feature (*WebRTC Gateway*) can also operate with mobile device users that are registered to the device's WebRTC service, allowing them to make and receive WebRTC calls between registered users. For this support, you can use AudioCodes WebRTC client Software Development Kit (SDK) and Application Program Interface (API) to integrate the WebRTC functionality into the mobile applications (iOS and Android). For more information, refer to the following documents:
  - ✓ *WebRTC iOS Client SDK API Reference Guide*
  - ✓ *WebRTC Android Client SDK API Reference Guide*
- For integrating the device's WebRTC functionality into client Web browsers for making calls from their Web browsers through the device, you can use AudioCodes WebRTC client Software Development Kit (SDK) and Application Program Interface (API). For more information, refer to the document *WebRTC Web Browser Client SDK API Reference Guide*.
- You can implement the device's WebRTC widget, which can be embedded in websites and blogs without any previous knowledge of JavaScript. The widget creates a click-to-call button on your website. It can make calls to any user that is registered with the device. For more information, see the [WebRTC Click-to-Call Widget Installation and Configuration Guide](#).
- You can also implement voice quality (MOS) measurement and reporting by the device per registered WebRTC client (user). This also includes configuring actions to take (reject calls or use an alternative IP Profile with a more efficient voice coder) when MOS measurements are low. For more information, see [Configuring Voice Quality for Registered Users](#) on page 544.
- To implement MOS reporting triggered by the WebRTC client, see [Reporting MOS Triggered by WebRTC Client](#) on page 1279.

#### ➤ To configure WebRTC:

1. Configure a TLS Context (certification):
  - a. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
  - b. Add a new TLS Context (e.g., "WebRTC") or edit an existing one, and then configure the 'DTLS Version' parameter to the desired DTLS version.

- c. Create a certificate signing request (CSR) to request a digitally signed certificate from a Certification Authority (CA).
- d. Send the CSR to the CA for signing.
- e. When you have received the signed certificate, install it on the device as the "Device Certificate" and install the CA's root certificate into the device's trusted root store ("Trusted Certificates").

For more information on CSR, see [Assigning CSR-based Certificates to TLS Contexts](#) on page 234.

2. Configure the keep-alive interval with the WebSocket client:

- a. On the Transport Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Transport Settings**), and then in the 'WebSocket Keep-Alive Period' field (WebSocketProtocolKeepAlivePeriod), enter the keep-alive interval:

**WebSocket Keep-Alive Period [sec]**

- b. Click **Apply**.

3. Configure a SIP Interface for the WebRTC clients that identifies WebSocket traffic:

- a. Open the SIP Interfaces table (see [Configuring SIP Interfaces](#) on page 570).
- b. Do the following:
  - ◆ From the 'Encapsulating Protocol' drop-down list, select **WebSocket**.
  - ◆ In the 'TLS Port' field, configure the TLS port.
  - ◆ From the 'TLS Context Name' drop-down list, assign the TLS Context that you configured in Step 1 (e.g., "WebRTC").

The screenshot shows the 'SIP Interfaces' configuration window. At the top, there is a dropdown for 'SRD' set to '#0 [DefaultSRD]'. Below this, the configuration is divided into two main sections: 'GENERAL' and 'MEDIA'. The 'GENERAL' section includes fields for 'Index' (1), 'Name' (WebRTC clients), 'Topology Location' (Down), 'Network Interface' (#0 [O+M+C]), 'Application Type' (SBC), 'UDP Port' (0), 'TCP Port' (0), 'TLS Port' (10081), 'Encapsulating Protocol' (WebSocket), and 'Enable TCP Keepalive' (Disable). The 'MEDIA' section includes 'Media Realm' (--) and 'Direct Media' (Disable). Below these is a 'SECURITY' section with 'TLS Context Name' (#1 [WebRTC]), 'TLS Mutual Authentication' (empty), 'Message Policy' (--), 'User Security Mode' (Not Configured), 'Enable Un-Authenticated Registrations' (Not configured), and 'Max. Number of Registered Users' (-1). Each dropdown menu has a 'View' link next to it.

c. Click **Apply**.

4. Configure an IP Profile for the WebRTC clients:

a. Open the IP Profiles table (see [Configuring IP Profiles](#) on page 674).

b. Do the following:

- ◆ From the 'SBC Media Security Mode' drop-down list, select **Secured**:

SBC Media Security Mode Secured ▼

- ◆ From the 'SBC Media Security Method' drop-down list, select **DTLS** to secure and encrypt media traffic through DTLS for SRTP key exchange:

SBC Media Security Method DTLS ▼

- ◆ From the 'ICE Mode' drop-down list, select **Lite** or **Full** to enable ICE:

ICE Mode Lite ▼

- ◆ From the 'RTCP Mux' drop-down list, select **Supported** to enable RTCP multiplexing:

RTCP Mux Supported ▼

- ◆ From the 'RTCP Feedback' drop-down list, select **Feedback On** to enable RTCP feedback:

RTCP Feedback Feedback On ▼

- ◆ From the 'Re-number MID' drop-down list, select **Enable** to enable the device to change the value of the 'a=mid:n' attribute (where *n* is a unique value) in the outgoing SDP offer (if the attribute is present) so that in the first media ('m=' line) the value will be 0, the next media the value will be 1, and so on.

Re-number MID Enable ▼

If the peer side also uses the 'mid' attribute in RTP extensions (e.g., a=extmap:3 urn:ietf:params:rtp-hdrext:sdes:mid), you also need to enable the 'Re-number MID' parameter for the IP Profile of the peer side.

- ◆ In the 'RFC 2833 DTMF Payload Type' parameter, enter payload type "126":

RFC 2833 DTMF Payload Type

126

- ◆ From the 'RTCP Mode' drop-down list, select **Transparent**:

RTCP Mode

Transparent

- c. Click **Apply**.

## 5. Configure an IP Group for the WebRTC clients:

- Open the IP Groups table (see [Configuring IP Groups](#) on page 591).
- Do the following:
  - ◆ From the 'Type' drop-down list, select **User**.
  - ◆ From the 'IP Profile' drop-down list, select the IP Profile that you configured for the WebRTC clients in Step 3 (e.g., "WebRTC").
  - ◆ From the 'Media TLS Context' drop-down list, select the TLS Context that you configured in Step 1. For more information on DTLS, see [SRTP using DTLS Protocol](#) on page 324.

SRD #0 [DefaultSRD]

GENERAL		QUALITY OF EXPERIENCE	
Index	1	QoE Profile	-- View
Name	WebRTC clients	Bandwidth Profile	-- View
Topology Location	Down		
Type	User		
Proxy Set	-- View		
IP Profile	#2 [WebRTC] View		
		MESSAGE MANIPULATION	
		Inbound Message Manipulation Set	-1
		Outbound Message Manipulation Set	-1

## 6. Configure IP-to-IP routing rules to route calls between the WebRTC clients and the enterprise:

- Open the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186).
- Configure routing rules for the following call scenarios:
  - ◆ Call routing from WebRTC clients (IP Group configured in Step 4) to the enterprise.

- ◆ Call routing from the enterprise to the WebRTC clients (IP Group configured in Step 4).
- 7. Enable the device to include all previously negotiated media lines ('m=') in the SDP offer-answer exchanges for the WebRTC session:
  - a. Open the Media Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Settings**).
  - b. Under the **SBC Settings** group, select the 'Enforce Media Order' check box (SBCEnforceMediaOrder):
 

  - c. Click **Apply**.
- 8. To implement voice quality (MOS) measurement and reporting per registered WebRTC client (user), see [Configuring Voice Quality for Registered Users](#) on page 544.

## Reporting MOS Triggered by WebRTC Client

You can configure the device to test voice quality (MOS) with WebRTC clients.

The test is typically triggered when the WebRTC client accesses the web page on which the WebRTC click-to-call widget button is displayed. If the device reports low MOS, you can, for example, have the click-to-call button deactivated (grayed out) so that the client can't use it to call.

Implementation of this feature requires configuration on the WebRTC platform by the Web Developer using AudioCodesWebRTC web browser client SDK API, and configuration on the device:

- **AudioCodes WebRTC Web Browser Client SDK API:** The Developer needs to configure the WebRTC platform so that when the client opens the web page, the web browser automatically sends the device a SIP INVITE message containing the following:
  - Proprietary SIP header, 'X-AC-Action: test-voice-quality'. The device identifies this feature by the receipt of this header.
  - 'duration=' parameter in the Request-URI. This parameter specifies the duration of the test call (see [Using SIP INVITE to Specify Test Call Duration](#) on page 1684).
- **Device:** You need to configure the device to route the incoming SIP INVITE message (containing the previously mentioned header and parameter) to its embedded Test Call endpoint. Once the call is established, the device plays a pre-recorded tone (PRT) to the client during the entire duration of the call. When the duration expires, the device terminates the call and sends a SIP BYE message containing the proprietary SIP header, 'X-VoiceQuality'. This header indicates the measured MOS (value and color), for example, 'X-VoiceQuality: 42 green'. If, for whatever reason, there is no MOS measurement, the device sends 'X-VoiceQuality: N/A gray'.

The following procedure describes how to configure this feature. It uses example configuration entity names and assumes that you have already configured the device with the usual WebRTC settings, as described in [Configuring WebRTC](#) on page 1274.

The device can calculate MOS based on RTCP or RTCP-XR packets. As WebRTC clients typically don't send RTCP-XR reports, the device measures MOS for these clients based on RTCP.

➤ **To configure the test and report MOS to WebRTC clients feature:**

1. Open the SIP Interfaces table (see [Configuring SIP Interfaces](#) on page 570), and then configure a SIP Interface for the device itself ("outgoing" loopback leg and Test Call endpoint listening interface):
  - 'Name': **SBC-SIPInterface**
  - 'Network Interface': <local network interface>
  - 'Application Type': **SBC**
  - 'UDP Port': <local port>
2. Open the Proxy Sets table (see [Configuring Proxy Sets](#) on page 632), and then configure a Proxy Set for the device itself ("outgoing" loopback leg and Test Call endpoint):
  - 'Name': **SBC-Proxy**
  - 'SBC IPv4 SIP Interface': **SBC-SIPInterface**
  - 'Proxy Address': <IP address of device: same port as "SBC-SIP-Interface">
3. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then configure an IP Group for the device itself (i.e., "outgoing" loopback leg):
  - 'Name': **SBC-Outgoing**
  - 'Type': **Server**
  - 'Proxy Set': **SBC-Proxy**
  - 'Classify By Proxy Set': **Disable**
4. Open the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), and then configure a routing rule that routes WebRTC calls to the device itself:
  - 'Source IP Group': <normal IP Group configured for WebRTC clients>
  - 'Request Type': **INVITE**
  - 'Source Username Pattern': <special prefix determined by WebRTC SDK developer, e.g., "webrtcetestcall">
  - 'Destination Type': **IP Group**
  - 'Destination IP Group': **SBC-Outgoing**

5. Open the Test Call Rules table (see [Configuring Test Call Endpoints](#) on page 1672), and then configure a Test Call endpoint for the WebRTC call:
  - 'Endpoint URI': <same URI as in SIP INVITE received from WebRTC client>
  - 'Route By': **Dest Address**
  - 'Destination Address': <IP address of device>
  - 'SIP Interface': **SBC-SIPInterface**
  - 'Application Type': **SBC**
  - 'Call Party': **Called**
  - 'Play': **PRT**
  - 'Play Tone Index': <index in installed PRT file>

## Call Forking

This section describes various Call Forking features supported by the device.

### Initiating SIP Call Forking

The SBC device supports call forking of an incoming call to multiple SBC users (destinations). Call forking is supported by the device's capability of registering multiple SIP client user phone contacts (mobile and fixed-line extensions) under the same Address of Record (AOR) in its registration database. This feature can be implemented in the following example scenarios:

- An enterprise Help Desk, where incoming customer calls are simultaneously sent to multiple customer service agent extensions.
- An employee's phone devices, where the incoming call is simultaneously sent to multiple devices (e.g., to the employee's office phone and mobile SIP phone).
- An enterprise reception desk, where an incoming call is simultaneously sent to multiple receptionists.

The device supports various modes of call forking. For example, in Parallel call forking mode, the device sends the INVITE message simultaneously to all the users registered under the same AOR, resulting in the ringing of all extensions; the first extension to pick up the call receives the call, and all other extensions stop ringing. The Call Forking feature is configured by creating a User-type IP Group and configuring the IP Groups table's parameter, 'SBC Client Forking Mode' (see [Configuring IP Groups](#) on page 591).

The device can also fork INVITE messages received for a Request-URI of a specific contact (user), belonging to the destination IP Group User-type, registered in the database to all other users located under the same AOR as the specific contact. This is configured by the [SBCSendInviteToAllContacts] parameter.

## Configuring SIP Forking Initiated by SIP Proxy

The device can handle the receipt of multiple SIP 18x responses as a result of SIP forking initiated by a proxy server. This occurs when the device forwards an INVITE, received from a user agent (UA), to a proxy server and the proxy server then forks the INVITE request to multiple UAs. Several UAs may answer and the device may therefore, receive several replies (responses) for the single INVITE request. Each response has a different 'tag' value in the SIP To header.

During call setup, forked SIP responses may result in a single SDP offer with two or more SDP answers. The device "hides" all the forked responses from the INVITE-initiating UA, except the first received response ("active" UA) and it forwards only subsequent requests and responses from this active UA to the INVITE-initiating UA. All requests/responses from the other UAs are handled by the device; SDP offers from these UAs are answered with an "inactive" media.

The device supports two forking modes:

- **Latch On First:** The device forwards only the first received 18x response to the INVITE-initiating UA and disregards subsequently received 18x forking responses (with or without SDP).
- **Sequential:** The device forwards all 18x responses to the INVITE-initiating UA, sequentially (one after another). If 18x arrives with an offer only, only the first offer is forwarded to the INVITE-initiating UA.

### ➤ To configure the call forking mode:

1. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
2. From the 'Forking Handling Mode' [SBCForkingHandlingMode] drop-down list, select the required mode:

Forking Handling Mode Latch On First ▼

3. Click **Apply**.

The device also supports media synchronization for call forking. If the active UA is the first one to send the final response (e.g., 200 OK), the call is established and all other final responses are acknowledged and a BYE is sent if needed. If another UA sends the first final response, it is possible that the SDP answer that was forwarded to the INVITE-initiating UA is irrelevant and thus, media synchronization is needed between the two UAs. Media synchronization is done by sending a re-INVITE request immediately after the call is established. The re-INVITE is sent without an SDP offer to the INVITE-initiating UA. This causes the INVITE-initiating UA to send an offer which the device forwards to the UA that confirmed the call. Media synchronization is enabled by the EnableSBCMediaSync parameter.

## Configuring Call Forking-based IP-to-IP Routing Rules

You can configure call forking routing rules in the IP-to-IP Routing table. This is done by configuring multiple routing rules under a forking group. These rules send an incoming IP call to multiple destinations of any type (e.g., IP Group or IP address). The device forks the call by sending simultaneous INVITE messages to all the specified destinations. It handles the multiple SIP dialogs until one of the calls is answered and then terminates the other SIP dialogs. For more information, see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186.

## Call Survivability

This section describes various call survivability features supported by the SBC device.

### Enabling Auto-Provisioning of Subscriber-Specific Information of BroadWorks Server for Survivability

This feature enables SBC user registration for interoperability with BroadSoft BroadWorks server to provide call survivability in case of connectivity failure with the BroadWorks server, for example, due to a WAN failure. The feature enables local users to dial a local extension (or any other configured alias) that identifies another local user, in survivability mode.

In normal operation, when subscribers (such as IP phones) register with the BroadWorks server through the device, the device includes the SIP Allow-Events header in the sent REGISTER message. In response, the BroadWorks server sends the device a SIP 200 OK containing an XML body with subscriber information such as extension number, phone number, and URIs (aliases), as shown in the example below:

```
<?xml version="1.0" encoding="utf-8"?>
<BroadsoftDocument version="1.0" content="subscriberData">
  <phoneNumbers>
    <phoneNumber>2403645317</phoneNumber>
    <phoneNumber>4482541321</phoneNumber>
  </phoneNumbers>
  <aliases>
    <alias>sip:bob@broadsoft.com</alias>
    <alias>sip:rhughes@broadsoft.com</alias>
  </aliases>
  <extensions>
    <extension>5317</extension>
    <extension>1321</extension>
  </extensions>
</BroadsoftDocument>
```

The device forwards the 200 OK to the subscriber (without the XML body). The call flow is shown below:

The device saves the users in its registration database with their phone numbers and extensions, enabling future routing to these destinations during survivability mode when communication with the BroadWorks server is lost. When in survivability mode, the device routes the call to the Contact associated with the dialed phone number or extension number in the registration database.

➤ **To enable BroadWorks survivability:**

1. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
2. Select the 'BroadWorks Survivability Feature' check box (SBCExtensionsProvisioningMode):

BroadWorks Survivability Feature ☒

3. Click **Apply**.

## Configuring BroadSoft's Shared Phone Line Call Appearance for Survivability

The device can provide redundancy for BroadSoft's Shared Call Appearance feature. When the BroadSoft application server switch (AS) fails or doesn't respond, or when there is no network connection between the device and the BroadSoft AS, the device manages the Shared Call Appearance feature for the SIP clients.

The feature is supported by configuring a primary extension and associating it with secondary extensions (i.e., *shared lines*) so that incoming calls to the primary extension also ring at the secondary extensions. The call is established with the first extension to answer the call and consequently, the ringing at the other extensions stop. For example, assume primary extension number 600 is shared with secondary extensions 601 and 602. In the case of an incoming call to 600, all three phone extensions ring simultaneously, using the device's call forking feature as described in [Configuring SIP Forking Initiated by SIP Proxy](#) on page 1282. Note that incoming calls specific to extensions 601 or 602 ring only at these specific extensions.

To configure this capability, you need to configure a shared-line, inbound manipulation rule for registration requests to change the destination number of the secondary extension numbers (e.g. 601 and 602) to the primary extension (e.g., 600). Call forking must also be enabled. The following procedure describes the main configuration required.

- The device enables outgoing calls from all equipment that share the same line simultaneously (usually only one simultaneous call is allowed per a specific shared line).
- You can configure whether REGISTER messages from secondary lines are terminated on the device or forwarded transparently (as is), using the `SBCSharedLineRegMode` parameter.
- The LED indicator of a shared line may display the wrong current state.

➤ **To configure BroadSoft's Shared Line feature:**

1. In the IP Groups table (see [Configuring IP Groups](#) on page 591), add a Server-type IP Group for the BroadWorks server.
2. In the IP Groups table, add a User-type IP Group for the IP phone users and set the 'SBC Client Forking Mode' parameter to **Parallel** so that the device forks incoming calls to all contacts under the same AOR registered in the device's registration database.
3. In the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), add a rule for routing calls between the above configured IP Groups.
4. In the Inbound Manipulations table (see [Configuring IP-to-IP Inbound Manipulations](#) on page 1231), add a manipulation rule for the secondary extensions (e.g., 601 and 602) so that they also register to the device's database under the primary extension contact (e.g., 600):
  - 'Manipulation Purpose': **Shared Line**
  - Match:
    - ◆ 'Request Type': **REGISTER**
    - ◆ 'Source IP Group': IP Group that you created for the users (e.g., 2)
    - ◆ 'Source Username Pattern': Represents the secondary extensions, e.g., 601 and 602
  - Action:
    - ◆ 'Manipulated URI': **Source** (manipulates the source URI)
    - ◆ 'Remove From Right': 1 (removes the last digit of the extensions, e.g., 601 is changed to 60)
    - ◆ 'Suffix to Add': 0 (adds 0 to the end of the manipulated number, e.g., 60 is changed to 600)

## Configuring Call Survivability for Call Centers

The device supports call survivability for call centers. When a communication failure (e.g., in the network) occurs with the remote voice application server responsible for handling the call center application (such as IVR), the device routes the incoming calls received from the customer (i.e., from the TDM gateway) to the call center agents.

In normal operation, the device registers the agents in its users registration database. Calls received from the TDM gateway are forwarded by the device to the application server, which processes the calls and sends them to specific call center agents, through the device. Upon a failure with the application server, the device routes the calls from the TDM Gateway to the agents. The device routes the call to the first available user it finds. If the call is not answered by the user, the device routes it to the next available user. The SBC can handle a sequence of up to five users, after which the session is timed out and the call is dropped.

### ➤ To configure call survivability for a call center application:

1. In the IP Groups table (see [Configuring IP Groups](#) on page 591), add IP Groups for the following entities:
  - TDM Gateway (Server-type IP Group). This entity forwards the customer calls through the device to the Application server.

- Application server (Server-type IP Group). This entity processes the call and sends the call through the device to the specific call center agent located on a different network (remote).
  - Call center agents (User-type IP Group). You can configure multiple IP Groups to represent different groups of call center agents, for example, agents and managers.
2. In the Classification table (see [Configuring Classification Rules](#) on page 1171), add rules to classify incoming calls that are received from the entities listed in Step 1, to IP Groups.
  3. In the SBC IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), add the following IP-to-IP routing rules:
    - For normal operation:
      - ◆ Routing from TDM Gateway to Application server.
      - ◆ Routing from Application server to call center agents.
    - For call survivability mode: Routing from TDM Gateway to call center agents. This configuration is unique due to the following settings:
      - ◆ The 'Source IP Group' field is set to the IP Group of the TDM Gateway.
      - ◆ The 'Destination Type' field is set to **Hunt Group**, which is specifically used for call center survivability.
      - ◆ The 'Destination IP Group' field is set to the IP Group of the call center agents.

The figure below displays a routing rule example, assuming IP Group #1 represents the TDM Gateway and IP Group #3 represents the call center agents:

The screenshot shows the 'IP-to-IP Routing' configuration window with two main sections: GENERAL and ACTION.

**GENERAL Section:**

- Index:** 3
- Name:** TDM GW > Call Center
- Alternative Route Options:** Route Row
- MATCH Section:**
  - Source IP Group:** #1 [TDM Gateway] (View)
  - Request Type:** All
  - Source Username Prefix:** \*
  - Source Host:** \*

- Group Policy:** None
- Cost Group:** -- (View)

## Enabling Survivability Display on Aastra IP Phones

If the SBC device is deployed in a network with Aastra IP phones and connectivity with the WAN fails, the device provides call survivability by enabling communication between IP phone users within the LAN enterprise. In such a scenario, the device can be configured to notify the IP phones that it is currently operating in Survivability mode. When this occurs, the Aastra IP phones display the message, "Stand Alone Mode" on their LCD screens.

If you enable the feature and the device is in Survivability mode, it responds to SIP REGISTER messages from the IP phones with a SIP 200 OK containing the following XML body:

```
Content-Type: application/xml
<?xml version="1.0" encoding="utf-8"?>
<LMIDocument version="1.0">
  <LocalModeStatus>
    <LocalModeActive>true</LocalModeActive>
    <LocalModeDisplay>StandAlone Mode</LocalModeDisplay>
  </LocalModeStatus>
</LMIDocument>
```

### ➤ To enable survivability display on Aastra phones:

1. Upload an ini file to the device that includes the following parameter setting:

```
SBCEnableSurvivabilityNotice = 1
```

## Alternative Routing upon Detection of Failed SIP Response

The device can detect failure of a sent SIP response (e.g., TCP timeout, and UDP ICMP). In such a scenario, the device re-sends the response to an alternative destination. This support is in addition to alternative routing if the device detects failed SIP requests.

For example, assume the device sends a SIP 200 OK in response to a received INVITE request. If the device doesn't receive a SIP ACK in response to this, it sends a new 200 OK to the next alternative destination. This new destination can be the next given IP address resolved from a DNS from the Contact or Record-Route header in the request related to the response.

## Configuring Push Notification Service

The device supports the Push Notification Service per IETF draft "[Push Notification with the Session Initiation Protocol \(SIP\)](#)". This service is used to wake end-user equipment (typically, mobile platforms) and operating systems that have gone to "sleep" (to save resources such as battery life) so that they can receive traffic. Typically, each operating system uses a dedicated Push Notification Service. For example, Apple iOS devices use the Apple Push Notification service (APNs) while Android devices use the Firebase Cloud Messaging (FCM) service. Without

using a Push Notification Service to wake SIP User Agents (UAs), UAs wouldn't be able to send binding-refresh SIP REGISTER requests, receive SIP requests (e.g., INVITE), or send periodic keep-alive messages for maintaining connectivity with SIP servers. The device communicates with third-party, HTTP-based Push Notification Servers over HTTP, using RESTful APIs for exchanging information (currently, only JSON format is supported).

The Push Notification Service feature is applicable only to the SBC application.

SIP users wanting to receive push notifications must specify the following parameters in the Contact header of the SIP REGISTER request that it sends to the device for registration:

- 'pn-provider': Specifies the type of Push Notification Service.
- 'pn-prid': Specifies the unique identifier (Push Resource ID / PRID) that the Push Notification Service uses to identify the user.
- 'pn-param': (Optional) Specifies additional implementation-specific data required by the Push Notification Service.

Below shows an example of a REGISTER message containing the Push Notification parameters (in bold):

```
REGISTER sip:alice@example.com SIP/2.0
Via: SIP/2.0/TCP alicemobile.example.com:5060;branch=z9hG4bKnashds7
Max-Forwards: 70
To: Alice <sip:alice@example.com>
From: Alice <sip:alice@example.com>;tag=456248
Call-ID: 843817637684230@998sdasdh09
CSeq: 1826 REGISTER
Contact: <sip:alice@alicemobile.example.com;
pn-provider=acme;
pn-param=acme-param;
pn-prid=ZTY4ZDJIMzODE1NmUgKi0K>
Expires: 7200
Content-Length: 0
```

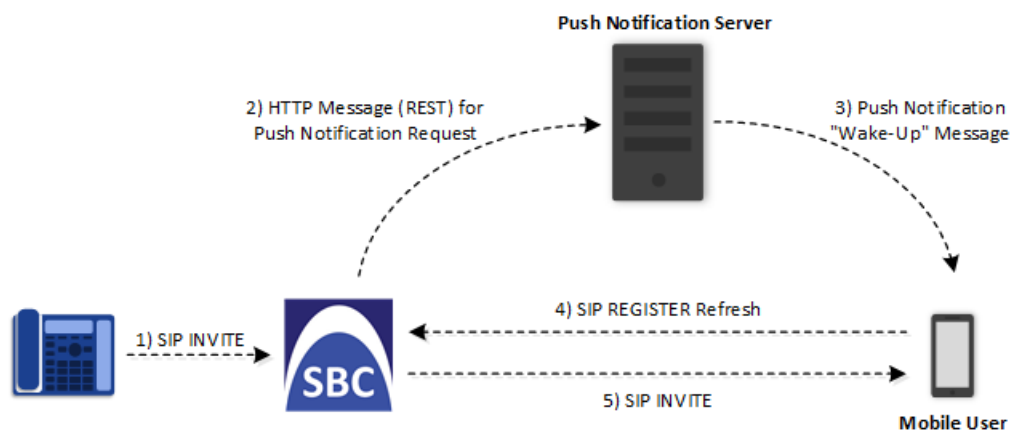

The device handles registrations from users requiring Push Notification Service, as follows:

1. The user sends a REGISTER request to the device that contains the Push Notification parameters in the Contact header, as mentioned previously.
2. The device searches its Push Notification Servers table for a row whose 'Provider' parameter has the \* wildcard character value, or the same value as the 'pn-provider' parameter in the REGISTER request.
3. Regardless of the search, the device adds the user in its registration database with the Push Notification parameters (mentioned previously).
4. If a matching row in the Push Notification Servers table is located, the device sends a SIP 200 OK response containing the Feature-Caps header with the 'sip.pns=' feature-capability indicator, identifying the type of Push Notification Service as specified in the 'pn-provider' parameter (e.g., Feature-Caps: \*;+sip.pns="acme";+sip.pnsreg="121"). If no matching row in the table is located (i.e., Push Notification Service is not supported), the device sends a 200 OK response, but without the Feature-Caps header.
5. (6 and 7) At a user-defined time (using the [PNSReminderPeriod] parameter) before the user's registration expires, the device sends a push notification request containing the user's PRID to the Push Notification Server to trigger it into sending a push notification to the user to remind it to send a refresh REGISTER message to the device.

If the user sends the device a refresh REGISTER request without the Push Notification parameters, the device considers the user as no longer using Push Notification Service. In this scenario, the device stops sending push notification requests to the Push Notification Server for the user.

Once a user is registered with the device, the device can route calls to it. The following figure shows how the device processes an incoming dialog-initiating SIP request (e.g., INVITE) whose destination is a mobile user that uses Push Notification Service:

6. The device receives an incoming call (SIP INVITE message) for the mobile user, which according to the device's registration database (i.e., user's registration includes Push Notification parameters), uses a Push Notification Service.
7. The device sends a push notification request containing the user's PRID (over HTTP) to the Push Notification Server. The device uses the Push Notification Servers table to determine which Push Notification Server to send this push notification request. The device searches the table for a row that is configured with the value of the user's 'pn-provider' parameter (table's 'Provider' parameter) and if located, sends the push notification request to the address of the associated Remote Web Service.
8. The Push Notification Server sends a push notification to the user to "wake" it up.
9. The user sends a refresh SIP REGISTER message to the device, which indicates that the user is "awake" and ready to receive the call.
10. The device sends the INVITE message to the user, using its regular routing logic.

- If the push notification request that is sent to the Push Notification Server fails, the device rejects the INVITE message with a SIP 480 response.
- If the device doesn't receive a refresh REGISTER message within a user-defined time (configured by the [PNSRegisterTimeout] parameter), the device rejects the INVITE with a SIP 480 response.
- When the device receives an incoming INVITE message for a user who is registered for push notification, but the corresponding row in the Push Notification Servers table has been deleted, the device immediately forwards the INVITE message to the user (as though the user had not requested push notification service).

#### ➤ To configure Push Notification Service:

1. Configure a Remote Web Service (see [Configuring Remote Web Services](#) on page 438) to represent the HTTP-based Push Notification Server (address and other required parameters). You must configure the Remote Web Service with the 'Type' parameter set to **General**.

2. Configure the Push Notification service in the Push Notification Servers table (see [Configuring Push Notification Servers](#) on page 853). This table configures the Push Notification Service type, the Remote Web Service that you configured in Step 1, and the information-exchange protocol (currently, only JSON) used between the device and the server. Therefore, the device uses this table to determine which Push Notification Server to send push notification requests for a specific user. The device searches the table for a row that is configured with the value of the user's 'pn-provider' parameter (table's 'Provider' parameter) and if located, sends the push notification request to the Push Notification Server using the address of the associated Remote Web Service.
3. Configure the time (in seconds) before the user's registration on the device expires, when the device sends a push notification request (over HTTP) to the Push Notification Server to trigger it into sending a push notification to the user to remind it to send a refresh REGISTER message to the device. This is configured by the [PNSReminderPeriod] parameter or CLI command `configure voip > sbc settings > pns-reminder-period`.
4. Configure the time (in seconds) that the device must wait for a refresh REGISTER message from the user after the device sends a push notification request to the Push Notification Server for the user, when the device receives an incoming SIP dialog-initiating request (e.g., INVITE) that it must send to the user. This is configured by the [PNSRegisterTimeout] parameter or CLI command `configure voip > sbc settings > pns-register-timeout`.

## VoIPerfect

The device's VoIPerfect™ feature combines Access and Enterprise SBC technology to ensure high speech (call) quality (MOS) between the Enterprise SBC and the Access SBC (located at the Internet service provider / ISP) during periods of adverse WAN network conditions (such as packet loss and bandwidth reduction). VoIPerfect adapts itself to current network conditions. Before adverse WAN network conditions can affect the quality of the call, VoIPerfect employs sophisticated technology using the Opus coder or G.729 (explained later in this section) to ensure that high call quality is maintained.

VoIPerfect guarantees that 95% of your calls will achieve a Perceptual Evaluation of Speech Quality (PESQ) score greater than or equal to 3.6 if the summation of bandwidth overuse and packet loss is less than or equal to 25%. However, for VoIPerfect with G.729 (Managed G.729, discussed later) operating in an MPLS environment, this PESQ score is achieved if bandwidth overuse is less than or equal to 50%. ISPs can therefore offer service level agreements (SLAs) to their customers based on the VoIPerfect feature. For more information, contact the sales representative of your purchased device. In addition, by ensuring high call quality even in adverse network conditions, VoIPerfect may reduce costs for ISPs such as SIP trunk providers and Unified Communications as a Service (UCaaS) by eliminating the need for dedicated WAN links (such as MPLS and leased links) and instead, allow the use of standard broadband Internet connections. However, it can also be used in tandem with existing infrastructure.

VoIPerfect uses Temporary Maximal Media Stream Bit Rate (TMMBR) negotiation capabilities for Opus coders. Through TMMBR, VoIPerfect can receive indications of network quality and dynamically change the coder's payload bit rate accordingly during the call to improve voice quality. TMMBR is an RTCP feedback message (per RFC 4585) which enables SIP users to exchange information regarding the current bit rate of the media stream. The information can be used by the receiving side to change the media stream parameters (e.g., coder rate or coder) to enhance voice quality. TMMBR is negotiated in the SDP Offer/Answer model using the 'tmb' attribute and following syntax:

```
a=rtcp-fb:<payload type> ccm tmmbr smaxpr=<sent TMMBR packets>
```

VoIPerfect also supports the SDP attribute 'a=rtcp-rsize', which reduces the RTCP message size (RFC 5506). As feedback messages are frequent and take a lot of bandwidth, the attribute attempts to reduce the RTCP size. The attribute can only be used in media sessions defined with the AVPF profile and must also be included in sessions supporting TMMBR; otherwise, the call is rejected.

VoIPerfect supports two modes of operation, where the Access SBC can be configured to support both modes and each Enterprise SBC serviced by the Access SBC can be configured to support one of the modes:

- **Managed Opus or Managed G.729:** If the SBC detects WAN network impairments during a call using the Opus or G.729 coder between the Enterprise SBC and Access SBC, it can adjust the coder's attributes (e.g., bit rate) for that specific call to ensure high voice quality is maintained. The advantage of these coders is that their bit rate can change dynamically according to bandwidth availability. This mode is useful for unstable networks, allowing the coders to dynamically adapt to adverse network conditions.

For Managed Opus, the Enterprise SBC performs transcoding from G.711 (used between Enterprise phones and SBC) to Opus (used between Enterprise and Access SBCs). For Managed G.729, the G.729 coder is used by all the involved entities and therefore, transcoding is not needed. For Managed G.729 operating in an MPLS environment, voice quality can also be maintained, as mentioned previously.

**Figure 37-1: VoIPerfect Managed Opus**

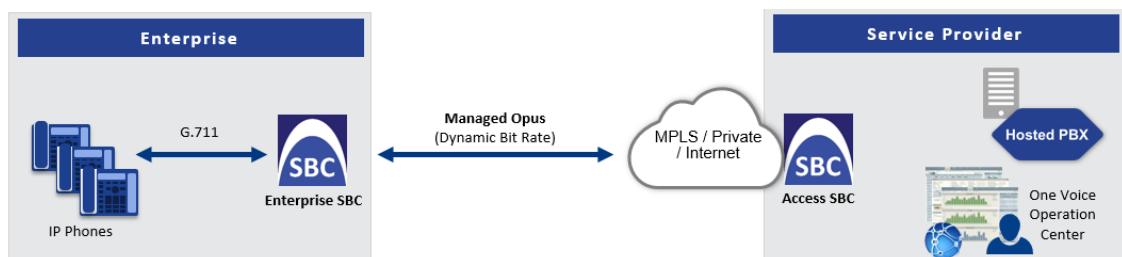

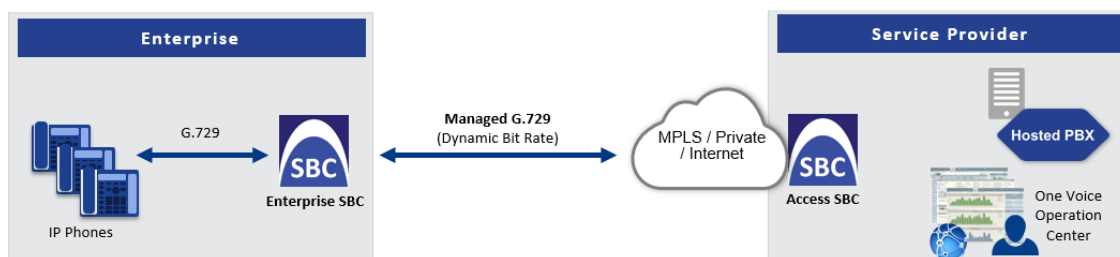

Figure 37-2: VolPerfect Managed G.729

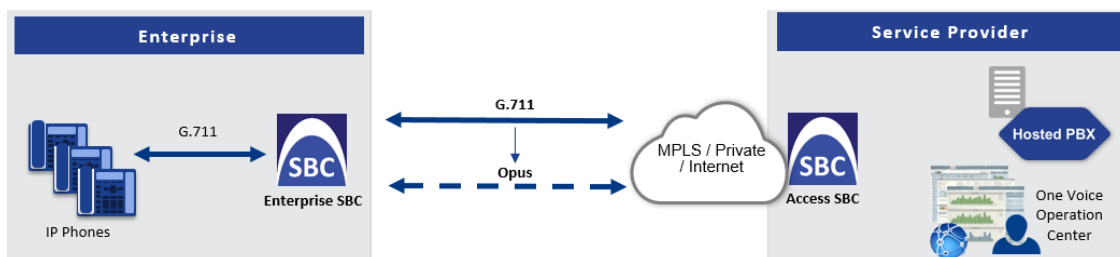

Configuration of the Enterprise SBC:

- Coders Groups table (see [Configuring Coders Groups](#) on page 661): Coder Group with Opus or G.729 (depending on Managed coder)
- Allowed Audio Coders Groups table (see [Configuring Allowed Audio Coder Groups](#) on page 669): Allowed Audio Coder Group with Opus or G.729 (depending on Managed coder)
- IP Profiles table (see [Configuring IP Profiles](#) on page 674):
  - ◆ (Managed Opus Only) 'Extension Coders Group': Select the Coders Group for Opus
  - ◆ 'Allowed Audio Coders': Select the Allowed Audio Coders Group with Opus or G.729 (depending on Managed coder)
  - ◆ 'Allowed Coders Mode': **Restriction**
  - ◆ 'Voice Quality Enhancement': **Enable**
  - ◆ 'RTCP Feedback': **Feedback On**
  - ◆ (Managed Opus Only) 'Max Opus Bandwidth': 0
  - ◆ (Managed G.729 Only) 'Jitter Compensation': **Enable**
  - ◆ (Managed G.729 Only) 'RTCP Mode': **Generate Always**
  - ◆ (Managed G.729 Only) 'Dynamic Jitter Buffer Minimum Delay': 40
  - ◆ (Managed G.729 Only) 'Jitter Buffer Max Delay': 500
- (Managed G.729 Only) MPLSMode (ini file parameter): 0 if no MPLS; 1 if operating in an MPLS environment

- **Smart Transcoding:** If the SBC (Enterprise or Access SBC) detects WAN network impairments during a call between the Enterprise SBC and Access SBC, the SBC employs voice transcoding by switching the coder from G.711 to Opus for that specific call only. Transcoding is done only on the path between the Enterprise SBC and Access SBC. As Smart Transcoding is applied only on a per call basis, it preserves valuable DSP resources that may be required for other functionalities. An advantage of using the Opus coder is that it consumes less bandwidth than G.711 and overcomes packet loss (by dynamic packet redundancy), allowing the SBC to support more concurrent calls than with G.711 for the same bandwidth. This mode is useful for WAN networks that are relatively stable, allowing

the use of G.711 whenever possible and switching to Opus only during adverse network conditions.

Configuration of the Enterprise SBC:

- Device's License Key includes the SBC transcoding feature
- Coders Groups table:
  - ◆ Coders Group with G.711
  - ◆ Coders Group with Opus
- Allowed Audio Coders Groups table:
  - ◆ Allowed Audio Coders Group with G.711
  - ◆ Allowed Audio Coders Group with Opus
- IP Profiles table - main IP Profile:
  - ◆ 'Extension Coders Group': Select the Coders Group with G.711
  - ◆ 'Allowed Audio Coders': Select the Allowed Audio Coders Group with G.711
  - ◆ 'Allowed Coders Mode': **Restriction**
  - ◆ 'RTCP Feedback': **Feedback On**
  - ◆ 'Voice Quality Enhancement': **Enable**
- IP Profiles table - alternative IP Profile:
  - ◆ 'Extension Coders Group': Select the Coders Group with Opus
  - ◆ 'Allowed Audio Coders': Select the Allowed Audio Coders Group with Opus
  - ◆ 'Allowed Coders Mode': **Restriction**
  - ◆ 'RTP Redundancy Mode': **Enable**
  - ◆ 'RTCP Feedback': **Feedback On**
  - ◆ 'Voice Quality Enhancement': **Enable**
  - ◆ 'Max Opus Bandwidth': 80000
- Quality of Service Rules table (see [Configuring Quality of Service Rules](#) on page 540):
  - ◆ 'Rule Metric': **Poor InVoice Quality**
  - ◆ 'Alternative IP Profile Name': name of Alternative IP Profile (above)

Configuration of the Access SBC for both Smart Transcoding and Managed Opus is listed below. (For Managed G.729, configuration is the same as the Enterprise SBC.)

■ Coders Groups table:

- Coders Group with G.711 and Opus
- Coders Group with Opus

■ Allowed Audio Coders Group table: Allowed Audio Coders Group with Opus

■ IP Profiles table - main IP Profile:

- 'Extension Coders Group': Select the Coders Group with G.711 and Opus
- 'Voice Quality Enhancement': **Enable**
- 'RTP Redundancy Mode': **Enable**
- 'RTCP Feedback': **Feedback On**
- 'Max Opus Bandwidth': 0

■ IP Profiles table - alternative IP Profile:

- 'Extension Coders Group': Select the Coders Group with Opus
- 'Allowed Audio Coders': Select the Allowed Audio Coders Group with Opus
- 'Allowed Coders Mode': **Restriction**
- 'Voice Quality Enhancement': **Enable**
- 'RTP Redundancy Mode': **Enable**
- 'RTCP Feedback': **Feedback On**
- 'Max Opus Bandwidth': 0

■ Quality of Service Rules table (see [Configuring Quality of Service Rules](#) on page 540):

- 'Rule Metric': **Poor InVoice Quality**
- 'Alternative IP Profile Name': name of Alternative IP Profile (above)

- VoIPerfect is applicable only to G.711 and G.729 calls.
- If you are deploying a third-party device between the Enterprise SBC and Access SBC, make sure that the third-party device adheres to the following:
  - ✓ Enable RFC 2198 in SDP negotiation
  - ✓ Enable TMMBR in SDP negotiation
  - ✓ Forward the SDP with feedback (SAVPF) as is
  - ✓ Forward TMMBR messages as is
  - ✓ Forward RTCP messages as is (not terminate them)
  - ✓ (Smart Transcoding only) Forward re-INVITE messages for using Opus as is
  - ✓ (Smart Transcoding only) Forward the SIP header, X-Ac-Action as is

## Configuring Maximum SBC Call Duration

You can configure the maximum allowed call duration (in minutes) for SBC calls. If an established call reaches this user-defined limit, the device ends the call. The feature ensures that calls are properly terminated, allowing available resources for new calls.

The following procedure describes how to configure the feature for all SBC calls (globally).

### ➤ To configure maximum call duration:

1. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
2. In the 'Max Call Duration' field [SBCMaxCallDuration], enter the maximum call duration for an SBC call:

Max Call Duration [min]

3. Click **Apply**.

Instead of configuring a global maximum call duration for all SBC calls as described in this section, you can configure maximum call duration for specific calls, using any of the following configuration methods:

- Using the IP Profile parameter 'Max Call Duration' (see [Configuring IP Profiles](#) on page 674). This parameter overrides the global parameter.
- Using Message Manipulation rules with call variables `Var.Call.Dst.MaxDuration` or `Var.Call.Src.MaxDuration`. You then need to assign the Manipulation Set ID of the rule(s) to the desired IP Group, using the 'Inbound Message Manipulation Set' or 'Outbound Message Manipulation Set' parameters. This call duration overrides all other parameters that configure maximum call duration. For more information on this call variable, refer to the *SIP Message Manipulation Syntax Reference Guide*, by clicking [here](#).

## Configuring Maximum Concurrent Calls per Specific User

You can configure a different maximum concurrent call limit (incoming or outgoing) for each user. This is done using tags in Call Setup Rules and Dial Plans, which are assigned to the relevant SIP Interface, IP Group, or IP-to-IP Routing rule.

This feature uses the device's hardcoded tag called `cac`. This tag has the format *key/value*, where *key* identifies the call (SIP URL user-part or IP address) and *value* defines maximum concurrent call. For example, '`cac=+12345678|3`' (or '`cac=10.4.4.4|3`') limits the user (or IP address) with phone number +12345678 (or IP address 10.4.4.4) to a maximum of three concurrent calls.

The following procedure describes how to configure maximum concurrent incoming calls for each specific users.

➤ **To configure maximum concurrent calls for each user:**

1. Configure a Dial Plan with multiple rules, where each rule defines a user by prefix number, and the maximum concurrent calls value by any user-defined tag. For example:
  - 'Name': MyMaxCall
  - 'Prefix': +123
  - 'Tag': cacMax=3
2. Configure a Call Setup Rule to check the existence and value of your Dial Plan tag. For example:
  - 'Condition': SrcTags.cacMax exists And SrcTags.cac !exists
  - 'Action Subject': SrcTags.cac
  - 'Action Type': Modify
  - 'Action Value': Header.From.URL.User + '|' + SrcTags.cacMax
3. Assign the Dial Plan and Call Setup Rule to the relevant SIP Interface, IP Group, or IP-to-IP Routing rule.

If you want all users to have the **same** maximum concurrent calls, you only need to use a Call Setup Rule. For example, the below applies a maximum concurrent incoming call value of 3 to every user (defined by SIP user-part or IP address):

- 'Action Subject': SrcTags.cac
- 'Action Type': Modify
- 'Action Value': (one of following)
  - Per IP address: Param.Message.Address.Src.IP + '|3'
  - Per user: Header.From.Url.User + '|3'

To view a list of 'cac' keys with their current concurrent calls out of their maximum allowed concurrent calls, use the following CLI command:

```
show voip tags-cac
```

To view the above output for a specific user, use the following command:

```
show voip tags-cac key <SIP user part or IP Address>
```

If the maximum number of concurrent calls is reached, the device rejects new calls and sends the following syslog message:

- For incoming calls: "RELEASE\_BECAUSE\_IN\_PER\_KEY\_CAC\_LIMIT\_REACHED"
- for outgoing calls: "RELEASE\_BECAUSE\_OUT\_PER\_KEY\_CAC\_LIMIT\_REACHED"

- This section is applicable only to the SBC application.
- You can also configure maximum concurrent calls using the following configuration entities, but different limits per user can't be configured:
  - ✓ Call Admission Control Profiles (configured in the Call Admission Control Profile table see [Configuring Call Admission Control](#) on page 1164) - applies the same limit to all users associated with the specific Call Admission Control Profile.
  - ✓ IP Profiles (see the 'Number of Calls Limit' parameter in [Configuring IP Profiles](#) on page 674) - applies the same limit to the entire IP Group to which the IP Profile is assigned.

## Playing Tone upon Call Connect

You can configure the device to play a specific tone (recorded audio message / announcement) from a loaded PRT file upon call connection (after SIP 200 OK). The tone can be played to both called and calling parties. When the device finishes playing the tone, the call is connected and the call parties can begin talking.

This feature is configured using a Message Manipulation rule that contains the variable `var.call.src|dst.PlayToneOnConnect`, which specifies the recorded tone to play from the PRT file. The rule is then assigned to the call party (IP Group) to which you want the device to play the tone.

If the device fails to play the tone for whatever reason (for example, the PRT file is not loaded or the specified tone index doesn't exist in the file), you can configure the device to connect or disconnect the call.

This section is applicable only to the SBC application.

### ➤ To configure play of tone upon call connect:

1. Record your tone (.wav file) and convert it to a loadable PRT file, using AudioCodes DConvert utility (see [Call Progress Tones File](#) on page 1351). The tone must be defined in DConvert as an **acUserDefineTone**<Index> tone type (e.g., **acUserDefineTone50**).
2. Upload the PRT file to the device (see [Uploading Auxiliary Files](#) on page 1347).
3. In the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856), configure a rule to specify the tone (index) you recorded in Step 1 and the call party (source or destination) you want it played to. Below is an example for configuring the device to play the tone to call source and destination:
  - 'Index': 0 (plays to called party)
    - ◆ 'Manipulation Set ID': 1
    - ◆ 'Message Type': **invite.request**
    - ◆ 'Condition': **Header.From contains '100'**

- ◆ 'Action Subject': **var.call.dst.PlayToneOnConnect**
- ◆ 'Action Type': **Add**
- ◆ 'Action Value': **'50'**
- 'Index': 1 (plays to calling party)
  - ◆ 'Manipulation Set ID': **1**
  - ◆ 'Message Type': **invite.request**
  - ◆ 'Condition': **Header.From contains '100'**
  - ◆ 'Action Subject': **var.call.src.PlayToneOnConnect**
  - ◆ 'Action Type': **Add**
  - ◆ 'Action Value': **'50'**
- 4. In the IP Groups table, assign the Manipulation Set ID that you configured in Step 3 to the relevant IP Group (see [Configuring IP Groups](#) on page 591).
- 5. Configure what the device should do if it can't play the tone:
  - a. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
  - b. From the 'Play Tone on Connect Failure Behavior' drop-down list, select one of the following:
    - ◆ **Disconnect** - disconnects the call
    - ◆ **Ignore** - connects the call

Play Tone on Connect Failure Behavior

Disconnect ▼

# Part VII

## High-Availability System

## 38 Overview of High Availability Mode

The device's High Availability (HA) feature provides 1+1 system redundancy using two devices. If failure occurs in the active device, a switchover occurs to the redundant device which takes over the call handling process. Thus the continuity of call services is ensured. All active calls (signaling and media) are maintained upon switchover.

- Only IP calls are maintained during a switchover; PSTN calls are dropped (by sending a SIP BYE message to the IP side). This is because only the active device is physically connected to the PSTN interfaces (e.g., E1/T1). For more information, see [Device Switchover upon Failure](#) on the next page.
- HA is supported only on Mediant 800 Gateway & E-SBC H/W Rev. B and C.

The figure below illustrates the Active-Redundant HA devices under normal operation. Communication between the two devices is through a Maintenance interface, having a unique IP address for each device. The devices have identical software and configuration including network interfaces (i.e., OAMP, Control, and Media), and have identical local-port cabling of these interfaces.

### Connectivity and Synchronization between Devices

In HA mode, the Ethernet connectivity between the two devices is through a special LAN interface on each device, referred to as the *Maintenance* interface. Each device has its own Maintenance interface with a unique address, and each device knows the Maintenance address of the other. The Maintenance interface can use a dedicated Ethernet port group or share the same Ethernet port group with the other network interface types (i.e., OAMP, Media, and Control).

When only one of the devices is operational it is in HA stand-alone state. This means that the device has no connectivity to the second device. When the second device is powered up, it recognizes the active device through the Maintenance network and acquires the HA redundant state. It then begins synchronizing for HA with the active device through the Maintenance network. During synchronization, the active device sends the redundant device its current configuration settings, including Auxiliary files. The active device also sends its software file (.cmp) if the redundant device is running a different software version. Once loaded to the redundant device, the redundant device reboots to apply the new configuration and/or

software. This ensures that the two units are synchronized regarding configuration and software.

Thus, under normal operation, one of the devices is in active state while the other is in redundant state, where both devices share the same configuration and software. Any subsequent configuration update or software upgrade on the active device is also done on the redundant device.

In the active device, all logical interfaces (i.e., Media, Control, OAMP, and Maintenance) are active. In the redundant device, only the Maintenance interface is active, which is used for connectivity to the active device. Therefore, management is done only through the active device. Upon a failure in the active device, the redundant device becomes active and activates all its logical interfaces exactly as was used on the active device.

- If the active device runs an earlier version (e.g., 7.0) than the redundant device (e.g., 7.2), the redundant device is downgraded to the same version as the active device (e.g., 7.0).
- You can delay the transition from HA non-operational state, which occurs during HA synchronization between the active and redundant device, to HA operational state. This is configured by the [HAOperationalStateDelayInSec] parameter. This may be useful, for example, to delay HA switchover when using switches with spanning tree protocol (STP) that take a long time until their ports (to which the redundant device is connected) is ready.

## Device Switchover upon Failure

When a failure occurs in the active device, a switchover occurs to the redundant device making it the new active device. Whether a switchover is later done back to the repaired failed device, depends on whether you have enabled the Preempt mode:

- **Enabled:** The Preempt mode specifies one of the device's as the "preferred" device. This is done by assigning different priority levels (1 to 10, where 1 is the lowest) to the two devices. Typically, you would configure the active device with a higher priority level (number) than the redundant device. The only factor that influences the configuration is which device has the greater number; the actual number is not important. For example, configuring the active with 5 and redundant with 4, or active with 9 and redundant with 2 both assign highest priority to the active device. Whenever the device with higher priority recovers from a failure, it first becomes the redundant device but then initiates a switchover to become the active device once again; otherwise, after recovery, it becomes the redundant device and remains as redundant. If you change the priority level of the redundant device to one that is higher than the active device and then restart the redundant device, a switchover occurs to the redundant device making it the active device and the "preferred" device. If both devices are configured with the same priority level, Preempt mode is disabled. Please see note below when using priority level 10.
- **Disabled:** A switchover is done only upon failure of the currently active device.

As only the active device is cabled to the PSTN interfaces (e.g., E1/T1), you MUST enable the Preempt mode and set the active device with the higher priority. When a switchover to the redundant device occurs, only the IP calls are maintained; the PSTN calls are dropped (by sending a SIP BYE message to the IP side). Thus, whenever the PSTN-connected device recovers from failure, it becomes the active device again, providing connectivity to the PSTN.

When a switchover from active to redundant device occurs and the active failed unit requires a return merchandise authorization (RMA), meaning that it will be out of service for a long period, in order to maintain your PSTN calls, connect the same PSTN equipment and in the same manner (same ports) to the redundant device. The configuration between the devices is identical and thus, call routing process is unaffected. When connected to the PSTN, new Gateway calls can be handled by the newly active unit.

Failure detection by the devices is done by the constant keep-alive messages they send between themselves to verify connectivity. Upon detection of a failure in one of the devices, the following occurs:

- **Failure in active device:** The redundant device initiates a switchover. The failed device restarts and the previously redundant device becomes the active device in stand-alone mode. If at a later stage this newly active device detects that the failed device has been repaired, the system returns to HA mode. If Preempt mode is enabled and the originally active device was configured with a higher priority, a switchover occurs to this device; otherwise, if it was configured with a lower priority (or Preempt mode was disabled), the repaired device is initialized as the redundant device.
- **Failure in redundant device:** The active device moves itself into stand-alone mode until the redundant device is returned to operation. If the failure in the redundant device is repaired after restart, it's initialized as the redundant device once again and the system returns to HA mode.

Connectivity failure triggering a switchover can include, for example, one of the following:

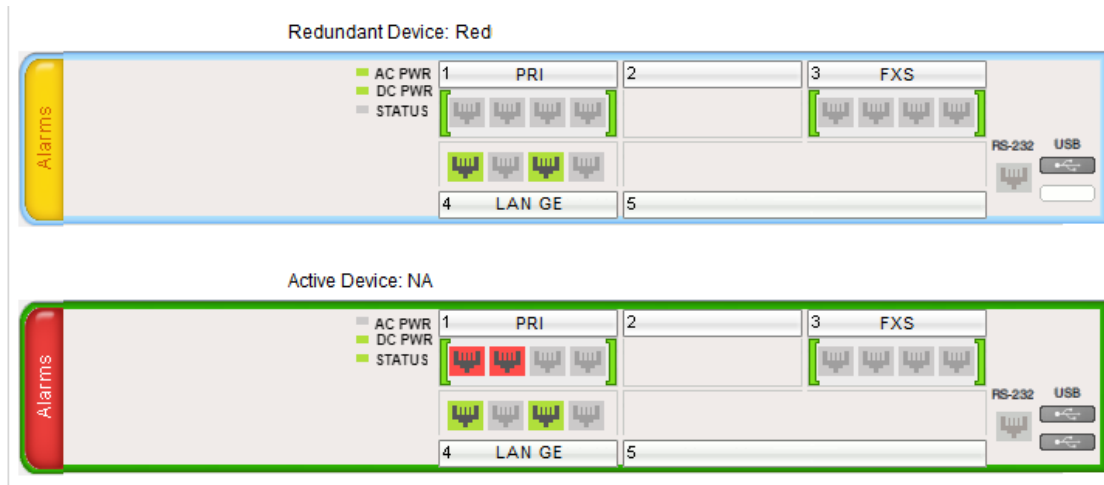

- **Loss of physical (link) connectivity:** If one or more physical network groups (i.e., Ethernet port pair) used for one or more network interfaces of the active device disconnects (i.e., no link) and these physical network groups are connected OK on the redundant device, a switchover occurs to the redundant device.
- **Loss of network (logical) connectivity:** No network connectivity, verified by keep-alive packets between the devices. This applies only to the Maintenance interface.

- Switchover triggered by loss of physical connectivity in one or more Ethernet Group is not done if the active device has been configured to a Preempt mode level of 10. In such a scenario, the device remains active.
- After HA switchover, the active device updates other hosts in the network about the new mapping of its Layer-2 hardware address to the global IP address, by sending a broadcast gratuitous Address Resolution Protocol (ARP) message.

## Viewing HA Status on Monitor Web Page

You can view the status of the HA system on the Monitor page of the device's Web interface. The page provides a graphical display of both active and redundant devices, as shown below:

You can distinguish between active and redundant devices as follows:

### ■ Active device:

- Color of border surrounding device is green.
- Title above device is "Active Device". The default name is "Device 1".

### ■ Redundant device:

- Color of border surrounding device is blue.
- Title above device is "Redundant Device". The default name is "Device 2".

The Monitor page also displays the HA operational status of the device to which you are currently logged in. This is displayed in the 'HA Status' field under the Device Information pane:

- "Synchronizing": Redundant device is synchronizing with Active device
- "Operational": The device is in HA mode
- "Stand Alone": HA is configured, but the Redundant device is missing and HA is currently unavailable

To view active alarms raised by the Active and Redundant devices, click the **Alarms** area to open the Active Alarms page (see [Viewing Active Alarms](#) on page 1454).

- The trunk status icons of the redundant device on the Monitor page are not operational (i.e., displayed in gray color).
- When the redundant device's trunks are connected to the remote side (e.g., PBX), they are synchronized on the physical E1/T1 layer, but without D-channel synchronization (not in service) and a D-channel alarm will be sent for the remote side.

You can change the name of each device, as described in the following procedure:

➤ **To define a name for the device:**

1. Open the HA Settings page (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Settings**).
2. In the 'HA Device Name' field, enter a name for the active device.

HA Device Name • 84

3. In the 'HA Remote Device Name' field, enter a name for the redundant device.

HA Remote Device Name • 86

4. Click **Apply**.

- Once the devices are running in HA mode, you can change the name of the redundant device through the active device only, in the 'HA Remote Device Name' field.
- When the device sends alarms to OVOC, the name is displayed at the beginning of the alarm description in OVOC, for example, "(SBCSITE01): Proxy lost. looking for another proxy". However, the name is not displayed when OVOC **initially** connects to the device and retrieves the alarms (from the device's Active Alarms table).

## 39 HA Configuration

This section describes HA configuration.

### Prerequisites for HA

The following lists the prerequisites for the HA feature:

- The HA feature is available only if both devices participating in the HA system are installed with a License Key that includes this feature. For installing a License Key, see [License Key](#) on page 1362.
- The hardware configuration of the two devices must be identical; they must have the same amount and type (e.g., E1/T1) of telephony interfaces, housed in the same chassis slot location.
- The physical connections of the first and second devices to the network (i.e., Maintenance interface and OAMP, Control and Media interfaces) **must be identical**. This also means that the two devices must use the same Ethernet Groups and the port numbers belonging to these Ethernet Groups. For example, if the first device uses Ethernet Group 1 (with ports 1 and 2), the second device must also use Ethernet Group 1 (with ports 1 and 2).
- Each network interface of the first device must be connected to the same broadcast domain as the identical network interface on the second device. For example, both Management interfaces must be connected to the same broadcast domain, and so on.
- Before configuring HA, determine the required network topology, as described in [Network Topology Types and Rx/Tx Ethernet Port Group Settings](#) on the next page.
- Maintenance interfaces restrictions:
  - The Maintenance interface on each device must be configured (each with a different IP address).
  - The maximum delay allowed between the Maintenance interfaces of both devices is 50 ms.
  - The Maintenance interface should be able to perform a fast switchover in case of link failure. Therefore, Spanning Tree Protocol (STP) should not be used in this network. The Ethernet connectivity of the Maintenance interface between the two devices should be constantly reliable without any disturbances.

### Initial HA Configuration

By default, HA is disabled on the device. When a device is loaded with valid HA configuration and is the first device to be loaded, it becomes the active device. The second device that is loaded with HA configuration becomes the redundant (standby) device.

## Network Topology Types and Rx/Tx Ethernet Port Group Settings

Initial HA configuration depends on how you want to deploy your HA system in the network. The Maintenance interface, which is used for the HA link between Active and Redundant units, can use a dedicated Ethernet Device and Ethernet Group, or share the same Ethernet Device and Ethernet Group with other IP network interface types (such as OAMP, Media and Control). However, it is recommended that you configure the Maintenance interface with a dedicated Ethernet Device and Ethernet Group (port) to separate it from other IP network interfaces.

If you want to separate the Maintenance interface from other interfaces, the separation must also be done externally to the units, either physically (different physical networks) or logically (using VLANs). When using VLANs, make sure that you use a different Ethernet Device for each IP network interface (see [Configuring Underlying Ethernet Devices](#) on page 156 and [Configuring IP Network Interfaces](#) on page 159).

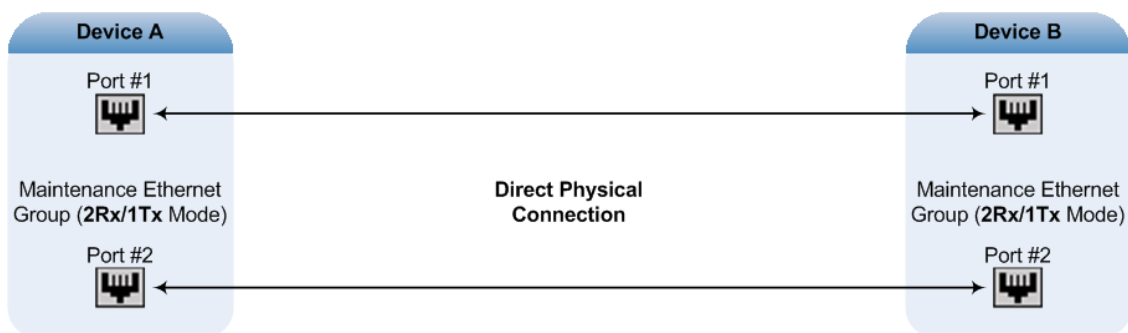

- The Maintenance interface is used for heartbeats and data transfer from active to standby device and therefore, any short interval interruption in communication may cause undesired switchovers.
- If you assign the same Underlying Ethernet Device to all the IP network interfaces, logical separation of traffic may not occur.

The Maintenance interface can employ Ethernet port redundancy (recommended), by using two ports. This is enabled by configuring the Ethernet Group associated with the Maintenance interface with two ports.

The required receive (Rx) and transmit (TX) mode for the port pair in the Ethernet Group used by the Maintenance interface is as follows:

- (Recommended Physical Connectivity) If the Maintenance ports of both devices are connected directly to each other without intermediation of switches, configure the mode to **2RX/1TX**:

- If the two devices are connected through two (or more) isolated LAN switches (i.e., packets from one switch cannot traverse the second switch), configure the mode to **2RX/2TX**:

- For Geographical HA (both units are located far from each other), **2Rx/1Tx** port mode connected to a port aggregation switch is the recommended option:

- When two LAN switches are used, the LAN switches must be in the same subnet (i.e., broadcast domain).
- Don't use port mode **REDUN\_1RX\_1TX** for the Maintenance interface where the Ethernet cables are connected back to back between the two devices (as both sides may choose different ports, resulting in disconnected traffic).
- To configure Rx/Tx modes of the Ethernet ports, see [Configuring Ethernet Port Groups](#) on page 152

## Configuring the HA Devices

To initially configure the two devices comprising the HA system:

1. Configure the first device for HA (see [Step 1: Configure the First Device](#) below)
2. Configure the second device for HA (see [Step 2: Configure the Second Device](#) on page 1311)
3. Activate HA on the devices (see [Step 3: Initialize HA on the Devices](#) on page 1312)

### Step 1: Configure the First Device

The first stage is to configure the first device for HA.

During this stage, make sure that the second device is powered off or disconnected from the network.

➤ **To configure the first device for HA:**

1. Cable the device to the necessary PSTN interfaces (e.g., E1/T1).
2. Configure the network interfaces, including the default OAMP interface:
  - a. Connect your PC to the device using a local, direct physical cable connection and then access the Web interface using the default OAMP network address. For more information on initial access, see [Configuring OAMP Interface](#) on page 14.
  - b. Open the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
  - c. Change the default OAMP network settings to suit your networking scheme.
  - d. Configure the Control and Media network interfaces, as required.
  - e. Add the HA Maintenance interface (i.e., the **MAINTENANCE** Application Type).

Make sure that the Maintenance interface uses an Ethernet Device and Ethernet Group that is **not** used by any other IP network interface. The Ethernet Group is associated with the Ethernet Device, which is assigned to the interface.

The IP Interfaces table below shows an example where the Maintenance interface is configured with Ethernet Device "vlan 2" (which is associated with Ethernet Group "GROUP\_2"), while the other interface is assigned "vlan 1" (associated with Ethernet Group "GROUP\_1"):

INDEX	NAME	APPLICATION TYPE	INTERFACE MODE	IP ADDRESS	PREFIX LENGTH	DEFAULT GATEWAY	PRIMARY DNS	SECONDARY DNS	ETHERNET DEVICE
0	Voice	OAMP + Media	IPv4 Manual	10.8.40.47	16	10.8.0.1	0.0.0.0	0.0.0.0	vlan 1
1	maint	MAINTENANCE	IPv4 Manual	10.3.0.11	16	10.3.0.1	0.0.0.0	0.0.0.0	vlan 2

3. If the connection is through a switch, the packets of both interfaces should generally be untagged. To do this, open the Ethernet Devices table (see [Configuring Underlying Ethernet Devices](#) on page 156 ), and then configure the 'Tagging' parameter to **Untagged** for the Ethernet Device assigned to the Maintenance interface. The figure below shows an example (highlighted) where VLAN 2 is configured as the Native (untagged) VLAN ID of the Ethernet Group "GROUP\_2":

INDEX	VLAN ID	UNDERLYING INTERFACE	NAME	TAGGING
0	1	GROUP_1	vlan 1	Untagged
1	2	GROUP_2	vlan 2	Untagged

4. Set the Ethernet port Tx / Rx mode of the Ethernet Group used by the Maintenance interface (see [Configuring Ethernet Port Groups](#) on page 152). The port mode depends on the type of Maintenance connection between the devices, as described in [Network Topology Types and Rx/Tx Ethernet Port Group Settings](#) on page 1308.
5. Configure HA parameters:
  - a. Open the HA Settings page (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Settings**):

HIGH AVAILABILITY	
HA Remote Address	• 10.3.4.61 
Preempt Mode	• <input checked="" type="checkbox"/>
Preempt Priority	• 5
HA Device Name	• Device 1
HA Remote Preempt Priority	• 4
HA Remote Device Name	• Device 2

- b. In the 'HA Remote Address' field, enter the Maintenance IP address of the **second** device.
  - c. Enable the HA Preempt feature, by selecting the 'Preempt Mode' check box, and then setting the priority level of the device in the 'Preempt Priority' field. Make sure that you configure different priority levels for the two devices. Typically, you would configure the active device with a higher priority level (number) than the redundant device. The only factor that influences the configuration is which device has the greater number; the actual number is not important. For example, configuring the active with 5 and redundant with 4, or active with 9 and redundant with 2 both assign highest priority to the active device. Configuring the level to 10 doesn't cause a switchover upon Ethernet connectivity loss. For more information on the feature, see [Device Switchover upon Failure](#) on page 1303.
6. Click **Apply**, and then save configuration to flash **without** a restart.
  7. Power down the device.
  8. Configure the second device (see [Step 2: Configure the Second Device](#) below).

## Step 2: Configure the Second Device

Once you have configured the first device for HA, you can configure the second device for HA. As the configuration of the second device is similar to the first device, the following procedure briefly describes each step. For detailed configuration such as the path to the Web configuration pages, refer to the section on configuring the first device ([Step 1: Configure the First Device](#) on page 1309).

During this stage, ensure that the first device is powered off or disconnected from the network.

### ➤ To configure the second device for HA:

1. Connect to the device in the same way as you did with the first device.

2. Configure the **same** OAMP, Media, and Control interfaces as configured for the first device.
3. Configure a Maintenance interface for this device. The IP address must be different to that configured for the Maintenance interface of the first device. The Maintenance interfaces of the devices must be in the same subnet.
4. Configure the **same** Ethernet Groups and VLAN IDs of the network interfaces as configured for the first device.
5. Configure the **same** Ethernet port Tx / Rx mode of the Ethernet Group used by the Maintenance interface as configured for the first device.
6. Configure HA parameters in the HA Settings page:
  - a. In the 'HA Remote Address' field, enter the Maintenance IP address of the **first** device.
  - b. Enable the HA Preempt feature by selecting the 'Preempt Mode' check box, and then setting the priority level of the device in the 'Preempt Priority' field. Make sure that you configure different priority levels for the two devices. Typically, you would configure the active device with a higher priority level (number) than the redundant device. The only factor that influences the configuration is which device has the greater number; the actual number is not important. For example, configuring the active with 5 and redundant with 4, or active with 9 and redundant with 2 both assign highest priority to the active device. Configuring the level to 10 doesn't cause a switchover upon Ethernet connectivity loss. For more information on the HA Preempt feature, see [Device Switchover upon Failure](#) on page 1303.
7. Click **Apply**, and then save configuration to flash **without** a restart.
8. Power down the device.
9. Continue to [Step 3: Initialize HA on the Devices](#) below.

### Step 3: Initialize HA on the Devices

Once you have configured both devices for HA as described in the previous sections, follow the procedure below to complete and initialize HA so that the devices become operational in HA. This last stage applies to both devices.

#### ➤ To initialize the devices for HA:

1. Cable the devices to the network.

You must connect both ports (two) in the Ethernet Group of the Maintenance interface to the network (i.e., two network cables are used). This provides 1+1 Maintenance port redundancy.

2. Power up the devices; the redundant device synchronizes with the active device and updates its configuration according to the active device. The synchronization status is indicated as follows:

- Active device: The Web interface's Monitor page displays "Synchronizing" in the 'HA Status' field.

When synchronization completes, the redundant device restarts to apply the received configuration and software.

When both devices become operational in HA, the HA status is indicated as follows:

- Both devices: The Web interface's Monitor page displays "Operational" in the 'HA Status' field.
  - Active device: The **Status** LED is lit green - slow-flash, steady on, and then slow flash.
  - Redundant device: The **Status** LED is lit green - slow-fast flash.
3. Access the active device with its' OAMP IP address and configure the device as required. For information on configuration done after HA is operational, see [Configuration while HA is Operational](#) on the next page.

## Quick-and-Easy Initial HA Configuration

You can quickly set up two stand-alone devices into an HA system, by loading the same ini configuration file with special parameters to each device. This ini file contains basic configuration that identifies the devices by MAC address and applies the configuration accordingly.

### ➤ To quickly set up two devices for HA:

1. Make sure that the License Key installed on both devices includes the HA license (see [Viewing the License Key](#) on page 1362).
2. Obtain the MAC address of each device. The MAC address is displayed on the Device Information page (see [Viewing Device Information](#) on page 1441).
3. Prepare a single ini file with the following configuration:
  - Parameters relating to the first device ("local"):
    - ◆ HALocalMAC - specifies the MAC address
    - ◆ (Optional) HAUUnitIdName - defines a descriptive name
    - ◆ (Optional) HAREvertiveEnabled - enables the HA Preempt feature
    - ◆ (Optional) HAPriority - defines the priority of the device if the HA Preempt feature is enabled
  - Parameters relating to the second device ("remote"):
    - ◆ HARemoteMAC - specifies the MAC address
    - ◆ HARemoteAddress - defines the HA Maintenance interface address
    - ◆ (Optional) HARemoteUnitIdName - defines a descriptive name

- ◆ (Optional) `HARemotePriority` - defines the priority of the device if the HA Preempt feature is enabled
- `InterfaceTable` - defines the IP Interfaces table with two network interfaces for the following Application Types:
  - ◆ `OAMP + Media + Control`: This is the same for both devices.
  - ◆ `HA Maintenance`: This is the Maintenance address of the device whose MAC address is the value of the `HALocalMAC` parameter.

An example of a configured ini file is shown below:

```
HALocalMAC = '00908f737a89'
HAUnitIdName = 'Device_1'
HARevertiveEnabled = 1
HAPriority = 6
HARemoteMAC = '00908f594667'
HARemoteAddress = 1.1.1.2
HARemoteUnitIdName = 'Device_2'
HARemotePriority = 4

[ InterfaceTable ]
FORMAT Index = ApplicationTypes, InterfaceMode, IPAddress, PrefixLength,
Gateway, InterfaceName, PrimaryDNSServerIPAddress,
SecondaryDNSServerIPAddress, UnderlyingDevice;
InterfaceTable 0 = 6, 10, 10.33.45.40, 16, 10.33.0.1, "Voice", 0.0.0.0, 0.0.0.0,
"vlan 1";
InterfaceTable 1 = 99, 10, 1.1.1.1, 24, 0.0.0.0, "HA", 0.0.0.0, 0.0.0.0, "vlan 2";
[ \InterfaceTable ]
```

4. Upload the file to both devices (see [Uploading an ini File to Device](#) on page 130).
5. To test your HA system, perform an HA switchover (see [Initiating an HA Switchover](#) on page 1323).

- If the HA Preempt feature is enabled, the device with the highest priority becomes the active unit. If the HA Preempt feature is not enabled, the first device to upload the file becomes the active unit, or if both upload the file simultaneously, the device with the "highest" IP address becomes the active unit.
- When configuration is applied to the device whose MAC is the value of the `HARemoteMAC` parameter, all HA configuration is swapped between local and remote parameters, including the IP address of the Maintenance interface, which is swapped with the address configured for the `HARemoteAddress` parameter.

## Configuration while HA is Operational

When the devices are operating in HA state, subsequent configuration is as follows:

- All configuration, including HA, is done on the active device **only**.
- Non-HA configuration on the active device is automatically updated on the redundant device (through the Maintenance interface).
- HA-related configuration on the active device is automatically updated on the redundant device:
  - Maintenance interface:
    - ◆ Modified Maintenance interface address of the active device: The address is set as the new 'HA Remote Address' value on the redundant device.
    - ◆ Modified 'HA Remote Address' value on the active device: The address is set as the new Maintenance interface address on the redundant device (requires a device restart).
    - ◆ Modifications on all other Maintenance interface parameters (e.g., Default Gateway and VLAN ID): updated to the Maintenance interface on the redundant device.
  - 'Preempt Mode' parameter.
  - 'Preempt Priority' parameter is set for the active device.
  - Modified 'HA Remote Preempt Priority' value is set for the redundant device.

If the HA system is already in HA Preempt mode and you want to change the priority of the device, to ensure that system service is maintained and traffic is not disrupted, it is recommended to set the higher priority to the redundant device and then restart it. After it synchronizes with the active device, it initiates a switchover and becomes the new active device (the former active device restarts and becomes the new redundant device).

## Configuring Firewall Allowed Rules

The Active device communicates with the Redundant device through the Maintenance interface. This interface is used by the Active device for HA maintenance with the Redundant device, for example, synchronizing configuration and software updates, and performing an HA switchover (see [Connectivity and Synchronization between Devices](#) on page 1302 for more information).

For HA maintenance, the following ports are used:

Type	Protocol	Direction	Source Port	Destination Port
HA Messages	UDP	Both directions (Active-Redundant)	669	669
HA Keep-	UDP	Both directions	670+n (multiple	680

Type	Protocol	Direction	Source Port	Destination Port
Alive		(Active- Redundant)	streams)	
HA Control and Data	TCP	Redundant to Active	Any	2442
HA Files	TCP/TLS	Redundant to Active	Any	80/443

- By default, the device's internal firewall keeps the above listed ports open. If you have an **external** firewall located between the Active and Redundant devices, make sure that it keeps these ports open as well (i.e., allows this traffic).
- If the device needs to communicate with AudioCodes OVOC, you must add rules to the external firewall (if required) and also to the device's internal firewall to allow incoming traffic from OVOC. For more information, see [Configuring Firewall Rules to Allow Incoming OVOC Traffic](#) on page 261.

## Configuring DiffServ for HA Maintenance Traffic

You can configure Differentiated Services (DiffServ) for HA Maintenance traffic which flows between the active and redundant devices on the HA Maintenance network interface. The default DiffServ value for this traffic is 46, which should be sufficient in most setups. However, you may need to increase the DiffServ priority if you are also running non-HA traffic on this network. Prioritizing HA Maintenance traffic ensures low latency for this critical network traffic.

### ➤ To configure DiffServ for HA Maintenance traffic:

1. Upload an ini file with the [HAMaintenanceIFDiffServValue] parameter configured to the required DiffServ value - 0 is the lowest priority (best effort) and 63 is the highest priority.
2. Restart the device with a save-to-flash for your settings to take effect.

## Configuring Ports for File Transfer between Active and Redundant Devices

By default, file transfer between active and redundant devices uses port 80 for unsecured transfers and port 443 for secured (HTTPS) transfers. You can change these local device ports according to your security and network requirements.

### ➤ To configure ports for HA file transfer:

1. Open the HA Settings page (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Settings**).
2. In the 'HA File Transfer Port' field, enter a port number for unsecured file transfer.

3. In the 'HA Secure File Transfer Port' field, enter a port number for secured file transfer.

HA File Transfer Port	<input type="text" value="80"/>	
HA Secure File Transfer Port	<input type="text" value="443"/>	

4. Click **Apply**, and then restart the device with a burn-to-flash for your settings to take effect.

## Enabling Secured TLS Communication between Active and Redundant Devices

You can enable secure communication between the active and redundant devices in the HA system. This ensures that all data exchanges, including file transfers and other packets, are encrypted using TLS (HTTPS). This means that communication through the HA Maintenance interface, which handles all maintenance operations between the active and redundant devices is secure.

### ➤ To enable secure communication between active and redundant device:

1. Open the HA Settings page (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Settings**).
2. Select the 'HA Secured Connectivity Mode' check box:

HA Secured Connectivity Mode ☒ 

3. Click **Apply**, and then restart the device with a burn-to-flash for your settings to take effect.

## Monitoring IP Entities and HA Switchover upon Ping Failure

The device's HA Network Monitor feature monitors the connectivity (*reachability*) with network entities (destinations), by pinging them using Internet Control Message Protocol (ICMP) Echo messages. This feature can be used, for example, to check connectivity with nearby routers (or first hops) that the device uses to reach other destinations for sending calls.

The HA Network Monitor table lets you configure up to 10 monitored rows, where each row can include up to 5 destinations to monitor, defined by IP address or hostname (FQDN). You can then configure the device to perform an HA switchover if a user-defined number of monitored rows whose destinations fail to reply to the device's sent pings (i.e., *unreachable* destinations) is reached or exceeded.

- The HA Network Monitor feature is a license-based feature (which is part of the general HA license) and is available only if it is included in the device's License Key.
- Switchover decisions of the HA Network Monitor feature are non-functional under the following conditions:
  - ✓ HA is disabled (i.e., active device is in standalone mode).
  - ✓ The HA Preempt Priority feature is used (enabled by the 'Preempt Mode' and 'Preempt Priority' parameters).
  - ✓ The number of Ethernet Groups (Ethernet links) on the redundant device that are in "up" status are less than on the active device.
- Destinations that have never replied to the device's pings are not used to determine reachability status and the unreachability threshold for triggering a switchover. They need to reply at least once to the device's pings in order to participate in the device's logic for this feature.
- Once a switchover occurs, the device doesn't perform switchover loops due to continued ping failures with the monitored row(s). Once a switchover occurs, the device changes the status of the monitored row(s) to "Reachability Unverified". A second switchover occurs only if the row(s) become reachable again and then unreachable.
- The following SNMP alarms are related to the HA Network Monitor feature:
  - ✓ acHASystemFaultAlarm: This alarm is sent to indicate that you have configured the HA Network Monitor feature, but switchover decisions are non-functional (see above).
  - ✓ acHANetworkMonitorAlarm: This alarm is sent to indicate that all destinations of a specific row in the HA Network Monitor table that replied in the past to the device's pings are now "unreachable".
  - ✓ acHASystemSwitchOverAlarm: This alarm is sent to indicate that an HA switchover has occurred due to the HA Network Monitor feature.

The following procedure describes how to configure monitored network entities through the Web interface. You can also configure it through ini file [HaNetworkMonitor] or CLI (`configure network > high-availability network-monitor`).

➤ **To configure monitoring of network entities:**

1. Open the HA Settings page (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Settings**), and then do the following:

- a. Select the 'HA Network Monitor' check box (HAPingEnabled):

HA Network Monitor ☒

- b. In the 'Monitor Threshold' (HaNetworkMonitorThreshold) field, enter the minimum number of failed ("Not Reachable") monitored rows that are required to trigger an HA switchover:

Monitor Threshold

2. Open the HA Network Monitor table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Network Monitor**), and then do the following:
  - a. Click **New**; the following dialog box appears:

- b. Configure an HA network monitor entry according to the parameters described in the table below.
  - c. Click **Apply**.

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Destination Address' dest-address [DestAddress]	Defines destination addresses of network hosts that you want monitored by the device for the monitored row. The valid value is an IP address (IPv4 or IPv6) or hostname (FQDN). You can configure only one hostname (which can be resolved by DNS into up to five IP addresses). You can configure up to five IP addresses, where each IP address is separated by a comma or space, for example, "10.1.1.1 20.2.2.2,30.3.3.3" (without quotation marks). <b>Note:</b> <ul style="list-style-type: none"> <li>■ You can configure the parameter with either a hostname or an IP address, but not both.</li> <li>■ The IP address version (IPv4 or IPv6) of the 'Destination</li> </ul>

Parameter	Description
	Address' parameter and the 'Network Interface' parameter (below) must be the same.
'Network Interface' network- interface [NetworkInterface]	<p>Assigns one of the device's IP network interfaces from where you want to send ping requests to the monitored destinations configured for the monitored row.</p> <p>To configure IP interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can assign any IP Interface type (OAMP, Media or Control).</li> <li>■ The IP address version (IPv4 or IPv6) of the 'Network Interface' parameter and the 'Destination Address' parameter (above) must be the same.</li> </ul>
'Ping Timeout' ping-timeout [PingTimeout]	<p>Defines how often (in milliseconds) the device sends ping requests to the destinations configured for the monitored row. This also provides the device time to wait for a reply (if any) from the destination. For example, if configured to 100, the device pings the destination every 100 ms.</p> <p>If the device receives a reply from a destination within this timeout, it considers the destination as online (reachable). If no reply has been received from a user-defined number of consecutive pings (see the 'Ping Count' parameter, below), the device considers the destination as offline (unreachable).</p> <p>The valid value is 100 to 60000. The default is 1000.</p>
'Ping Count' ping-count [PingCount]	<p>Defines the number of consecutive failed pings (no replies) before the device considers the destination as offline (unreachable). For example, if you configure the parameter to 2, the destination is considered unreachable after 2 consecutive pings evoked no reply. If this destination later replies to any subsequent ping, the device considers it reachable.</p> <p>The valid value is 1 to 10. The default is 3.</p> <p><b>Note:</b> If the destination has never replied to a ping, the device doesn't consider it unreachable. Instead, it considers it as undetermined ("Reachability Unverified").</p>
'Entry Reachability Status'	Read-only field displaying the connectivity (reachable) status with the monitored row, which is based on ping results of all its configured destinations:

Parameter	Description
	<ul style="list-style-type: none"> <li>■ "Reachability Unverified": The reachability status of the monitored row is currently undetermined. In other words, <b>all</b> the destinations configured for the monitored row have never replied to the device's pings.</li> <li>■ "Reachable": The device considers the monitored row as online (reachable). In other words, the device has received a ping reply from <b>at least one</b> of the destinations configured for the monitored row.</li> <li>■ "Not Reachable": The device considers the monitored row as offline (unreachable). In other words, the number of failed pings equals to (or is greater than) that configured by the 'Ping Count' parameter, for <b>all</b> the destinations configured for the monitored row and on condition that all these destinations have replied in the past to the device's pings. The status of the monitored row returns to "Reachable" if at least one of the destinations replies to a ping.</li> <li>■ "Host not resolved": The hostname (if configured in the 'Destination Address' parameter) couldn't be resolved into an IP address.</li> </ul>

Once you have configured the destinations to monitor, you can view the status of each destination of a selected monitored row, as described in the following procedure.

➤ **To view reachability status of destinations per monitored row:**

1. Open the HA Network Monitor table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **HA Network Monitor**).
2. In the table, select the required index row (monitored row), and then click the **HA Network Monitor Peers Status** link located below the table; the HA Network Monitor Peers Status table appears, displaying the reachability status of each destination ('Peer Destination Address') of the monitored row, as shown in the below example:

INDEX ↕	PEER DESTINATION ADDRESS	PEER REACHABILITY STATUS
0	10.4.4.60	Reachable
1	10.4.0.1	Reachable

The reachability status is displayed in the 'Peer Reachability Status' read-only field:

- "Reachability unverified": The reachability status of the destination is currently undetermined. In other words, the destination has never replied to the device's pings.
- "Reachable": The device considers the destination as online (reachable). In other words, the device has received a ping reply from the destination.

- "Not reachable": The device considers the destination as offline (unreachable). In other words, the number of consecutive failed pings equaled to (or was greater than) that configured by the 'Ping Count' parameter.
- "Terminated by ping error": The device is unable to send a ping to the destination (typically, due to a routing issue or incorrect destination address). To resolve the problem, correct your routing configuration or the address of the destination, and then enter the edit mode of the HA network monitor row belonging to the destination and click **Apply** to refresh your changes.

The 'Ping Loss Percentage' read-only field displays the percentage of pings sent to the destination that failed to get a reply, in the last five minutes.

## 40 HA Maintenance

This section describes HA maintenance.

### Maintenance of Redundant Device

The only interface that is operational on the redundant device is the Maintenance interface. The following protocols can be used for maintenance purposes for this interface:

- **Syslog:** To receive syslog messages from the redundant device, make sure that you have configured a valid VLAN and routing rule from the Maintenance network to the syslog server.
- **Telnet:** A Telnet server is always available on the redundant device (even if disabled by configuration).

The active device runs the above maintenance protocols on its' OAMP interface.

### Replacing a Failed Device

If you need to replace a faulty device, the new device must be configured exactly as the second device, as described in [Configuring the HA Devices](#) on page 1309.

### Initiating an HA Switchover

You can initiate a switchover from the Active to Redundant device.

When performing an HA switchover, the HA mode becomes temporarily unavailable.

#### ➤ To perform a switch-over:

1. Open the High Availability Maintenance page:
  - Toolbar: Click the **Actions** button, and then from the drop-down menu, choose **Switchover**.
  - Navigation tree: **Setup** menu > **Administration** tab > **Maintenance** folder > **High Availability Maintenance**.

#### SWITCH OVER

Switch between Active and Redundant Devices

Switch Over

2. Click **Switch Over**; a confirmation box appears requesting you to confirm.
3. Click **OK**.

## Restarting Redundant Device

You can restart the Redundant device if necessary.

When restarting the Redundant device, the HA mode becomes temporarily unavailable.

### ➤ To restart the Redundant device:

1. Open the High Availability Maintenance page:
  - Toolbar: Click the **Actions** button, and then from the drop-down menu, choose **Switchover**.
  - Navigation tree: **Setup** menu > **Administration** tab > **Maintenance** folder > **High Availability Maintenance**.

### REDUNDANT OPTIONS

Restart Redundant Device

Restart

2. Click **Restart**; a confirmation box appears.
3. Click **OK** to confirm.

## Software Upgrade

You can perform the following types of software upgrades on the HA system:

- **Software Upgrade with Device Restart:** Both active and redundant devices save and restart with the new software version. This method is quick and simple, but it disrupts traffic (i.e., traffic affecting).
- **Hitless Software Upgrade:** This method maintains service (i.e., not traffic affecting).

For more information, see [Upgrading the Device's \(.cmp\) Software](#) on page 1339.

## Disconnecting and Reconnecting HA

You can disconnect the two devices in the HA system and return them to standalone devices.

### ➤ To disconnect HA through CLI:

1. From the CLI of the active device, connect (Telnet) to the redundant device, by typing the following command:

```
# debug ha conn-to-red
```

2. Log in to the redundant device's CLI with its username (e.g., **Admin**) and password:

```
Username: Admin
Password:
```

3. Access the Privileged mode, by typing the following command, and the mode's password:

```
> enable
Password:
#
```

4. At the prompt, type the following command and enter a new OAMP IP address for the redundant device:

```
# debug ha disconnect-system <New OAMP Address for Redundant Device>
```

The redundant device restarts, the HA status of the active device changes to "Standalone", and the redundant device now becomes a non-HA device.

- The new OAMP address of the redundant device must be different to the active device.
- The HA Maintenance network interface (in the IP Interfaces table) on the redundant device is unaffected by the command.
- All **Media + Control** network interfaces (in the IP Interfaces table) on the redundant device are deleted.
- The 'HA Remote Address' [HARemoteAddr] field value, which specifies the HA Maintenance address of the active device is deleted on the redundant device.

You can later restore the HA system, by following the below procedure.

➤ **To restore the HA system through CLI:**

1. On the previously **redundant** device, configure the HA Maintenance interface address of the active device:

```
(config-network)# high-availability
(ha)# remote-address <HA Maintenance Address of Active Device>
```

The HA Maintenance address can alternatively be configured in the Redundant device's Web interface's 'HA Remote Address' parameter.

2. Restart the redundant device:

(ha)# do reload now

The procedure assumes that no network changes were made to both devices' HA Maintenance interface or Ethernet Devices (VLAN); otherwise, the devices may not be able to communicate with each other.

## Accessing Files on Redundant Device from Active through SSH

From the active device, you can access files stored on the redundant device's flash memory, through SSH (or SFTP). Once accessed, your SSH client can download files to your PC (e.g., debug file, locally stored CDR, and Configuration Package file). This eliminates the need to perform an HA switchover to change the redundant device to active in order to access the device's files.

Access to the redundant device uses a proxy SSH server port on the active device. As this is a secure connection, your SSH client needs to authenticate itself with the device (SSH server). The device performs standard user authentication, where you can configure it to check the user's credentials in the device's Local Users table or with a remote authentication server. Access is granted only to users with **Security Administrator** user level.

Perform the following procedure on the **active** device.

### ➤ To access redundant device from active device for file download:

1. Enable SSH (see [Configuring CLI over SSH using Public Key Authentication](#) on page 93).
2. Open the Administration Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Administration Settings**).
3. In the 'Redundant Device Server Port' field (SSHRedundantProxyPort), configure a port for SSH through which the active device accesses the redundant device. This proxy port must be different to the active device's regular SSH server port (configured in the 'Server Port' parameter).

Redundant Device Server Port

4. Click **Apply**.

- The device may take a long time to prepare the debug file for transfer when it contains much information. Some SFTP clients (for example, WinSCP and FileZilla) have a short default connection timeout and if the file transfer is not started within this timeout, the transfer attempt is aborted. Therefore, it is recommended to configure a longer timeout for your SFTP client application.
- For more information on the Configuration Package file, see [Downloading or Uploading Configuration Package File](#) on page 1389.

## Backing Up and Restoring HA Configuration

Once you have your HA system up and running, you can make a backup of your HA configuration, by saving an ini configuration file from the active device. If your HA system fails, for whatever reason, you can simply upload this file to the devices to restore HA.

➤ **To backup and then restore HA:**

1. Save the ini file from the active device to a folder on your PC. Store this file in a safe location for future use (i.e., HA backup).
2. If a failure occurs in one or both devices, upload the backup ini file to the failed device(s).

If one or both devices in the HA system have been replaced (RMA) for whatever reason (e.g., a hardware failure), before loading the file, update the file with the new MAC addresses ([HALocalMAC] or [HARemoteMAC] parameters).

# Part VIII

## Maintenance

## 41 Basic Maintenance

This section describes basic maintenance.

### Restarting the Device

You can restart the device through the device's management tools. Device restart may be required for maintenance purposes. Certain parameters require a device restart for their settings to take effect. These parameters are displayed in the Web interface with the lightning ⚡ icon. In addition, whenever you make any configuration change that requires a restart, the **Restart** button on the Web interface's toolbar is displayed with a red border, as shown below:

The Web interface also provides you with the following options when restarting the device:

- Saving current configuration to the device's flash memory (non-volatile) prior to the restart.
- Restarting the device only after a user-defined time (*Graceful Restart*) to allow current calls to end (calls are terminated after this interval).

To restart the device (and save configuration to flash) through CLI, use the following command:

```
# reset now
```

#### ➤ To restart device through Web interface:

1. Open the Maintenance Actions page:
  - Toolbar: Click the **Restart** button.
  - Navigation tree: **Setup** menu > **Administration** tab > **Maintenance** folder > **Maintenance Actions**.

RESTART DEVICE	
Restart Device	<input type="button" value="RESTART"/>
Save To Flash	<input type="text" value="Yes"/>
Graceful Restart	<input type="text" value="Yes"/>
Graceful Timeout [sec]	<input type="text" value="0"/>

2. From the 'Save To Flash' drop-down list, select one of the following:

- **Yes:** Current configuration is saved to flash memory prior to restart (default).
  - **No:** The device restarts without saving the current configuration to flash. All configuration done after the last configuration save will be discarded (lost) after restart.
3. From the 'Graceful Restart' drop-down list, select one of the following:
- **Yes:** The device restarts only after a user-defined time, configured in the 'Graceful Timeout' field (see next step). During this interval, the device rejects all new traffic. If no traffic exists and the time has not yet expired, the device restarts immediately.
  - **No:** The device restarts immediately, regardless of traffic. Any existing traffic is immediately terminated.
4. In the 'Graceful Timeout' field (available only if you have configured the 'Graceful Restart' field to **Yes**), enter the time (in seconds) after which the device restarts. Note that if no traffic exists and the time has not yet expired, the device restarts.
5. Click the **Restart** button; a confirmation message box appears.
6. Click **OK** to confirm device restart; if you configured the 'Graceful Restart' field to **Yes** (in Step 3), restart is delayed and a screen appears displaying the number of remaining calls and time. When the device begins to restart, a message appears notifying you.

## Remotely Restarting Device using SIP NOTIFY

The device can be remotely restart upon the receipt of a SIP NOTIFY message that contains an Event header set to 'check-sync;reboot=true' (proprietary to AudioCodes), as shown in the example below:

```
NOTIFY sip:<user>@<dsthost> SIP/2.0
To: sip:<user>@<dsthost>
From: sip:sipsak@<srchost>
CSeq: 10 NOTIFY
Call-ID: 1234@<srchost>
Event: check-sync;reboot=true
```

### ➤ To enable remote restart upon receipt of SIP NOTIFY:

1. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
2. Select the 'Remote Management by SIP NOTIFY' check box (EnableSIPRemoteReset):

Remote Management by SIP NOTIFY

3. Click **Apply**.

## Locking and Unlocking the Device

You can lock the device so that it stops processing calls. This may be useful, for example, when you want to upload new software files to the device and you don't want any traffic to interfere with the process. Locking the device may be done gracefully, whereby the device stops accepting new calls, but allows existing calls to continue for up to a user-defined duration before terminating them.

You can also configure the device to wait without a timeout until all active calls end on their own, before going into lock state. This is done through the CLI, using the following command: `# admin state lock graceful forever`

### ➤ To lock the device:

1. Open the Maintenance Actions page:
  - Toolbar: Click the **Restart** button.
  - Navigation tree: **Setup** menu > **Administration** tab > **Maintenance** folder > **Maintenance Actions**.

LOCK / UNLOCK	
Lock	<input type="button" value="LOCK"/>
Graceful Option	<input type="text" value="Yes"/>
Disconnect Client Connections	<input type="text" value="Disable"/>
Lock Timeout [sec]	<input type="text" value="180"/>
Device Operational State	UNLOCKED

2. From the 'Graceful Option' drop-down list, select one of the following options:
  - **Yes:** The device locks only after a user-defined duration, configured in the 'Lock Timeout' field (see next step). During this interval, no new traffic is accepted, allowing only existing calls to continue until the timeout expires. If at any time during this timeout there are no active calls, the device locks. If there are still active calls when the timeout expires, the device terminates them and locks.
  - **No:** The device locks immediately, terminating all existing traffic.

**Note:** These options are available only if the current status of the device is in "UNLOCKED" state.
3. If you configured 'Graceful Option' to **Yes** (see previous step), then in the 'Lock Timeout' field, enter the time (in seconds) after which the device locks.

4. If you also want the device to terminate (close) existing TLS/TCP client connections and reject new incoming TLS/TCP client connections during the locked state, then from the 'Disconnect Client Connections' drop-down list, select **Enable**. If disabled (default), existing client connections will remain and incoming TLS/TCP client connections will be accepted during the locked state.
5. Click the **LOCK** button; a confirmation message box appears requesting you to confirm device lock.
6. Click **OK** to confirm;
  - If you configured 'Graceful Option' to **Yes**, a lock icon is displayed and a window appears displaying the number of remaining calls and time. To cancel the lock, click the **Cancel Graceful Lock** button.

**Graceful reset initiated.**

**Device will be reset when all active calls are terminated,  
or when shutdown timer expires.**

Remaining Active Calls  Remaining Time [sec]

Click button to cancel the Graceful Lock

**Cancel Graceful Lock**

- If you configured 'Graceful Option' to **No**, the lock process begins immediately.

The 'Device Operational State' read-only field displays "LOCKED" and the device doesn't process any calls.

#### ➤ To unlock the device:

- Click the **UNLOCK** button; the device unlocks immediately and accepts new incoming calls. The 'Device Operational State' read-only field displays "UNLOCKED".

## Saving Configuration

When you configure parameters and tables in the Web interface and then click the **Apply** button, changes are saved to the device's *volatile* memory (RAM). These changes revert to their previous settings when the device restarts (hardware or software) or powers off. Therefore, to ensure that your configuration changes are retained, you must save them to the device's non-volatile memory (i.e., flash memory).

To save your settings to flash, click the **Save** button located on the toolbar. To remind you to save your settings to flash, the **Save** button is displayed with a red border, as shown below:

**Save**

To save configuration to flash through CLI, use the following command:

# write

## 42 Channel Maintenance

This chapter describes channel-related maintenance.

### Disabling Analog Ports

You can disable an analog port (FXS or FXO). When disabled, the port cannot be used and signaling is not transmitted through the port. The port's LED is lit red. By default, all analog ports are enabled.

➤ **To disable an analog port through CLI:**

```
(config-voip)# interface fxs-fxo
(fxs-fxo)# analog-port-enable <module>/<port> [on|off]
```

For example, to disable Port 2 on Module 1:

```
(fxs-fxo)# analog-port-enable 1/2 off
```

### Resetting an Analog Channel

You can reset an analog (FXO or FXS) channel by disconnecting the current call (if exists). This is sometimes useful, for example, when the device (FXO) is connected to a PBX and communication between the two cannot be disconnected (e.g., when using reverse polarity).

➤ **To reset an analog channel:**

1. Open the Monitor page (**Monitor** menu >  **Monitor**).
2. Click the required **FXS** or **FXO** port icon; a shortcut menu appears.

3. From the shortcut menu, choose **Reset Channel**; a message appears informing you when the channel has reset.

### Restarting a B-Channel

You can restart a specific B-channel belonging to an ISDN or CAS trunk, using the SNMP MIB variable, `acTrunkISDNCommonRestartBChannel`. This may be useful, for example, for troubleshooting specific voice channels.

- If a voice call is currently in progress on the B-channel, it is disconnected when the B-channel is restarted.
- B-channel restart can only be done if the D-channel of the trunk to which it belongs is synchronized (Layer 2).
- B-channel restart doesn't affect the B-channel's configuration.

## Locking and Unlocking Trunk Groups

You can lock a Trunk Group to take its trunks (and their channels) out of service. When you initiate a lock, the device rejects all new incoming calls for the Trunk Group and immediately terminates active calls (busy channels), eventually taking the entire Trunk Group out of service.

For digital interfaces: You can lock a Trunk Group “gracefully”, whereby the device rejects new incoming calls, but terminates busy channels only after a user-defined graceful period if they are still busy by the end of the period. When configured to 0, graceful lock is disabled.

For analog interfaces: For Tel-to-IP calls, the device plays a fast busy tone when the phone is off-hooked on the Tel side. For IP-to-Tel calls, the device rejects the incoming INVITE message.

When you lock a Trunk Group, the method for taking channels out-of-service is determined by the following parameters:

- Digital interfaces: DigitalOOSBehaviorForTrunk parameter per trunk or DigitalOOSBehavior parameter for all trunks.
- FXS interfaces: FXSOOSBehavior parameter

If you have configured registration for the Trunk Group (see the 'Registration Mode' parameter in the Trunk Group Settings table) and you subsequently lock the Trunk Group, it stops performing registration requests (un-registers) with the Serving IP Group with which you have configured it to register. When you unlock such a Trunk Group, it starts performing registration requests (re-registers) with the Serving IP Group once its trunks return to service.

### ➤ To lock or unlock a Trunk Group:

1. (Digital Interfaces Only) Configure a graceful lock:
  - a. Open the Gateway Advanced Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway Advanced Settings**).
  - b. In the 'Graceful Busy Out Timeout' (GracefulBusyOutTimeout) field, enter the period after which the Trunk Group is locked:

Graceful Busy Out Timeout [sec]

- c. Click **Apply**.
2. Lock the Trunk Group:

- a. Open the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937).
- b. Select the row of the Trunk Group that you want to lock or unlock.
- c. Click the **Action** button located on the table's toolbar, and then from the drop-down list, choose one of the following:
  - ◆ **Lock:** Locks the Trunk Group.
  - ◆ **Un-Lock:** Unlocks a locked Trunk Group.

The Trunk Group Settings table provides the following read-only fields related to locking and unlocking of a Trunk Group:

- 'Admin State': Displays the administrators state - "Locked" or "Unlocked"
- 'Status': Displays the current status of the channels in the Trunk Group:
  - "In Service": Indicates that all channels in the Trunk Group are in service, for example, when the Trunk Group is unlocked or Busy Out state cleared (see the EnableBusyOut parameter for more information).
  - "Going Out Of Service": Appears as soon as you choose the **Lock** button and indicates that the device is starting to lock the Trunk Group and take channels out of service.
  - "Going Out Of Service (<duration remaining of graceful period> sec / <number of calls still active> calls)": Appears when the device is locking the Trunk Group and indicates the number of busy channels and the time remaining until the graceful period ends, after which the device locks the channels regardless of whether the call has ended or not.
  - "Out Of Service": All fully configured trunks in the Trunk Group are out of service, for example, when the Trunk Group is locked or in Busy Out state (see the EnableBusyOut parameter).

- If the device restarts, a locked Trunk Group remains locked. If the device restarts while graceful lock is in progress, the Trunk Group is forced to lock immediately after the device finishes its restart.
- When the device is in High Availability (HA) mode:
  - ✓ After an HA switchover, a locked Trunk Group remains locked.
  - ✓ If an HA switchover is initiated while a Trunk Group is in locking progress, the locking process is stopped and only starts again (with the configured graceful period) once switchover completes.
  - ✓ When HA status is in "Synchronizing" state, the Trunk Group status is not updated in the Trunk Group Settings table. In addition, the lock/unlock actions cannot be invoked during this time. When HA synchronization finishes and HA status is in "Operational" state, the Trunk Group Settings table is refreshed with the lock/unlock status. The HA state is displayed on the Monitor home page.

## Disconnecting Active Calls

You can forcibly disconnect all active calls, or specific calls based on Session ID or Dial Plan tag (name=value) through CLI.

- To disconnect all calls:

```
# clear voip calls
```

- To disconnect a call with a specific Session ID:

```
# clear voip calls <Session ID>
```

- To disconnect calls with a specific Dial Plan tag:

```
# clear voip calls tag <name=value>
```

## Remotely Disconnecting Calls using SIP NOTIFY

The device can be triggered to disconnect all current calls upon the receipt of a SIP NOTIFY message containing an Event header with the value 'soft-sync' (proprietary to AudioCodes), as shown in the example below:

```
NOTIFY sip:<user>@<dsthost> SIP/2.0
To: sip:<user>@<dsthost>
From: sip:sipsak@<srchost>
CSeq: 10 NOTIFY
Call-ID: 1234@<srchost>
Event: soft-sync
```

### ➤ To enable remote call disconnect upon receipt of SIP NOTIFY:

1. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
2. Select the 'Remote Management by SIP NOTIFY' check box (EnableSIPRemoteReset):

Remote Management by SIP NOTIFY

3. Click **Apply**.

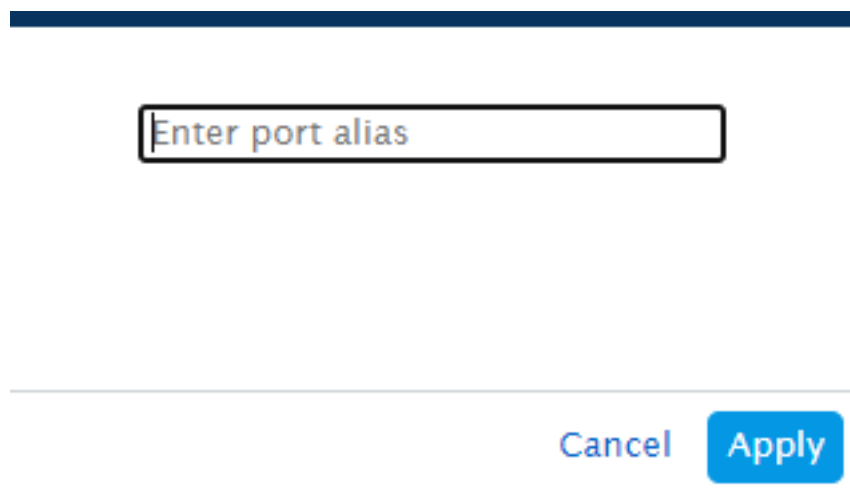

## Configuring a Description for Telephony Ports

You can configure a short description per telephony port. The port's description is displayed as a tooltip when you hover your mouse over the port on the Web interface's Monitor page, and displayed in the output of various CLI commands (e.g., `show run`).

The following procedure describes how to configure a port description through the Web interface. You can also configure it through ini file ([AnalogPortInfo\_x] or [DigitalPortInfo\_x]) or CLI (`port-info` under relevant interface).

➤ **To configure a port description:**

1. Open the Monitor home page (see [Viewing Device Status on Monitor Page](#) on page 1443).
2. Click the required port icon, and then from the shortcut menu, choose **Port Description**; the following dialog box appears (top area cropped for convenience):

The description can contain only alphanumerical characters (without spaces).

3. Type a short description, and then click **Apply**.

For digital port interfaces, you can also configure the port description using the 'Description' field on the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878).

## 43 Upgrading the Device's (.cmp) Software

You can use the Web interface's Software Upgrade Wizard to easily upgrade the device's software version (.cmp file).

For upgrading your standalone device, see [Upgrading a Standalone Device](#) below.

For upgrading devices operating in High-Availability mode, see [Upgrading Devices in High-Availability Mode](#) on page 1342.

### Recommendations Before Upgrading

Before upgrading the device, it's recommended to do the following:

- Make sure that the device's License Key is compatible with the software version to which you want to upgrade the device (see [License Key](#) on page 1362).
- Enable the Graceful Lock feature (see [Locking and Unlocking the Device](#) on page 1331) because the device restarts at the end of the software upgrade process, terminating all active calls. The Graceful Lock feature minimizes traffic disruption by blocking the establishment of new calls.
- Back up the device's configuration to your computer. If an upgrade failure occurs (for whatever reason), you can restore configuration by uploading the backup file to the device. For more information, see [Downloading and Uploading Configuration Files](#) on page 1386.

### Upgrading a Standalone Device

You can use the Web interface's Software Upgrade wizard to easily upgrade your standalone device.

- Prior to upgrading your device, read the pre-upgrade recommendations in [Recommendations Before Upgrading](#) on the previous page.
- You can download the latest software version files from AudioCodes website (registered users only) at <https://www.audiocodes.com/library/firmware>.
- The device cannot be configured during the upgrade.
- You can cancel the upgrade process at any time before the restart stage begins, by clicking the dialog's close (X) button.
- If the "SW version mismatch" message appears in the syslog or web interface after the upgrade, it indicates that the device's License Key doesn't support the new .cmp file version. In this case, contact AudioCodes Support for assistance.
- If the device disconnects from power (power outage or power cable disconnected) during the upgrade, the upgrade process fails. When the device is powered up again, it falls back to the previously installed software version. This feature is configured by the [DisableDualImageFeature] parameter. The feature is applicable only to Mediant 800 Gateway & E-SBC **Hardware Revision C**.
- Instead of manually upgrading the device, you can use the device's Automatic Update feature for automatic provisioning (see [Automatic Provisioning](#)).
- You can also upgrade the device by uploading the .cmp file from an external USB hard drive connected to the device's USB port. For more information, see [USB Storage Capabilities](#).

➤ **To upgrade device using Software Upgrade wizard:**

1. Start the Software Upgrade wizard:

- **Toolbar:** From the **Actions** drop-down menu, choose **Software Upgrade**.
- **Navigation tree:** **Setup** menu > **Administration** tab > **Maintenance** folder > **Software Upgrade**.

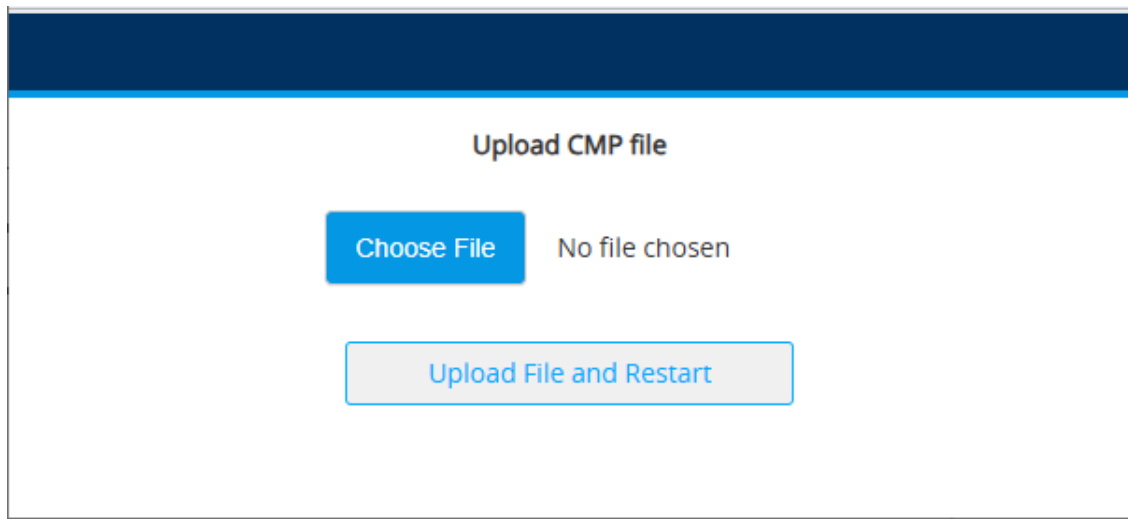

Software Upgrade page appears:

**Software Upgrade**

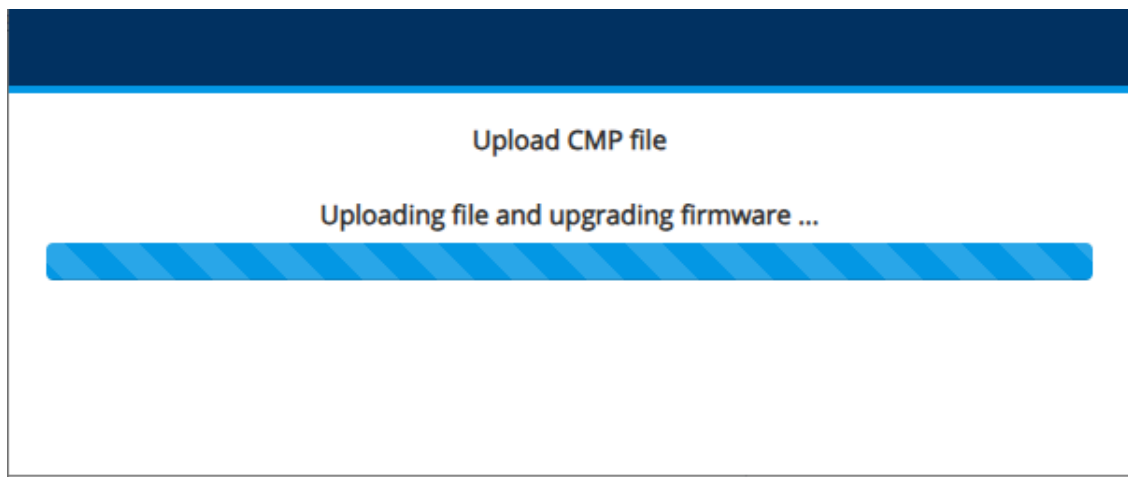

Start Software Upgrade

**Warning:**  
In case of an upgrade failure, the device will restart and the previous configuration saved to flash will be restored.

2. Click **Start Software Upgrade**; the wizard starts, prompting you to choose the software version file (.cmp):

3. Click **Choose File**, and then navigate to and select the .cmp file.
4. Click **Upload File and Restart**; the device begins uploading the .cmp file and upgrading the firmware:

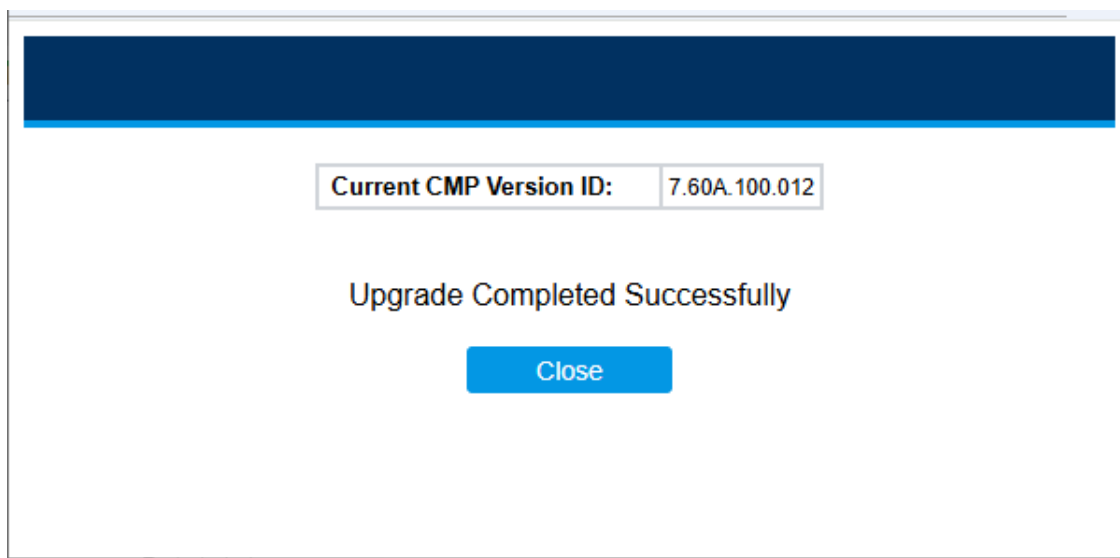

When the file is uploaded and installed, the device automatically restarts:

Device restart may take several minutes (even up to 30 minutes), depending on .cmp file version.

After restart completes, the "Upgrade Completed Successfully" message appears, along with the upgraded software version number:

5. Click **Close**; the wizard closes and you're automatically logged out of the device.
6. Log in again with your credentials; the following pop-up message appears, informing you that the device is now running a new software version:

7. Click **Close** to close the message box.

## Upgrading Devices in High-Availability Mode

You can use the Web interface's Software Upgrade wizard to upgrade devices operating in High-Availability (HA) mode.

You can choose between two HA upgrade methods:

- **Non-Hitless Upgrade):** In a Non-Hitless Upgrade, both the active and redundant devices are upgraded simultaneously. This method doesn't trigger an HA switchover, making it traffic-affecting and causing active calls to terminate during the upgrade process.

The upgrade process proceeds as follows:

- a. The active device uploads the .cmp file.

- b. The active device transfers the .cmp file to the redundant device.
- c. Both devices install the file, save it to flash memory, and then restart.

■ **Hitless Upgrade:** A Hitless Upgrade updates both the active and redundant devices without disrupting traffic. It ensures ongoing calls are maintained using the HA switchover feature.

The upgrade process proceeds as follows:

- a. The active device uploads the .cmp file.
- b. The active device transfers the file to the redundant device.
- c. The redundant device installs the file, saves it to flash memory, and then restarts, now running the new software version.
- d. The redundant device initiates an HA switchover to become the new active device. Ongoing calls are uninterrupted and now processed by this device.
- e. The previously active device (now redundant) installs the file, saves it to flash memory, and then restarts. Both devices now run the new software version.
- f. The redundant device initiates an HA switchover to become the active device again. Only the initial redundant device restarts to resume redundant mode.

- The software upgrade process, which includes a device restart, may take several minutes (even up to 30 minutes), depending on .cmp file version.
- Hitless downgrade (i.e., to an earlier version) is **not** supported. For software downgrade, use the Non-Hitless upgrade.
- Instead of upgrading through the Web interface, you can use the device's CLI:
  - ✓ **Hitless Upgrade:** # copy firmware from <URL and file name>
  - ✓ **Non-Hitless Upgrade:** # copy firmware from <URL and file name> non-hitless

- Prior to upgrading your device, read the pre-upgrade recommendations in [Recommendations Before Upgrading](#) on page 1339.
- You can download the latest software version files from AudioCodes website (registered users only) at <https://www.audiocodes.com/library/firmware>.
- The device cannot be configured during the upgrade.
- You can cancel the upgrade process at any time before the restart stage begins, by clicking the dialog's close (X) button.
- If the "SW version mismatch" message appears in the syslog or web interface after the upgrade, it indicates that the device's License Key doesn't support the new .cmp file version. In this case, contact AudioCodes Support for assistance.
- If the device disconnects from power (power outage or power cable disconnected) during the upgrade, the upgrade process fails. When the device is powered up again, it falls back to the previously installed software version. This feature is configured by the [DisableDualImageFeature] parameter. The feature is applicable only to Mediant 800 Gateway & E-SBC **Hardware Revision C**.
- Instead of manually upgrading the device, you can use the device's Automatic Update feature for automatic provisioning (see [Automatic Provisioning](#)).
- You can also upgrade the device by uploading the .cmp file from an external USB hard drive connected to the device's USB port. For more information, see [USB Storage Capabilities](#).

The following procedure describes how to perform a Hitless upgrade.

➤ **To upgrade device in HA mode using Software Upgrade wizard:**

1. Start the Software Upgrade wizard:
  - **Toolbar:** From the **Actions** drop-down menu, choose **Software Upgrade**.
  - **Navigation tree:** **Setup** menu > **Administration** tab > **Maintenance** folder > **Software Upgrade**.

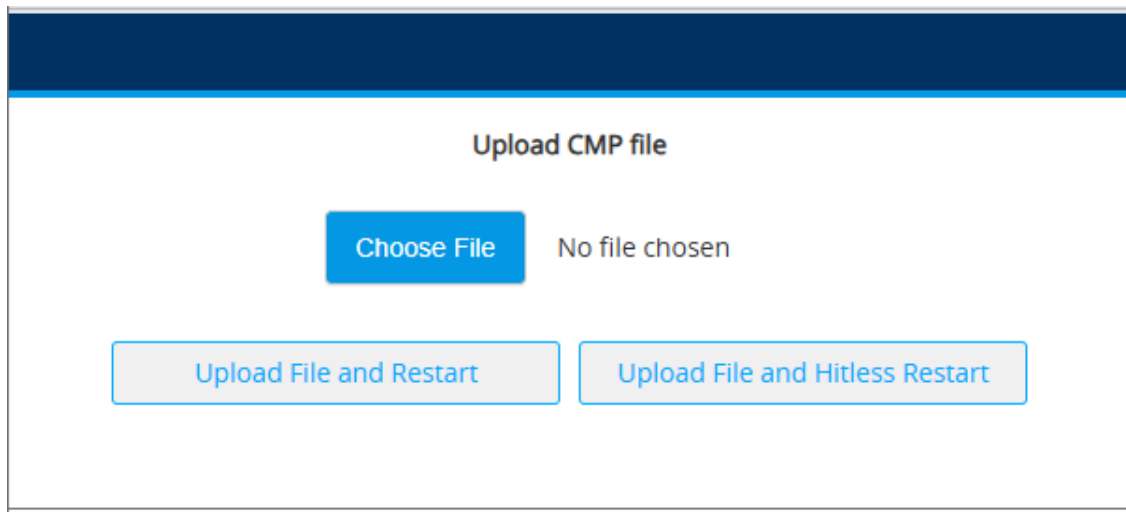

The Software Upgrade page is displayed:

**Software Upgrade**

Start Software Upgrade

**Warning:**  
In case of an upgrade failure, the device will restart and the previous configuration saved to flash will be restored.

2. Click **Start Software Upgrade**; the wizard starts, prompting you to choose the software version file (.cmp):

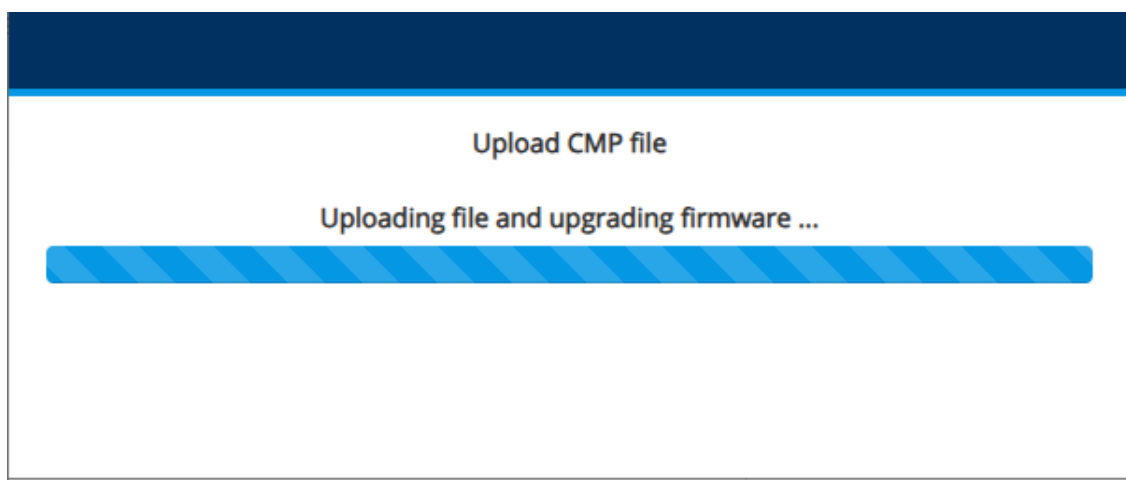

Upload CMP file

Choose File No file chosen

Upload File and Restart Upload File and Hitless Restart

3. Click **Choose File**, and then navigate to and select the .cmp file.
4. Choose the upgrade method:
  - **For Non-Hitless upgrade:** Click **Upload File and Restart**.
  - **For Hitless upgrade:** Click **Upload File and Hitless Restart**; the active device uploads the .cmp file, and then transfers it to the redundant device:

Upload CMP file

Uploading file and upgrading firmware ...

Once the active device uploads the file and transfers it to the redundant device, the redundant device saves the software to flash memory and then restarts to install the software.

When the redundant device completes the software upgrade, it initiates an HA switchover to become the active device, and now handles all the currently active calls (Stage 1/3):

Hitless Software Upgrade process currently in progress

Stage 1/3: Burning and initiating switch-over...

The previously active device (now redundant) saves the file to flash memory, and then restarts to install the software.

When the currently redundant device (previously active) completes the software upgrade, it initiates an HA switchover to become the active device once again, and now handles all the currently active calls (Stage 2/3):

Hitless Software Upgrade process currently in progress

Stage 1/3: Burning and initiating switch-over...

Stage 2/3: Burning and initiating switch-back...

The active device then reconnects with the redundant device (Stage 3/3):

Hitless Software Upgrade process is currently in progress

Stage 1/3: Burning and initiating switch-over...

Stage 2/3: Burning and initiating switch-back...

Stage 3/3: Connecting to redundant device...

5. When the upgrade process completes, the Web Login page is displayed. Log in again to the device with your credentials.

## 44 Uploading Auxiliary Files

You can upload Auxiliary files to the device using any of the following methods:

- Web interface (see [Uploading Auxiliary Files through Web Interface](#) on the next page)
- CLI (see [Uploading Auxiliary Files through CLI](#) on page 1350)
- Automatic Update mechanism (see [Automatic Update Mechanism](#))
- One Voice Operations Center (OVOC) – refer to the *OVOC User's Manual*

The following table lists the different types of Auxiliary files.

**Table 44-1: Auxiliary Files**

File	Description
<b>INI</b>	Configures the device. The Web interface enables practically full device provisioning. However, some features may only be configured by ini file or you may wish to configure your device through ini file. For more information, see <a href="#">INI File-Based Management</a> on page 127.
<b>CAS</b>	Contains CAS Protocol definitions for CAS-terminated trunks (for various types of CAS signaling). You can use the supplied files or construct your own files. Up to eight different CAS files can be installed on the device. For more information, see <a href="#">Uploading CAS Files</a> on page 1359.
<b>Call Progress Tones</b>	Region-specific, telephone exchange-dependent file that contains the Call Progress Tones (CPT) levels and frequencies for the device. The default CPT file is U.S.A. For more information, see <a href="#">Call Progress Tones File</a> on page 1351.
<b>Prerecorded Tones</b>	The Prerecorded Tones (PRT) file enhances the device's capabilities of playing a wide range of telephone exchange tones that cannot be defined in the CPT file. For more information, see <a href="#">Uploading a Prerecorded Tones File</a> on page 1357.
<b>User Info</b>	Uploads a User Information file. <b>Note:</b> Upload a User Information file using the Auxiliary Files page only for <b>backward compatibility</b> (old file format); otherwise, upload the file or configure users in the SBC User Information table for SBC users (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803) and for Gateway users (see <a href="#">Configuring Gateway User Information Table through Web Interface</a> on page 797).
<b>AMD Sensitivity</b>	Answer Machine Detector (AMD) Sensitivity file containing the AMD Sensitivity suites. For more information, see <a href="#">Uploading an AMD Sensitivity File</a> on page 1360.

File	Description
<b>SBC Wizard Template Package</b>	<p>Contains the vendor-interoperability configuration templates for the SBC Configuration Wizard. For more information, see <a href="#">SBC Configuration Wizard</a> on page 1424.</p> <p><b>Note:</b> The SBC Configuration Wizard isn't supported (and not available in the Web interface) if you have configured any IPv6 IP Interfaces in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159).</p>

## Uploading Auxiliary Files through Web Interface

The following procedure describes how to upload Auxiliary files through the Web interface.

- When uploading an ini file through the Auxiliary Files page, only parameter settings specified in the ini file are applied to the device; all other parameters remain at their current settings. This is known as an *incremental* ini file upload.
- If you upload an ini file containing Auxiliary file(s), the Auxiliary files specified in the file overwrite the Auxiliary files currently installed on the device.
- For the User Information file, use the Auxiliary Files page **only for backward compatibility** (old file format). If backward compatibility is not needed, upload the file or configure users in the SBC User Information table for SBC users (see [Configuring SBC User Information Table through Web Interface](#) on page 803) and for Gateway users (see [Configuring Gateway User Information Table through Web Interface](#) on page 797).

### ➤ To upload Auxiliary files through Web interface:

1. Open the Auxiliary Files page:
  - Toolbar: From the **Actions** drop-down menu, choose **Auxiliary Files**.
  - Navigation tree: **Setup** menu > **Administration** tab > **Maintenance** folder > **Auxiliary Files**.

## Auxiliary Files

INI file (incremental)

Choose File

Load File

SBC Wizard Template package file

Choose File

No file chosen

Load File

The above figure is used only as an example; some Auxiliary files may not be supported by your device.

2. Click the **Browse** or **Choose File** button (depending on browser) corresponding to the Auxiliary file type that you want to upload, navigate to the folder in which the file is located, and then click **Open**; the name of the file appears next to the **Browse** button.
3. Click the corresponding **Load File** button.
4. Repeat steps 2 through 3 for each file you want to upload.
5. If you uploaded a file that requires a device restart (e.g., Call Progress Tones file), the **Restart** button on the toolbar appears with a red border, which you need to click to restart the device with a save-to-flash for your settings to take effect. If you uploaded a file that doesn't need a device restart, only the **Save** button on the toolbar appears with a red border, which you need to click for your settings to take effect.

## Uploading Auxiliary Files through CLI

You can upload Auxiliary files from remote servers through CLI:

### ■ Single Auxiliary file:

```
# copy <file> from <URL of remote server>
```

For example:

```
# copy call_progress_tones from http://192.169.11.11:80/cpt_us.dat
```

- ### ■ Multiple (batch) Auxiliary files:
- The Auxiliary files must be contained in a TAR (Tape Archive) file (.tar). The TAR file can contain any number and type of Auxiliary files (e.g., Dial Plan file and CPT file).

```
# copy aux-package from | to <URL of remote server with TAR file name>
```

For example:

```
# copy aux-package from http://192.169.11.11:80/aux_files.tar
```

For more information on CLI, refer to the *CLI Reference Guide*.

## Deleting Auxiliary Files

You can delete loaded Auxiliary files through the Web interface, as described below.

### ➤ To delete a loaded Auxiliary file:

1. Open the Device Information page (see [Viewing Device Information](#) on page 1441); the loaded files are listed under the Loaded Files group:

LOADED FILES		
Call Progress Tones File Name:	usa_tones_13.dat	<b>Delete</b>
Loaded Coder Table :	Default CODERTABLE	

2. Click the **Delete** button corresponding to the file that you want deleted; a confirmation message box appears.
3. Click **OK** to confirm.
4. Restart the device with a save-to-flash for your settings to take effect.

## Uploading an ini File

You can upload an ini file to the device using the Auxiliary page.

When using the Auxiliary Files page to upload an ini file, **only** parameters specified in the ini file are applied to the device's configuration; all other parameters remain at their current settings. This is referred to as *incremental* ini file upload.

- If you upload an ini file that also contains other Auxiliary files, the Auxiliary files specified in the file overwrite the Auxiliary files currently installed on the device.
- Only if the ini file contains the parameter [ResetNow = 1], does the device restart after the file is uploaded.

### ➤ To upload an ini file:

1. Open the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348).
2. Under the **INI file (incremental)** group, click the **Choose File** button (or **Browse** button, depending on browser) to select the file from a folder on your computer, and then click **Load File**:

#### INI file (incremental)

<b>Choose File</b>	No file chosen	<b>Load File</b>
--------------------	----------------	------------------

3. On the toolbar, click **Save** for your settings to take effect.

## Call Progress Tones File

The Call Progress Tones (CPT) and Distinctive Ringing (analog interfaces only) file contains definitions of the CPT (levels and frequencies) that are detected and generated by the device.

The CPT file for analog interfaces is comprised of two sections:

- The first section contains the definitions of the Call Progress Tones (levels and frequencies) that are detected/generated by the device.

- The second section contains the characteristics of the Distinctive Ringing signals that are generated by the device (see [Distinctive Ringing](#) on page 1355).

You can use one of the supplied Auxiliary files (.dat file format) or create your own file. To create your own file, it's recommended to modify the supplied *usa\_tone.ini* file (in any standard text editor) to suit your specific requirements and then convert the modified *ini* file into binary *dat* file format, using AudioCodes DConvert utility. For more information, refer to the document [DConvert Utility User's Guide](#).

The CPT file can only be loaded in .dat file format.

You can create up to 32 different Call Progress Tones, each with frequency and format attributes. The frequency attribute can be single or dual-frequency (in the range of 300 to 1980 Hz) or an Amplitude Modulated (AM). Up to 64 different frequencies are supported. Only eight AM tones, in the range of 1 to 128 kHz, can be configured (the detection range is limited to 1 to 50 kHz). Note that when a tone is composed of a single frequency, the second frequency field must be set to zero.

The format attribute can be one of the following:

- **Continuous:** A steady non-interrupted sound (e.g., a dial tone). Only the 'First Signal On time' should be specified. All other on and off periods must be set to zero. In this case, the parameter specifies the detection period. For example, if it equals 300, the tone is detected after 3 seconds (300 x 10 msec). The minimum detection time is 100 msec.
- **Cadence:** A repeating sequence of on and off sounds. Up to four different sets of on/off periods can be specified.
- **Burst:** A single sound followed by silence. Only the 'First Signal On time' and 'First Signal Off time' should be specified. All other on and off periods must be set to zero. The burst tone is detected after the off time is completed.

You can specify several tones of the same type. These additional tones are used only for tone detection. Generation of a specific tone conforms to the first definition of the specific tone. For example, you can define an additional dial tone by appending the second dial tone's definition lines to the first tone definition in the *ini* file. The device reports dial tone detection if either of the two tones is detected.

The Call Progress Tones section of the *ini* file comprises the following segments:

- **[NUMBER OF CALL PROGRESS TONES]:** Contains the following key:  
'Number of Call Progress Tones' defining the number of Call Progress Tones that are defined in the file.
- **[CALL PROGRESS TONE #X]:** containing the Xth tone definition, starting from 0 and not exceeding the number of Call Progress Tones less 1 defined in the first section (e.g., if 10 tones, then it is 0 to 9), using the following keys:
  - **Tone Type:** Call Progress Tone types:
    - ◆ **[1] Dial Tone**

- ◆ [2] Ringback Tone
- ◆ [3] Busy Tone
- ◆ [4] Congestion Tone
- ◆ [6] Warning Tone
- ◆ [7] Reorder Tone
- ◆ [8] Confirmation Tone (analog interfaces)
- ◆ [9] Call Waiting Tone - heard by called party (analog interfaces)
- ◆ [15] Stutter Dial Tone (analog interfaces)
- ◆ [16] Off Hook Warning Tone (analog interfaces)
- ◆ [17] Call Waiting Ringback Tone (heard by the calling party)
- ◆ [18] Comfort Tone
- ◆ [23] Hold Tone
- ◆ [46] Beep Tone
- **Tone Modulation Type:** Amplitude Modulated (1) or regular (0)
- **Tone Form:** The tone's format can be one of the following:
  - ◆ Continuous (1)
  - ◆ Cadence (2)
  - ◆ Burst (3)
- **Low Freq [Hz]:** Frequency (in Hz) of the lower tone component in case of dual frequency tone, or the frequency of the tone in case of single tone. This is not relevant to AM tones.
- **High Freq [Hz]:** Frequency (in Hz) of the higher tone component in case of dual frequency tone, or zero (0) in case of single tone (not relevant to AM tones).
- **Low Freq Level [-dBm]:** Generation level 0 dBm to -31 dBm in dBm (not relevant to AM tones).
- **High Freq Level:** Generation level of 0 to -31 dBm. The value should be set to 32 in the case of a single tone (not relevant to AM tones).
- **First Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the first cadence on-off cycle. For continuous tones, the parameter defines the detection period. For burst tones, it defines the tone's duration.
- **First Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the first cadence on-off cycle (for cadence tones). For burst tones, the parameter defines the off time required after the burst tone ends and the tone detection is reported. For continuous tones, the parameter is ignored.

- **Second Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the second cadence on-off cycle. Can be omitted if there isn't a second cadence.
- **Second Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the second cadence on-off cycle. Can be omitted if there isn't a second cadence.
- **Third Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the third cadence on-off cycle. Can be omitted if there isn't a third cadence.
- **Third Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the third cadence on-off cycle. Can be omitted if there isn't a third cadence.
- **Fourth Signal On Time [10 msec]:** 'Signal On' period (in 10 msec units) for the fourth cadence on-off cycle. Can be omitted if there isn't a fourth cadence.
- **Fourth Signal Off Time [10 msec]:** 'Signal Off' period (in 10 msec units) for the fourth cadence on-off cycle. Can be omitted if there isn't a fourth cadence.
- **Carrier Freq [Hz]:** Frequency of the carrier signal for AM tones.
- **Modulation Freq [Hz]:** Frequency of the modulated signal for AM tones (valid range from 1 to 128 Hz).
- **Signal Level [-dBm]:** Level of the tone for AM tones.
- **AM Factor [steps of 0.02]:** Amplitude modulation factor (valid range from 1 to 50). Recommended values from 10 to 25.

- When the same frequency is used for a continuous tone and a cadence tone, the 'Signal On Time' parameter of the continuous tone must have a value that is greater than the 'Signal On Time' parameter of the cadence tone. Otherwise, the continuous tone is detected instead of the cadence tone.
- The tones frequency must differ by at least 40 Hz between defined tones.

Below shows an example of a configured dial tone to 440 Hz only:

```
[NUMBER OF CALL PROGRESS TONES]
Number of Call Progress Tones=1
#Dial Tone
[CALL PROGRESS TONE #0]
Tone Type=1
Tone Form =1 (continuous)
Low Freq [Hz]=440
High Freq [Hz]=0
Low Freq Level [-dBm]=10 (-10 dBm)
High Freq Level [-dBm]=32 (use 32 only if a single tone is required)
First Signal On Time [10msec]=300; the dial tone is detected after 3 sec
First Signal Off Time [10msec]=0
Second Signal On Time [10msec]=0
Second Signal Off Time [10msec]=0
```

➤ **To upload a Call Progress Tones file:**

1. Open the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348).
2. Under the **Call Progress Tones file** group, click the **Choose File** button (or **Browse** button, depending on browser) to select the file from a folder on your computer, and then click **Load File**:

3. Restart the device with a burn-to-flash for your settings to take effect.

Uploading a CPT file requires a device restart. After you have uploaded the file, the **Restart** button on the toolbar appears with a red border, which you need to click.

## Distinctive Ringing

Distinctive Ringing is applicable only to FXS interfaces. Using the Distinctive Ringing section of the Call Progress Tones Auxiliary file, you can create up to 16 Distinctive Ringing patterns. Each ringing pattern configures the ringing tone frequency and up to four ringing cadences. The same ringing frequency is used for all the ringing pattern cadences. The ringing frequency can be configured in the range of 10 to 200 Hz with a 5 Hz resolution.

The feature is applicable only to FXS interfaces.

Each of the ringing pattern cadences is specified by the following parameters:

- **Burst Ring On Time:** Configures the cadence to be a burst cadence in the entire ringing pattern. The burst relates to On time and the Off time of the same cadence. It must appear between 'First/Second/Third/Fourth' string and the 'Ring On/Off Time'. This cadence rings once during the ringing pattern. Otherwise, the cadence is interpreted as cyclic: it repeats for every ringing cycle.
- **Ring On Time:** Specifies the duration of the ringing signal.
- **Ring Off Time:** Specifies the silence period of the cadence.

The Distinctive Ringing section of the *ini* file format contains the following strings:

- **[NUMBER OF DISTINCTIVE RINGING PATTERNS]:** Contains the following key:
  - 'Number of Distinctive Ringing Patterns' defining the number of Distinctive Ringing signals that are defined in the file.

- **[Ringing Pattern #X]:** Contains the Xth ringing pattern definition (starting from 0 and not exceeding the number of Distinctive Ringing patterns defined in the first section minus 1) using the following keys:
  - **Ring Type:** Must be equal to the Ringing Pattern number.
  - **Freq [Hz]:** Frequency in hertz of the ringing tone.
  - **First (Burst) Ring On Time [10 msec]:** 'Ring On' period (in 10 msec units) for the first cadence on-off cycle.
  - **First (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the first cadence on-off cycle.
  - **Second (Burst) Ring On Time [10 msec]:** 'Ring On' period (in 10 msec units) for the second cadence on-off cycle.
  - **Second (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the second cadence on-off cycle.
  - **Third (Burst) Ring On Time [10 msec]:** 'Ring On' period (in 10 msec units) for the third cadence on-off cycle.
  - **Third (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the third cadence on-off cycle.
  - **Fourth (Burst) Ring On Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the fourth cadence on-off cycle.
  - **Fourth (Burst) Ring Off Time [10 msec]:** 'Ring Off' period (in 10 msec units) for the fourth cadence on-off cycle.

In SIP, the Distinctive Ringing pattern is selected according to the Alert-Info header in the INVITE message. For example:

Alert-Info:<Bellcore-dr2>

--or--

Alert-Info:<http://.../Bellcore-dr2>

"dr2" defines ringing pattern #2.

If the Alert-Info header is not present, the default ringing tone #0 is played.

An example of a **ringing burst** definition is shown below:

#Three ringing bursts followed by repeated ringing of 1 sec on and 3 sec off.

[NUMBER OF DISTINCTIVE RINGING PATTERNS]

Number of Ringing Patterns=1

[Ringing Pattern #0]

Ring Type=0

Freq [Hz]=25

First Burst Ring On Time [10msec]=30

```

First Burst Ring Off Time [10msec]=30
Second Burst Ring On Time [10msec]=30
Second Burst Ring Off Time [10msec]=30
Third Burst Ring On Time [10msec]=30
Third Burst Ring Off Time [10msec]=30
Fourth Ring On Time [10msec]=100
Fourth Ring Off Time [10msec]=300

```

An example of **various ringing signals** definition is shown below:

```

[NUMBER OF DISTINCTIVE RINGING PATTERNS]
Number of Ringing Patterns=3

```

```

#Regular North American Ringing Pattern
[Ringing Pattern #0]
Ring Type=0
Freq [Hz]=20
First Ring On Time [10msec]=200
First Ring Off Time [10msec]=400

```

```

#GR-506-CORE Ringing Pattern 1
[Ringing Pattern #1]
Ring Type=1
Freq [Hz]=20
First Ring On Time [10msec]=200
First Ring Off Time [10msec]=400

```

```

#GR-506-CORE Ringing Pattern 2
[Ringing Pattern #2]
Ring Type=2
Freq [Hz]=20
First Ring On Time [10msec]=80
First Ring Off Time [10msec]=40
Second Ring On Time [10msec]=80
Second Ring Off Time [10msec]=400

```

## Uploading a Prerecorded Tones File

The Prerecorded Tones (PRT) file can contain up to 80 user-defined prerecorded tones (and up to 10 minutes of recorded audio in total) that can be played by the device. The PRT file overcomes the limitations of the CPT file (such as limited number of predefined tones and limited number of frequency integrations in a single tone).

Some usage examples of the PRT file include:

- Playing a held tone (music on hold) to a call party that has been put on hold, or playing a ringback tone to a calling party.
- Playing different held and ringback tones to different groups of users. To do this, configure an IP Profile (see [Configuring IP Profiles](#) on page 674) with the desired ringback tone ('Local Ringback Tone Index' parameter) and/or held tone ('Local Held Tone Index' parameter), and then associate the IP Profile with the desired IP Group.
- Playing background tones to the call parties (caller and/or callee) in an SBC call. For more information, see [Configuring Background Tones for SBC Calls](#) on page 1268.

- Playing tones from the PRT file is applicable to Gateway and SBC calls.
- The PRT file only generates (plays) tones; detection of tones is according to the CPT file.
- The PRT file can be up to 4 megabytes in size.
- If the PRT file contains a tone that also exists in the CPT file, the tone in the PRT file is played instead (i.e., overrides the tone in the CPT file).
- For SBC calls, you can define a PRT file with multiple tones for the same tone type, but where each tone is defined with a different coder. If the coder of the tone is the same as that used in the current call, DSPs are not required by the device to play the tone. Therefore, if a tone is defined with a coder that is also used in the call, the device always selects this specific tone. However, if the coders are different, the device uses DSPs to play the appropriate tone from the Call Progress Tones (CPT) file (if the tone and CPT file exist).
- The device requires DSPs for local generation of tones.
- The PRT file supports only the ringback tone and hold tone for SBC calls.

You can record the tones using a standard third-party, recording utility. You need to record the tones (raw data files) with the following properties:

- Coders: G.711 A-law, G.711  $\mu$ -law, or G.729
- Rate: 8 kHz
- Resolution: 8-bit
- Channels: mono

The PRT file can include prerecorded audio tones of different coders (e.g., some with G.711 and some with G.729). The prerecorded tones are played repeatedly. This allows you to record only part of the tone and then play the tone for the full duration. For example, if a tone has a cadence of 2 seconds on and 4 seconds off, the recorded file should contain only these 6 seconds. The device repeatedly plays this cadence for the configured duration. Similarly, a continuous tone can be played by repeating only part of it.

Once recorded, you need to combine the recorded files into a single and loadable PRT file (.dat), using the latest version of AudioCodes DConvert utility. In DConvert, each recording must be added to the PRT file with the tone type "acUserDefineTone<Index>". When you want to specify the tone (ringback or held tone) to play for a specific IP Profile ('Local Ringback Tone

Index' and 'Local Held Tone Index' parameters), you need to use this index number. For more information on the DConvert utility, refer to the [DConvert Utility User's Guide](#). Once you have created the PRT .dat file, you need to upload it to the device (flash memory).

The following figure shows an example of creating a PRT file with multiple user-defined tones ("acUserDefineTone<Index>"), using the DConvert utility:

### ➤ To upload a Prerecorded Tones file:

1. Open the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348).
2. Under the **Prerecorded Tones** file group, click the **Choose File** button (or **Browse** button, depending on browser) to select the file from a folder on your computer, and then click **Load File**:

#### Prerecorded Tones file

Choose File

No file chosen

Load File

3. On the toolbar, click **Save** for your settings to take effect.

## Uploading CAS Files

The CAS files contain the CAS Protocol definitions that are used for CAS-terminated trunks. You can use the supplied CAS files or create your own files. You can upload up to eight files to the device. You can assign different files to different trunks (CASTableIndex\_x), and different CAS tables to different B-channels (CASChannelIndex) in the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878).

All CAS files that are uploaded together must belong to the same trunk type (i.e., either E1 or T1).

➤ **To upload a CAS file:**

1. Open the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348).
2. Under the **CAS file** group, click the **Choose File** button (or **Browse** button, depending on browser) to select the file from a folder on your computer, and then click **Load File**:

CAS file

<b>Choose File</b>	No file chosen	<b>Load File</b>
--------------------	----------------	------------------

3. On the toolbar, click **Save** for your settings to take effect.

## Uploading an AMD Sensitivity File

The device is shipped with a default, pre-installed *AMD Sensitivity* file for its Answering Machine Detection (AMD) feature (as described in [Answering Machine Detection \(AMD\)](#) on page 311). This file includes the detection algorithms for detecting whether a human or answering machine has answered the call, and is based on North American English. In most cases, the detection algorithms in this file suffice even when your deployment is in a region where a language other than English is spoken. However, if you wish to replace the default file with a different AMD Sensitivity file containing customized detection algorithms, please contact the your AudioCodes sales representative for more information.

The AMD Sensitivity file is created in .xml format and then converted to a binary .dat file that can be installed on the device. The XML-to-binary format conversion can be done using AudioCodes DConvert utility. For more information, refer to the document [DConvert Utility User's Guide](#).

- You can upload only one AMD Sensitivity file to the device.
- When you upload an AMD Sensitivity file, it replaces the currently installed AMD Sensitivity file (if exists).

➤ **To upload an AMD Sensitivity file:**

1. Open the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348).
2. Under the **AMD Sensitivity file** group, click the **Choose File** button (or **Browse** button, depending on browser) to select the file from a folder on your computer, and then click **Load File**:

AMD Sensitivity file

<b>Choose File</b>	No file chosen	<b>Load File</b>
--------------------	----------------	------------------

3. On the toolbar, click **Save** for your settings to take effect.

You can also upload an AMD Sensitivity file, using the following methods:

- **TFTP during initialization:** Configure the [AMDSensitivityFileName] parameter, and then copy the AMD Sensitivity file to the TFTP directory.
- **Automatic Update mechanism:** Configure the [AMDSensitivityFileUrl] parameter through ini file. For more information, see [Automatic Update Mechanism](#).

## Uploading a User Info File

For uploading a User Info (User Information) file, use the Auxiliary Files page **only for backward compatibility** (old file format).

If backward compatibility is not required, upload the file (or configure users) in the SBC User Information table for SBC users (see [Configuring SBC User Information Table through Web Interface](#) on page 803) and for Gateway users (see [Configuring Gateway User Information Table through Web Interface](#) on page 797). For file syntax when uploading the file using the Auxiliary Files page, see the notes in these sections.

## 45 License Key

The License Key determines the licensed features (e.g., Test Call and voice coders) and various capacity figures (e.g., number of Test Calls and SBC call sessions) that you have ordered for your device.

The local License Key, which is installed on the device through ini file (locally or through the Automatic Update mechanism), contains all the licenses for the ordered features and capacity.

However, capacity licenses for WebRTC, SIPREC and SBC sessions (regular sessions, transcoding sessions, and registered far-end users), you can use AudioCodes OVOC management tool to provide and manage them. OVOC provides various SBC capacity licensing modes, as described in [OVOC-Managed Capacity Licenses](#) on page 1372.

- The availability of certain Web pages in the Web interface depends on the licensed features in the License Key.

### Viewing the License Key

The License Key is displayed on the License Key page, showing all the device's licensed features and capacity.

#### ➤ To view License Key through Web interface:

- Open the License Key page:

- **Toolbar:** From the **Actions** drop-down menu, choose **License Key**.
- **Navigation tree:** **Setup** menu > **Administration** tab > **License** folder > **License Key**.

- Ordered features are always licensed by the **local** License Key. In other words, even if you are using OVOC to manage the device's WebRTC, SIPREC and SBC capacity licenses, all the other features and capacity figures are licensed by the local License Key.
- If you save the device's ini configuration file to a folder on your computer, the local License Key is also included (see [Downloading or Uploading ini File](#) on page 1386). If the device is in High-Availability mode, the saved ini file of the Active device also includes the License Key of the Redundant device.

In addition to displaying the licensed features and capacity, the License Key page also displays general information on a bar at the top of the page, as shown in the example below:

Product Key	NA	Floating License	5967925	72	Not connected
	OVOC Product Key	Mode	Serial Number	Device Type	License Server Status

**Table 45-1: Description of General information on License Key Page**

Field	Description
<b>Serial Number</b>	Displays the device's serial number.
<b>Product Key</b>	Displays the device's Product Key. For more information, see <a href="#">Viewing the Device's Product Key</a> on page 1385.
<b>OVOC Product Key</b>	Displays the Product Key of OVOC that is providing and managing the SBC capacity licenses for the device. <b>Note:</b> The field is displayed only if the device uses OVOC to manage its SBC capacity licenses, as described in <a href="#">OVOC-Managed Capacity Licenses</a> on page 1372.
<b>Mode</b>	Displays the type of license used for the device's SBC capacity licenses: <ul style="list-style-type: none"> <li>■ "Local License Key": SBC capacity licenses are only based on the local License Key.</li> <li>■ "License Pool": SBC capacity licenses are obtained remotely from the Fixed License Pool, which is managed by OVOC. For more information, see <a href="#">Fixed License Pool Model</a> on page 1372.</li> <li>■ "Floating License": WebRTC, SIPREC and SBC capacity licenses are obtained remotely from the Floating License, which is managed by OVOC. For more information, see <a href="#">Floating License Model</a> on page 1374.</li> <li>■ "Flex License": WebRTC, SIPREC and SBC capacity licenses are obtained remotely from the Flex License, which is managed by OVOC. For more information, see <a href="#">Flex License Model</a> on page 1377.</li> </ul>
<b>Device Type</b>	Displays AudioCodes internal model identification number of the device.
<b>License Server Status</b>	Displays the connectivity status between the device and OVOC when the device uses OVOC to manage its SBC capacity licenses (Fixed License, Floating License, or Flex License): <ul style="list-style-type: none"> <li>■ "Connected": This indicates that the device is connected to OVOC.</li> <li>■ "Disconnected": This indicates that the device was connected to OVOC, but has lost connection with</li> </ul>

Field	Description
	<p>OVOC due to network problems (HTTPS TCP connection).</p> <p>■ "Not Connected": This indicates that the device has not connected to OVOC.</p> <p><b>Note:</b> The field is displayed only when the device uses OVOC to manage its SBC capacity licenses, as described in <a href="#">OVOC-Managed Capacity Licenses</a> on page 1372.</p>

## Local License Key

The local License Key contains all the licenses for your ordered features and capacity. This License Key is installed locally on the device.

- When you install a new License Key, it overwrites the previously installed License Key. Therefore, features that were licensed by the previous License Key and not included in the new License Key will no longer be available.
- The local License Key is unique to the device (based on Serial Number) and cannot be installed on other devices.
- You can also install the local License Key remotely using the device's Automatic Update mechanism (see [Automatic Provisioning](#) on page 1395).
- If you want to use OVOC to manage WebRTC, SIPREC and SBC capacity licenses, see [OVOC-Managed Capacity Licenses](#) on page 1372.

## Installing License Key through Web Interface

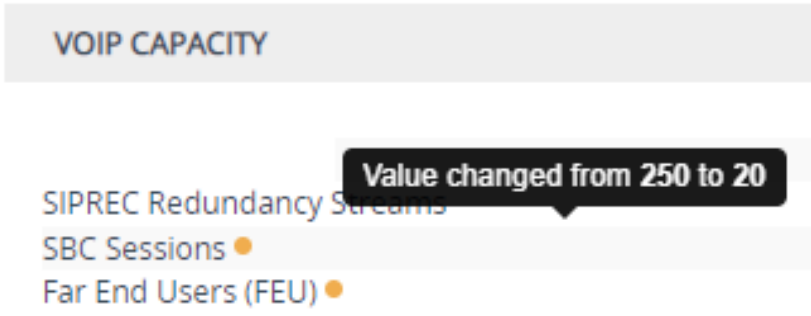

You can install the local License Key through the Web interface, using one of the following methods:

- Installing a License Key file (see [Installing a License Key File](#) on page 1367)
- Installing a License Key string (see [Installing a License Key String](#) on the next page)

When you initially upload the License Key before installing it, the License Key page uses color-coded icons to indicate the changes between the currently installed License Key and the new License Key that you loaded. The following table describes these color codes:

**Table 45-2: Color-Coded Icons for Newly Loaded License Key**

Icon	Color	Description
	Green	Indicates new features added by the new License Key.
	Orange	Indicates the capacity change of an existing feature. Move your mouse over the icon to view a pop-up describing the capacity

Icon	Color	Description
		<p>change, as shown in the following example for the SBC Sessions license:</p> 
	Red	Indicates features of the previously installed License Key that are not included in the new License Key and are no longer available.

After you install the License Key with a device restart, the icons are no longer displayed and the License Key page displays only the features and capacity that are licensed by the new License Key.

### Installing a License Key String

You can install the License Key as a string in encrypted format through the Web interface.

- The License Key installation process includes a device restart and therefore, is traffic-affecting. To minimize disruption of current calls, it is recommended to perform this procedure during periods of low traffic.
- Installation of the License Key in string format is not applicable to devices in HA mode. To install the License Key for devices in HA mode, you need to upload a License Key file, as described in [Installing License Key on HA Devices](#) on page 1368.

#### ➤ To install a License Key string through Web interface:

1. Open the License Key page (see [Viewing the License Key](#) on page 1362).
2. Back up the currently installed License Key as a precaution. If the new License Key doesn't comply with your requirements, you can re-upload the backed-up License Key to restore the device's original capabilities. For backing up the License Key, see [Backing up Local License Key](#) on page 1371.
3. Copy the License Key string (from the License Key file or email) to your clipboard. Make sure that you copy **only** the encrypted string (and not the serial number or any other part of the string), as shown in the example below:

```
[LicenseKeys]
S/N5967925-r4Rqr5to27458ANud3hru6x402R5c0lcbgNfuhcsiP8ealNefjQ9ay0c405bcindhbgM8f9G1iP8ealNe8OcpdHio4055c019bg
MfehcsiJjgealp4820ba28e4055c0lcbgMfehcsiP8ealtestNefjQba20c4055c0lcbgMfeggkqN8ealNefjQba20c4057ciV9bgMD4hcsiP8
eal17pmkba3Ui4055c0lcbgMfehcsiJgcaRVcf3Maai4d4050dZCMkDfPNhgrh3c19BZanBUba24d4idhcypfQwk62y00
```

4. Click **Load String**; the Load License Key String dialog box appears.
5. In the text box, paste your License Key string, as shown in the following example:

Load License Key String

Paste your License Key string:

```
r4Rqr5to274caQZtd3hru6R14it7citebMUdeN8tiP8280gmjfQldy0c4055c0tebgMfehMth3Qbbq2OgAbTR2sb52vcKylcbgMfejlQIP

```

384 chars

Cancel

Apply

6. Click **Apply**; the dialog box closes and the "String Uploaded!" message is briefly displayed at the bottom of the page when the License Key is successfully loaded to the device. The License Key page uses color-coded icons to indicate the changes between the currently installed License Key and the newly loaded License Key. For more information, see [Installing License Key through Web Interface](#) on page 1364.

7. Click **Apply New License Key**; the following message box appears:

Apply New License Key

A new local license key was loaded and a restart is required for it to take effect

The License Key is installed on the device with a restart. Current calls will be disconnected!

8. Click **Restart**; the device saves the file to flash memory with a device restart, displaying a progress message box. When installation completes, the following message box appears:

Apply New License Key

Restart burn succeeded.

Close

9. Click **Close** to close the message box; you are logged out of the Web interface and prompted to log in again. The features and capabilities displayed on the License Key page now reflect the newly installed License Key.

## Installing a License Key File

You can install the License Key as a file through the Web interface. The procedure depends if the device is in standalone mode (see [Installing on Standalone Devices](#) below) or operating in HA mode (see [Installing License Key on HA Devices](#) on the next page).

### Installing on Standalone Devices

You can install the License Key as a file through the Web interface when the device operates as a standalone device. For standalone devices, you can also install the License Key as a string, as described in [Installing a License Key String](#) on page 1365.

The License Key installation process includes a device restart and is therefore, traffic-affecting. To minimize disruption of current calls, it is recommended to perform this procedure during periods of low traffic.

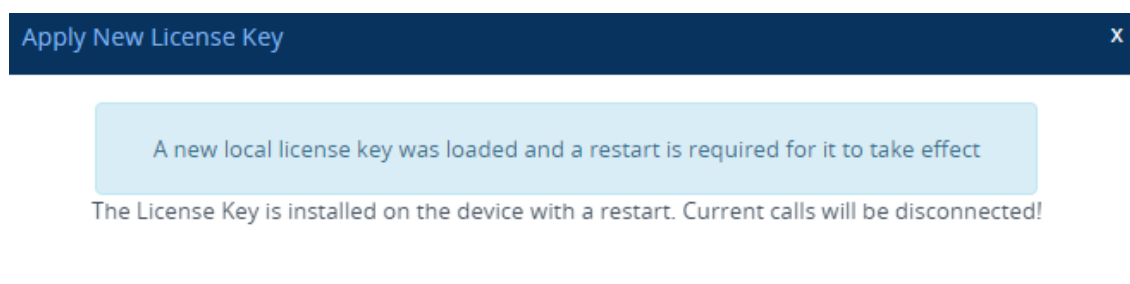

#### ➤ To install License Key file through Web interface:

1. Place the purchased License Key file in a folder on the computer from where you are logged into the device.
2. Open the License Key page (see [Viewing the License Key](#) on page 1362).
3. Back up the currently installed License Key as a precaution. If the new License Key doesn't comply with your requirements, you can re-upload the backed-up License Key to restore the device's original capabilities. For backing up the License Key, see [Backing up Local License Key](#) on page 1371.
4. Click the **Load File** button to select the License Key file on your computer; the **Apply New License Key** button appears. The License Key page uses color-coded icons to indicate the changes between the currently installed License Key and the newly loaded License Key (see [Installing License Key through Web Interface](#) on page 1364).

If want to cancel installation, restart the device without a save to flash. For more information, see [Restarting the Device](#) on page 1329.

5. Click **Apply New License Key**; the following message box appears:

6. Click **Restart**; the device saves the file to flash memory with a restart and a progress message box appears. When installation completes, a message box appears informing you that the License Key was successfully loaded,
7. Click **Close** to close the message box; you are logged out of the Web interface and prompted to log in again. The features and capabilities displayed on the License Key page now reflect the newly installed License Key.

### Installing License Key on HA Devices

When the device operates in HA mode, you can install the License Key **only** from a License Key file.

The License Key file for HA contains two License Keys - one for the active device and one for the redundant device. Each License Key has a different serial number ("S/N"), which reflects the serial number of each device in the HA system.

You can install the License Key using one of the following methods:

- **Hitless Installation:** This method allows you to install the License Key on both active and redundant devices without affecting traffic. The installation process is as follows:
  - a. The License Key file is loaded to the active device.
  - b. The active device sends the file to the redundant device.
  - c. The redundant device installs the file and saves it to flash memory with a restart.
  - d. The active device saves the file to flash memory (**but without** a restart).
  - e. The devices undergo an HA switchover, whereby the active device becomes redundant and the redundant device becomes active. Current calls are maintained and handled by the active device (previously the redundant device).
  - f. The redundant device (previously the active device) restarts to install the file.

Hitless installation of the License Key is applicable only if the new License Key includes changes, compared to the currently installed License Key, within the limited set of features below:

- FEU
- SBC
- Coder Transcoding
- SBC Signaling
- WebRTC
- SIPREC

- **Non-hitless Installation:** This method allows you to install the License Key simultaneously on both active and redundant devices (both restart at the same time). Therefore, this method is traffic-affecting and current calls are terminated. The installation process is as follows:

- a. The License Key file is loaded to the active device.
- b. The active device sends the file to the redundant device.
- c. Both devices install the file and save it to flash memory with a restart.

➤ **To install License Key file for HA through Web interface:**

1. Place the purchased License Key file in a folder on the computer from where you are logged into the device.
2. Open the License Key page (see [Viewing the License Key](#) on page 1362).
3. Back up the currently installed License Key as a precaution. If the new License Key doesn't comply with your requirements, you can re-upload this backed-up License Key to restore the device's original capabilities. For backing up the License Key, see [Backing up Local License Key](#) on page 1371.
4. Click the **Load File** button to select the License Key file on your computer; the **Apply New License Key** button appears. The License Key page uses color-coded icons to indicate the changes between the currently installed License Key and the newly loaded License Key (see [Installing License Key through Web Interface](#) on page 1364).

If want to cancel the License key installation, restart the device without a save to flash. For more information, see [Restarting the Device](#) on page 1329.

5. Click **Apply New License Key**; the following appears:

Apply New License Key x

A new local license key was loaded. For the license key to take effect, perform a hitless license key update (Hitless-Apply) or reset the device

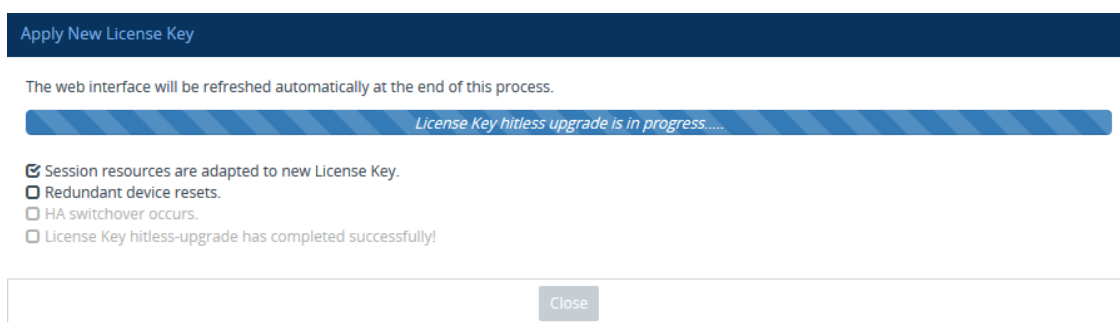

The License Key is installed on both devices with a reset, using the active-redundant switchover method which doesn't affect current traffic.	The License Key is installed simultaneously on both devices with a reset. Current calls will be disconnected!
<a href="#" style="background-color: #0070c0; color: white; padding: 5px 15px; text-decoration: none; border-radius: 3px;">Hitless Installation</a>	<a href="#" style="background-color: #0070c0; color: white; padding: 5px 15px; text-decoration: none; border-radius: 3px;">Non-Hitless Installation</a>

[Close](#)

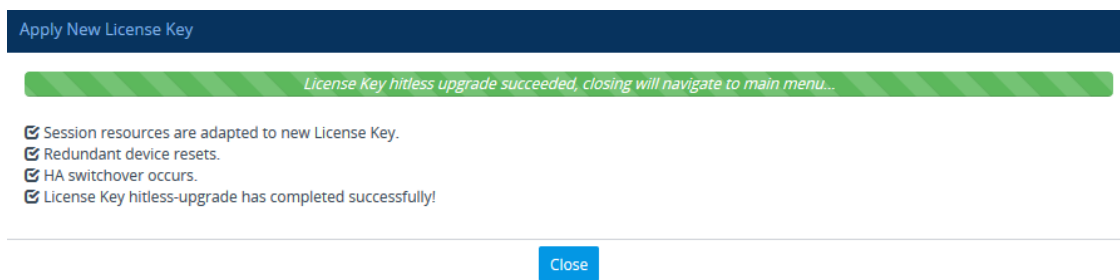

If the new License Key includes changes in licenses for features other than (or in addition to) FEU, SBC, Codex Transcoding, and/or SBC Signaling, then you can **only** use the **Non-Hitless Installation** method. Instead of the above page, the Web interface displays a page prompting you to click **Reset** (or **Close** to cancel the operation) to perform a non-hitless installation. In this scenario, skip Step 5.

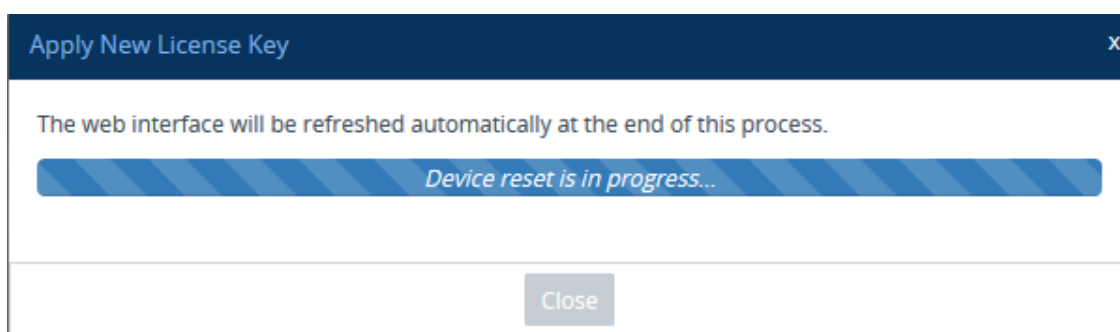

6. Click one of the following buttons:
  - **Hitless Installation:** Installs the License Key without affecting traffic by employing the HA switchover mechanism. When you click the button, the process starts and a message box is displayed indicating the installation progress:

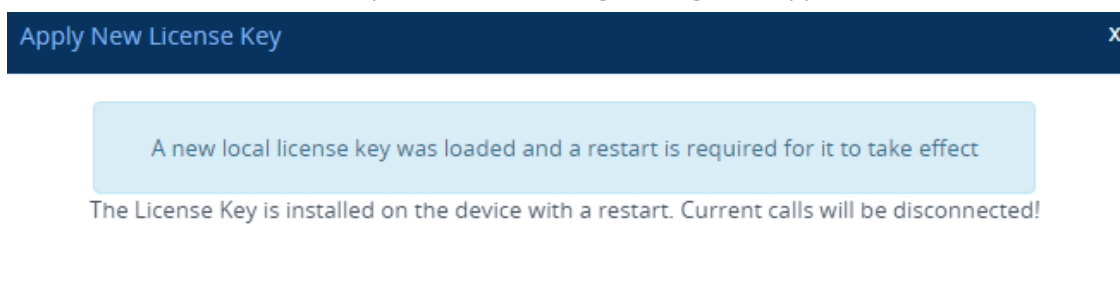

When installation completes, the following message box appears:

- Non-Hitless Installation:** Installs the License Key simultaneously on both devices where both undergo a restart and therefore, current calls are terminated. When you click the button, the process starts and the following progress message box appears:

When installation completes, the following message box appears:

- Click **Close** to close the message box; you are logged out of the Web interface and prompted to log in again. The features and capabilities displayed on the License Key page now reflect the newly installed License Key.

## Installing License Key String through CLI

To install the License Key string through CLI, use the following command:

```
(config-system)# feature-key <"License Key string enclosed in double quotation marks">
```

To view the installed License Key, use the following command:

```
show system feature-key
```

## Verifying Installed License Key

To verify that the new License Key has been installed:

1. On the License Key page, check that the listed features and capabilities of the new License Key match those that you ordered.
2. Access the syslog server and check that the following message appears:  
"S/N<serial number> Key Was Updated. The Board Needs to be Reloaded with ini file\n"  
If the syslog server indicates that the License Key was unsuccessfully loaded (i.e., the "SN\_" line is blank), do the following preliminary troubleshooting procedures:
  - a. Open the License Key file and check that the "S/N" line appears. If it doesn't appear, contact your AudioCodes sales representative.
  - b. Verify that you have loaded the correct file. Open the file and ensure that the first line displays "[LicenseKeys]".
  - c. Verify that the content of the file has not been altered.

## Backing up Local License Key

You can back up the installed local License Key. This may be useful, for example, if you have installed a new License Key and you want to revert to the previous License Key.

### ➤ To back up local License Key:

1. Open the License Key page (see [Viewing the License Key](#) on page 1362).
2. Click one of the following buttons:
  -  : Saves the License Key as a file to a folder on your computer. By default, the device saves the License Key as a .txt file type with the name license.txt.
  -  : Copies the License Key as a string to your computer's clipboard. You can then paste the string into, for example, an e-mail message or a text-based program such as Notepad.

## OVOC-Managed Capacity Licenses

The device's licenses for WebRTC, SIPREC and SBC capacity (SBC sessions and far-end user registrations) can be provided and managed remotely by OVOC.

OVOC offers the following capacity licensing models:

- Fixed License Pool (see [Fixed License Pool Model](#) below)
- Floating License ([Floating License Model](#) on page 1374)
- Flex License ([Flex License Model](#) on page 1377)

### Fixed License Pool Model

The device can receive SBC capacity licenses from a centralized pool of SBC licenses that is located on and managed by AudioCodes OVOC management tool. The license pool is purchased for OVOC as one bulk license and is used to provide SBC licenses to multiple devices. The OVOC user manually allocates a specific number of SBC licenses per license type (see list below) from the pool to each device in the network. Whenever required, the OVOC user can increase or decrease the number of allocated SBC licenses according to the device's capacity demands. The allocation of licenses to the devices cannot exceed the purchased Fixed License pool.

The Fixed License pool includes the following SBC capacity license types:

- SBC Sessions (maximum number of concurrent SBC call sessions - media and signaling)
- Far End Users (maximum number of SIP endpoints or users that can be registered with the device)

- The Fixed License doesn't involve any configuration on the device; it is enabled and managed entirely by OVOC. For more information on the OVOC License Pool, refer to the *OVOC User's Manual*.
- The Fixed License doesn't affect transcoding session capacity. By default, transcoding session capacity is at maximum (as supported by the device).

As an example of how the Fixed License pool allocates licenses, assume that the pool contains a maximum of 20 SBC far-end user (registration) licenses and it needs to service three devices (A, B and C). It can allocate 10 to A, 8 to B, and 2 to C. In this example, because all the far-end user licenses in the pool have been allocated, it cannot allocate any more far-end user licenses to the devices. However, if it de-allocates 5 licenses from A, for example, it can allocate these additional licenses to B and/or C.

As another example, assume that an OVOC tenant is allocated 500 SBC Session licenses to service 4 devices (A, B, and C), where each device has a capacity of 250 SBC sessions. If A and B are operating at maximum capacity (i.e. aggregated number of active SBC call sessions is 500), and C requires 50 SBC sessions, then C is taken out-of-service until the number of active calls on A and B combined drops to 450 sessions. When this occurs, the 50 free licenses can be

allocated by the pool to C. If over a period of time, call traffic on A and B is showing a downward trend, the OVOC user can reallocate extra licenses to C.

The device periodically (and after a device restart or HA switchover if operating in HA mode) checks with OVOC for any SBC capacity license updates. OVOC identifies the device by serial number and sends licenses to the device according to OVOC configuration. If the device's local License Key already includes SBC capacity licenses, the SBC licenses allocated by OVOC are added to it (but up to the device's maximum supported capacity capabilities). When the device applies the licenses received from OVOC, the License Key page displays "License Pool" in the 'Mode' field (see [Viewing the License Key](#) on page 1362) and displays the allocated SBC licenses under the **SBC Capacity** group, as shown in the example below:

SBC CAPACITY			
	<u>Remote</u>	<u>Local</u>	<u>Actual</u>
SBC Sessions	5	10	15
SBC Signaling Sessions	2	5	7
SBC Media Sessions		5	5
Far End Users (FEU)	2	22	24
Transcoding Sessions	2	20	22

- 'Remote': This column displays the number of SBC licenses per license type received from the OVOC Fixed License pool.
- 'Local': This column displays the number of SBC licenses per license type from the locally installed License Key.
- 'Actual': This column displays the total SBC licenses per license type, which is the summation of the remote and local licenses.

(Standalone devices only) For the SBC licenses allocated by OVOC to take effect, the device **must** restart with a save to flash. The restart can be initiated by the OVOC user or locally on the device by you. The total licenses (displayed in the "Actual" column) is only updated once the device completes this restart.

Communication between the device and OVOC is through HTTPS (port 443) and SNMP. If a firewall exists in the network, make sure that ports for these applications are opened. If the device loses connectivity with OVOC for a long duration, it discards the allocated SBC licenses and restarts with its initial SBC licenses according to the local License Key. This mechanism prevents misuse of SBC licenses allocated by the OVOC license pool. Connectivity status with OVOC is displayed in the 'License Server Status' field on the License Key page (see [Viewing the License Key](#) on page 1362).

When the device operates in High-Availability (HA) mode, the SBC licenses allocated from the OVOC Fixed License pool are installed on the active and redundant devices without affecting traffic. This is achieved by the Hitless Installation mechanism:

1. OVOC downloads the licenses to the redundant device, and then restarts it.

2. OVOC triggers an HA switchover.
3. OVOC downloads the same licenses to the previously active device (now redundant), and then restarts it.
4. OVOC triggers another HA switchover.

The device sends the following SNMP alarms to indicate various conditions relating to the allocation of SBC licenses by the OVOC Fixed License pool:

- `acLicensePoolInfraAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.106): Sent if the device loses connection with OVOC, for example.
- `acLicensePoolApplicationAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.107): Sent when the device receives new SBC licenses from the Fixed License pool.
- `acLicensePoolOverAllocationAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.125): Sent when the device receives new SBC licenses from the Fixed License pool, which has caused the device to exceed its maximum supported capacity.

For more information, refer to the [SBC-Gateway Series SNMP Alarm Reference Guide](#).

- The Fixed License only provides SBC capacity licenses (listed in the beginning of this section). Therefore, your device must still be installed with a local License Key to enable other ordered license-based features (e.g., Test Calls) and capacity.
- The allocation and de-allocation of SBC licenses to standalone devices by the OVOC Fixed License pool is service affecting because it requires a device restart.
- For HA systems, the OVOC Fixed License pool automatically allocates an equal number of SBC licenses to the active and redundant devices. For example, if the license pool allocates 200 signaling sessions to the active device, it also allocates 200 to the redundant. Therefore, it is important to take this into consideration when ordering a license pool.
- If the device is restored to factory defaults, the SBC licenses allocated by the OVOC Fixed License pool are removed and only the SBC licenses from the locally installed License Key are applied instead.
- If the device is allocated SBC licenses by the OVOC Fixed Licenses pool that exceeds the maximum number of sessions that the device can support, the device sets the number of sessions to its maximum supported capacity.
- The Fixed License pool cannot operate with the other OVOC-managed license modes (e.g., Floating License). Therefore, before using the Fixed License, make sure that the other license modes are disabled on the device and OVOC.

## Floating License Model

The Floating License is a network-wide license pool for WebRTC, SIPREC and SBC capacity, which is managed by AudioCodes OVOC and the cloud-based License Manager, and shared dynamically among multiple devices. The Floating License is a pay-as-you-grow service, eliminating the need to manually purchase additional licenses each time your capacity requirements increase. You initially purchase a Floating License based on your estimated

capacity requirements. If you later experience business growth and your devices use more licenses (sessions) than specified by the Floating License, you are billed for these additional licenses. In other words, the Floating License pool capacity can be exceeded.

- The Floating License model supports WebRTC and SIPREC session capacity licensing only from OVOC Version 8.0.3000 and later. If you are using an earlier OVOC version, WebRTC and SIPREC capacity is according to the device's **local** License Key only.
- To enable the use of the Floating License model for licensing WebRTC or SIPREC sessions, the device's local License Key must have WebRTC or SIPREC sessions (whichever functionality is required) set to zero (0).

The Floating License pool includes the following capacity license types:

- "SBC Sessions" - maximum number of concurrent SBC call sessions (media and signaling)
- "Far End Users" - maximum number of SIP endpoints (user agents) that can be registered with the device
- "WebRTC Sessions" - maximum number of WebRTC sessions
- "SIPREC Streams" - maximum number of SIPREC sessions
- "SIPREC Redundancy Streams" - maximum number of SIPREC sessions for the standby SRS in the active-standby redundancy pair

As an example of how the Floating License pool operates, assume that an OVOC tenant is allocated 500 SBC Session licenses and the tenant has deployed three devices (A, B, and C), where each device has a maximum capacity of 250 SBC sessions. If A and B are operating at maximum capacity (i.e. the aggregated number of active SBC call sessions is 500), and then C requires 50 SBC sessions, even though the initially purchased Floating License pool capacity has been reached (500), C is allowed to process these 50 new call sessions. When you are next billed, you are charged for these extra 50 SBC session licenses.

For providing the Floating License service, OVOC and the Cloud License Manager need to be set up accordingly (refer to the *OVOC User's Manual*). The Floating License service also needs to be enabled on these devices. Once these devices connect to OVOC, they are "open" to use any number of licenses in the Floating License pool. However, capacity is limited by the device's inherent maximum capacity support and by an optional user-defined limit called *Allocation Profile* (discussed later in this section), which specifies a capacity that is less than the device's inherent capacity per SBC license type.

Connection between the devices and OVOC is established over SNMP. Functionality of the Floating License service is managed over TCP/HTTPS REST. For more information, see the *One Voice Operations Center IOM Manual* and the *OVOC Security Guidelines*. Connectivity status with OVOC is displayed in the 'License Server Status' field on the License Key page (see [Viewing the License Key](#) on page 1362). If the device loses connectivity with OVOC, it continues using the licenses that it received before the disconnection for a specific grace period, and then once this period expires, it stops accepting new calls.

The devices report their SBC license consumption per license type to OVOC at fixed intervals (typically, every five minutes). OVOC accumulates these reports and sends them to AudioCodes Cloud License Manager every 12 hours with all the SBC licenses usage in the last 12 hours. OVOC uses REST APIs over HTTPS to report to the Cloud License Manager. AudioCodes personnel analyze these license consumption reports in the Cloud License Manager on a monthly basis to check if capacity specified by your Floating License was exceeded. If it was exceeded, AudioCodes sends you a report detailing the excess licenses and requests that you purchase additional SBC licenses for your Floating License. To view the Floating License reports of SBC license consumption that the device sends OVOC, see [Viewing Floating or Flex License Reports](#) on page 1384.

When the device uses the Floating License, the License Key page (see [Viewing the License Key](#) on page 1362) displays "Floating License" in the 'Mode' field and displays the capacity licenses received from the Floating License under the **VoIP Capacity** group, as shown in the following example:

VOIP CAPACITY			
	<u>Local</u>	<u>Floating</u>	<u>Actual</u>
Far End Users (FEU)	<del>5</del>	0	0
SBC Media Sessions		250	250
SBC Signaling Sessions		250	250
Transcoding Sessions		0	0
SBC Sessions	<del>2</del>		

- 'Local': Displays the licensed capacity from the locally installed License Key. These licenses are not used by the device and the figures are displayed crossed out (strikethrough).
- 'Floating': Displays the number of licensed capacity received from the OVOC Floating License pool.
- 'Actual': (see the 'Floating' above).

The device sends the following SNMP alarms to indicate various conditions relating to the allocation of licenses from the OVOC Floating License pool:

- acFloatingLicenseAlarm: Sent if you have configured an Allocation Profile that exceeds the device's maximum supported capacity.
- acCloudLicenseManagerAlarm: Sent upon various conditions such as loss of connectivity between the device and OVOC.

For more information, refer to the [SBC-Gateway Series SNMP Alarm Reference Guide](#).

- The Floating License only provides the WebRTC, SIPREC and SBC capacity licenses (listed previously). Therefore, your device must still be installed with a local License Key to enable the other ordered license-based features (e.g., Test Calls) and capacity.
- The Floating License uses the device's IPv4 OAMP interface.
- The Floating License doesn't affect transcoding session capacity. By default, transcoding session capacity is at maximum (as supported by the device).
- For configuring the Floating License on OVOC, refer to the *OVOC User's Manual*.
- The Floating License cannot operate with other OVOC-managed capacity license modes (e.g., Fixed License). Therefore, before enabling the Floating License, make sure that the other license modes are disabled on OVOC.
- The Floating License ignores OVR, TDM2SBC, and LAD capacity licenses in the local License Key.

## Flex License Model

The Flex License model is a network-wide license for WebRTC, SIPREC and SBC capacity, managed by AudioCodes OVOC, which is dynamically shared among multiple devices. The Flex License is ordered as a single license, which provides a pool of these licenses that cannot be exceeded. The Flex License pool includes the following capacity license types:

- "SBC Sessions" - maximum number of concurrent SBC call sessions (media and signaling)
- "Far End Users" - maximum number of SIP endpoints (user agents) that can be registered with the device
- "WebRTC Sessions" - maximum number of WebRTC sessions
- "SIPREC Streams" - maximum number of SIPREC sessions
- "SIPREC Redundancy Streams" - maximum number of SIPREC sessions for the standby SRS in the active-standby redundancy pair

The Flex License model supports WebRTC and SIPREC capacity licensing only from OVOC Version 8.0.3000 and later. If you are using an earlier OVOC version, WebRTC and SIPREC capacity is according to your local License Key only.

The Flex License model is similar to the Floating License model (as described in [Floating License Model](#) on page 1374), but provides some important advantages:

- The Flex License is solely managed by OVOC; it doesn't employ a cloud-based license manager like the Floating License. This reduces the exposure of OVOC to security risks from its connectivity with the public cloud.
- The Flex License gracefully enforces license capacity of the pool, whereas the Floating License allows devices to exceed pool capacity, resulting in you being billed at the end of the month for unexpected license usages.

The Flex License is managed by OVOC, which defines the devices using the Flex License. Once connected to OVOC, each device can handle calls using the licenses of the different license types in the Flex License pool, as long as the pool has available (unused) licenses. However, the device's capacity is limited by its inherent maximum capacity support and by an optional user-defined limit called *Allocation Profile* (discussed later in this section), which specifies a capacity that is less than the device's inherent capacity per license type.

The devices periodically (typically, every five minutes) report their current license consumption (usage) per license type to OVOC. OVOC uses these reports to calculate the total number of currently used licenses from the pool and therefore, determines the remaining licenses in the pool per license type. To view the license usage reports, see [Viewing Floating or Flex License Reports](#) on page 1384.

Each device in OVOC is configured with a priority level (Low, Normal, or Critical). When all the licenses of a specific license type in the Flex License pool are being used (or even exceeded) by the devices, OVOC uses this priority level to determine which of the devices to initially "take out" of service. OVOC first notifies a certain percentage of devices of this "over-license" status, instructing them to **reject all new calls** that require this specific license type. This percentage of devices starts from those with Low priority level, then Normal priority level, and lastly Critical priority level.

For example, assume there are 100 devices in the network, 10 configured with Low priority, 20 with Normal priority, and 70 with Critical priority, and OVOC notifies 20% of them of an "over-license" state for a specific license type. In this example, OVOC takes out of service the 10 devices with Low priority and 10 devices with Normal priority (i.e., total of 20, which is 20% of 100). This selective process allows devices with higher priority to continue providing call service, while attempting to restore licenses to the Flex License pool due to the rejection of new calls by the selected devices. During this period, the devices send their usage reports more frequently to OVOC, providing OVOC with a more up-to-date status of license usages in the network. If licenses become available for the specific license type in the pool, OVOC allows the selected devices to start accepting new calls ("ok" status). However, if after a certain period there are still unavailable licenses for the specific license type in the pool, OVOC notifies all devices (including those with Critical priority level) of this "over-license" status, and instructs **all of them to reject new calls**. To view the device's current license utilization (in percentage) per license type of the OVOC Flex License pool and the status ("ok" and "overlicense") of each license type, see [Viewing Flex License Utilization and Status](#) on page 1381.

Connection between the devices and OVOC is established over SNMP and functionality of the Flex License service is managed over TCP/HTTPS REST. If the device loses connectivity with OVOC, the device continues handling calls for a graceful period. If connectivity is not restored when this period expires, the device is blocked from handling new calls. When the device succeeds in connecting again with OVOC, it continues using the Flex License pool as normal.

When the device uses the Flex License, the License Key page (see [Viewing the License Key](#) on page 1362) displays "Flex License" in the 'Mode' field and displays the licensed capacity received from the Flex License pool per license type under the **VoIP Capacity** group, as shown in the following example:

## VOIP CAPACITY

	<u>Local</u>	<u>Flex</u>	<u>Actual</u>
Far End Users (FEU)	<del>240</del>	10	200
SBC Media Sessions		9	20
SBC Signaling Sessions		12	60
Transcoding Sessions		5	120
SBC Sessions	<del>240</del>		

- 'Local': Displays the number of licensed capacity per license type from the locally installed License Key. These licenses are not used by the device and the figures are displayed crossed out (strikethrough).
- 'Flex': Displays the maximum number of licensed capacity per license type in the OVOC Flex License pool.
- 'Actual': (This column can be ignored.)

After a device restart or HA switchover, the figures in the 'Flex' column appear only after the device receives its first report from OVOC on the Flex License pool capacity. This typically takes about five minutes.

The device sends the following SNMP alarms to indicate various conditions relating to the OVOC Flex License pool:

- **acFloatingLicenseAlarm:** Sent if you have configured an Allocation Profile that exceeds the device's resource capability.
- **acCloudLicenseManagerAlarm:** Sent upon various conditions such as loss of connectivity between device and OVOC.

For more information, refer to the document [SBC-Gateway Series SNMP Alarm Reference Guide](#).

- The Flex License doesn't affect transcoding session capacity. By default, transcoding session capacity is at maximum (as supported by the device).
- For configuring the Flex License on OVOC, refer to the document *OVOC User's Manual*, which can be downloaded from AudioCodes [website](#).
- The Fixed License only provides WebRTC, SIPREC and SBC capacity licenses (listed in the beginning of this section). Therefore, your device must still be installed with a local License Key to enable other ordered license-based features (e.g., Test Call) and capacity.
- The Flex License cannot operate with the other OVOC-managed license modes (e.g., Fixed License and Floating License). Therefore, before enabling the Flex License, make sure that the other license modes are disabled on OVOC.
- The Flex License ignores OVR, TDM2SBC, and LAD capacity licenses in the local License Key.

## Enabling Floating or Flex License

Before you can use the Floating or Flex license, you need to enable this feature.

Prior to enabling the Floating or Flex License, make sure that the following OVOC-related prerequisites have been fulfilled:

- The Floating or Flex License has been purchased from AudioCodes with the required SBC license capacities and installed on OVOC.
  - The devices for which you want to use the Floating or Flex License have been configured on OVOC.
  - For Floating License, OVOC has been configured for communication with AudioCodes Cloud License Manager.
  - For Flex License, the devices have been configured with priority levels on OVOC.
- For more information on configuring and managing the Floating or Flex License on OVOC, refer to the document *OVOC User's Manual*, which can be downloaded from AudioCodes [website](#).

### ➤ To enable the Floating or Flex License:

1. Open the Floating License page (**Setup** menu > **Administration** tab > **License** folder > **Floating License**).
2. From the 'Floating License' drop-down list, select **Enable**.

**Figure 45-1: Enabling the Floating or Flex License**

GENERAL	
Floating License	Enable 
Connection with OVOC	Connected 
OVOC IP Address	10.8.6.250
OVOC Product Key	F83FBC1BFBCF

3. Restart the device with a save-to-flash for your settings to take effect. After the device restarts, it connects with OVOC and OVOC-related information is displayed in the read-only fields:
  - **'Connection with OVOC':** Displays the device's connectivity status with OVOC:
    - ◆ "Connected": The device is connected to OVOC.
    - ◆ "Disconnected" The device has disconnected from OVOC due to problems with the network (HTTPS TCP connection).
    - ◆ "Not Connected": The device is not connected to OVOC.
  - **'OVOC IP Address':** Displays the IP address of OVOC.

- **'OVOC Product Key':** Displays the Product Key of OVOC that is providing the Floating or Flex License.

Once you enable the Floating or Flex License, OVOC initiates a connection with the device. In other words, you don't configure the address of OVOC. The device connects with OVOC over SNMP and an SNMP manager is automatically added to the SNMP Trap Destinations table for this connection (see [Configuring SNMP Trap Destinations](#) on page 111).

The status of the Floating License or Flex License is also displayed on the top bar of the License Key page, as shown below (e.g., Flex License mode):

Product Key	E25B13DE2205 OVOC Product Key	Flex License Mode	2576900 Serial Number	72 Device Type	Connected License Server Status
-------------	----------------------------------	----------------------	--------------------------	-------------------	------------------------------------

- **'OVOC Product Key':** Product Key of the OVOC tool providing the Floating License or Flex License
- **'Mode':** Indicates the license type:
  - "Floating License": Floating License mode
  - "Flex License": Flex License mode
- **'License Server Status':** Connectivity status with OVOC (for more information, see [Viewing the License Key](#) on page 1362)

## Viewing Flex License Utilization and Status

You can view the device's current license utilization (in percentage) per license type of the OVOC Flex License pool.

- The **Flex Pool** group (below) appears only if you have enabled the Floating License or Flex License feature (see [Floating License Model](#) on page 1374).
- The Flex License doesn't affect transcoding session capacity. By default, transcoding session capacity is at maximum (as supported by the device).

### ➤ To view Flex License utilization and status:

1. Open the Floating License page (**Setup** menu > **Administration** tab > **License** folder > **Floating License**).
2. Scroll down to the **Flex Pool** group:

## FLEX POOL

	Utilization	Status
SBC Media Sessions	66.67%	OK
SBC Signaling Sessions	50.00%	OK
Far End Users	<1%	OK
Transcoding Sessions	120.00%	Reached/ Exceeded License
WebRTC Sessions	<1%	OK
SIPREC Streams	<1%	OK

- 'Utilization': Displays the percentage (%) of the license capacity per license type in the OVOC Flex License pool that the device is currently using. Utilization of less than 1% is displayed as "<1%".
- 'Status': Displays the utilization status of the OVOC Flex License pool by all devices:
  - ◆ "OK": Utilization is within the pool capacity.
  - ◆ "Reached/Exceeded License": Utilization has reached or exceeded the Flex License pool capacity. In this case, OVOC first attempts to return licenses to the pool by instructing certain devices (based on their priority level) to block new calls. If this doesn't help after a graceful period, OVOC instructs all devices to block new calls until licenses return to the pool. For more information, see [Flex License Model](#) on page 1377

## Configuring Floating or Flex License Allocation Profiles

The Floating and Flex License allows you to configure *Allocation Profiles*, which specify license capacity per license type that you want allocated to the device by OVOC. For example, you may want to limit the device to only 20 Far End Users, even though OVOC could allocate up to 100 Far End Users.

You can choose a default Allocation Profile (**SIP Trunking** or **Registered Users**) that has a predefined capacity suited for these applications, or you can configure a customized Allocation Profile. In addition, once you have chosen an Application Profile and restarted the device to apply it, you can easily reduce (*limit*) the predefined capacity or customized capacity when needed, without restarting the device.

You can only configure Allocation Profiles once you have enabled the Floating or Flex License (see [Enabling Floating or Flex License](#) on page 1380).

➤ **To configure Allocation Profiles:**

1. Open the Floating License page (**Setup** menu > **Administration** tab > **License** folder > **Floating License**).
2. From the 'Allocation Profile' drop-down list, select an SBC license Allocation Profile:
  - **SIP Trunking:** Provides default capacity (cannot be modified) in the 'Allocation' field per license type and is suited for SIP Trunking applications (i.e., where user registration is typically not required). You can later reduce the capacity using the 'Limit' field after you restart the device, as described in Step 4.
  - **Registered Users:** Provides default capacity (cannot be modified) in the 'Allocation' field per license type and is suited for applications where user registration is required. You can later reduce the capacity using the 'Limit' field after you restart the device, as described in Step 4.
  - **Custom:** Allows you to configure a customized Allocation Profile. In the 'Allocation' field corresponding to each license type, configure the desired capacity.

**Figure 45-2: Configuring Allocation Profile (e.g., Custom)**

Allocation Profile	Custom	
	Allocation ⚡	Limit
Far End Users	1600	<input type="checkbox"/>
SBC Media Sessions	400 <small>Range: 0-400</small>	<input type="checkbox"/>
SBC Signaling Sessions	400	<input type="checkbox"/>
Transcoding Sessions	60	<input type="checkbox"/>
WebRTC Sessions	60	<input type="checkbox"/>
SIPREC Streams	60	<input type="checkbox"/>

When configuring a customized Allocation Profile (i.e., 'Allocation Profile' configured to **Custom**):

- To view the device's maximum supported capacity per license type, hover your mouse over the corresponding 'Allocation' field and a pop-up appears displaying the capacity.
- The 'Transcoding Sessions' license type capacity cannot be modified in the 'Allocation' field. However, you can reduce the license using its corresponding 'Limit' field, as described below.
- The Floating or Flex Licenses don't affect transcoding session capacity. By default, transcoding session capacity is at maximum (as supported by the device).

3. Restart the device with a save-to-flash for your settings to take effect.
4. You can now reduce each SBC license type capacity whenever needed **without** restarting the device:
  - a. Select the check box corresponding to the license type you want reduced.
  - b. In the corresponding 'Limit' field, enter a new capacity. The value can be equal to or less than the value in the 'Allocation' field.
  - c. Click **Apply**.

The figure below shows an example of using the 'Limit' field to reduce the allocation of SBC Media Sessions to 40 and the SBC Signaling Sessions to 80 for the **SIP Trunking** Allocation Profile:

**Figure 45-3: Configuring Limits for Allocation Profile**

ALLOCATION			
Allocation Profile	Allocation	Limit	
SBC Media Sessions	250	40	<input checked="" type="checkbox"/>
SBC Signaling Sessions	250	80	<input checked="" type="checkbox"/>
Far End Users	0		<input type="checkbox"/>
Transcoding Sessions	15		<input type="checkbox"/>

## Viewing Floating or Flex License Reports

You can view resource consumption reports of the Floating or Flex License that the device periodically sends to OVOC. This includes SBC capacity (signaling sessions, media sessions, transcoding sessions, and far-end user registrations), WebRTC sessions, and SIPREC streams.

- The Floating License Reports page is available only if you have enabled the Floating License or Flex License feature (see [Floating License Model](#) on page 1374).
- The Floating License doesn't affect transcoding session capacity. By default, transcoding session capacity is at maximum (as supported by the device).

### ➤ To view the Floating License or Flex License Report through Web interface:

- Open the Floating License Reports page (**Setup** menu > **Administration** tab > **License** folder > **Floating License Reports**).

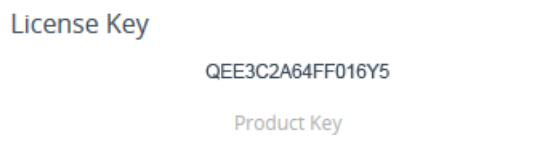

REPORT DATE	SIGNALING SESSIONS	FAR END USERS	TRANSCODING SESSIONS	MEDIA SESSIONS	WEBRTC SESSIONS	SIPREC STREAMS
2022-01-19 17:04:37	0	0	0	0	0	0
2022-01-19 17:03:37	0	0	0	0	0	0
2022-01-19 17:02:36	0	0	0	0	0	0
2022-01-19 17:01:36	0	0	0	0	0	0
2022-01-19 17:00:36	0	0	0	0	0	0

## Viewing the Device's Product Key

The Product Key identifies a specific purchase of your device installation for the purpose of subsequent communication with AudioCodes (e.g., for support and software upgrades). The Product Key is your chassis' serial number--"S/N(Product Key)"--which also appears on the product label affixed to the chassis.

The Product Key is included in the License Key. You can view the Product Key on the following Web pages:

- License Key page (see [Viewing the License Key](#) on page 1362). The Product Key is displayed in the read-only 'Product Key' field, as shown in the example below:

- Device Information page (see [Viewing Device Information](#) on page 1441).

If your License Key was purchased in an earlier version, the 'Product Key' field may appear empty.

## 46 Downloading and Uploading Configuration Files

This section describes how to download and upload the device's configuration:

- ini file - see [Downloading or Uploading ini File](#) below
- CLI Script file - see [Downloading or Uploading CLI Script File](#) on the next page
- CLI Startup Script file - see [Uploading CLI Startup Script File](#) on page 1388
- Configuration Package file - see [Downloading or Uploading Configuration Package File](#) on page 1389

### Downloading or Uploading ini File

You can download the device's configuration as an ini file to a folder on your computer or upload an ini file to the device. Downloading an ini file can serve as a backup of your configuration and if needed, you can later upload the file to the device to restore your previous configuration settings.

The file is downloaded as a .ini file with the file name "BOARD\_SN<Serial>" (e.g., BOARD\_SN5967925.ini). The uploaded file must have a .ini extension (and any file name).

- When uploading the file, the device restarts for the parameter settings to take effect.
- When uploading the file, parameters not included in the file **are restored to default settings**. If you want to keep the device's current configuration settings and also apply the settings specified in the ini file, upload the file through the Auxiliary Files page (see [Uploading Auxiliary Files through Web Interface](#) on page 1348).
- The downloaded file includes only the following:
  - ✓ Configuration tables that contain row entries (default and non-default).
  - ✓ Standalone parameters whose values you changed from default. However, it also includes parameters whose values you changed from non-default back to default without subsequently restarting the device. If you changed from non-default back to default but subsequently restart the device, then they'll not be included.
  - ✓ All SNMP performance monitoring MIBs whose threshold values (low or high) you changed from default. (To apply these same threshold values to other devices, upload the ini file to the devices.)
  - ✓ The device's License Key. If the device is in High-Availability mode, the ini file of the Active device also includes the Redundant device's License Key.
- To download the file to a USB device plugged into the device, use the following CLI command: # write-and-backup to usb:///<file name>

#### ➤ To download or upload an ini file through Web interface:

1. Open the Configuration File page:
  - **Toolbar:** From the **Actions** drop-down menu, choose **Configuration File**

- **Navigation tree:** Setup menu > Administration tab > Maintenance folder > Configuration File

The relevant buttons for downloading and loading an ini file are located under the INI File group:

Download INI file to the PC

Download INI File

Upload INI file to the device.

Choose File No file chosen

Upload INI File

2. To download the file, click the **Download INI File** button, and then save the file to a folder on your computer.
3. To upload the file:
  - a. Click the **Choose File** button, and then browse to and select the .ini file on your computer.
  - b. Click the **Upload INI File** button; a message box appears, informing you that the device will restart.
  - c. Click **Yes** to continue; the device uploads the file and then restarts with a save to flash for the settings to take effect.

## Downloading or Uploading CLI Script File

You can download the device's configuration as a CLI Script file to a folder on your computer or upload a CLI Script file to the device. Downloading the file to your computer can serve as a backup of your configuration and if needed, you can later upload the file to the device to restore previous configuration settings.

The file is download as a .cli file with the file name "BOARD\_SN<Serial Number>" (e.g., BOARD\_SN5967925.cli). The uploaded file must have the .cli extension (and any file name).

- When uploading the file, you need to restart the device if it contains the **reload now** command (on the last line).
- The downloaded file includes only parameters whose values you have modified.
- To save the file to a remote server (TFTP or HTTP/S), use the following CLI command: `# write-and-backup to <URL with file name>`
- To download the file to a USB stick plugged into the device: `# write-and-backup to usb:///<file name>`

### ➤ To download or upload a CLI Script file:

1. Open the Configuration File page:
  - **Toolbar:** From the **Actions** drop-down menu, choose **Configuration File**

- **Navigation tree:** Setup menu > Administration tab > Maintenance folder > Configuration File

2. To download the file:

- Under the CLI Script group, click the **Download CLI Script File** button, and then save the file to a folder on your computer.

Download CLI Script file to the PC

Download CLI Script File

3. To upload the file:

- Under the CLI Script group, click the **Choose File** button, and then browse to and select the .cli file on your computer.

Upload CLI Script file to the device.

Choose File No file chosen

Upload CLI Script File

- Click the **Upload CLI Script File** button; the device uploads the file and displays a message box confirming when the file has been successfully uploaded:

Upload CLI Script File

x

File was uploaded successfully!

Close

- Click **Close**.
- If the CLI Script file contains changes to configuration, click the **Save** button on the toolbar to save your settings to flash memory. If a device restart is required for the new settings to take effect, instead of clicking the **Save** button, click the **Restart** button (which appears with a red border).

## Uploading CLI Startup Script File

You can upload a CLI Startup Script file to the device. The uploaded file must have a .cli extension (and any file name).

- The CLI Startup Script file is not supported when the device operates in HA mode.
- When uploading the file, the device restarts twice for its settings to take effect.

### ➤ To upload a CLI Startup Script file:

- Open the Configuration File page:

- **Toolbar:** From the **Actions** drop-down menu, choose **Configuration File**.
  - **Navigation tree:** **Setup** menu > **Administration** tab > **Maintenance** folder > **Configuration File**.
2. Under the CLI Startup Script to the device group, click the **Choose File** button, and then browse to and select the .cli file on your computer.

Upload CLI Startup Script to the device.

**Choose File** No file chosen

**Upload CLI Startup Script**

3. Click the **Upload CLI Startup Script** button; the following message box appears:

Upload CLI Startup Script File

X

After the file is uploaded to the device, the device will automatically restart. Do you want to continue?

No

Yes

4. Click **Yes** to continue; the device uploads the file and then restarts with a save to flash for the settings to take effect.

## Downloading or Uploading Configuration Package File

You can download and upload a bundle of files used by the device in a single, packaged file called the Configuration Package file. This file is in 7-Zip archive file format (.7z) using the LZMA2 compression algorithm. In addition, you can optionally password-protect the file and encrypt it using the AES-256 algorithm.

You can use the Configuration Package file to fully back up the device's configuration. If needed, you can later restore the device to this backup configuration for whatever reason (e.g., configuration failure). You can also upload the Configuration Package file to other devices that need similar configuration.

The Configuration Package file can include the following files:

File	Description
ini.ini	INI configuration file.
cli-startup-script.txt	CLI Startup Script file. <b>Note:</b> This file is applicable only for uploading a Configuration Package file.

File	Description
<TLS Context ID>.pkey	Private key of the TLS Context (by ID). <b>Note:</b> You can only choose to include certificates in the Configuration Package file if you enable the password-protect (encrypt) option.
<TLS Context ID>.cert	TLS certificate of the TLS Context (by ID). <b>Note:</b> You can only choose to include certificates in the Configuration Package file if you enable the password-protect (encrypt) option.
<TLS Context ID>.root	Trusted root certificate of the TLS Context (by ID). <b>Note:</b> You can only choose to include certificates in the Configuration Package file if you enable the password-protect (encrypt) option.
LOGO.dat	Image file used as the logo in the Web interface.
FAVICON.dat	Favicon file used by Web browsers to represent the device's Web interface.
CPT.dat	Call Progress Tone file (CPT).
PRT.dat	Pre-recorded Tone file (PRT).
AMD.dat	Answer Machine Detection file (AMD).
SBC_WIZARD.dat	SBC Configuration Wizard template file
CAS-<ID>.dat	CAS file.
DPLN.dat	Dial Plan file. <b>Note:</b> Only for backward compatibility for versions that supported a Dial Plan file. For current versions, the Dial Plan is included in the ini file.
DialPlanRule.csv	Dial Plan file.

- The device downloads the Configuration Package file with the name "ConfBackupPkg<Serial Number>.7z".
- When uploading the Configuration Package file, the device restarts for the settings to take effect.
- The Configuration Package file is included in the device's debug file and core dump file (see [Debug \(and Core Dump\) File Contents](#) on page 1659).
- The device's SNMP MIB allows OVOC to back up the Configuration Package file. OVOC only uploads the file if it was modified, compared to the current file in OVOC, using file checksum (acSysConfigurationPackageChecksum).
- For configuring (and clearing) an encryption key for password obfuscation using the Configuration Package file, see [Password Obfuscation in CLI Script and ini Files](#) on page 212.
- For backward compatibility, a Configuration Package file in TAR format (.tar.gz) can still be uploaded to the device.

You can download or upload the Configuration Package file, using the following methods:

#### ■ CLI:

```
# copy configuration-pkg from|to <URL> [encrypted <password>] [certificates]
```

- For uploading a Configuration File that is password-protected, use the `encrypted` option to specify the password: `copy configuration-pkg from <URL> encrypted <password>`
- For downloading the Configuration File, if you want to password-protect it (and optionally include the TLS certificates), use the `encrypted` and `certificates` options, respectively: `copy configuration-pkg from <URL> encrypted <password> certificates`

#### ■ Auto-Update Mechanism:

```
(config-system)# automatic-update
(auto-update)# configuration-pkg <URL>
```

If the file is password-protected, specify the password using the following CLI command:

```
(config-system)# automatic-update
(auto-update)# default-configuration-package-password <password>
```

- **SFTP:** You can also download (Get) the Configuration Package file through SFTP. The file is located in the device's `/configuration` directory. Your SFTP client needs to authenticate itself with the SFTP server (i.e., the device).

**SFTP Notes:**

- You can access the `/configuration` folder only if you are a **Security Administrator** user.
- The Configuration Package file can only be downloaded.
- When the file is password-protected, it includes the TLS certificates and the file is listed in the device's `/configuration` directory as `configuration-package-full.7z`. If it's not password-protected (and therefore, doesn't include certificates), the file is listed as `configuration-package.7z`.
- For configuring the password for protecting the Configuration Package file, see [Configuring Default Password for Configuration Package File](#) on the next page.

■ **Web interface:**

- a. Open the Configuration File page:

- ◆ **Toolbar:** From the **Actions** drop-down menu, choose **Configuration File**
- ◆ **Navigation tree:** **Setup** menu > **Administration** tab > **Maintenance** folder > **Configuration File**

#### CONFIGURATION PACKAGE

Encrypted Configuration Package ☐

Download Configuration Package to the PC.

Download Configuration Package

Upload Configuration Package to the device.

Choose File No file chosen

Upload Configuration Package

- b. To download Configuration Package file:

- To password-protect the file, select the 'Encrypted Configuration Package' check box.
- Click the **Download Configuration Package** button; if the 'Encrypted Configuration Package' check box was selected, the following dialog box appears (otherwise, the file is downloaded to your computer):

Download Configuration Package
X

Password

Verify

☐ Include Private Keys and device Certificates

No Yes

- In the 'Password' and 'Verify' fields, type the password to protect the file.

iv. To include the TLS certificates, select the 'Include Private Keys and device Certificates' check box.

v. Click **Yes**.

c. **To upload Configuration Package file:**

i. If the file is password-protected, select the 'Encrypted Configuration Package' check box.

ii. Click the **Choose File** button, and then browse to and select the file on your computer.

iii. Click the **Upload Configuration Package** button:

If the file is password-protected (i.e., you selected the check box in Step i), the following appears:

**Upload Configuration Package** X

After the file is uploaded to the device, the device will automatically restart. Do you want to continue?

Password

---

No **Yes**

If the file is not password-protected (i.e., you didn't select the check box in Step i), the following appears:

**Upload Configuration Package** X

After the file is uploaded to the device, the device will automatically restart. Do you want to continue?

---

No **Yes**

iv. If the file is password-protected, in the 'Password' field, type the password.

v. Click **Yes**; the device uploads the file and then restarts with a save to flash for the settings to take effect.

## Configuring Default Password for Configuration Package File

You can configure the default password that protects (encrypt) the Configuration Package file for the following scenarios:

- When uploading a password-protected Configuration Package file to the device through the Automatic Update feature (see the `configuration-pkg` command).
- When downloading a password-protected Configuration Package file from the device through SFTP.

➤ **To configure default password for Configuration Package file:**

1. Open the Administration Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Administration Settings**).
2. In the 'Default password for configuration package' field, type the password.
3. Click **Apply**.

## 47 Automatic Provisioning

This chapter describes automatic provisioning of the device.

### Automatic Configuration Methods

The device supports the following automatic provisioning methods:

- DHCP (Option 66, Option 67, Option 160)
- HTTP/S
- TFTP
- FTP
- SNMP (AudioCodesOVOC)

### DHCP-based Provisioning

You can use a third-party DHCP server to automatically provide each device (acting as a DHCP client) with an IP address for the management interface so that individual MAC addresses are not required. The DHCP server can provide additional networking parameters such as subnet mask, default gateway, primary and secondary DNS servers, and two SIP server addresses. These network parameters have a time limit, after which the device 'renews' its lease on the addresses from the DHCP server.

The device can use a host name in the DHCP request. The host name is set to "acl\_nnnnn", where *nnnnn* denotes the device's serial number. The serial number is the last six digits of the device's MAC address converted into decimal representation. In networks that support this feature and if the DHCP server registers this host name to a DNS server, you can access the device (through a Web browser) using the URL "http://acl\_<serial number>" instead of the device's IP address. For example, if the device's MAC address is 00908f010280, the DNS name is "acl\_66176".

- For DHCP-based provisioning of IPv4 or IPv6 interfaces, in the IP Interfaces table, configure the IP Interface with the 'Interface Mode' parameter set to **IPv4 DHCP** or **IPv6 DHCP** respectively (see [Configuring IP Network Interfaces](#) on page 159).
- When using DHCP to acquire an IP address, VLANs and other advanced configuration options are disabled.
- For additional DHCP parameters, see [DHCP Parameters](#) on page 1758.

#### ➤ To enable device as a DHCP client:

1. In the IP Interfaces table, configure the IP Interface with the 'Interface Mode' parameter set to **IPv4 DHCP** or **IPv6 DHCP** (depending on IP version).
2. Restart the device to activate the DHCP process.

The following shows an example of a configuration file for a Linux DHCP server (dhcpd.conf). The devices are allocated temporary IP addresses in the range 10.31.4.53 to 10.31.4.75. TFTP is assumed to be on the same computer as the DHCP server (alternatively, the "next-server" directive may be used).

```
ddns-update-style ad-hoc;  
default-lease-time 60;  
max-lease-time 60;
```

```
class "gateways" {  
    match if(substring(hardware, 1, 3) = 00:90:8f);  
}  
subnet 10.31.0.0 netmask 255.255.0.0 {  
    pool {  
        allow members of "AudioCodes";  
        range 10.31.4.53 10.31.4.75;  
        filename "SIP_F6.60A.217.003.cmp -fb;device.ini";  
        option routers          10.31.0.1;  
        option subnet-mask      255.255.0.0;  
    }  
}
```

- If the DHCP server denies the use of the device's current IP address and specifies a different IP address (according to RFC 1541), the device must change its networking parameters. If this occurs while calls are in progress, they are not automatically rerouted to the new network address. Therefore, administrators are advised to configure DHCP servers to allow renewal of IP addresses.
- If the device's network cable is disconnected and then reconnected, a DHCP renewal is performed (to verify that the device is still connected to the same network). The device also includes its product name in the DHCP Option 60 Vendor Class Identifier. The DHCP server can use this product name to assign an IP address accordingly.
- After power-up, the device performs two distinct DHCP sequences. Only in the second sequence is DHCP Option 60 included. If the device is software restart (e.g., from the Web interface or SNMP), only a single DHCP sequence containing Option 60 is sent.

### Provisioning from HTTP Server using DHCP Option 67

You can provision the device through HTTP using DHCP Option 67. In this setup, DHCP Option 67 informs the device of the URL address of the HTTP server from where it can download the configuration file. This provisioning method is possible only if the DHCP server allows configuration of DHCP Option values for different equipment in the network.

Upon device startup, the device sends a DHCP request. The DHCP response received from the DHCP server contains IPv4 networking (e.g., management IP address and DNS server) information. In addition, the response includes DHCP Option 67, which specifies the URL address of the HTTP server where the device's configuration file is located. The device then automatically downloads the configuration file from this HTTP server.

Below is an example of a configuration file (dhcpd.conf) of a Linux-based DHCP server, showing the required format of Option 67:

```
ddns-update-style ad-hoc;
default-lease-time 3600;
max-lease-time 3600;
```

```
class "AudioCodes" {
    match if(substring(hardware, 1, 3) = 00:90:8f);
}
subnet 10.31.0.0 netmask 255.255.0.0 {
    pool {
        allow members of "AudioCodes";
        range 10.31.4.53 10.31.4.75;
        option routers          10.31.0.1;
        option subnet-mask      255.255.0.0;
        option domain-name-servers 10.1.0.11;
        option bootfile-name     "INI=http://www.corp.com/master.ini";
        option dhcp-parameter-request-list 1,3,6,51,67;
    }
}
```

- The value of Option 67 must include the URL address, using the following syntax: "INI=<URL with ini file name>"
- This method is NAT-safe.

➤ **To configure the device for automatic provisioning through HTTP/S using DHCP Option 67:**

1. In the IP Interfaces table, configure the IP Interface with the 'Interface Mode' parameter set to **IPv4 DHCP** or **IPv6 DHCP** (depending on IP version).
2. Enable the device to include DHCP Option 67 in DHCP Option 55 (Parameter Request List) when requesting HTTP provisioning parameters from a DHCP server, using the following ini file parameter:

```
DHCPRequestTFTPParams = 1
```

3. Restart the device with a save-to-flash for your settings to take effect.

### Provisioning from TFTP Server using DHCP Option 66

Provisioning the device from a third-party TFTP server is suitable when the network in which the device is deployed includes a provisioning TFTP server for all network equipment, without the capability of distinguishing between the device and other third-party devices.

Upon startup, the device checks for DHCP Option 66 in the DHCP response received from the DHCP server. If Option 66 contains a valid IP address (or FQDN) of the TFTP provisioning server, the device attempts to download through TFTP, a configuration file whose filename contains the device's MAC address (e.g., 00908f0130aa.ini).

This method uploads the configuration file to the device as a one-time action. The download is repeated only if the device is manually restored to factory defaults (by pressing the hardware reset button while the Ethernet cable is not connected).

#### ➤ To configure the device for automatic provisioning through TFTP using DHCP Option 66:

1. In the IP Interfaces table, configure the IP Interface with the 'Interface Mode' parameter set to **IPv4 DHCP** or **IPv6 DHCP** (depending on IP version).
2. Enable the device to include DHCP Option 66 in DHCP Option 55 (Parameter Request List) when requesting TFTP provisioning parameters from a DHCP server, using the following ini file parameter:

```
DHCPRequestTFTPPParams = 1
```

3. Restart the device with a save-to-flash for your settings to take effect.

- Access to the core network through TFTP is not NAT-safe.
- The TFTP data block size (packets) when downloading a file from a TFTP server for the Automatic Update mechanism can be configured using the AUPDTftpBlockSize parameter.

### Provisioning the Device using DHCP Option 160

You can provision the device using DHCP Option 160. DHCP Option 160 provides the device with the URL address of the provisioning server from where it can download its software (.cmp) and configuration (.ini) files. The URL can also include the names of the required files to download and their folder location on the server.

If you enable DHCP client functionality with DHCP Option 160, upon a device restart or power up, the device (as a DHCP client) sends a DHCP request to the DHCP server to obtain networking information (device's IPv4 management IP address) and the URL address of the provisioning server.

The following syntax is supported for defining the URL and configuration/firmware filenames in DHCP Option 160 (on the DHCP server):

- <protocol>://<server IP address or hostname>
- <protocol>://<server IP address or hostname>/<software filename>
- <protocol>://<server IP address or hostname>/<configuration filename>
- <protocol>://<server IP address or hostname>/<software filename>;<configuration filename>

The protocol can be HTTP, HTTPS, FTP, or TFTP. As shown above, the URL can include both the software and configuration filenames. In this case, they must be separated by a semicolon (;) and without spaces.

If the URL doesn't specify a configuration filename or the file doesn't exist on the provisioning server, the device requests from the server a "default" configuration file whose name includes the device's product name and MAC address (<Product><MAC>.ini, for example, "M800B00908f5b1035.ini"). If this "default" file also doesn't exist on the server, the device attempts to retrieve another "default" configuration file whose name includes only the device's product name (<Product>.ini, for example, "M800B.ini"). The device makes up to three attempts to download the configuration file if a failure occurs (i.e., file not exist or any other failure reason). This applies to each of the configuration files, as mentioned previously.

If the URL specifies a software file, the device makes only one attempt to download the file (even if a failure occurs). If the URL doesn't specify a software file, the device doesn't make any attempt to download a software file.

Once the device downloads the file(s), it restarts to apply the configuration and/or software. In addition, once the file(s) has been downloaded, the device ignores all future DHCP Option 160 messages. Only if the device is restored to factory defaults will it process Option 160 again (and download any required files).

➤ **To enable provisioning using DHCP Option 160:**

1. Make sure that the DHCP server is configured with the appropriate information (including the URL address of the provisioning server for Option 160).
2. Make sure that the required configuration and/or software files are located on the provisioning server.
3. Enable DHCP client functionality, as described in [DHCP-based Provisioning](#) on page 1395
4. Enable the device to include DHCP Option 160 in the DHCP Parameter Request List field of the DHCP request packet that is sent to the DHCP server. Do this by loading an ini file to the device with the following parameter setting:

```
DhcpOption160Support = 1
```

1. Restart the device with a save-to-flash for your settings to take effect.

## HTTP-based Provisioning

An HTTP or HTTPS server can be located in the network in which the device is deployed, storing configuration and software files for the device to download. This doesn't require additional servers and is NAT-safe.

For example, assume the core network HTTPS server is `https://www.corp.com`. A master configuration ini file can be stored on the server, for example, `https://www.corp.com/gateways/master.ini`. This file could point to additional ini files, Auxiliary files (e.g., call progress tones), and software files (cmp), all on the same HTTP server or different HTTP servers in the network.

The main advantage of this method is that the device can be configured to periodically check the HTTP server for file updates. HTTP(S) is not sensitive to NAT devices, enabling configuration whenever needed without on-site intervention. For additional security, the URL may contain a different port, and username and password.

The only configuration required is to preconfigure the device(s) with the URL of the initial (master) ini file. This can be done using one of the following methods:

- DHCP, as described in [DHCP-based Provisioning](#) on page 1395 or via TFTP at a staging warehouse. The URL is configured using the `IniFileURL` parameter.
- Private labeling (preconfigured during the manufacturing process).
- Using DHCP Option 67 (see [Provisioning from HTTP Server using DHCP Option 67](#) on page 1396).
- Manually on-site, using the RS-232 port or Web interface.

When the device is deployed at the customer site, local DHCP server provides the devices with IP addressing and DNS server information. From the URL provided in the DHCP response, the device can then contact the HTTP server at the core network and automatically download its configuration. The URL can be a simple file name or contain the device's MAC or IP address, e.g.:

- `http://corp.com/config-<MAC>.ini` - which becomes, for example, `http://corp.com/config-00908f030012.ini`
- `http://corp.com/<IP>/config.ini` - which becomes, for example, `http://corp.com/192.168.0.7/config.ini`

For more information on HTTP-based provisioning, see [HTTP/S-Based Provisioning using the Automatic Update Feature](#) on the next page.

## FTP-based Provisioning

The Automatic Update feature provides limited support for FTP/FTPS connectivity. Periodic polling for updates is not possible since these protocols do not support conditional fetching (i.e., updating files only if they are changed on the server).

The only difference between FTP-based provisioning and those described in [HTTP-based Provisioning](#) on the previous page and [Provisioning from HTTP Server using DHCP Option 67](#) on page 1396 is that the protocol in the URL is "ftp" (instead of "http").

## Provisioning through OVOC

AudioCodes One Voice Operations Center (OVOC) server functions as a core-network provisioning server. The device's SNMP Manager should be configured with the IP address of the OVOC server, using one of the methods detailed in the previous sections. As soon as a registered device contacts OVOC through SNMP, OVOC handles all required configuration automatically, upgrading software as needed. This alternative method doesn't require additional servers at the customer premises, and is NAT-safe.

## HTTP/S-Based Provisioning using the Automatic Update Feature

The Automatic Update feature can be used for automatic provisioning of the device through HTTP/S. Automatic provisioning is useful for large-scale deployment of devices. In some cases, the devices are shipped to the end customer directly from the manufacturer. In other cases, they may pass through a staging warehouse. Configuration may occur at the staging warehouse or at the end-customer premises.

The device may be preconfigured during the manufacturing process (commonly known as private labeling). Typically, a two-stage configuration process is implemented whereby initial configuration includes only basic configuration, while the final configuration is done only when the device is deployed in the live network.

If you use the [IniFileURL] parameter for the Automatic Update feature, do **not** use the Web interface to configure the device. If you do configure the device through the Web interface and save the new settings to the device's flash memory, the [IniFileURL] parameter is automatically set to 0 and Automatic Updates is consequently disabled. To enable Automatic Updates again, you need to upload the ini file again (using the Web interface or BootP) with the correct [IniFileURL] settings. As a safeguard to an unintended save-to-flash when restarting the device, if the device is configured for Automatic Updates, the 'Save To Flash' field in the Web interface's Maintenance Actions page is automatically set to **No** by default.

- For a description of all the Automatic Update parameters, see [Automatic Update Parameters](#) on page 1732.
- For additional security, use HTTPS or FTPS. The device supports HTTPS (RFC 2818) and FTPS using the AUTH TLS method <draft-murray-auth-ftp-ssl-16>.

## File Provisioning

This section discusses file provisioning for the Automatic Update mechanism.

## Files Provisioned by Automatic Update

You can use the Automatic Update feature to update the device with any of the following files:

- Software file (.cmp)
- License Key file
- Configuration Package file (for more information, see [Downloading or Uploading Configuration Package File](#) on page 1389)
- Auxiliary files (e.g., Dial Plan file, CAS file, SBC User Information file, and Call Progress Tones file)
- TLS security files (trusted root certificate file, TLS certificate file, and private key)
- Web GUI file (favicon file)
- Configuration file:
  - **ini File:** Contains only ini file parameters and configures all the device's functionality.
  - **CLI Script File:** Contains only CLI commands and configures all the device's functionalities (except commands such as show, debug or copy). The file updates the device's configuration only according to the configuration settings in the file and existing configuration settings (not included in the file) are retained (i.e., **incremental** configuration). The device doesn't restart and therefore, this file typically contains configuration settings that do not require a device restart. If a restart is required, for example, to apply certain settings, you must include the following CLI command (root level) at the end of the file:

```
# reload if-needed
```

To configure the URL of the server where the file is located, use the [CliScriptURL] ini file parameter or CLI command `configure system > automatic-update > cli-script <URL>`.

- **Startup Script File:** Contains only CLI commands and configures all the device's functionality (except commands such as show, debug or copy). The file updates the device's configuration according to the configuration settings in the file and sets all other parameters that are not included in the file to factory defaults. The file causes two device restarts to apply the settings. Therefore, the file typically contains the Automatic Update settings and other configuration settings that require a device restart.

To configure the URL of the server where the file is located, use the [CLIScriptURL] ini file parameter or CLI command `configure system > automatic-update > startup-script <URL>`.

- You can use any filename extension for the CLI script files.
- The CLI Startup Script file is not supported when the device operates in HA mode.

### File Location for Automatic Update

The files for updating the device can be stored on any standard Web (HTTP/S), TFTP, or FTP server. The files can be loaded periodically to the device using HTTP/S, TFTP, or FTP. This mechanism can be used even when the device is installed behind NAT and firewalls. The Automatic Update feature is done per file and configured by specifying the file name and URL address of the provisioning server where the file is located. If the device needs to authenticate itself with the server, you can use the same parameters to configure the authentication username and password (for more information, see [Access Authentication with HTTP Server](#) on page 1410). For a description of the parameters for configuring the URLs of the servers of the files, see [Automatic Update Parameters](#) on page 1732.

Below are examples for configuring the file names and their URLs for Automatic Update:

#### ■ ini File:

```
IniFileURL = 'http://www.corp.com/configuration.ini'  
CptFileURL = 'http://www.corp.com/call_progress.dat'  
AutoCmpFileUrl = 'http://www.corp.com/SIP_F7.20A.008.cmp'  
FeatureKeyURL = 'https://www.company.com/License_Key.txt'
```

#### ■ CLI:

```
# configure system  
(config-system)# automatic update  
(auto-update)# cli-script https://company.com/cli/<MAC>  
(auto-update)# startup-script https://company.com/startup/<MAC>  
(auto-update)# ini-file http://www.company.com/configuration.ini  
(auto-update)# call-progress-tones http://www.company.com/call_  
progress.dat  
(auto-update)# feature-key http://www.company.com/License_Key.txt  
(auto-update)# auto-firmware http://www.company.com/SIP_F7.20A.008.cmp
```

- When using the Auto-Update mechanism to upload the Configuration Package file (`automatic update > configuration-pkg`), if the file is password-protected (encrypted), specify the password using the command `automatic update > default-configuration-package-password`.
- For configuration files, the file name in the URL can automatically contain the device's MAC address for enabling the device to download a file unique to the device. For more information, see [MAC Address Placeholder in URL and File Name](#) below.
- When using the `[IniFileURL]` parameter, parameters not included in the file are restored to default settings. If you want to keep the settings of these parameters, use the `[IncrementalIniFileURL]` parameter instead.

### MAC Address Placeholder in URL and File Name

You can use the placeholder "`<MAC>`" or "`<mac>`" (case-sensitive) to include the device's MAC address in the URL path (folders) and the filename when configuring the Auto-Update file parameters ([File Location for Automatic Update](#) on the previous page). The device automatically replaces the placeholder with its MAC address.

For example, the following Auto-Update file parameters are configured with the placeholder for a folder and for filenames:

```
IniFileURL = 'https://www.company.com/config_<MAC>.ini'
(auto-update)# cli-script https://company.com/files-<MAC>/cli_script.txt
(auto-update)# startup-script https://company.com/files/startup_<MAC>.txt
```

The device automatically replaces the string with its MAC address, resulting in a file name request that contains the device's MAC address, for example, `config_00908F033512.ini` or `startup_00908F033512.txt`. Therefore, you can configure all the devices with the same URL and file name.

If you write the MAC address placeholder string in lowercase (i.e., "`<mac>`"), the device adds the MAC address in lowercase to the file name (e.g., `config_<mac>.ini` results in `config_00908f053736e`); if in uppercase (i.e., "`<MAC>`"), the device adds the MAC address in uppercase to the file name (e.g., `config_<MAC>.ini` results in `config_00908F053736E`).

### Downloading TLS-Related Files for a Specific TLS Context

For downloading a TLS-related file through the Automatic Update mechanism, you can specify the TLS Context for which you want to download the file. This is done by including the "`#<TLS Context index row>`" placeholder in the URLs of the following file provisioning parameters:

- `[TLSCertFileUrl]` - certificate file
- `[TLSPkeyFileUrl]` - private key file
- `[TLSRootFileUrl]` - trusted root file

For example, if you want the device to download a certificate file for the TLS Context that is configured in the TLS Contexts table for index row #2, configure the [TLSCertFileUrl] parameter to "http://10.1.1.12/certs.pem#2". In this example, the device downloads the file from URL http://10.1.1.12/cert.pem (i.e., without the placeholder) and adds it to TLS Context #2. If such a TLS Context doesn't appear in the TLS Contexts table, the device doesn't download the file (and generates a syslog message with the appropriate error).

- If the URL doesn't contain the "#<TLS Context index row>" placeholder (e.g., "http://10.1.1.12/certs/cert.pem"), the device attempts to download the TLS-related file for TLS Context #0 only.
- You can provision the device with a Configuration Package file that contains all the device's certificates (automatic update > configuration-pkg). If this file contains the certificates, it's password-protected (encrypted) and therefore, you need to specify the password (automatic update > default-configuration-package-password). For more information on this file, see [Downloading or Uploading Configuration Package File](#) on page 1389.

### Downloading TLS-related Files for All TLS Contexts

You can download a specific TLS-related file in one configuration through the Automatic Update mechanism, for all TLS Contexts in the TLS Contexts table. This is done by including the <ID> meta-variable in the URLs of the following file provisioning parameters:

- [TLSCertFileUrl] - certificate file
- [TLSPkeyFileUrl] - private key file
- [TLSRootFileUrl] - trusted root file

If you configure a parameter with a URL containing the <ID> meta-variable (e.g., "http://10.1.1.12/certs/<ID>/cert.pem"), the device attempts to download the TLS-related file for **every** existing TLS Context in the TLS Contexts table. For each URL, the device replaces the <ID> placeholder with a number, which is consecutively incremented, starting from 0, according to the number of configured TLS Contexts.

For example, assume that you have configured three TLS Contexts in the TLS Contexts table (Index 0, 1, and 2) and you have configured the [TLSCertFileUrl] parameter to "http://10.1.1.12/certs/<ID>/cert.pem". In this example, the device attempts to download certificate files from the following three URLs:

- http://10.1.1.12/certs/0/cert.pem (file for TLS Context #0)
- http://10.1.1.12/certs/1/cert.pem (file for TLS Context #1)
- http://10.1.1.12/certs/2/cert.pem (file for TLS Context #2)

- If the URL doesn't contain the <ID> meta-variable (e.g., "http://10.1.1.12/certs/cert.pem"), the device attempts to download the TLS-related file for TLS Context #0 only.
- You can provision the device with a Configuration Package file that contains all the device's certificates (automatic update > configuration-pkg). If this file contains the certificates, it's password-protected (encrypted) and therefore, you need to specify the password (automatic update > default-configuration-package-password). For more information on this file, see [Downloading or Uploading Configuration Package File](#) on page 1389.

## File Template for Automatic Provisioning

To facilitate automatic provisioning setup, you can use a single template to define the files to download during automatic provisioning. The template uses special keywords to denote the different file types to download and in the URL address of the provisioning server it uses a placeholder for the file names which is replaced by hardcoded file names and extensions according to file type, as described in more detail below.

- Unlike the parameters that define specific URLs for Auxiliary files (e.g., [CptFileURL]), the file template feature always retains the URLs after each automatic update process. Therefore, with the file template the device always attempts to download the files upon each automatic update process.
- If you configure a parameter used to define a URL for a specific file (e.g., [CptFileURL]), the settings of the [TemplateUrl] parameter is ignored for the specific file type (e.g., CPT file).
- Additional placeholders can be used in the file name in the URL, for example, <MAC> for MAC address (see [MAC Address Placeholder in URL and File Name](#) on page 1404).

### ➤ To use a file template for automatic provisioning:

1. Define the file **types** to download by the file template, using the [AupdFilesList] parameter. Use the keywords listed in the table below to specify each file type. For example, to specify ini, License Key, and CPT files:

- ini File:

```
AupdFilesList = 'ini', 'fk', 'cpt'
```

- CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# template-files-list ini,fk,cpt
```

2. Define the URL address of the provisioning server on which the files (specified in Step 1) are located for download, using the [TemplateUrl] parameter. When you configure the URL, you must include the file type placeholder, "<FILE>", which represents the file name. For each file type specified in Step 1, the device sends an HTTP request to the server, where the placeholder in the URL is replaced with the filename and extension, as listed in the below table. For example, if you configure the [AupdFilesList] parameter as in Step 1 and the [TemplateUrl] parameter to:

- ini File:

```
TemplateUrl = 'http://10.8.8.20/Site1_<FILE>'
```

- CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# template-url http://10.8.8.20/Site1_<FILE>
```

The device sends HTTP requests to the following URLs:

- http://10.8.8.20/Site1\_\*\*device.ini
  - http://10.8.8.20/Site1\_\*\*fk.ini
  - http://10.8.8.20/Site1\_\*\*cpt.data
3. Place the files to download on the provisioning server. Make sure that their file names and extensions are based on the hardcoded string values specific to the file type for the <FILE> placeholder (e.g., "Site1\_device.ini" for the ini file), as shown in the table below.

**Table 47-1: File Template Keywords and Placeholder Values per File Type**

File Type	Keywords for Template File	Value Replacing <FILE> Placeholder
ini file	ini	device.ini
CLI Script file	cli	cliScript.txt
CLI Startup Script file	clis	cliStartupScript.txt
CMP file based on timestamp	acmp	autoFirmware.cmp
User Information file	usrinf	userInfo.txt
CMP file	cmp	firmware.cmp
License Key file	fk	fk.ini

File Type	Keywords for Template File	Value Replacing <FILE> Placeholder
Call Progress Tone (CPT) file	cpt	cpt.dat
Prerecorded Tones (PRT) file	prt	prt.dat
CAS file	cas	cas.dat
Dial Plan file	dpln	dialPlan.dat
Answering Machine Detection (AMD) file	amd	amd.dat
TLS Private Key file	sslp	pkey.pem pkey<ID>.pem (for multi-certificate system)
TLS Root Certificate file	sslr	root.pem root<ID>.pem (for multi-certificate system)
TLS Certificate file	sslc	cert.pem cert<ID>.pem (for multi-certificate system)

## Triggers for Automatic Update

The Automatic Update feature can be triggered by the following:

- Upon device startup (restart or power up). To disable this trigger, run the following CLI command:

```
(config-system)# automatic-update
(auto-update)# run-on-reboot off
```

- Periodically:
  - Specified time of day (e.g., 18:00), configured by the ini file parameter [AutoUpdatePredefinedTime] or CLI command `configure system > automatic-update > predefined-time`. You can configure (using the [AutoUpdatePredefinedRandomTime] parameter) an interval from the specified time in which the automatic update is randomly triggered. This is useful for reducing load on the provisioning server when you have deployed multiple devices that are implementing the Automatic Update feature. For example, if you configure [AutoUpdatePredefinedTime] to 18:00 and

[AutoUpdatePredefinedRandomTime] to 300 seconds (i.e., 5 min.), the automatic update process is randomly triggered anywhere between 18:00 and 18:05.

- Interval between Automatic Updates (e.g., every 60 minutes), configured by the ini file parameter [AutoUpdateFrequencySeconds] or CLI command `configure system > automatic-update > update-frequency-sec`.

Configure either [AutoUpdatePredefinedTime] or [AutoUpdateFrequencySeconds]; not both. When configuring one of the parameters, make sure that the other parameter is at its default value (i.e., disabled).

#### ■ Centralized provisioning server request:

- Upon receipt of an SNMP request from the provisioning server.
- Upon receipt of a special SIP NOTIFY message from the provisioning server. The NOTIFY message includes an Event header with the AudioCodes proprietary value, "check-sync;reboot=false", as shown in the example below:

```
NOTIFY sip:<user>@<dsthost> SIP/2.0
To: sip:<user>@<dsthost>
From: sip:sipsak@<srchost>
CSeq: 10 NOTIFY
Call-ID: 1234@<srchost>
Event: check-sync;reboot=false
```

#### To enable the feature:

- Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
- Select the 'Remote Management by SIP NOTIFY' check box (EnableSIPRemoteReset):

Remote Management by SIP NOTIFY ☒

- Click **Apply**.

To enable this feature through CLI: `configure voip > sip-definition advanced-settings > sip-remote-reset`

## Applying Downloaded ini File after Graceful Timeout

If you use the Automatic Update feature for updating the device's configuration from an ini file, you can configure the device to gracefully lock itself before applying the settings of the ini file. When the Automatic Update feature is triggered (for example, by a device restart) and the device downloads the ini file from the remote provisioning server, the graceful timeout begins. During this period, the device doesn't accept any new calls, allowing only existing calls to continue until the timeout expires. If all existing calls end before the timeout expires, the device

applies the configuration of the downloaded ini file. If there are still existing calls when the timeout expires, the device terminates the calls, and then applies the configuration of the downloaded ini file.

➤ **To configure graceful timeout for automatic update of ini file:**

1. In the ini file used for enabling and configuring the device for Automatic Update, include the following parameters with the other parameters (such as IniFileURL) relating to Automatic Update setup:

```
...
AupdGracefulShutdown=1
AdminStateLockControl=<Graceful Timeout>
...
```

2. Upload the ini file to the device.

## Assigning IP Interface for Auto-Update Mechanism

By default, the device uses the IPv4 OAMP interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159) for the Auto-Update mechanism. You can assign a different IP Interface (IPv4 or IPv6), using the [AUPDInterface] parameter.

- The IP version (IPv4 or IPv6) of the assigned IP Interface and the configured addresses (IP addresses or FQDNs) in the URLs that define the locations of the different files for Auto-Update (e.g., [CmpFileURL] parameter) must be the same. If the IP version is different between the IP Interface and a file's URL, auto-update fails for that specific file.
- You can assign any IP Interface type to the Auto-Update mechanism (configured by the 'Application Type' parameter in the IP Interfaces table).

## Access Authentication with HTTP Server

You can configure the device to authenticate itself with the HTTP/S server storing the files that you want to download for the Automatic Update mechanism. The device authenticates itself by providing the HTTP/S server with its authentication username and password. The credentials are used for both Digest access authentication (MD5 cryptographic hashing) and the non-secured Basic access authentication method.

When configuring the URL of the server with the name of the file that you want downloaded, you can also include the username and password in the format "username:password" (without quotation marks), as shown in the example below for the software file (.cmp):

- ini file:

```
AutoCmpFileUrl = 'https://JoeD:1234@10.1.1.1/mysw.cmp'
```

## ■ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# auto-firmware https://JoeD:1234@10.1.1.1/mysw.cmp
```

If you have not included the username and password in the parameters used for configuring the URL of the server with the name of the file that you want downloaded, the device uses the username and password that you configured for the ini file parameter [AUPDUserPassword] or CLI command `configure system > automatic-update > credentials`.

The password cannot be configured with wide characters (for example, Chinese characters).

## Querying Provisioning Server for Updated Files

Each time the Automatic Update feature is triggered, for each file and its configured URL the device does the following:

1. If you have configured the device to authenticate itself to the HTTP/S server for secure access, the device sends the access authentication username and password to the HTTP/S server (for more information, see [Access Authentication with HTTP Server](#) on the previous page). If authentication succeeds, Step 2 occurs.
2. The device establishes an HTTP/S connection with the URL host (provisioning server). If the connection is HTTPS, the device verifies the certificate of the provisioning server, and presents its own certificate if requested by the server.
3. The device queries the provisioning server for the requested file by sending an HTTP Get request. This request contains the HTTP User-Agent Header, which identifies the device to the provisioning server. By default, the header includes the device's model name, MAC address, and currently installed software and configuration versions. Based on its own dynamic applications for logic decision making, the provisioning server uses this information to check if it has relevant files available for the device and determines which files must be downloaded (working in conjunction with the HTTP If-Modified-Since header, described further on in this section).

You can configure the information sent in the User-Agent header, using the [AupdHttpUserAgent] parameter or CLI command, `configure system > http-user-agent`. The information can include any user-defined string or the following supported string variable tags (case-sensitive):

- **<NAME>**: product name, according to the installed License Key
- **<MAC>**: device's MAC address
- **<VER>**: software version currently installed on the device, e.g., "7.00.200.001"

- **<CONF>**: configuration version, as configured by the ini file parameter, [INIFileVersion] or CLI command, `configuration-version`

The device automatically populates these tag variables with actual values in the sent header. By default, the device sends the following in the User-Agent header:

```
User-Agent: Mozilla/4.0 (compatible; AudioCodes;
<NAME>;<VER>;<MAC>;<CONF>)
```

For example, if you configure [AupdHttpUserAgent] to "MyWorld-<NAME>;<VER> (<MAC>)", the device sends the following User-Agent header:

```
User-Agent: MyWorld-Mediant;7.00.200.001(00908F1DD0D3)
```

If you configure the [AupdHttpUserAgent] parameter with the <CONF> variable tag, you must restart the device with a save-to-flash for your settings to take effect.

4. If the provisioning server has relevant files available for the device, the following occurs, depending on file type and configuration:

- **File Download upon each Automatic Update process:** This is applicable to software (.cmp) and configuration files. In the sent HTTP Get request, the device uses the HTTP If-Modified-Since header to determine whether to download these files. The header contains the date and time (timestamp) of when the device last downloaded the file from the specific URL. This date and time is regardless of whether the file was installed or not on the device. An example of an If-Modified-Since header is shown below:

```
If-Modified-Since: Mon, 1 January 2014 19:43:31 GMT
```

If the file on the provisioning server was unchanged (not modified) since the date and time specified in the header, the server replies with an HTTP 304 response and the file is not downloaded. If the file was modified, the provisioning server sends an HTTP 200 OK response with the file in the body of the HTTP response. The device downloads the file and compares the version of the file with the currently installed version on its flash memory. If the downloaded file is of a later version, the device installs it after the device restarts (which is only done after the device completes all file downloads); otherwise, the device doesn't restart and doesn't install the file.

To enable the automatic software (.cmp) file download method based on this timestamp method, use the [AutoCmpFileUrl] parameter or CLI command `configure system > automatic-update > auto-firmware <URL>`. The device uses the same configured URL to download the .cmp file for each subsequent Automatic Update process.

You can also enable the device to run a CRC on the downloaded configuration file to determine whether the file has changed in comparison to the previously downloaded file. Depending on the CRC result, the device can install or discard the downloaded file.

For more information, see [Cyclic Redundancy Check on Downloaded Configuration Files](#) on page 1415.

- When this method is used, there is typically no need for the provisioning server to check the device's current firmware version using the HTTP-User-Agent header.
- The Automatic Update feature assumes that the Web server conforms to the HTTP standard. If the Web server ignores the If-Modified-Since header or doesn't provide the current date and time during the HTTP 200 OK response, the device may restart itself repeatedly. To overcome this problem, modify the update frequency, using the [AutoUpdateFrequencySeconds] parameter or CLI command `configure system > automatic update > update-frequency-sec`.

- **One-time File Download:** This is applicable to software (.cmp) and Auxiliary (e.g., License Key, CPT and Dial Plan) files. The device downloads these files only **once**, regardless of how many times the device may repeat the Automatic Update process. Once they are downloaded, the device discards their configured URLs. To update these files again, you need to configure their URL addresses and filenames again. Below is an example of how to configure URLs for some of these files:

**Auxiliary Files:**

- ◆ ini:

```
CptFileURL = 'https://www.company.com/call_progress.dat'  
FeatureKeyURL = 'https://www.company.com/License_Key.txt'
```

- ◆ CLI:

```
(config-system)# automatic-update  
(auto-update)# call-progress-tones http://www.company.com/call_  
progress.dat  
(auto-update)# tls-root-cert https://company.com/root.pem
```

**Software (.cmp) File:**

- ◆ ini:

```
CmpFileUrl = 'https://www.company.com/device/7.60A.100.022.cmp'
```

- ◆ CLI:

```
(config-system)# automatic-update  
(auto-update)# firmware  
https://www.company.com/device/7.60A.100.022.cmp
```

- For one-time file download, the HTTP Get request sent by the device doesn't include the If-Modified-Since header. Instead, the HTTP-User-Agent header can be used in the HTTP Get request to determine whether firmware update is required.
- When downloading TLS certificate files, it is recommended to use HTTPS with mutual authentication for secure transfer of the TLS Private Key.
- For devices in HA mode, the License Key is applied to both active and redundant units.

5. If the device receives an HTTP 301/302/303 redirect response from the provisioning server, it establishes a connection with the new server at the redirect URL and re-sends the HTTP Get request.

## File Download Sequence

Whenever the Automatic Update feature is triggered (see [Triggers for Automatic Update](#) on page 1408), the device attempts to download the files (if available) from the configured URLs in the following order:

1. ini file
2. CLI Script file
3. CLI Startup Script file
4. Periodic software file (.cmp) download
5. One-time software file (.cmp) download
6. Auxiliary file(s)

The following files instruct the device to restart:

- CLI Startup Script file
- Periodic software file (.cmp)
- One-time software file (.cmp)

When multiple files requiring a restart are downloaded, the device restarts only **after** it has downloaded and installed **all** the files. However, you can explicitly instruct the device to immediately restart for the following files:

- ini file: Use the [ResetNow] in file parameter
- CLI Script file: Use the `reload if-needed` CLI command

If you use the [ResetNow] parameter in an ini file for periodic automatic provisioning with non-HTTP (e.g., TFTP) and without CRC, the device restarts after every file download. Therefore, use the parameter with caution and only if necessary for your deployment requirements.

- For ini file downloads, parameters excluded from the file are set to default. To retain the current settings of these parameters, configure the [SetDefaultOnINIFileProcess] parameter to 0.
- The CLI Startup Script file is not supported when the device operates in HA mode.
- If you have configured one-time software file (.cmp) download (configured by the [CmpFileURL] parameter or CLI command `configure system > automatic-update > firmware`), the device will only apply the file if one-time software updates are enabled. This is disabled by default to prevent unintentional software upgrades. To enable one-time software upgrades, set the [AutoUpdateCmpFile] parameter to [1] or CLI command, `configure system > automatic-update > update-firmware on`.
- If you need to update the device's software and configuration, it is recommended to first update the software. This is because the current ("old") software (before the upgrade) may not be compatible with the new configuration. However, if both files are available for download on the provisioning server(s), the device first downloads and applies the new configuration, and only then does it download and install the new software. Therefore, this is a very important issue to take into consideration.
- If more than one file needs to be updated:
  - ✓ CLI Script and cmp: The device downloads and applies the CLI Script file on the currently ("old") installed software version. It then downloads and installs the cmp file with a restart. Therefore, the CLI Script file **MUST** have configuration compatible with the "old" software version.
  - ✓ CLI Startup Script and cmp: The device downloads both files, restarts, applies the new cmp, and then applies the configuration from the Startup Script file on the new software version.
  - ✓ CLI Script and Startup Script: The device downloads and applies both files; but the Startup Script file overwrites all the configuration of the CLI Script file.
- To configure the maximum time (timeout) allowed for downloading a file from the provisioning server, use the [AupdMaxTransferTime] parameter.

## Cyclic Redundancy Check on Downloaded Configuration Files

You can enable the device to perform cyclic redundancy checks (CRC) on downloaded configuration files during the Automatic Update process. The CRC checks whether the content (raw data) of the downloaded file is different to the content of the previously downloaded file from the previous Automatic Update process. The device compares the CRC check value (code) result with the check value of the previously downloaded file. If the check values are identical, it indicates that the file has no new configuration settings, and the device discards the file. If the check values are different, it indicates that the downloaded file is different (i.e., includes updates), and the device installs the downloaded file and applies the new configuration settings.

CRC is useful, for example, when the service provider replaces a file, on the provisioning server, with another file whose contents are the same. When the device sends an HTTP Get request during the Automatic Update process, the provisioning server sends the new file to the device. This occurs as the timestamp between the previously downloaded file and this new file is

different (determined by the HTTP If-Modified-Since header in the Get request). Therefore, the CRC feature can be used to prevent the device from installing such files.

For enabling CRC, use the ini file parameter AUPDCheckIfIniChanged or CLI command, configure `system > automatic-update > crc-check regular`. By default, CRC is disabled. For more information on the parameter, see [Automatic Update Parameters](#) on page 1732.

## Automatic Update Configuration Examples

This section provides a few examples on configuring the Automatic Update feature.

### Automatic Update for Single Device

This simple example describes how to configure the Automatic Update feature for updating a single device. In this example, the device queries the provisioning server for software, configuration and Auxiliary files every 24 hours.

#### ➤ To set up Automatic Provisioning for single device (example):

1. Set up an HTTP Web server (e.g., `http://www.company.com`) and place all the required configuration files on this server.
2. Configure the device with the IP address of the DNS server for resolving the domain name (e.g., `http://www.company.com`) that is used in the URL of the provisioning server. You configure this in the IP Interfaces table:

- ini File:

```
[ InterfaceTable ]
FORMAT Index = ApplicationTypes, InterfaceMode, IPAddress,
PrefixLength, Gateway, VlanID, InterfaceName,
PrimaryDNSServerIPAddress, SecondaryDNSServerIPAddress,
UnderlyingDevice;InterfaceTable 0 = 6, 10, 10.15.7.95, 16, 10.15.0.1, 1,
"Voice", 80.179.52.100, 0.0.0.0, "vlan 1";
[ \InterfaceTable ]
```

- CLI:

```
# configure network
(config-network)# interface network-if 0
(network-if-0)# primary-dns 80.179.52.100
```

3. Configure the device with the following Automatic Update settings:

- a. Automatic Update is done every 24 hours (1440 minutes):

- ◆ ini File:

```
AutoUpdateFrequencySeconds = 1440
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
automatic-update)# update-frequency 1440
```

**b.** Automatic Update of software file (.cmp):

- ◆ ini File:

```
AutoCmpFileUrl = 'https://www.company.com/sw.cmp'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# auto-firmware 'http://www.company.com/sw.cmp'
```

**c.** Automatic Update of Call Progress Tone file:

- ◆ ini File:

```
CptFileURL = 'https://www.company.com/call_progress.dat'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# call-progress-tones 'http://www.company.com/call_
progress.dat'
```

**d.** Automatic Update of ini configuration file:

- ◆ ini File:

```
IniFileURL = 'https://www.company.com/config.ini'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# ini-file 'http://www.company.com/config.ini'
```

- e. Enable Cyclical Redundancy Check (CRC) on downloaded ini file:

- ◆ ini File:

```
AUPDCheckIfIniChanged = 1
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# crc-check regular
```

4. Power down and then power up the device.

### Automatic Update from Remote Servers

This example describes how to configure the Automatic Update feature where files are stored and downloaded from different file server types. The example scenario includes the following:

- FTPS server at ftpserver.corp.com for storing the License Key file. The login credentials to the server are username "root" and password "wheel".
- HTTP server at www.company.com for storing the configuration file.
- DNS server at 80.179.52.100 for resolving the domain names of the provisioning servers (FTPS and HTTP).

#### ➤ To set up Automatic Provisioning for files stored on different server types (example):

##### 1. License Key file:

- a. Set up an FTPS server and copy the License Key file to the server.
- b. Configure the device with the URL path of the License Key file:

- ◆ ini File:

```
FeatureKeyURL = 'ftps://root:wheel@ftpserver.corp.com/license_
key.txt'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# feature-key
'ftp://root:wheel@ftpsrvr.corp.com/license_key.txt'
```

## 2. Software (.cmp) and ini files:

- a. Set up an HTTP Web server and copy the .cmp and configuration files to the server.
- b. Configure the device with the URL paths of the .cmp and ini files:

### ◆ ini File:

```
AutoCmpFileUrl = 'http://www.company.com/device/sw.cmp'
IniFileURL = 'http://www.company.com/device/inifile.ini'
```

### ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# auto-firmware 'http://www.company.com/sw.cmp'

(auto-update)# startup-script https://company.com/files/startup_
script.txt
```

3. Configure the device with the IP address of the DNS server for resolving the domain names of the FTPS and HTTP servers:

```
[ InterfaceTable ]
FORMAT Index = ApplicationTypes, InterfaceMode, IPAddress, PrefixLength,
Gateway, VlanID, InterfaceName, PrimaryDNSServerIPAddress,
SecondaryDNSServerIPAddress, UnderlyingDevice;
InterfaceTable 0 = 6, 10, 10.15.7.95, 16, 10.15.0.1, 1, "Voice", 80.179.52.100,
0.0.0.0, "vlan 1";
[ \InterfaceTable ]
```

4. Configure the device to perform the Automatic Update process daily at 03:00 (3 a.m):

### ● ini File:

```
AutoUpdatePredefinedTime = '03:00'
```

### ● CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# predefined-time 03:00
```

## Automatic Update for Mass Deployment

This example describes how to configure the Automatic Update feature for updating multiple devices (i.e., mass deployment) using an HTTP provisioning server. In this example, all the devices are configured to download the same "master" configuration file. This file serves as the configuration template and instructs the devices which files to download and how often to perform the Automatic Update process. In addition, the master file also instructs each device to download an ini configuration file whose file name contains the MAC address of the device.

The example scenario is as follows:

- All devices download a "master" configuration file that contains the following:
  - Common configuration shared by all device's.
  - [MAC Address Placeholder in URL and File Name](#) on page 1404.
- Device queries the provisioning server daily at 24:00 (midnight) for software, configuration and Auxiliary files.
- HTTP-based provisioning server at [www.company.com](http://www.company.com) for storing the files.
- DNS server at 80.179.52.100 for resolving the domain name of the provisioning server.

### ➤ To set up automatic provisioning for mass provisioning (example):

1. Create a "master" configuration file template named "master\_configuration.ini" or "master\_startup.txt" with the following settings:
  - Common configuration for all devices:
    - ◆ ini file:

```
AutoUpdatePredefinedTime = '24:00'
CptFileURL = 'https://www.company.com/call_progress.dat'
AutoCmpFileUrl = 'https://www.company.com/sw.cmp'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# predefined-time 24:00
(auto-update)# call-progress-tones https://www.company.com/call_
progress.dat
(auto-update)# auto-firmware https://www.company.com/sw.cmp
```

- Configuration per device based on MAC address:

- ◆ ini file:

```
IniFileURL = 'http://www.company.com/config_<MAC>.ini'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# cli-script https://company.com/files/cli_script_
<MAC>.txt
(auto-update)# ini-file http://www.company.com/config_<MAC>.ini
```

2. Copy the master configuration file that you created in Step 1 as well as the CPT and .cmp files to the HTTP-based provisioning server.

3. Configure **each** device with the following:

- a. URL of the master configuration file:

- ◆ ini File:

```
IniFileURL = 'http://www.company.com/master_configuration.ini'
```

- ◆ CLI:

```
# configure system
(config-system)# automatic update
(auto-update)# ini-file http://www.company.com/master_
configuration.ini
(auto-update)# cli-script https://company.com/files/master_startup.txt
```

- b. Configure the device with the IP address of the DNS server for resolving the domain name (e.g., http://www.company.com) that is used in the URL for the provisioning server. This is done in the IP Interfaces table:

- ◆ ini File:

```
[ InterfaceTable ]
FORMAT Index = ApplicationTypes, InterfaceMode, IPAddress,
PrefixLength, Gateway, VlanID, InterfaceName,
PrimaryDNSServerIPAddress, SecondaryDNSServerIPAddress,
UnderlyingDevice;
InterfaceTable 0 = 6, 10, 10.15.7.95, 16, 10.15.0.1, 1, "Voice",
```

```
80.179.52.100, 0.0.0.0, "vlan 1";  
[ \InterfaceTable ]
```

◆ CLI:

```
# configure network  
(config-network)# interface network-if 0  
(network-if-0)# primary-dns 80.179.52.100
```

4. Power down and then power up the device.

## 48 USB Storage Capabilities

The device supports USB storage using an external USB hard drive or flash disk (disk on key) connected to its USB port. The storage capabilities are configured using the CLI and include the following:

- To save network captures to the USB:

```
# debug capture data physical stop usb
```

- To update the device's firmware from the USB:

```
# copy firmware from usb:///<cmp file name>
```

- To update the device's configuration from the USB:

```
# copy ini-file from usb:///<ini configuration file name>
```

- To save the current configuration to the USB:

```
# copy ini-file to usb:///<ini configuration file name>
```

Only a single USB storage (formatted to FAT/FAT32) operation is supported at any given time.

## 49 SBC Configuration Wizard

The SBC Configuration Wizard provides you with a quick-and-easy method for initial configuration of your device. The SBC Configuration Wizard guides you through a sequence of pages, assisting you in defining your device. Once the wizard is complete, your device is sufficiently configured to successfully process and route calls in your deployment.

The SBC Configuration Wizard is based on partially and fully tested interoperability setups between the device and a wide range of vendors, including SIP trunking providers, IP PBXs, and contact centers. Once you have selected the involved vendors and defined basic settings in the SBC Configuration Wizard, it then generates a configuration file based on the matching interoperability configuration template. Alternatively, instead of basing your configuration on specific vendors, you can use the SBC Configuration Wizard to generate a configuration file based on a generic template for commonly used setups. In such cases, you may later need to manually fine-tune your configuration to suit your setup needs.

The SBC Configuration Wizard can automatically load the generated configuration (with a restart) to the device, or you can simply download the generated configuration file to a folder on your PC and then upload the file to the device at a later stage.

The generated configuration is a good starting point to enable the successful establishment of basic calls. For complete device configuration, you may need to manually configure additional functionality. For example, you may need to configure security settings (e.g., firewalls and IDS) to ensure that the device is protected from malicious activity and DoS attacks.

For AudioCodesfull interoperability list, click [here](#).

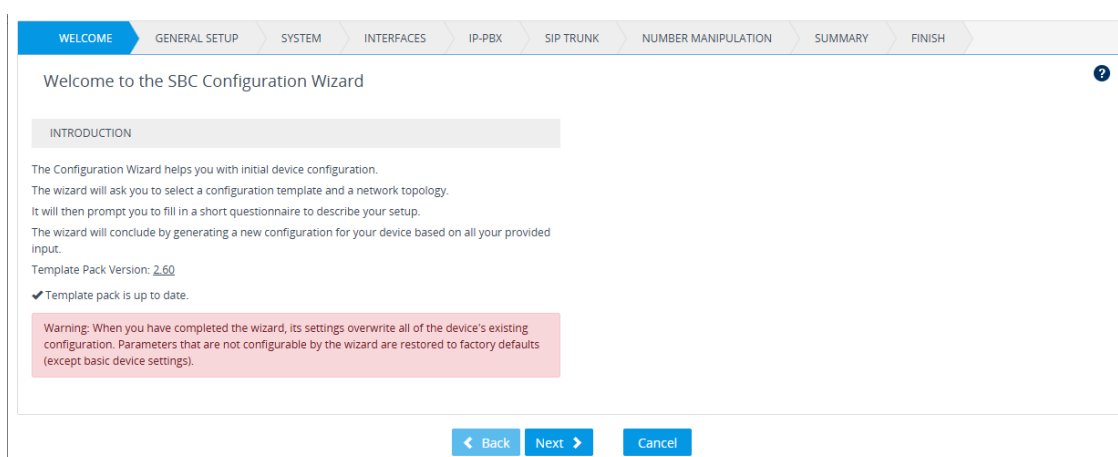

- The SBC Configuration Wizard is not supported (and not available in the Web interface) in the following cases:
  - ✓ If the device is operating in High-Availability (HA) mode.
  - ✓ If you have configured IPv6 interfaces in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
  - ✓ If you have configured WebSocket tunneling with OVOC (see [Configuring WebSocket Tunnel with OVOC](#) on page 123).
- When the SBC Configuration Wizard applies the configuration template to the device, all parameters configured by the SBC Configuration Wizard overwrite the device's existing configuration of those parameter. Parameters not configured by the SBC Configuration Wizard are restored to factory defaults, except basic device settings such as management users (Web and CLI). Some of these basic settings also appear in the SBC Configuration Wizard and their fields are automatically populated with their current settings; if you do modify them in the SBC Configuration Wizard, their new settings are used.
- On some wizard pages, the availability of certain fields depends on the selected application.

## Starting the SBC Configuration Wizard

The following procedure describes how to start the SBC Configuration Wizard. Throughout the wizard, you can get help on the current wizard page, by clicking the  icon, located on the top-right of the page.

### ➤ To start the SBC Configuration Wizard:

1. Access the SBC Configuration Wizard's Welcome page:
  - **Toolbar:** Click **Actions**, and then from the drop-down list, choose **Configuration Wizard**.
  - **Navigation Tree:** **Setup** menu > **Administration** tab > **Maintenance** folder > **Configuration Wizard**.

2. The version of the template pack currently installed on the device is displayed by the 'Template Pack Version' field. The template pack contains the interoperability configuration templates available on the SBC Configuration Wizard. If the template pack is the latest, "Template pack is up to date" is displayed below the field. If the template pack is not the latest version, you can update it by clicking the **Update from Remote Server** button (see below note). Alternatively, if you have received a template pack file from the sales representative of your purchased device, you can install it on the device using the Auxiliary Files page (see [Uploading Auxiliary Files](#) on page 1347). If you click the version number, the Template Pack Version History window appears, displaying the updates for the current and previous versions.

The device checks with AudioCodes server if it has the latest template pack only if it has Internet connectivity. Therefore, the **Update from Remote Server** button is displayed only if the device has connectivity to the Internet and has subsequently found that the template pack is not the latest.

3. Click **Next**; the General Setup page appears (see [General Setup Page](#) on the next page).

## General Setup Page

The General Setup wizard page defines the network topology of the device, which includes the application (e.g., SIP trunk) and the involved third-party vendors, configuration template based on the selected vendor interoperability, and physical network (ports).

### ➤ To define the general setup:

#### 1. Select one of the following 'Application' options:

- SIP Trunk (IP-PBX with SIP Trunk):** The device connects the Enterprise IP PBX with the Internet Telephony Service Provider (ITSP) or SIP Trunk Provider. The IP PBX resides on the Enterprise LAN, while the ITSP resides on the WAN. Only calls between the IP PBX and ITSP traverse the device. Calls between Enterprise phones, users and certain SIP messages (REGISTER, SUBSCRIBE and NOTIFY) are managed locally by the IP PBX and do not traverse the device.
- SIP Normalization (two IP-PBX's):** The device performs SIP "normalization" of traffic between two IP PBXs. The first IP PBX resides on the Enterprise LAN (co-located with the device) and the second IP PBX resides on the WAN (or at another branch site). Only calls between the IP PBXs traverse the device. Calls between the phones and users of the same IP PBX, and certain SIP messages (REGISTER, SUBSCRIBE and NOTIFY) are managed locally by each IP PBX and do not traverse the device.
- Hosted IP-PBX (IP-PBX with Users):** The device connects phones (users) with the "hosted" IP PBX. The users reside on the Enterprise LAN (co-located with the device) and the IP PBX resides on the WAN (or at the datacenter). All traffic between users and IP PBX traverse the device, including SIP REGISTER, SUBSCRIBE and NOTIFY messages.
- Remote Users (IP-PBX with Remote Users):** The device connects remote phones (users) with the "local" IP PBX (additional IP PBX servers can be configured). The IP PBX resides on the Enterprise LAN (co-located with the device) and the remote users reside on the WAN (or at the datacenter). All traffic between users and IP PBX traverse the device, including SIP REGISTER, SUBSCRIBE and NOTIFY messages.

#### 2. If you selected the **SIP Trunk** application in Step 1, do the following:

- a. From the 'IP-PBX' drop-down list, select the IP PBX model. If the model is not listed, select **Generic IP-PBX**.
  - b. From the 'SIP-Trunk' drop-down list, select the SIP trunk provider. If the provider is not listed, select **Generic SIP Trunk**.
3. From the 'Network Setup' drop-down list, select the physical network topology:
  - **Two ports: LAN and WAN:** The device connects to the network through two separate physical network links (interfaces). The first interface ("LAN") is connected to the Enterprise LAN (typically, a switch) and has a private IP address. The second interface ("WAN") is connected to the DMZ port of the Enterprise router and has a public (globally routable) IP address. Each link may be accompanied with a backup link for Ethernet link redundancy.
  - **One port: LAN:** The device connects to the Enterprise LAN (typically, a switch) through a single physical network link (interface). The interface ("LAN") has a private IP address. You must enable port forwarding on the Enterprise router to forward all VoIP traffic from the ITSP (located on the WAN) to the device. The exact port forwarding configuration is shown on the Conclusion page and consists of the device's address, SIP port (e.g. 5060) and a media port range (e.g. 6000-6999).
  - **One port: WAN:** The device connects to the DMZ port of the Enterprise router through a single physical network link (interface). The interface ("WAN") has a public (globally routable) IP address. You must enable port forwarding on the Enterprise router to forward all VoIP traffic from the device to the IP PBX (located on the LAN). The exact port forwarding configuration is shown on the Conclusion page and consists of the IP PBX address, SIP port (e.g. 5060) and a media port range (e.g. 6000-6999).
  - **One port: LAN only:** The device connects to the Enterprise LAN (typically, a switch) through a single physical network link (interface). All SIP entities (IP PBX and users) connect to the same LAN. Note that this option is applicable to all applications (see Step 1), except **SIP Trunk**.
4. Click **Next**; the System page appears (see [System Page](#) below).

## System Page

The System wizard page configures the device's basic system settings, including management interface protocol, date and time, and syslog.

➤ **To configure system settings:**

1. Configure the protocol for accessing the management interfaces:
  - 'Web Interface': Select the type of Web interface protocol (**HTTP** or **HTTPS**).
  - 'CLI Interface': Select the type of CLI protocol (**Disabled**, **Telnet**, **SSH**).
2. (Optional) Enable syslog by selecting the 'Enable Syslog' check box, and then in the 'Syslog IP' field, configuring the syslog server's IP address. Note that if you enable syslog, the device generates verbose logs (debug level 5), which adversely affects performance. For more information on syslog, see [Configuring Syslog](#) on page 1614.
3. Configure the time and date:
  - 'Time Zone': Select the GMT time zone in which the device is located.
  - 'Primary NTP Server' and 'Secondary NTP Server': Configure the IP address (or hostname) of the primary (and optionally, secondary) NTP server in your network. The NTP server synchronizes the time of the device. This is mandatory when the IP PBX or ITSP uses a TLS connection, as correct time is required for certificate validation.

For more information on configuring date and time, see [Date and Time](#) on page 136.

4. (Optional) Configure a local DNS table, which allows the device to resolve domain names (hostnames) using a locally defined address resolution table. This may be needed when your setup lacks a DNS server and the IP PBX or ITSP require the use of hostnames instead of IP addresses. Select the 'Apply local DNS' check box, and then configure the following parameters:
  - 'Domain Name': Domain name to resolve into an IP address.
  - 'First IP address': IP address of the domain name.
  - 'Secondary IP address': Second IP address of the domain name (optional).

For more information on configuring the device's DNS table, see [Configuring the Internal DNS Table](#) on page 199.

5. Click **Next**; the Interfaces page appears (see [Interfaces Page](#) on the next page).

## Interfaces Page

The Interfaces wizard page configures the device's LAN and WAN settings.

### ➤ To configure LAN and WAN interface settings:

1. From the 'Physical Port' drop-down list, select the Ethernet Group containing the required physical Ethernet port for connecting the device to the 1) Enterprise LAN (typically, a switch) or 2) DMZ port of the Enterprise router for WAN. You may configure two physical ports for Ethernet link redundancy.
2. Select the **VLAN Tagging** check box, and then in the 'VLAN ID' field, configure the VLAN ID for the interface. For untagged traffic, clear the check box.
3. In the 'IP Address' field, configure the device's IP address on the interface.
  - For LAN interfaces: The IP address must be part of the Enterprise LAN and therefore, is typically a private IP address. The address is used for communicating with the IP PBX and/or users that reside on the LAN, as well as for management (OAMP) traffic.
  - For WAN interfaces: The IP address must be a public (globally routable) address and is used for communicating with the ITSP and/or IP PBX that resides on the WAN. If the WAN is the only interface, it is also used for management (OAMP) traffic.
4. In the 'Subnet Mask' field, configure the subnet mask of the interface.
5. In the 'Default Gateway' field, configure the default gateway of the interface.
6. If the device is connected through an Enterprise router that performs NAT, then in the 'NAT Public IP' address, configure the public IP address (of the Enterprise router) used by the device to communicate with the ITSP (for the **SIP Trunk** application) or IP PBX (for the **Hosted IP-PBX** application).

7. In the 'Primary DNS Server' (and optionally, 'Secondary DNS Server') field, configure your primary (and optionally, secondary) DNS server in the network. This is mandatory if you use a hostname (FQDN) for ITSP (WAN only) and IP PBX addresses.
8. From the 'OAM Interface' drop-down list, select the device's interface for management traffic:
  - **LAN:** Management traffic is carried over the regular LAN interface, as defined above.
  - **WAN:** Management traffic is carried over the WAN interface, as defined above.
  - **Additional:** Configure a different interface for management traffic.
9. Click **Next**; the IP-PBX page appears (see [IP-PBX Page](#) below).

## IP-PBX Page

The IP-PBX wizard page configures the IP PBX settings.

The screenshot shows the 'IP-PBX configuration' page with the following sections and fields:

- WELCOME** | **GENERAL SETUP** | **SYSTEM** | **INTERFACES** | **IP-PBX** | **SIP TRUNK** | **REMOTE USERS(FEU)** | **NUMBER MANIPULATION** | **SUMMARY** | **FINISH**
- IP-PBX configuration**
- NETWORK INTERFACE**
  - Network Type:
- IP-PBX**
  - Address:
  - Backup Address:
  - SIP Domain:
  - Keep Alive: ☐
- SIP INTERFACE**
  - Transport Type:
  - Destination Port:
  - Listening Port:
- MEDIA PORTS (REALM)**
  - Media Protocol:
  - Base Port:
  - Number Of Sessions:
- Navigation buttons: **< Back** | **Next >** | **Cancel**

- The following fields are read-only:
  - ✓ 'Network Type': Displays the IP network interface for communicating with the IP PBX.
  - ✓ 'NAT Public IP': Displays the public IP address (of the Enterprise router) for communicating with the IP PBX. The field is applicable only when the device is connected to a router that performs NAT.
- Depending on the application type that you selected on the General Setup page ([General Setup Page](#) on page 1426), the wizard may provide additional IP-PBX pages ("IP-PBX2" and "IP-PBX3") for configuring additional servers.

### ➤ To configure IP PBX settings:

1. Under the IP-PBX group, configure the following:

- 'Address': Configure the IP address (or hostname) of the IP PBX. Note that for the **One port: WAN** network topology, when the device is assigned a public IP address, you must use the public IP address (of the Enterprise router) instead of the private address of the IP PBX, and configure the Enterprise router to forward VoIP traffic from the device to the IP PBX.
  - 'Backup Address': (Optional) Configure the backup IP address (or hostname) of the IP PBX.
  - 'SIP Domain': Configure the SIP domain name used for communication with the IP PBX. The domain name is used in the following SIP message headers:
    - ◆ Outbound calls: Request-URI and To headers
    - ◆ Inbound calls: From header
  - 'Keep Alive': Enable the periodic keep-alive check for multiple IP PBX addresses.
2. Under the Media Ports (Realm) group, configure the media protocol type and ports used by the device for communicating with the IP PBX:
    - 'Media Protocol': Configure the media protocol type (**RTP** or **SRTP**).
    - 'Base Port' Configure the first media port in the port range.
    - 'Number Of Sessions': Configure the number of required media sessions. For more information on media port ranges and number of sessions, see [Configuring RTP Base UDP Port](#) on page 301.
  3. Under the SIP Interface group, configure SIP ports and transport type for communicating with the IP PBX:
    - 'Transport Type': Configure the SIP transport type.
    - 'Destination Port': Configure the SIP port used by the IP PBX.
    - 'Listening Port': Configure the SIP port used by the device when communicating with the IP PBX.
  4. Click **Next**; the SIP Trunk page appears ([SIP Trunk Page](#) below).

## SIP Trunk Page

The SIP Trunk wizard page configures the SIP Trunk settings.

The following fields are read-only:

- 'Network Type': Displays the IP network interface for communicating with the SIP Trunk.
- 'NAT Public IP': Displays the public IP address (of the Enterprise router) for communicating with the SIP Trunk. The field is applicable only when the device is connected to a router that performs NAT. Note that the Enterprise router must be configured to "port forward" all VoIP traffic from the SIP Trunk (located on the WAN) to the device. The exact port forwarding configuration is displayed on the Conclusion page and consists of the device's address, SIP listening port (e.g. 5060) and a range of media ports defined below (e.g. 6000-6999).

➤ **To configure SIP Trunk settings:**

1. Under the SIP Trunk group, configure the following:
  - 'Address': Configures the IP address or hostname of the SIP Trunk.
  - 'Backup Address': (Optional) Configures the backup IP address or hostname of the SIP Trunk.
  - 'SIP Domain': Configures the SIP domain name for communicating with the SIP Trunk. The domain name is used in the following SIP message headers:
    - ◆ Outbound calls: Request-URI and To headers
    - ◆ Inbound calls: From header
  - 'Keep Alive': Enables the periodic keep-alive check of multiple SIP Trunk addresses.
2. Under the SIP Interface group, configure the SIP ports and transport type for communicating with the SIP Trunk:
  - 'Transport Type': Configure the SIP transport type.
  - 'Destination Port': Configure the SIP port used by the SIP Trunk.

- 'Listening Port': Configure the SIP port used by the device for communicating with the SIP Trunk. Note that for the **One port: WAN** network topology, the device must use different Listening Ports when communicating with the IP PBX and SIP Trunk.
3. Under the Media Ports (Realm) group, configure the media protocol type and ports used by the device for communicating with the IP PBX:
- 'Media Protocol': Configure the media protocol type.
  - 'Base Port': Configure the first media port.
  - 'Number Of Sessions': Configure the number of required media sessions. For more information on media port ranges and number of sessions, see [Configuring RTP Base UDP Port](#) on page 301.
4. Under the SIP Account group, configure the device's registration with the SIP Trunk:
- 'Account Type': Configure whether the device must perform registration or authentication with the SIP Trunk (**None**, **Registration** or **Authentication**).
  - 'Trunk Main Line': Configure the "leading number" assigned by the SIP Trunk. Many SIP Trunks use the same value for Trunk Main Line and Username parameters.
  - 'Username': Configure the SIP authentication username (as provided by the SIP Trunk provider).
  - 'Password': Configure the SIP authentication password (as provided by the SIP Trunk provider).

The password cannot be configured with wide characters.

5. Click **Next**; the Number Manipulation page appears (see [Number Manipulation Page](#) on the next page).

## Remote Users or Users Page

The Remote Users or Users wizard page configures remote users settings.

- This page is applicable only to IP PBXs that support such configuration.
- The parameters displayed on the page depends on the application type and template that you selected on the General Setup wizard page (see [General Setup Page](#) on page 1426).

### ➤ To configure remote users:

1. Select the 'Enable remote users' check box.
2. Under the SIP Interface group, configure the SIP interface for the remote users:
  - 'Transport Type': Configure the SIP transport type.
  - 'Listening Port': Configure the SIP port used by the device for communicating with remote users. For **One Port: LAN** and **One Port: WAN** network topologies, you must configure different listening ports for communication with the IP PBX and remote users.
3. Under the Media Ports (Realm) group, configure the media protocol type and ports used by the device for communicating with the remote users:
  - 'Media Protocol': Configure the media protocol type (RTP or SRTP).
  - 'Base Port': Configure the first media port.
  - 'Number Of Sessions': Configure the number of required media sessions. For more information on media port ranges and number of sessions, see [Configuring RTP Base UDP Port](#) on page 301.
4. Click **Next**; the Summary page appears (see [Summary Page](#) on page 1436).

## Number Manipulation Page

The Number Manipulation wizard page configures caller (source) and callee (destination) number manipulation for outbound and inbound calls, and allows you to use AudioCodes Routing Manager (ARM) to determine the routing.

Number Manipulation configuration

OUTBOUND CALLS (IP-PBX → SIP TRUNK)

Destination Number Manipulation ☒

Prefix

Remove

Add

Source Number Manipulation ☐

INBOUND CALLS (SIP TRUNK → IP-PBX)

Destination Number Manipulation ☒

Prefix

Remove

Add

Source Number Manipulation ☐

ADVANCED ROUTING MANAGER

Use ARM for call routing ☐

[< Back](#) [Next >](#) [Cancel](#)

➤ **To configure number manipulation:**

**1. Configure number manipulation:**

- a. Under the Outbound Calls and/or Inbound Calls groups, select the required manipulation check box:
  - ◆ Destination Number Manipulation: Manipulates the destination number.
  - ◆ Source Number Manipulation: Manipulates the source number.
- b. In the 'Prefix' field, configure the prefix (digits at the beginning of the number) to which you want to apply manipulation. If configured to "\*" (asterisk), manipulation is applied to all numbers.
- c. In the 'Remove' field, configure the number of digits to be removed from the beginning of the number. If configured to "0", no digits are removed.
- d. In the 'Add' field, configure a new prefix to be added to the beginning of the number. If not configured, no prefix is added.

The example below changes the number "+15033311432" to "03311432":

- Prefix: "+1503"
  - Remove: "4"
  - Add: "0"
2. To enable routing by ARM, select the 'Use ARM for call routing' check box, and then configure the following fields:
    - 'Host': IP address or FQDN of the ARM server.
    - 'Username': Username for communication with ARM.
    - 'Password': Password for communication with ARM.
  3. Click **Next**; Remote Users (FEU) page appears (see [Remote Users or Users Page](#) on page 1433).

## Summary Page

The Summary wizard page displays a summary of your configuration.

### ➤ To review your configuration:

1. Review the configuration:
  - To view the configuration in ini-file format, click the **INI File** tab.
  - To view the configuration in normal format, click the **Configuration Summary** tab.
2. To download the configuration as an ini file to a folder on your PC, click the **Save INI file** button. You can later upload the file to the device (see [Uploading an ini File to Device](#) on page 130).
3. Click **Next**; the Congratulations page appears (see [Finish Page](#) below).

## Finish Page

The Finish wizard page is the last wizard page and allows you to complete configuration.

### ➤ To complete the SBC Configuration Wizard:

- Click **Apply & Reset** to apply configuration to the device or click **Save INI File** to save configuration as an ini file on your PC.

## 50 Restoring Factory Defaults

This section describes how to restore the device's configuration to factory defaults.

### Restoring Factory Defaults through CLI

You can restore the device to factory defaults through CLI. You can restore all configuration to factory defaults or you can restore all configuration to factory defaults except the current network settings. Preserving network settings allows you to remotely connect to the device using its current OAMP IP address even after the device has been restored to default settings.

#### ➤ To restore factory defaults through CLI:

1. Access the CLI:
  - a. Connect the RS-232 serial port of the device to the communication port on your computer. For serial cabling, refer to the Hardware Installation Manual.
  - b. Establish serial communication with the device using a serial communication program (such as HyperTerminal™) with the following communication port settings:
    - ◆ Baud Rate: 115,200 bps
    - ◆ Data Bits: 8
    - ◆ Parity: None
    - ◆ Stop Bits: 1
    - ◆ Flow Control: None
2. At the CLI prompt, type the username (default is "Admin" - case sensitive), and then press Enter:

```
# Username: Admin
```

3. At the prompt, type the password (default is "Admin" - case sensitive), and then press Enter:

```
# Password: Admin
```

4. At the prompt, type the following, and then press Enter:

```
# enable
```

5. At the prompt, type the password again, and then press Enter:

```
# Password: Admin
```

6. At the prompt, type one of the following commands, and then press Enter:

- To restore all configuration to factory defaults:

```
# write factory
```

- To restore configuration to factory defaults except current network settings:

```
# write factory keep-network-and-users-configuration
```

- To restore configuration to factory defaults and delete all TLS-related files (e.g., certificates, root certificates and public keys):

```
# write factory clear-keys-and-certs
```

## Restoring Factory Defaults through Web Interface

You can restore the device to factory defaults through the Web interface.

When restoring the device to factory defaults, you can preserve basic IP network settings (configured in the IP Interfaces table - see [Configuring IP Network Interfaces](#) on page 159), as described below. This ensures that connectivity to the device (through the OAMP interface) is maintained after factory defaults have been applied.

### ➤ To restore factory defaults through Web interface:

1. Open the Configuration File page:

- **Toolbar:** From the **Actions** drop-down menu, choose **Configuration File**.
- **Navigation tree:** **Setup** menu > **Administration** tab > **Maintenance** folder > **Configuration File**.

RESTORE THE DEFAULT CONFIGURATION OF THE DEVICE

Restore Factory Defaults

☒ Preserve basic connectivity.

2. To keep your current IP network settings (e.g., OAMP), select the **Preserve basic connectivity** check box. To overwrite all your IP network settings with the default IP network interface, clear this check box.
3. Click the **Restore Defaults** button; a message appears requesting you to confirm.
4. Click **OK** to confirm or **Cancel** to return to the page.

5. Once the device is restored to factory defaults, restart the device for the settings to take effect.

## Restoring Defaults using Hardware Reset Button

You can restore the device to factory defaults by pressing the device's hardware reset pinhole button.

### ➤ To restore default settings using the hardware reset pinhole button:

- With a paper clip or any other similar pointed object, press and hold down the device's reset pinhole button for at least 15 seconds (but no more than 25 seconds).

For the exact location of the reset pinhole button on the device, refer to the *Hardware Installation Manual*.

## Restoring Defaults through ini File

You can restore the device to factory defaults as described below.

### ➤ To restore the device to factory defaults:

1. Create an **empty** text-based file and save it in a folder on your PC with the filename extension .ini.
2. Upload the file to the device using the Configuration File page (see [Downloading and Uploading Configuration Files](#) on page 1386).

The only settings that are not restored to default are the management (OAMP) LAN IP address and the Web interface's login username and password.

# **Part IX**

## **Status, Performance Monitoring and Reporting**

## 51 System Status

This section describes how to view system status.

### Viewing Device Information

You can view hardware and software information about the device on the Device Information page.

➤ **To view device information:**

- Open the Device Information page (**Monitor** menu > **Monitor** tab > **Summary** folder > **Device Information**).

GENERAL		LOADED FILES	
MAC Address	00:90:8f:5b:10:35	Loaded Call Progress Tones	Default Progress Tones
Serial Number	5967925		
BID	5b1035:238		
Product Key			
Device Name	M500		
Device Up Time	0d:0h:30m:51.13s		
Device Administrative State	Unlocked		
Device Operational State	Enabled		
Flash Size [Mbytes]	64		
RAM Size [Mbytes]	512		
CPU Model	Cavium Networks Octeon V0.1 @ 500Mhz		
CPU Speed [MHz]	500		
VERSIONS			
Version ID	7.40A.250.235		
DSP Software Version	0724.20		
DSP Software Name	5014AE3_R		

**Table 51-1: Device Information Page Description**

Parameter	Description
<b>General Info</b>	
'MAC Address'	Media access control (MAC) address.
'Serial Number'	Serial number of the CPU. This serial number also appears on the product label that is affixed to the chassis.
'BID'	Board ID, which is a unique number that identifies the device and non-SIP session related logs generated by the device. For more

Parameter	Description
	information, see <a href="#">Syslog Message Format</a> on page 1614.
'Product Key'	Product Key, which identifies the specific device purchase (and used for communication with AudioCodes, for example, for support and software upgrades). The Product Key also appears on the product label that is affixed to the chassis. For more information, see <a href="#">Viewing the Device's Product Key</a> on page 1385.
'Device Name'	Numerical identification of the product (device).
'Device Up Time'	Duration that the device has been up and running since the last restart (uptime). The duration is displayed in the following format: <i>dd:hh:mm:ss.ss</i> . For example, "1d:21h:40m:21s:75.22" means that the device has been running for one day and 21 hours, 40 minutes and 21.22 seconds.
'Device Administrative State'	Administrative status, as performed in <a href="#">Locking and Unlocking the Device</a> on page 1331. <ul style="list-style-type: none"> <li>■ "Unlocked"</li> <li>■ "Locked"</li> </ul>
'Device Operational State'	Operational status: <ul style="list-style-type: none"> <li>■ "Disabled"</li> <li>■ "Enabled"</li> <li>■ "Error"</li> <li>■ "Unknown"</li> </ul>
'Flash Size'	Size of the non-volatile storage memory (flash), measured in megabytes.
'RAM Size'	Size of the random access memory (RAM), measured in megabytes.
'CPU Model'	CPU model.
'CPU Speed'	Clock speed of the CPU, measured in megahertz (MHz).
<b>Versions</b>	
'Version ID'	Software version number.

Parameter	Description
'DSP Software Version'	DSP software version.
'DSP Software Name'	DSP software name.
<b>Loaded Files</b>	
'<File Type> File Name'	Displays installed Auxiliary files (e.g., Dial Plan). You can delete a file, by clicking the corresponding <b>Delete</b> button.
<b>Redundant Info</b>	
<b>Note:</b> This group is only displayed if the device is operating in High-Availability (HA) mode.	
'Redundant MAC Address'	MAC address of the redundant device.
'Redundant Serial Number'	Serial number of the redundant device.

## Viewing Device Status on Monitor Page

The Web interface's Monitor page provides basic status and information on the device. The page is useful in that it allows you to easily obtain an overview of the device's operating status at a glance.

### ➤ To view device status and information on the Monitor home page:

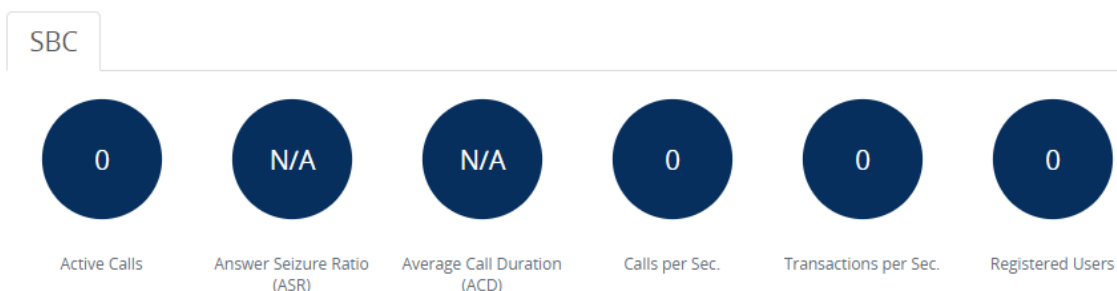

- On the Menu bar, click **Monitor** or if you are already in the Monitor menu's Navigation tree, click  **Monitor**.

The Monitor page displays the following groups of information:

#### ■ Top bar, displaying general device information:

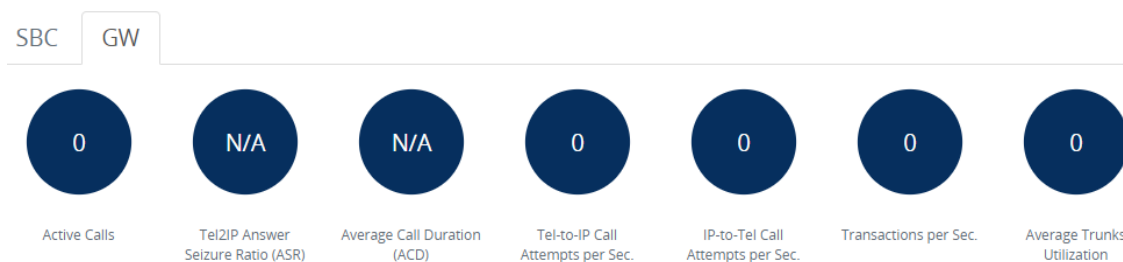

- **Address:** IP address of the device's OAMP interface
- **Firmware:** Software version currently running on the device
- **Type:** Name of device
- **HA Status:** High-Availability (HA) status of the device, if configured for HA. For more information, see [Viewing HA Status on Monitor Web Page](#) on page 1305.
- **S/N:** Serial number of device

#### ■ SBC tab:

- **Active Calls:** Displays the total number of currently active SBC calls. The corresponding SNMP performance monitoring MIB is `ackPisbcCallStatsCurrentGlobalActiveCallsIn`.
- **Answer Seizure Ratio (ASR):** Displays the number of successfully answered calls out of the total number of attempted calls. The corresponding SNMP performance monitoring MIB is `ackPisbcCallStatsCurrentGlobalAnswerSeizureRatio`.
- **Average Call Duration (ACD):** Displays the average call duration in seconds of established calls. The value is refreshed every 15 minutes and therefore, this value reflects the average duration of all established calls made within a 15 minute period. The corresponding SNMP performance monitoring MIB is `ackPisbcCallStatsCurrentGlobalAverageCallDuration`.
- **Calls per Sec:** Displays the total number of new calls per second (CPS).
- **Transactions per Sec:** Displays the total number of new SIP transactions per second (out-of-dialog transactions such as INVITE and REGISTER, or in-dialog transactions such as UPDATE and BYE). The corresponding SNMP performance monitoring MIB is `ackPiotherStatsCurrentGlobalTransactionRate`. The counter is applicable to SBC and Gateway calls.
- **Registered Users:** Displays the number of users registered with the device. The corresponding SNMP performance monitoring MIB is `ackPiotherStatsCurrentGlobalRegisteredUsers`.

#### ■ GW tab:

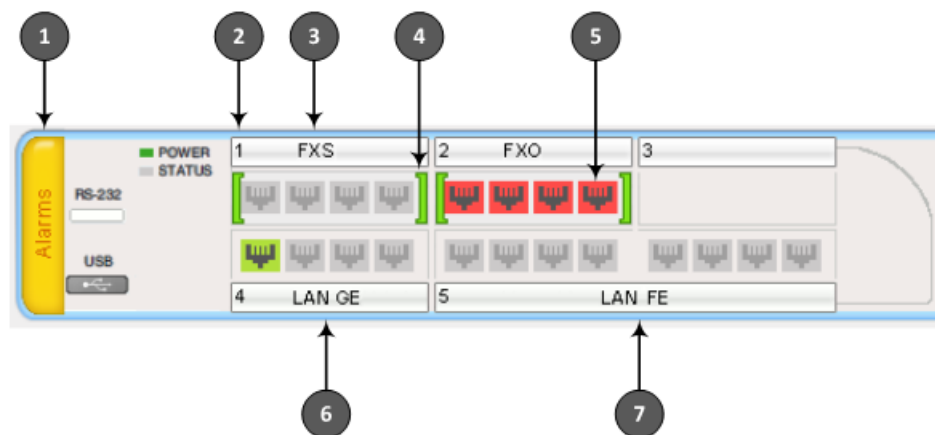

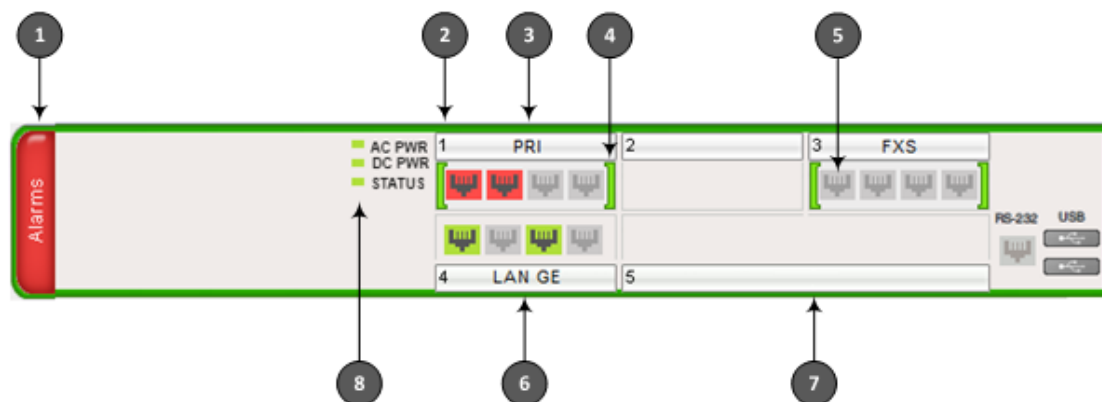

- **Active Calls:** Displays the total number of currently active Gateway calls. The corresponding SNMP performance monitoring MIB is `ackPigatewayCallStatsIntervalGlobalActiveCallsMax`.
- **Tel-to-IP Answer Seizure Ratio (ASR):** Displays the number of successfully answered Tel-to-IP calls out of the total number of attempted calls. The corresponding SNMP performance monitoring MIB is `ackPigatewayCallStatsIntervalGlobalAnswerSeizureRatioAvg`.

- **Average Call Duration (ACD):** Displays the average call duration in seconds of established calls. The value is refreshed every 15 minutes and therefore, this value reflects the average duration of all established calls made within a 15 minute period. The corresponding SNMP performance monitoring MIB is `ackpiGatewayCallStatsCurrentGlobalAverageCallDuration`.
- **Tel-to-IP Call Attempts per Sec.:** Displays the current number of attempted Tel-to-IP calls per second. The corresponding SNMP performance monitoring MIB is `ackpiGatewayCallStatsIntervalGlobalAttemptedCallsRateTel2IpAvg`.
- **IP-to-Tel Call Attempts per Sec:** Displays the current number of attempted IP-to-Tel calls per second. The corresponding SNMP performance monitoring MIB is `ackpiGatewayCallStatsIntervalGlobalAttemptedCallsRateIp2TelAvg`.
- **Transactions per Sec.:** Displays the current number of SIP transactions per second (i.e., transaction rate). The corresponding SNMP performance monitoring MIB is `ackpiGatewayOtherStatsCurrentGlobalTransactionRate`.
- **Average Trunks Utilization:** Displays the average number of trunks currently in use (busy). Only SIP requests are considered in the SIP transaction count. For example, a single SIP transaction is from the initial SIP INVITE request to the final SIP 200 OK response. The corresponding SNMP performance monitoring MIB is `ackpiTrunkStatsIntervalTrunkUtilizationAvg`.

- **Graphical Display of device:** Shows color-coded status icons, as shown in the figure below and described in the subsequent table:

Figure 51-1: Graphical Display of Device on Monitor Page - Mediant 800 Gateway & E-SBC H/W Rev B

**Figure 51-2: Graphical Display of Device on Monitor Page - Mediant 800 Gateway & E-SBC H/W Rev. C**

- The figure above is used only as an example as the graphical display of your device in the Web interface reflects your specific ordered hardware configuration.
- For a description of the Monitor page when the device is in High Availability (HA) mode, see [Viewing HA Status on Monitor Web Page](#) on page 1305 Viewing Device Status on Monitor Page.

**Table 51-2: Description of Graphical Display of Device on Monitor Page**

Item #1	Description
1	<p><b>Alarms:</b> Displays the highest severity of an active alarm raised (if any) by the device:</p> <ul style="list-style-type: none"> <li>■ Green = no alarms</li> <li>■ Red = Critical alarm</li> <li>■ Orange = Major alarm</li> <li>■ Yellow = Minor alarm</li> </ul> <p>To view active alarms, click <b>Alarms</b> to open the Active Alarms page (see <a href="#">Viewing Active Alarms</a> on page 1454).</p>
2	Module slot number.
3	Module interface type.
4	<p>Module status icon:</p> <ul style="list-style-type: none"> <li>■  (green): Module has been inserted or is correctly configured</li> <li>■  (gray): Module was removed and "Reserved" is displayed</li> <li>■  (red): Module failure and "Failure" is displayed</li> </ul>

Item #1	Description
5	<p><b>Port analog channel status icon:</b></p> <ul style="list-style-type: none"> <li>■  (gray): <ul style="list-style-type: none"> <li>✓ <b>FXS</b> (one of the following): <p>The port is physically connected to an FXS analog device (e.g., telephone), which is in idle state (i.e., on-hook position).</p> <p>-or-</p> <p>The port is not physically connected.</p> </li> <li>✓ <b>FXO</b>: The port is physically connected to an FXO analog device (e.g., PBX), which is in idle state (i.e., on-hook position).</li> </ul> </li> <li>■  (green): The FXS or FXO port is physically connected to an analog device, which is in off-hook state with an established call (i.e., active RTP stream).</li> <li>■  (red): <ul style="list-style-type: none"> <li>✓ <b>FXS</b>: n/a</li> <li>✓ <b>FXO</b>: <p>The port is not physically connected.</p> <p>-or-</p> <p>If the port is physically connected to an FXS analog device, it is out-of-service due to Serial Peripheral Interface (SPI) failure.</p> </li> </ul> </li> <li>■  (blue): The FXS or FXO port is physically connected to an analog device which is in off-hook state, but no established call.</li> </ul> <p><b>Port trunk status icon:</b></p> <ul style="list-style-type: none"> <li>■  (gray): The trunk is not configured (i.e., not in use or disabled).</li> <li>■  (green): The trunk is synchronized.</li> <li>■  (yellow): The trunk has a Remote Alarm Indication (RAI), also known as the Yellow Alarm.</li> <li>■  (red): The trunk has a loss due to LOS (Loss of Signal) or LOF (Loss of Frame).</li> <li>■  (blue): The trunk has an Alarm Indication Signal (AIS), also known as the Blue Alarm.</li> </ul>

Item #1	Description
	<ul style="list-style-type: none"> <li> (orange): The trunk has a D-channel alarm.</li> <li> (dark orange): The trunk has an NFAS alarm.</li> </ul> <p>If you click a port, a shortcut menu appears with commands allowing you to do the following:</p> <ul style="list-style-type: none"> <li><b>Reset Channel:</b> (Analog ports only) Resets the analog port. For more information, see <a href="#">Resetting an Analog Channel</a> on page 1334</li> <li><b>Port Status:</b> Displays trunk status (see <a href="#">Viewing Trunks &amp; Channels Status</a> on page 1497) and analog port status (see <a href="#">Viewing Voice Channel Information</a> below).</li> <li><b>Port Description:</b> Let's you configure a description for the port (see <a href="#">Configuring a Description for Telephony Ports</a> on page 1338).</li> </ul> <p><b>Note:</b> For HA mode, the trunk status icons of the redundant device are not operational (i.e., displayed in gray color).</p>
6	<p>Gigabit Ethernet port status icons:</p> <ul style="list-style-type: none"> <li> (green): Ethernet link is working.</li> <li> (gray): Ethernet link is not configured.</li> <li> (red): Ethernet link error</li> </ul> <p>To view detailed port information, click the port icon. For more information, see <a href="#">Viewing Ethernet Port Information</a> on page 1502.</p>
7	Fast Ethernet LAN port status icons. See above for description.
8	<p>Power icons indicating the type of power supply (i.e., AC and/or DC).</p> <p><b>Note:</b> DC power is applicable only to Mediant 800 Gateway &amp; E-SBC H/W Rev. C.</p>

## Viewing Voice Channel Information

You can view detailed information per voice port (channel).

### ➤ To view channel information:

1. Open the Monitor home page (see [Viewing Device Status on Monitor Page](#) on page 1443).
2. On the graphical display of the device, click a telephony port.
3. From the shortcut menu, choose **Port Status**.

4. (Digital ports only) In the Trunks & Channel Status page (see [Viewing Trunks & Channels Status](#) on page 1497), click a trunk's channel.

The following pop-up appears:

Channel Id 34

PHYSICAL		SIP	MEDIA	
Status			Inactive

**Table 51-3: Channel Description**

Tab / Field	Description
<b>Physical</b>	
Last Current Disconnect Duration	Duration of the last current disconnect signal (far-end call party has disconnected call).
Line Current	Line current (in mA).
Line Voltage	Line voltage (in V).
Ring (0-Off, 1-On)	Displays the ringing state ("Off" or "On").
Line Connected	Displays if the line is connected or not ("Disconnected" or "Connected").
Polarity State	Displays the polarity state.
Line Polarity	Displays the line polarity ("Positive" or "Negative").

Tab / Field	Description
Message Waiting Indication	Displays if MWI is enabled or disabled ("On" or "Off").
Hook	Displays the hook state ("On Hook" or "Off Hook").
<b>SIP</b>	
Status	Status of port ("Inactive" - no call; "Active" - active call).
Call Type	Type of call: <ul style="list-style-type: none"> <li>■ "Voice" - voice call</li> <li>■ "Fax" - fax call</li> </ul>
Endpoint Status	Status of the endpoint: <ul style="list-style-type: none"> <li>■ "IDLE" - no call</li> <li>■ "ACTIVE" - active call</li> </ul>
Assigned Phone Number	Phone number assigned to the port.
MWI Information	Indicates if the phone has a voicemail (Message Waiting Indicator): <ul style="list-style-type: none"> <li>■ "yes" - endpoint has a voicemail message</li> <li>■ "..." - no voicemail</li> </ul>
Call ID	ID of the call (SIP Call-ID header).
Call Originator	Where the call originated from (caller): <ul style="list-style-type: none"> <li>■ "TEL" - call made from Tel side (i.e., the port)</li> <li>■ "IP" - call made from IP side</li> </ul>
Source Tel Number	Telephone number of the caller.
Destination Tel Number	Telephone number of the called party.
Redirect Calling Number	Telephone number of the redirected number.
Remote Signaling IP	IP address used for SIP on the IP side.

Tab / Field	Description
Remote RTP	IP address and port used for RTP on the IP side.
Call Establishment Duration	Length of time (in seconds) it took to establish the call.
Call Duration	Call duration (in seconds) from when the call was established.
Call State	<p>Current state of the call:</p> <ul style="list-style-type: none"> <li>■ "IDLE" - no call.</li> <li>■ "SETUP" - signaling to setup call (SIP INVITE)</li> <li>■ "ALERT" - ringing at remote end (SIP 180 Ringing)</li> <li>■ "RINGBACK" - ringback played to port</li> <li>■ "SESSION" - call has been answered and is established</li> <li>■ "RELEASE" - call has been terminated (SIP 200 OK)</li> </ul>
Coder + PTime	Coder and packetization time used for the call.
Call Type	<p>Type of call:</p> <ul style="list-style-type: none"> <li>■ "Voice" - voice call</li> <li>■ "Fax" - fax call</li> </ul>
Call Establishment Method	<p>Mode of call:</p> <ul style="list-style-type: none"> <li>■ "Normal" - no early media during SIP session establishment (before call accepted).</li> <li>■ "EarlyMedia" - media sent (e.g., announcements) before call accepted by called party.</li> </ul>
DTMF Selected Method for Tx/Rx	DTMF Transport method used for the call. For configuring the transport method, see <a href="#">Configuring DTMF Transport Types</a> on page 299.
<b>Media</b>	
RTP Direction	<p>Direction of RTP.</p> <p>"Tx &amp; Rx": both directions (transmit and receive)</p>
Local UDP Port	Local UDP port on the device.
Remote IP	IP address of the remote IP side.

Tab / Field	Description
Address	
Remote UDP Port	Port of the remote IP side.
Rx Octet Count	Total number of received packets.
Tx Octet Count	Total number of transmitted packets.
Network Jitter	Network jitter (in msec).
Roundtrip Delay	Round-trip delay time (in msec).
Packet Loss	Packet loss (in %).
Frame Duration	Frame duration (in msec).
Echo Canceller	Displays whether echo cancellation is enabled or disabled.
Silence Suppression	Displays whether silence suppression is enabled or disabled.
Input Gain	Displays the input volume gain (in dB).
Voice Volume	Displays the voice volume (in dB).
Enabled Detectors	Displays enabled detectors (e.g., AMD).
DTMF Transport Type	Displays the DTMF transport type (e.g., RFC 2833).
Fax Transport Type	Displays the fax/modem transport type (e.g., T.38).

## 52 Reporting DSP Utilization through SNMP MIB

You can obtain information on the percentage of DSP resources utilized by the device, through the SNMP MIB table, `acPMDSPUsage`. You can also configure low and high DSP utilization thresholds for this MIB, that if crossed, the SNMP trap event, `acPerformanceMonitoringThresholdCrossing` is sent by the device. For more information, refer to the [SBC-Gateway Series SNMP Alarm Reference Guide](#).

## 53 Viewing Carrier-Grade Alarms

This section describes how to view SNMP alarms raised by the device.

### Viewing Active Alarms

You can view current (active) alarms in the Web interface that have been raised by the device. If an alarm is cleared, it is moved into the History Alarms table (see [Viewing History Alarms](#) on the next page). The alarms are displayed from newest to oldest. In other words, the most recently raised alarm is shown first in the list. The table is automatically refreshed every 60 seconds.

If the device is in High Availability (HA) mode, the table also displays alarms raised by the Redundant device. These alarms are shown in the 'Source' field with the alarm source varbind prefix, "Redundant" (e.g., "Redundant#1/EthernetLink#7"). Alarms raised by the Active device are shown without this source varbind prefix (e.g., Board#1/EthernetLink#7).

- The alarms in the table are deleted upon a device restart.
- If the device is in HA mode, the Redundant device's alarms in the table are deleted upon an HA switchover or if the device changes from HA to a Standalone device.
- To configure the maximum number of active alarms that can be displayed in the table, see the ini file parameter, ActiveAlarmTableMaxSize.
- The alarm bell icon, located on the top-right of the Web interface's window, displays the number of currently active alarms raised by the device and the highest severity (color coded - see below) of these alarms. If the device is in HA mode, the icon displays the number of currently active alarms raised by both Active and Redundant devices as well as the highest severity of all these active alarms.
- For more information, refer to the [SBC-Gateway Series SNMP Alarm Reference Guide](#).

#### ➤ To view active alarms:

##### 1. Open the Active Alarms table:

- Navigation tree: **Monitor** menu > **Monitor** tab > **Summary** folder > **Active Alarms**.
- Monitor home page: Click the "Alarms" area on the graphical display of the device (see [Viewing Device Status on Monitor Page](#) on page 1443).
- Alarm bell  icon (located in the top-right area of the Web interface)

SEQUENTIAL #	SEVERITY	SOURCE	DESCRIPTION	TIME
5	Major	Board#1/EthernetGroup#2	Ethernet Group alarm. Ethernet Group 2 is Down.	18/10/2023, 06:46:52
4	Minor	Board#1/EthernetLink#4	Ethernet link alarm. LAN port number 4 is down.	18/10/2023, 06:46:49
3	Minor	Board#1/EthernetLink#2	Ethernet link alarm. LAN port number 2 is down.	18/10/2023, 06:46:49
2	Major	Board#1/IPGroup#1	IP Group is temporarily blocked. IP Group (Joe) Blocked Reasc	18/10/2023, 06:46:47

**Table 53-1: Active Alarms Table Description**

Field	Description
<b>Sequential #</b>	The number of the alarm. Alarms are numbered sequentially as they are raised by the device. The numbering resets to 1 after a device restart (i.e., the first alarm raised after a restart is assigned #1).
<b>Severity</b>	Severity level of the alarm:   Critical (red)   Major (orange)   Minor (yellow)
<b>Source</b>	Component of the device from which the alarm was raised.
<b>Description</b>	Brief description of the alarm.
<b>Time</b>	Date (DD/MM/YYYY) and time (HH:MM:SS) the alarm was raised.

## Viewing History Alarms

You can view all SNMP alarms, in the Web interface's Alarms History table, that have been raised (active alarms) as well as cleared (resolved). One of the benefits of this is that you can view alarms that may have been raised and then cleared on a continuous basis. For example, such an alarm may be raised due to an Ethernet cable that is not securely attached to the device's Ethernet port, causing the Ethernet link to be sometimes up and sometimes down. This alarm would not be listed in the Active Alarms table due to it being cleared.

The alarms in the table are displayed from newest to oldest. In other words, the most recently raised alarm is shown first in the list. The table displays both the cleared alarm and the alarm for which it was cleared adjacent to one another, as shown in the figure below for alarms #8 and #9.

To configure the maximum number of alarms that can be displayed in the table, use the [AlarmHistoryTableMaxSize] parameter. If the maximum is reached and a new alarm is added to the table, the oldest alarm is removed from the table to accommodate the new alarm.

If the device is in High Availability (HA) mode, the table also displays alarms raised by the Redundant device. These alarms are shown in the 'Source' field with the alarm source varbind prefix, "Redundant" (e.g., "Redundant#1/EthernetLink#7"). Alarms raised by the Active device are shown without this source varbind prefix (e.g., Board#1/EthernetLink#7).

- The alarms in the table are deleted upon a device restart (or power off). In other words, all the alarms listed in the Alarms History table occurred from after the last device restart. If you want to store the alarms on the device's flash memory so that they also remain listed after a restart, see [Storing Alarms History on Flash](#) on the next page.
- If the device is in HA mode, the Redundant device's alarms in the table are deleted upon an HA switchover or if the device changes from HA to a Standalone device.
- For more information, refer to the [SBC-Gateway Series SNMP Alarm Reference Guide](#).

➤ **To view history alarms:**

- Open the Alarms History table (**Monitor** menu > **Monitor** tab > **Summary** folder > **Alarms History**).

SEQUENTIAL #	SEVERITY	SOURCE	DESCRIPTION	TIME
6	Cleared	Interface#0/trunk#0	Alarm cleared: Trunk LOS Alarm.	18/10/2023, 07:13:16
5	Major	Board#1/EthernetGroup#2	Ethernet Group alarm. Ethernet Group 2 is Down.	18/10/2023, 06:46:52
4	Minor	Board#1/EthernetLink#4	Ethernet link alarm. LAN port number 4 is down.	18/10/2023, 06:46:49
3	Minor	Board#1/EthernetLink#2	Ethernet link alarm. LAN port number 2 is down.	18/10/2023, 06:46:49
2	Major	Board#1/IPGroup#1	IP Group is temporarily blocked. IP Group (Joe) Blocked Reason	18/10/2023, 06:46:47
1	Critical	Interface#0/trunk#0	Trunk LOS Alarm.	18/10/2023, 06:46:46

**Table 53-2: Alarms History Table Description**

Field	Description
<b>Sequential #</b>	The number of the alarm. The alarms are numbered sequentially as they are raised by the device. The numbering resets to 1 immediately after a device restart (i.e., the first alarm raised after a restart is assigned the number #1).
<b>Severity</b>	Severity level of the alarm: Critical (red) Major (orange) Minor (yellow) Cleared (green)
<b>Source</b>	Component of the device from which the alarm was raised.
<b>Description</b>	Brief description of the alarm.
<b>Time</b>	Date (DD/MM/YYYY) and time (HH:MM:SS) the alarm was raised.
<b>Note</b>	This column is displayed only if you have enabled the device to save alarms to flash memory. For more information, see <a href="#">Storing Alarms</a>

Field	Description
	<a href="#">History on Flash</a> on the next page

## Deleting Alarm History Table

You can delete all the alarms listed in the Alarms History table.

### ➤ To delete all alarms in Alarms History table:

1. Click the **Delete History Table** button; a confirmation message box appears.
2. Click **OK** to confirm.

## Storing Alarms History on Flash

By default, alarms in the Alarms History table are automatically deleted upon a device restart. You can avoid this by enabling the device to store these alarms on its flash memory.

Currently, the device can't be connected to (and operate with) OVOC when this feature is enabled.

### ➤ To enable persistent storage of alarms history on flash:

1. Enable the feature, by configuring the [AlarmsPersistentHistory] parameter to 1.
2. Configure how often you want the device to save all the alarms of the Alarms History table to flash, using the [SavePersistentHistoryInterval] parameter. By default, the device saves the alarms every 24 hours. When the device does a new save, it overwrites the previously stored alarms.
3. Restart the device.

After you enable this feature, the Alarms History table displays an additional column titled 'Note'. This column indicates if the alarm occurred before or after the last device restart. If the alarm occurred (raised or cleared) after the last restart, the column displays "Stored after last restart". If the alarm occurred before the last restart, the column is empty. The following figure shows an example of the Alarms History table with four alarms that occurred after the last restart (bottom of table):

SEQUENTIAL #	SEVERITY	SOURCE	DESCRIPTION	TIME	NOTE
1	Critical	Board#1/CertificateExpiry#1	Rsa keys mismatch: CTX 1: Private key and Certificate do not r	01/01/2020, 08:59:30	
2	Minor	Board#1/EthernetLink#2	Ethernet link alarm. LAN port number 2 is down.	01/01/2020, 08:59:33	
3	Minor	Board#1/EthernetLink#3	Ethernet link alarm. LAN port number 3 is down.	01/01/2020, 08:59:33	
4	Minor	Board#1/EthernetLink#4	Ethernet link alarm. LAN port number 4 is down.	01/01/2020, 08:59:33	
5	Major	Board#1/EthernetGroup#2	Ethernet Group alarm. Ethernet Group 2 is Down.	01/01/2020, 08:59:36	
6	Minor	Board#1	SYS_HA: Maintenance Group - One of the links is down - NO H	01/01/2020, 08:59:36	
7	Cleared	Board#1/EthernetLink#3	Alarm cleared: Ethernet link alarm. LAN port number 3 is down.	01/01/2020, 09:27:16	
8	Cleared	Board#1/EthernetGroup#2	Alarm cleared: Ethernet Group alarm. Ethernet Group 2 is Dow	01/01/2020, 09:27:16	
9	Minor	Board#1/EthernetLink#3	Ethernet link alarm. LAN port number 3 is down.	01/01/2020, 09:27:18	
10	Major	Board#1/EthernetGroup#2	Ethernet Group alarm. Ethernet Group 2 is Down.	01/01/2020, 09:27:18	
11	Cleared	Board#1/EthernetLink#3	Alarm cleared: Ethernet link alarm. LAN port number 3 is down.	01/01/2020, 09:27:39	
12	Cleared	Board#1/EthernetGroup#2	Alarm cleared: Ethernet Group alarm. Ethernet Group 2 is Dow	01/01/2020, 09:27:39	
13	Critical	Board#1/CertificateExpiry#1	Rsa keys mismatch: CTX 1: Private key and Certificate do not r	01/01/2020, 09:30:16	
14	Minor	Board#1/EthernetLink#2	Ethernet link alarm. LAN port number 2 is down.	01/01/2020, 09:30:19	
15	Minor	Board#1/EthernetLink#4	Ethernet link alarm. LAN port number 4 is down.	01/01/2020, 09:30:19	
16	Minor	Board#1	SYS_HA: Maintenance Group - One of the links is down - NO H	01/01/2020, 09:30:22	
17	Major	Board#1	No HA! SYS_HA: Redundant unit is disconnected. HA is not op	01/01/2020, 09:43:47	Stored after last restart
18	Critical	Board#1/CertificateExpiry#1	Rsa keys mismatch: CTX 1: Private key and Certificate do not r	01/01/2020, 09:44:20	Stored after last restart
19	Minor	Board#1/EthernetLink#2	Ethernet link alarm. LAN port number 2 is down.	01/01/2020, 09:44:23	Stored after last restart
20	Minor	Board#1/EthernetLink#4	Ethernet link alarm. LAN port number 4 is down.	01/01/2020, 09:44:23	Stored after last restart

- If the device powers off, the alarms stored on flash are deleted (and the alarms in the Alarms History table are removed).
- To configure the maximum number of stored alarms (rows in Alarms History table), use the [AlarmHistoryTableMaxSize] parameter.
- This feature is not supported by the High-Availability mode (i.e., table not synchronized between active and redundant device; each has its own alarms).

## 54 Viewing Management User Activity Logs

If you have enabled the reporting of management user activities performed in the device's management interfaces (see [Reporting Management User Activities](#) on page 1634), you can view the logged activities in the Web interface, as described in the procedure below.

➤ **To view management user activity logs:**

- Open the Activity Log table (**Monitor** menu > **Monitor** tab > **Summary** folder > **Activity Log**).

ID	TIME	DESCRIPTION	USER	INTERFACE	CLIENT
10	18/10/2023, 06:51:23	CLI: 'sip-definition settings'	Admin	Telnet	10.13.2.3
9	18/10/2023, 06:51:06	CLI: 'configure voip'	Admin	Telnet	10.13.2.3
8	18/10/2023, 06:51:00	CLI: 'enable'	Admin	Telnet	10.13.2.3
7	18/10/2023, 06:50:59	User login succeeded	Admin	Telnet	10.13.2.3
6	18/10/2023, 06:50:40	CodersTable row 3 - 'PacketizationTimeIndex' was changed from '0' to '1'	Admin	WEB	10.13.2.3
5	18/10/2023, 06:50:40	CodersTable row 3 - 'CoderIndex' was changed from '99' to '1'	Admin	WEB	10.13.2.3
4	18/10/2023, 06:50:17	System configuration has been saved	Admin	WEB	10.13.2.3
3	18/10/2023, 06:50:12	Fake Retry After was changed from '6' to '7'	Admin	WEB	10.13.2.3
2	18/10/2023, 06:50:08	Reject Cancel after Connect was changed from '1' to '0'	Admin	WEB	10.13.2.3
1	18/10/2023, 06:49:42	WEB: Successful login at 10.15.7.96:80	Admin	WEB	10.13.2.3

**Table 54-1: Activity Log Table Description**

Parameter	Description
Time	Date (DD/MM/YYYY) and time (hh:mm:ss) that the activity was performed.
Description	Description of the activity.
User	Username of the user account that performed the activity.
Interface	Protocol used for connecting to the device's management interface (e.g., Telnet, SSH, Web, or HTTP).
Client	IP address of the client PC from where the user accessed the management interface.

## 54 Performance Monitoring

This section describes configuration of various performance monitoring features:

- [Configuring Alarm Thresholds for Performance Monitoring](#) below
- [Configuring User-Defined Performance Monitoring for SIP Failure Responses](#)
- [Configuring Performance Monitoring for Short and Long Calls](#) on page 1466
- [Performance Monitoring Graphs](#) on page 1468

For a detailed description of the device's performance monitoring parameters, refer to the [SBC-Gateway Performance Monitoring Reference Guide](#).

### Configuring Alarm Thresholds for Performance Monitoring

The Alarm Thresholds table lets you configure up to 100 customized alarm threshold rules for any of the device's performance monitoring parameters. These alarms are sent by the device through SNMP as SNMP trap events, notifying the SNMP manager of alarm severity level changes in performance monitoring parameters.

For each performance monitoring parameter(s), you can configure an Alarm Threshold rule with the following:

- Thresholds:
    - You can configure a threshold value that if crossed by the performance monitoring parameter raises an alarm. This is referred to as the *raise watermark*.
    - You can configure a threshold value that if crossed by the performance monitoring parameter clears a raised alarm. This is referred to as the *clear watermark*.
- The area between these two thresholds provides a hysteresis. This allows fluctuation between the thresholds and eliminates false alarms.
- Threshold crossing direction to raise or clear the alarm:
    - You can configure the alarm to be raised when the performance monitoring parameter result becomes greater than the *raise watermark* threshold and cleared when it becomes less than the *clear watermark* threshold. This is referred to as the *up* direction.
    - You can configure the alarm to be raised when the performance monitoring parameter result becomes less than the *raise watermark* threshold and cleared when it becomes greater than the *clear watermark* threshold. This is referred to as the *down* direction.
  - Alarm text (description) that is displayed when the alarm is raised or cleared.
  - Alarm severity level of the raised alarm (e.g., Major). If you want alarms raised for different threshold crossings where each threshold has a different severity level, you need to configure multiple Alarm Threshold rules for the same performance monitoring parameter.

Each rule will have different thresholds and different severity levels. For example, if you want two alarm severity levels (Major and Minor) for a performance monitoring parameter, the following two Alarm Threshold rules need to be configured for that performance monitoring specific parameter:

Parameter	Rule #1	Rule #2
'Raise Watermark'	40	20
'Clear Watermark'	30	10
'Severity'	<b>Major</b>	<b>Minor</b>

When multiple severity levels are configured for a performance monitoring parameter, the device raises or clears the different alarm severity levels according to a certain logic, explained using scenarios (chronological) base on the above configuration example:

- a. Performance monitoring parameter measurement increases to 25: A minor alarm event message is sent.
- b. Performance monitoring parameter measurement increases to 63: A major alarm event message is sent; no clear minor alarm event message is sent.
- c. Performance monitoring parameter measurement decreases to 27: Another minor alarm event message is sent; no clear alarm event messages are sent for the previous minor and major alarms.
- d. Performance monitoring parameter measurement decreases to 9: A clear minor alarm event message is sent.

A performance monitoring parameter may match multiple threshold alarms definitions. As a result, multiple thresholds may be crossed simultaneously. However, the device raises only one threshold alarm at a time. The device regulates for which of the crossed thresholds to raise an alarm:

- Among the crossed threshold alarms that the performance monitoring parameter is associated with, an alarm event is sent only for the one with the **highest** severity.
- The device sends a clear alarm event only when there are no currently crossed threshold alarms.
- The device may send multiple raised alarm events if multiple threshold alarms partially overlap.

The following illustration provides an example of an alarm threshold configured for the *up* direction:

As shown in the illustration, the alarm is only raised once it crosses the *raise watermark* threshold in the up direction (i.e., performance monitoring parameter value is greater than the threshold). The raised alarm is only cleared when it crosses the clear watermark threshold.

The following procedure describes how to configure alarm threshold rules through the Web interface. You can also configure it through ini file [PMAAlarmThresholds] or CLI (`configure system > kpi alarm-thresholds`).

➤ **To configure an alarm threshold:**

1. Open the Alarm Thresholds table (**Setup** menu > **Administration** tab > **Performance Monitoring** folder > **Alarm Thresholds**).
2. Click **New**; the following dialog box appears:

**Alarm Thresholds** [Close]

**GENERAL**

Index	<input type="text" value="0"/>
Path	<input type="text"/>
Entity Index	<input type="text"/>
KPI Name	<input type="text"/>
Direction	<input type="text" value="Up"/>
Raise Watermark	<input type="text" value="0"/>
Clear Watermark	<input type="text" value="0"/>
Raise Message	<input type="text"/>
Clear Message	<input type="text"/>
Severity	<input type="text" value="Default"/>
Mode	<input type="text" value="Disabled"/>

3. Configure an alarm threshold rule according to the parameters described in the table below.

4. Click **Apply**.**Table 54-2: Alarm Thresholds Table Parameter Description**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Path' pm-path [PMPath]	Defines the path (application name, group name and element name) of the performance monitoring parameter. The valid value is a string of characters (case insensitive), where the path names are separated by forward slashes (/). For example, the path of the licenseFeuUsage performance monitoring parameter is "system/licensestats/global". The valid value is a string of up to 119 characters (case insensitive). <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ For the path of the performance monitoring parameter, refer to the document <i>Performance Monitoring Reference Guide</i>. In this document, the path (application, group and element names) are the titles of the section headings under which the parameter is located.</li> </ul>
'Entity Index' entity-index [EntityIndex]	Defines a specific index row of the entity with which the performance monitoring parameter is associated. For example, you may want to configure this Alarm Thresholds rule only for IP Group #7. The value can be a numerical index of an instance (e.g., "7"). For all indices (e.g., all IP Groups), leave the parameter's value empty. To configure a range of indices, use the syntax x-z (e.g., "1-4"). To configure multiple indices that are not consecutive, separate each by a comma without spaces before or after (e.g., "1-2,5").
'KPI Name' kpi-name [KPIName]	Defines the name of the performance monitoring parameter for which this alarm threshold rule applies. The valid value is a string of up to 255 characters (case insensitive). To configure the parameter with multiple performance monitoring parameters, separate each parameter by a comma without spaces before or after (e.g., "licenseFeuUsage,licenseSbcSignalingUsage"). <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ For the name of the performance monitoring parameter, refer to the document <i>Performance Monitoring Reference Guide</i>.</li> </ul>

Parameter	Description
'Direction' threshold- direction [Direction]	<p>Defines the direction of crossing the threshold values (watermarks) for which the alarm is raised or cleared.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Down</b> = An alarm is raised when the value of the performance monitoring parameter becomes less than the value configured for the 'Raise Watermark' parameter. The alarm is cleared when the value becomes greater than the value configured for the 'Clear Watermark' parameter.</li> <li>■ [1] <b>Up</b> = (Default) An alarm is raised when the value of the performance monitoring parameter becomes greater than the value configured for the 'Raise Watermark' parameter (threshold). The alarm is cleared when the value becomes less than the value configured for the 'Clear Watermark' parameter.</li> </ul> <p>For example, assume that you configure the parameter to <b>Down</b>, the 'Raise Watermark' parameter to 50 and the 'Clear Watermark' parameter to 60. When the performance monitoring parameter's value becomes less than 50 (e.g., 45), an alarm is raised. When the performance monitoring parameter's value becomes greater than 60 (e.g., 62), the alarm is cleared.</p> <p><b>Note:</b> The parameter is mandatory.</p>
'Raise Watermark' threshold- raise- watermark [RaiseWatermark]	<p>Defines a value that if crossed by the performance monitoring parameter, raises the alarm.</p> <p>The valid value is a number.</p> <p><b>Note:</b> The parameter is mandatory.</p>
'Clear Watermark' threshold- clear- watermark [ClearWatermark]	<p>Defines a value that if crossed by the performance monitoring parameter, clears the raised alarm.</p> <p>The valid value is a number.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ For performance monitoring parameters that logically cannot be negative (like activeSessions), a value of "0" is not allowed.</li> </ul>
'Raise Message' threshold- raise-message [RaiseMessage]	<p>Defines the alarm text that is displayed when the alarm is raised. The valid value is a string of up to 80 characters. You can also use the following placeholders in your customized text, which the device replaces with the actual value:</p> <ul style="list-style-type: none"> <li>■ <b>%CATEGORY%</b>: Name of the category ("Application Name") to which the performance monitoring parameter belongs (e.g.,</li> </ul>

Parameter	Description
	<p>"sbc")</p> <ul style="list-style-type: none"> <li>■ <b>%GROUP%:</b> Name of the group ("Group Name") to which the performance monitoring parameter belongs (e.g., "callstats")</li> <li>■ <b>%OBJECT%:</b> Name of the configuration element ("Element Name") to which the performance monitoring parameter belongs (e.g., "ipGroups/1")</li> <li>■ <b>%PATH%:</b> Full path and name of the performance monitoring parameter (e.g., "sbc/callstats/ipgroup/1/callDialogsIn")</li> <li>■ <b>%PM%:</b> Name of the performance monitoring parameter itself (e.g. "callDialogsIn")</li> <li>■ <b>%VALUE%:</b> Value of the performance monitoring parameter</li> <li>■ <b>%CLEARWM%:</b> Value configured for the 'Clear Watermark' parameter</li> <li>■ <b>%RAISEWM%:</b> Value configured for the 'Raise Watermark' parameter</li> </ul> <p>For example: "The %PM% parameter value (%VALUE%) has exceeded the high threshold (%RAISEWM%)."</p>
'Clear Message' threshold- clear-message [ClearMessage]	<p>Defines the alarm text that is displayed when the alarm is cleared. The valid value is a string of up to 80 characters. You can also use the following placeholders in your customized text, which the device replaces with the actual value:</p> <ul style="list-style-type: none"> <li>■ <b>%CATEGORY%:</b> Name of the category ("Application Name") to which the performance monitoring parameter belongs (e.g., "sbc")</li> <li>■ <b>%GROUP%:</b> Name of the group ("Group Name") to which the performance monitoring parameter belongs (e.g., "callstats")</li> <li>■ <b>%OBJECT%:</b> Name of the configuration element ("Element Name") to which the performance monitoring parameter belongs (e.g., "ipGroups/1")</li> <li>■ <b>%PATH%:</b> Full path and name of the performance monitoring parameter (e.g., "sbc/callstats/ipgroup/1/callDialogsIn")</li> <li>■ <b>%PM%:</b> Name of the performance monitoring parameter itself (e.g. "callDialogsIn")</li> <li>■ <b>%VALUE%:</b> Value of the performance monitoring parameter</li> <li>■ <b>%CLEARWM%:</b> Value configured for the 'Clear Watermark'</li> </ul>

Parameter	Description
	<p>parameter</p> <ul style="list-style-type: none"> <li>■ <b>%RAISEWM%:</b> Value configured for the 'Raise Watermark' parameter</li> </ul> <p>For example: "The %PM% parameter value (%VALUE%) has returned to below the high threshold value (%RAISEWM%)."</p>
'Severity' threshold-severity [Severity]	<p>Defines the severity level of the alarm.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Default</b> (Default)</li> <li>■ [1] <b>Indeterminate</b></li> <li>■ [2] <b>Warning</b></li> <li>■ [3] <b>Minor</b></li> <li>■ [4] <b>Major</b></li> <li>■ [5] <b>Critical</b></li> </ul>
'Mode' threshold-mode [Mode]	<p>Enables (activates) the Alarm Threshold rule.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disabled</b> (Default)</li> <li>■ [1] <b>Enabled</b></li> </ul>

## Configuring Performance Monitoring for Short and Long Calls

The device provides performance monitoring statistics for short and long calls. By default, a call duration of less than 2 seconds is considered a short call; a call duration greater than 30 minutes is considered a long call. However, you can change these duration threshold values, as described in the procedure below.

Statistics of short calls are provided by the performance monitoring parameters shortCallsCounterTotal and shortCallsCounter. Statistics of long calls are provided by the performance monitoring parameters longCallsCounterTotal and longCallsCounter.

### ➤ To configure performance monitoring for short and long calls:

1. Open the SBC General Settings page (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC General Settings**).
2. In the 'Call Duration for Short Calls' field, enter the duration (in seconds) for which calls that are less than or equal to this value are considered short calls.
3. In the 'Call Duration for Long Calls' field, enter the duration (in minutes) for which calls that are greater than or equal to this value are considered long calls.

Call Duration for Short Calls [sec]

Call Duration for Long Calls [min]

4. Click **Apply**.

## Performance Monitoring Graphs

This section describes how to configure performance monitoring graphs in the device's Web interface.

- Performance monitoring is also referred to as *key performance indicators* (KPI).
- For a detailed description of all the device's performance monitoring parameters, refer to the *SBC-Gateway Performance Monitoring Reference Guide* (click [here](#)).

### Configuring KPI Layouts

The KPI Layouts table lets you configure up to 20 graph layout pages for the device's performance monitoring parameters (key performance indicators or KPI). Each KPI Layout defines the number and positioning of the graphs on the page. The graphs contain the selected performance monitoring parameters (configured later in [Adding Performance Monitoring Graphs to KPI Layouts](#) on page 1471).

You can configure a KPI Layout with one of the following layout designs:

- 1x1 (one graph):

- 1x2 (two graphs, positioned side by side):

- 2x1 (two graphs, positioned one below the other):

- 2x2 (four graph panels, two positioned side by side on one row and another two below, also positioned side by side):

Once you have configured a KPI Layout, you can configure a graph to plot performance monitoring parameters, as described in [Adding Performance Monitoring Graphs to KPI Layouts](#) on page 1471.

The following procedure describes how to configure KPI layouts through the Web interface. You can also configure it through ini file [KPIGraphs] or CLI (`configure system > kpi > layouts`).

➤ **To configure a KPI layout:**

1. Open the KPI Layouts table (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts**).
2. Click **New**; the following dialog box appears:

3. Configure a KPI Layout according to the parameters described in the table below.
4. Click **Apply**.

**Table 55-1: KPI Layouts Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
'Title' layouts-title [Title]	<p>Defines a name for the layout. Once you have configured the layout, it is listed with this name in the Navigation pane under the <b>Performance Monitoring</b> folder &gt; <b>Layouts</b> subfolder.</p> <p>The valid value is a string of up to 39 characters.</p> <p><b>Note:</b> Configure each row with a unique name.</p>
'Description' layouts-description [Description]	<p>Defines an arbitrary name to easily identify the layout.</p>
'Layout' layouts-layout [Layout]	<p>Defines the layout, regarding number and positioning of graphs (see also the illustrations in the beginning of this section).</p> <ul style="list-style-type: none"> <li>■ [0] <b>1x1</b> = (Default) The layout has only one graph.</li> <li>■ [1] <b>1x2</b> = The layout has two graphs, positioned side by side.</li> <li>■ [2] <b>2x1</b> = The layout has two graphs, positioned one below the other.</li> <li>■ [3] <b>2x2</b> = The layout has four graphs, two positioned side by side on one row and another two below, also positioned side by side.</li> </ul>
'Graph 1-4' layouts-graph1-4 [Graph1], [Graph2], [Graph3], [Graph4]	<p>Selects the graphs (configured in <a href="#">Adding Performance Monitoring Graphs to KPI Layouts</a> on the next page) to add to the layout. This field is used after you have configured your graphs, especially when you want to select graphs that were originally added to other KPI layouts.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Even though the Web interface displays four fields for selecting graphs, the maximum number of</li> </ul>

Parameter	Description
	<p>graphs depends on the selected KPI layout ('Layout' field above).</p> <ul style="list-style-type: none"><li>■ You can assign the same graph to multiple KPI layouts.</li></ul>

## Adding Performance Monitoring Graphs to KPI Layouts

Once you have configured a KPI Layout (see [Configuring KPI Layouts](#) on page 1468), you can add graphs to it for the device's performance monitoring parameters. You can add and plot multiple performance monitoring parameters per graph. For example, if you have configured a KPI Layout with a 1x2 layout design (i.e., two graphs, positioned side by side), you can add two performance monitoring parameters to one graph and three performance monitoring parameters to the other graph.

Adding graphs to KPI Layouts offers the following main feature-rich capabilities:

- Each graph can be configured with customized labels (titles), for example, for the x and y axis.
- Each graph can be enabled to display a tooltip showing the values of a specific point on the graph when the mouse hovers over it.
- A powerful drill-down selection list allows you to quickly and easily select the required performance monitoring parameter from the device's hierarchical structure of performance monitoring parameters.
- Each plotted performance monitoring parameter can be configured with a specific line color on the graph for easy identification.

The following uses an example of a graph to show the graph's main areas. The example shows a graph containing two plotted performance monitoring parameters, where each has a different color line.

**Legend:**

1. KPI Layout name
2. Graph title
3. Tooltip
4. Y-axis title
5. X-axis title
6. Legend of plotted performance monitoring parameters
7. Hamburger button with a drop-down menu for adding graphs and for other functionality (discussed later in this chapter)

- You can plot up to 2,100 performance monitoring parameters in total (all KPI Layouts).
- If you delete a KPI Layout in the KPI Layouts table, its listing in the Navigation pane under the **KPI Layouts > Layouts** folder is removed. However, performance monitoring graphs that were added to the deleted KPI Layout are not deleted and can be used in any other KPI Layout.
- To configure alarm thresholds per performance monitoring parameter, see [Configuring Alarm Thresholds for Performance Monitoring](#) on page 1460.

The following procedure describes how to configure performance monitoring graphs through the Web interface. You can also configure it through ini file [KPIGraphs] or CLI (`configure system > kpi > graphs`).

➤ **To add performance monitoring graphs to KPI Layout:**

1. In the Navigation pane, select the required KPI Layout name (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**); the layout appears, as shown in the following example of a 1x2 graph layout:

2. In the required graph panel, from the 'Select Graph' drop-down list, click **Add New**; the following dialog box appears:

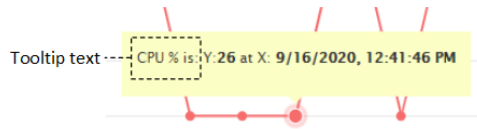

If you have already added performance monitoring parameters to graphs (regardless of KPI Layout), when you click the 'Select Graph' drop-down list, it also displays these performance monitoring parameters, which you can select and add to the graph.

3. Under the **General** group, configure the general settings for the graph, according to the parameters described in the table below.

**Table 55-2: Edit Graph Table Parameter Descriptions**

Parameter	Description
General	
'Graph Title' graphs-title	Defines a label (title) for the graph, which is displayed above the graph.

Parameter	Description
[KPIGraphs_Title]	<b>Note:</b> The graph's title must be unique.
'X-axis Title' graphs-xtitle [KPIGraphs_XTitle]	Defines a label for the graph's x axis, which is displayed horizontally below the x axis.
'Y-axis Title' graphs-ytitle [KPIGraphs_YTitle]	Defines a label for the y axis, which is displayed vertically alongside the y axis.
'Show Tooltip' graphs-tooltip [KPIGraphs_Tooltip]	<p>Enables a tooltip that appears when you hover your mouse over a point on the plotted line of the graph. The tooltip displays the values of the x and y axis at the specific point.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>When enabled, you can also add text to the tooltip that is displayed with the values (see the 'Tooltip Text' parameter below).</p>
'Tooltip Text' graphs-tooltip-text [KPIGraphs_TooltipText]	<p>Defines text that is displayed in the tooltip with the plotted values, as shown in the following example:</p>  <p>If you don't configure the parameter, no text is displayed with the values in the tooltip.</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'Show Tooltip' parameter to <b>Enable</b>.</p>

4. For each performance monitoring parameter that you want added to the graph, do the following:
  - a. Click the **Add New KPI** button; the following appears:

KEY PERFORMANCE INDICATORS (KPI) +

KPI # 1 ✎

Select KPI path

✎
📄
📄
🗑

- b. Use the 'Select KPI path' drop-down list to drill-down the device's hierarchical tree of performance monitoring parameters to select the performance monitoring parameter that you want added to the graph. Selection of the performance monitoring parameter includes the following drill-down stages:
- i. The type of performance monitoring parameter - realtime (**Real-time KPIs**) or historical (**Historical KPIs**).
  - ii. The application level to which the performance monitoring parameter belongs (**Gateway, Media, Network, SBC, or System**).
  - iii. The group level within the application to which the performance monitoring parameter belongs.
  - iv. The element level within the group to which the performance monitoring parameter belongs.
  - v. The performance monitoring parameter itself.

For example, the Answer Seizure Ratio performance monitoring parameter is selected as shown below:

Answer Seizure Ratio ✎

Select KPI path

▶ Real-time KPIs
 ▶ SBC application statistics
 ▶ Call statistics
 ▶ Per-IPGroup statistics

▶ IPGroup\_2

✎
📄
📄
🗑

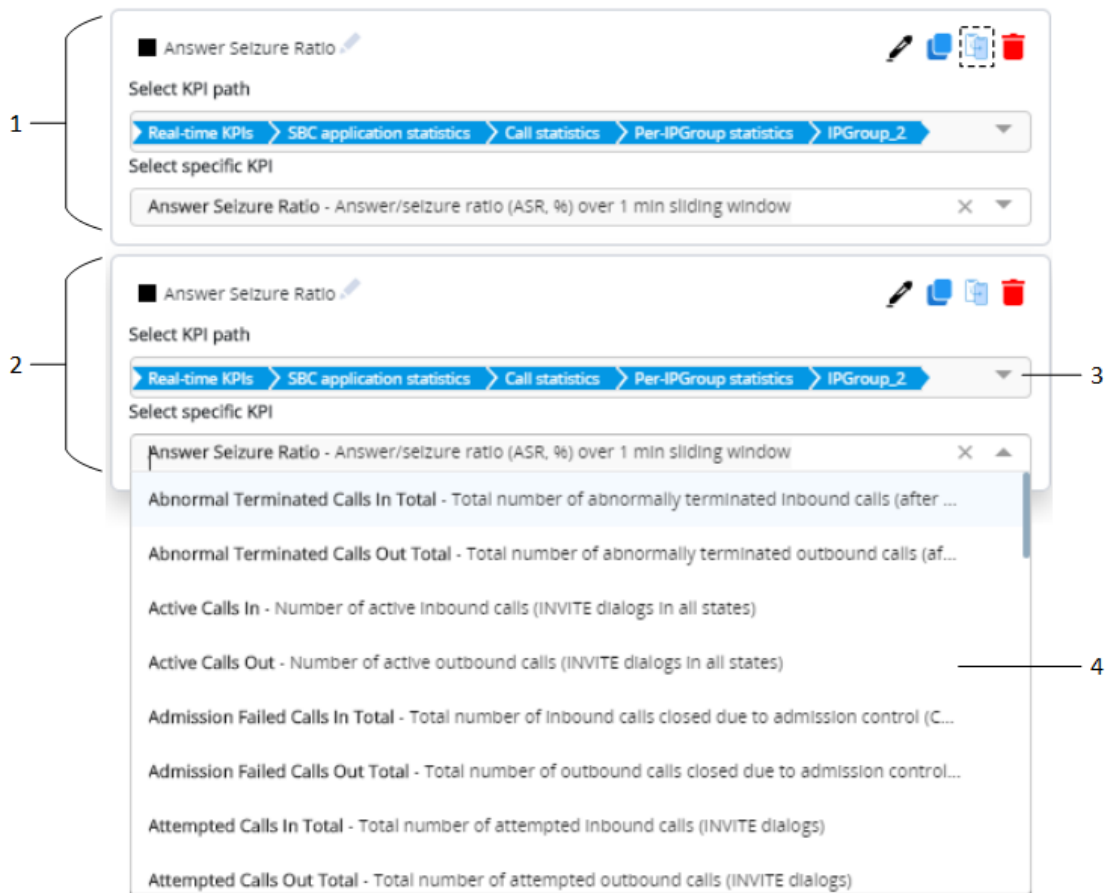

Select specific KPI

Answer Seizure Ratio - Answer/seizure ratio (ASR, %) over 1 min sliding window

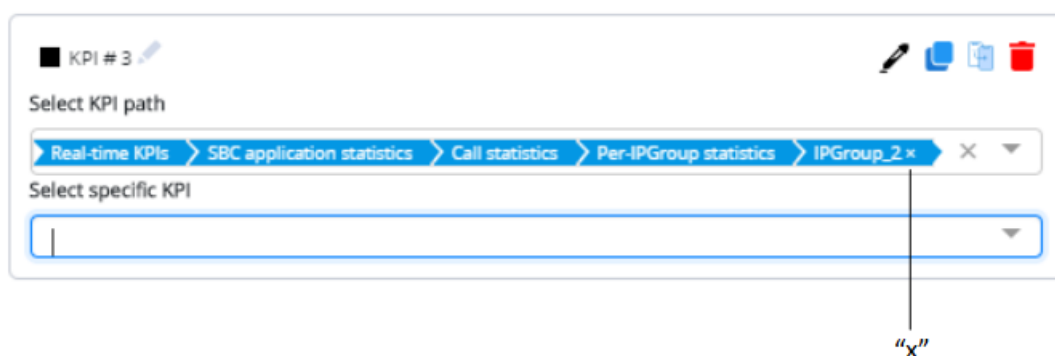

✕
▼

- c. If you are adding to the graph multiple performance monitoring parameters that are located on the same level (or near by) in the hierarchical tree, instead of drilling all the way down for each parameter, you can simply duplicate the KPI path of an already selected parameter, and then modify the path for the new parameter. To do this:
- i. Click the **Duplicate KPI** 📄 icon of the already configured KPI path (#1 in figure); the KPI path is duplicated (#2 in figure).

- ii. If you want to select a parameter that is located on the same level as the duplicated KPI path, then from the 'Select specific KPI' drop-down list (#3 in the figure), select the parameter (#4 in the figure), for example:

- iii. If you need to modify the path, in the 'Select specific KPI' field, click the x icon; the selected parameter is removed and an "x" appears at the end of the path in the 'Select KPI path' field, as shown in the following example:

In the 'Select KPI path' field, click the "x" at the end of the path; the lowest level in the hierarchical path is removed and a drop-down list appears, offering all the optional path values of that level. If you need to modify the path from a higher level in the path, keep clicking the "x" at the end of the path until the required

level. For example, the below shows the path (compare to previous figure) removed until the application level:

You can copy the path of a selected performance monitoring parameter in REST API format (e.g., `/api/v1/kpi/current/sbc/callStats/ipGroup/2/answerSeizureRatio`), by clicking the  icon corresponding to the configured performance monitoring parameter. This is useful, for example, when managing the device through REST API (see [REST-Based Management](#) on page 132) or when searching for the parameter in the *Performance Monitoring Parameters Reference Guide*. If the path includes an index, as shown in the example ("`.../ipGroup/2/...`"), when searching in the *Performance Monitoring Parameters Reference Guide*, replace the index number with "`<index>`" (e.g., `/api/v1/kpi/current/sbc/callStats/ipGroup/<index>/answerSeizureRatio`).

5. To apply a color to the graph's plotted line of the performance monitoring parameter:

- a. Click the color picker  icon; the color palette appears:

- b. Choose a line color, by using the main-colors bar (1), color slide (2), color field (3), or the hexadecimal color-code field (4).
  - c. Click **Save**.
- 6. Each plotted performance monitoring parameter has a default name, which is displayed as a legend below the graph. To modify the name:
  - a. Click the pencil icon (1) located next to the added performance monitoring name; the text box becomes available.
  - b. In the text box (2), enter a new name.
  - c. Click anywhere outside of the text box to apply your settings.

- 7. Click **Save** to save all your graph settings.

## Editing Performance Monitoring Graphs

You can edit configured graphs.

### ➤ To edit a graph:

1. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).
2. Click the hamburger button located in the top-right corner of the graph, and then from the drop-down menu, choose **Edit Graph**; the Edit Graph dialog box appears. For more information on modifying graphs, see [Adding Performance Monitoring Graphs to KPI Layouts](#) on page 1471.

## Deleting Performance Monitoring Graphs

The device provides various options for deleting performance monitoring graphs:

### ■ Deleting a specific plotted performance monitoring parameter from a graph:

- a. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).
- b. Click the hamburger button located in the top-right corner of the graph, and then from the drop-down menu, choose **Edit Graph**; the Edit Graph dialog box appears.

- c. Click the  icon corresponding to the performance monitoring parameter that you want to delete.

Deleting plotted performance monitoring parameters from graphs removes them from all KPI Layouts.

#### ■ Deleting all plotted performance monitoring parameters from a graph:

- a. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).
- b. Click the hamburger  button located in the top-right corner of the graph, and then from the drop-down menu, choose **Delete Graph**.

Deleting plotted performance monitoring parameters from graphs removes them from all KPI Layouts.

#### ■ Removing all performance monitoring parameters from a graph without deleting them.

These performance monitoring parameters are not deleted from the device, but simply removed from the specific graph. You can add them at any time to a graph, by clicking the 'Select Graph' drop-down list, and then selecting them from the list (see [Adding Performance Monitoring Graphs to KPI Layouts](#) on page 1471).

- a. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).
- b. Click the hamburger  button located in the top-right corner of the graph, and then from the drop-down menu, choose **Remove Graph from Layout**.

## Viewing Options for Performance Monitoring Graphs

The device provides the following options for viewing plotted performance monitoring parameters on graphs:

#### ■ Viewing a graph in full screen:

- a. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).
- b. Click the hamburger  located in the top-right corner of the graph, and then from the drop-down menu, choose **View in full screen**.
- c. To exit full-screen mode, press the Escape key.

#### ■ Zooming in and out on graphs:

- a. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).

- b. Left-click on the graph and drag the cursor to draw a box around the area into which you would like to zoom.
- c. Release the mouse; the display changes to show only the area within the box.

- d. To zoom out and return to normal view, click the **Reset Zoom** button (appears below the hamburger button).

#### ■ Showing or hiding plotted performance monitoring parameters in a graph:

- To hide a plotted performance monitoring parameter, click its legend name (located below the graph); the plotted parameter is hidden from the graph and its legend name is grayed out .
- To show a hidden plotted performance monitoring parameter, click its legend name again; the plotted parameter is displayed on the graph and its legend name is in normal font.

## Printing Performance Monitoring Graphs

You can send performance monitoring graphs to your local printer.

### ➤ To print a graph:

1. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).
2. Click the hamburger  button located in the top-right corner of the graph, and then from the drop-down menu, choose **Print Graph**.
3. Select and define your printer, and then click **Print**.

## Downloading Performance Monitoring Graphs

You can download the current view of performance monitoring graphs to your computer in various file formats (PNG, JPEG, SVG, PDF, or CSV). The downloaded image files (PNG, JPEG, and SVG) provide a screenshot of the current view of the graph. The PDF file provides a screenshot of the current view as well as general device information (e.g., serial number). The CSV file lists the plotted values of the current view of the graph.

### ➤ To download a performance monitoring graph:

1. In the Navigation pane, select the required KPI Layout (**Monitor** menu > **Monitor** tab > **Performance Monitoring** folder > **KPI Layouts** > **Layouts**).

2. Click the hamburger  button located in the top-right corner of the graph, and then from the drop-down menu, choose one of the following: **Download Graph as PNG Image**, **Download Graph as JPEG Image**, **Download Graph as SVG Image**, **Download Graph as PDF**, or **Download Graph as CSV**.

## 56 Configuring PacketSmart Agent for Network Monitoring

You can configure the device to send voice traffic data to BroadSoft's BroadCloud™ PacketSmart™ solution for monitoring and assessing the network in which the device is deployed. The support is offered by the PacketSmart management agent embedded in the device. The PacketSmart embedded agent allows network operators and service providers to remotely measure and manage network performance at the point of demarcation and simplify the deployment of VoIP networks. By providing real-time monitoring of live traffic, PacketSmart can identify any network issues as they arise that may impact VoIP quality, enabling service providers to address issues prior to customer complaints.

- The PacketSmart feature is a license-based feature and is available only if it is included in the License Key installed on the device. For ordering the feature, please contact the sales representative of your purchased device.
- Before configuring the PacketSmart agent, configure the following:
  - ✓ Correct data and time of the device. It is recommended to use an NTP server to obtain the date and time (see [Synchronizing Date and Time through SNTP](#) on page 138).
  - ✓ IP network interface for communicating with the PacketSmart server. Typically, the OAMP interface is used. To configure IP network interfaces, see [Configuring IP Network Interfaces](#) on page 159.
  - ✓ IP network interface for the VoIP traffic that you want monitored by PacketSmart.
- For detailed information on setting up the PacketSmart solution, refer to the document *Mediant Gateways and SBCs with BroadCloud PacketSmart Configuration Note*.

The following procedure describes how to configure PacketSmart through the Web interface. You can also configure it through ini file or CLI (`configure system > packetsmart`).

### ➤ To configure the PacketSmart agent:

1. Open the Network Settings page (**Setup** menu > **IP Network** tab > **Advanced** folder > **Network Settings**).

PACKETSMART	
PacketSmart Agent Mode	Disable
ID	AUDC_MEDIANT_00908F5B1035
Platform	MEDIANT
PacketSmart Server IP Address	0.0.0.0
PacketSmart Server Port	80
Monitoring Interface	0
Network Interface	0

2. From the 'PacketSmart Agent Mode' drop-down list, select **Enable** to enable the feature.
3. Configure the remaining parameters, as required. For parameter descriptions, see [PacketSmart Parameters](#) on page 1794.

The following read-only fields are displayed:

- 'ID': Displays the name and serial number of the PacketSmart agent (i.e., the device) on the PacketSmart server.
  - 'Platform': Displays the name of the device.
4. Click **Submit**, and then restart the device with a save-to-flash for your settings to take effect.

## 57 Viewing VoIP Status

This section describes how to view VoIP-related status.

### Viewing SBC Registered Users

You can view SBC users that are registered with the device and listed in its users registration database.

This section is applicable only to the SBC application.

The following procedure describes how to view registered users through the web interface. You can also view them through CLI - `show voip register db sbc list` or `show voip register db sbc user <Address Of Record>`.

#### ➤ To view registered SBC users:

1. Open the SBC Registered Users page (**Monitor** menu > **Monitor** tab > **VoIP Status** folder > **SBC Registered Users**).

SBC Registered Users Number of AORs: 100000

CONTACT	STATUS	AVERAGE MOS	IP GROUP	RECEIVED FROM ADDRESS
AOR: 1@0.0.0.0 (8 items)				
AOR: 2@0.0.0.0 (9 items)				
AOR: 3@0.0.0.0 (7 items)				
AOR: 4@0.0.0.0 (7 items)				
0:sip@0...	Active	● 4	IP Group (#0)	0.0.0.0
1:sip@7...	Active	● 11	IP Group (#7)	0.0.0.0
2:sip@1...	Inactive	● 39	IP Group (#14)	0.0.0.0
3:sip@2...	Inactive	● 36	IP Group (#21)	0.0.0.0
4:sip@2...	Inactive	● 25	IP Group (#28)	0.0.0.0
5:sip@3...	Active	● 20	IP Group (#35)	0.0.0.0
6:sip@4...	Active	● 26	IP Group (#42)	0.0.0.0
AOR: 5@0.0.0.0 (3 items)				

**BASIC DETAILS**

Contact	3:sip@21.21.21.21
Associated Contact	
User IP Group	IP Group (#21)
Status	Active

**FEATURE DETAILS**

User Info	No
Leg Type	SBC
IP Profile	IP Profile (#21)

**TRANSPORT DETAILS**

SIP Interface	SIP (#21)
Received From IP	0.0.0.0
Received From Port	0

**MOS**

Recent MOS Value	● 22
Recent MOS Update Time	8/7/2023 16:24:44 UTC+05:30
Average	● 11

The number of AORs in the device's registration database is displayed in the 'Number Of AORs' read-only field, located in the top-right corner of the page.

2. To search for a specific AOR, in the search box located in the top-right corner of the page, type the **user part** of the SIP URI. You must type the full user part (not partial). For example, to search for AOR 1000@10.8.5.91, type "1000".
3. Click the required AOR folder to expand its contents and view its associated contacts.
4. To view detailed information of a contact associated with an AOR, select the contact; a pane appears below the table, displaying the contact's information, as described below.

Each Address of Record (AOR) can include up to 10 registered contacts.

**Table 57-1: SBC Registered Users Table Description**

Parameter	Description
<b>Basic Details</b>	
'Contact'	<p>Displays a contact associated with the Address of Record (AOR). If the contact is registered, the field shows the contact of the SIP REGISTER request.</p> <p>If the user is from the SBC User Information table (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803), the field shows an arbitrarily constant value (e.g., "sip:ANY@CONTACT").</p>
'Associated Contact'	<p>Displays the contact or part of the contact in the outgoing SIP REGISTER request that is forwarded by the device to the registrar server.</p> <p><b>Note:</b> This field is not applicable when the contact is from the SBC User Information table (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803).</p>
'User IP Group'	Displays the IP Group associated with the contact (classified to this IP Group).
'Status'	<p>Displays the registration status:</p> <ul style="list-style-type: none"> <li>■ "Active": The contact is successfully registered with the device and calls for the contact can be processed.</li> <li>■ "Inactive": The contact is currently not active. Possible causes may also include that the contact is in the middle of the initial registration process, or the contact's registration has expired.</li> </ul>
<b>Transport Details</b>	
'SIP Interface'	Displays the SIP Interface associated with the contact.
'Received from IP'	Displays the IP address from where the device received the SIP REGISTER request.
'Received from Port'	Displays the port from where the device received the SIP REGISTER request.
'Behind NAT'	Indicates if the contact is located behind NAT ("Yes" or "No").

Parameter	Description
'Allocated Port'	Displays the local port allocated by the device for the contact, toward the server. <b>Note:</b> This field is applicable only if the 'User UDP Port Assignment' parameter of the IP Group associated with the contact is configured to <b>Enable</b> .
<b>Feature Details</b>	
'User Info'	Indicates if the contact is defined in the SBC User Information table ("Yes" or "No"). For more information on the SBC User Information table, see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803.
'Leg Type'	Displays the application type ("SBC", "LAD", or "OVR").
'IP Profile'	Displays the IP Profile associated with the contact. <b>Note:</b> This field is applicable only if the IP Profile is configured in the Classification table (not in the IP Groups table).
<b>MOS</b> For more information on MOS calculation and reporting of calls belonging to registered users, see <a href="#">Configuring Voice Quality for Registered Users</a> on page 544.	
'Recent MOS Value'	Displays the last (most recent) measured MOS (value and color) during the call. <b>Note:</b> The MOS value displayed for the registered user is reset ("0" and gray) if there have been no calls for the user for a user-defined period configured by the 'MOS Stored Timeout For No Calls' parameter.
'Recent MOS Update Time'	Displays the timestamp when the last (most recent) MOS during the call was measured (above).
'Average'	Displays the overall average MOS (value and color) of all 12 average MOS measurements done for the 12 observation intervals (12 or 24 hours).
'Minimum'	Displays the lowest average MOS (value and color) out of all the 12 average MOS measurements done for the 12 observation intervals (12 or 24 hours).

## Viewing Proxy Set Status

You can view the status of Proxy Sets that are used in your call routing topology. Proxy Sets that are not associated with any routing rule are not displayed. To configure Proxy Sets, see [Configuring Proxy Sets](#) on page 632.

### ➤ To view the status of Proxy Sets:

- Open the Proxy Sets Status page (**Monitor** menu > **Monitor** tab > **VoIP Status** folder > **Proxy Sets Status**).

PROXY SET ID	NAME	MODE	KEEP ALIVE	ADDRESS	PRIORITY	WEIGHT	SUCCESS COUNT	FAILURE COUNT	STATUS
0	ITSP-1	Load Balancing	Enabled						ONLINE
				10.8.6.88	-	-	0	18	OFFLINE
				10.8.6.89(*)	-	-	3	0	ONLINE
1	IP-PBX	Homing	Enabled						OFFLINE
				10.8.6.66	-	-	0	24	
2	ITSP-2	Parking	Enabled						NOT RESOLVED
				abc.com	-	-	0	0	NOT RESOLVED

**Table 57-2: Proxy Sets Status Table Description**

Parameter	Description
Proxy Set ID	Displays the Proxy Set ID.
Name	Displays the Proxy Set name.
Mode	Displays the Proxy Sets' operational mode: <ul style="list-style-type: none"> <li>■ "Parking" or "Homing": Redundancy mode, as configured by the Proxy Set parameter 'Redundancy Mode'.</li> <li>■ "Load Balancing: Proxy load balancing mode, as configured by the Proxy Set parameter 'Redundancy Mode'.</li> </ul>
Keep Alive	Displays whether the Proxy Keep-Alive feature is enabled ("Enabled") or disabled ("Disabled"), as configured by the Proxy Set parameter 'Proxy Keep-Alive'.
Address	Displays the IP address of the proxy server. This can be the IP address as configured in dotted-decimal notation for the Proxy Set, or the resolved IP address of a DNS query if an FQDN is configured for the Proxy Set. <ul style="list-style-type: none"> <li>■ IP addresses resolved from FQDNs are displayed as "&lt;FQDN name&gt; (&lt;resolved IP address&gt;)", for example, "abc.com(10.8.6.80)".</li> <li>■ The IP address that is currently used for routing is indicated with an</li> </ul>

Parameter	Description
	asterisk, for example, "10.8.6.89(*)". ■ If the FQDN failed to be resolved, only the FQDN name is displayed (e.g., "abc.com").
Priority	Displays the priority of IP addresses resolved from FQDNs. <b>Note:</b> The field is applicable only to Proxy Sets configured with FQDNs.
Weight	Displays the weight of IP addresses resolved from FQDNs. <b>Note:</b> The field is applicable only to Proxy Sets configured with FQDNs.
Success Count	Displays the total number of successful keep-alive messages (by SIP OPTIONS) sent by the device to the proxy.
Failure Count	Displays the total number of failed keep-alive messages (by SIP OPTIONS) sent by the device to the proxy.
Status	Displays the status of the Proxy Set and its' proxy servers. ■ "ONLINE": <ul style="list-style-type: none"> <li>✓ Proxy Set ID row: At least one proxy is online as determined by the device's keep-alive feature. The status is also "ONLINE" for IP addresses resolved from DNS queries even if keep-alive is disabled.</li> <li>✓ Proxy server rows (if multiple addresses): The proxy server is online as determined by the device's keep-alive feature.</li> </ul> ■ "OFFLINE": The proxy is offline as determined by the device's keep-alive feature and the Proxy Set is configured for Homing ('Redundancy Mode' parameter) or enabled for load balancing ('Proxy Load Balancing Method' parameter): <ul style="list-style-type: none"> <li>✓ Homing: The proxy is the main proxy, but the keep-alive has failed.</li> <li>✓ Load balancing: The keep-alive for the proxy has failed.</li> </ul> ■ "NOT RESOLVED": Proxy address is configured as an FQDN, but the DNS resolution has failed. ■ Empty field: Keep-alive for the proxy is disabled or the device has yet to send a keep-alive to the proxy.

## Viewing Registration Status

The Registration Status page displays registration status of the following:

- Registration status mode of the device. This displays if you have configured single registration and authentication for the entire device (i.e., 'Registration Mode' [AuthenticationMode] parameter set to **Per Gateway**).
- Registration status of the device's analog ports (FXS and FXO).
- Registration status of SIP Accounts, which are configured in the Accounts table (see [Configuring Registration Accounts](#) on page 777).
- Registration status of the device's FXS and BRI endpoints, per phone number.

➤ **To view registration status:**

- Open the Registration Status page (**Monitor** menu > **Monitor** tab > **VoIP Status** folder > **Registration Status**).

#### Registration Status

Registered Per Gateway    No

##### Port Registration Status

GROUP NAME	STATUS
Module 11 Port 1 FXS	Not Registered
Module 11 Port 2 FXS	Not Registered

##### Account Registration Status

#	GROUP TYPE	GROUP NAME	SERVER ADDRESS	STATUS
0	IP Group		N/A	Not Registered

##### Phone Numbers Status

PHONE NUMBER	GATEWAY PORT	STATUS
No table entries to display		

**Table 57-3: Registration Status Page Description**

Parameter	Description
'Registered Per Gateway'	<p>Displays the registration status of the device:</p> <ul style="list-style-type: none"> <li>■ "Yes"</li> <li>■ "No"</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<b>Ports Registration Status table</b> Displays the registration status per analog (FXS or FXO) port	
'Group Name'	Displays the analog port number.
'Status'	<p>Displays the port's registration status:</p> <ul style="list-style-type: none"> <li>■ "Registered"</li> <li>■ "Not Registered"</li> </ul>

Parameter	Description
<b>Accounts Registration Status table</b> Displays the registration status per Account.	
'Group Type'	Displays the row index number of the Served Trunk Group or IP Group.
'Group Name'	Displays the name of the Served Trunk Group or IP Group (if applicable).
'Server Address'	Displays the address (IP address and port) of the registrar server (Proxy Set of Serving IP Group) to which the Account is registered.
'Status'	Displays the Account's registration status: <div> <span>■</span> "Registered"               <span>■</span> "Not Registered"           </div>
<b>Phone Numbers Status table</b> Displays the registration status of FXS and BRI endpoints.	
'Phone Number'	Displays the phone number of the endpoint.
'Gateway Port'	Displays the port number of the endpoint.
'Status'	Displays the registration status of the endpoint: <div> <span>■</span> "Registered"               <span>■</span> "Not Registered"           </div>

## Viewing IP Connectivity

You can view on-line, read-only network diagnostic connectivity information on destination IP addresses configured in the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946).

The table is applicable only to the Gateway application.

### ➤ To view IP connectivity status:

1. Enable alternative Tel-to-IP routing that is triggered by connectivity loss with destination. This is done by configuring the AltRoutingTel2IPEnable parameter to **Enable** or **Status Only**. For more information, see [Alternative Tel-to-IP Routing Based on IP Connectivity](#) on page 970.

2. Open the IP Connectivity table (**Monitor** menu > **Monitor** tab > **VoIP Status** folder > **IP Connectivity**).

IP ADDRESS	HOST NAME	CONNECTIVITY METHOD	CONNECTIVITY STATUS	QUALITY STATUS	QUALITY INFO	DNS STATUS
------------	-----------	---------------------	---------------------	----------------	--------------	------------

Table 57-4: IP Connectivity Table Description

Column Name	Description
<b>IP Address</b>	<p>Displays the destination IP address, which can be one of the following:</p> <ul style="list-style-type: none"> <li>■ Destination IP address as configured in the Tel-to-IP Routing table.</li> <li>■ Destination IP address resolved from the host name (FQDN) as configured in the Tel-to-IP Routing table.</li> </ul>
<b>Host Name</b>	Displays the host name (or IP address) as configured in the Tel-to-IP Routing table.
<b>Connectivity Method</b>	Displays the method according to which the destination IP address is queried periodically by the device to check keep-alive connectivity status (SIP OPTIONS request). To configure the keep-alive mechanism, see <a href="#">IP Destinations Connectivity Feature</a> on page 969.
<b>Connectivity Status</b>	<p>Displays the connectivity status with the destination:</p> <ul style="list-style-type: none"> <li>■ "OK": Remote side responds to periodic connectivity queries.</li> <li>■ "Lost": Remote side didn't respond for a short period.</li> <li>■ "Fail": Remote side doesn't respond.</li> <li>■ "Init": Connectivity queries not started (e.g., IP address not resolved).</li> <li>■ "Disable": Connectivity option is disabled (i.e., [AltRoutingTel2IPMode] parameter is configured to <b>None</b> or <b>QoS</b>). For more information, see <a href="#">Alternative Tel-to-IP Routing Based on IP Connectivity</a> on page 970.</li> </ul>
<b>Quality Status</b>	<p>Displays the QoS (according to packet loss and delay) of the destination:</p> <ul style="list-style-type: none"> <li>■ "Unknown": Recent quality information isn't available.</li> <li>■ "OK"</li> <li>■ "Poor"</li> </ul> <p><b>Note:</b></p>

Column Name	Description
	<ul style="list-style-type: none"> <li>The parameter is applicable only if the parameter 'Tel-to-IP Alt Routing Mode' is configured to <b>QoS</b> or <b>Both</b>.</li> <li>The parameter is reset if two minutes elapse without a call to the destination.</li> </ul>
<b>Quality Info</b>	<p>Displays QoS information: delay and packet loss, calculated according to previous calls.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only if the parameter 'Tel-to-IP Alt Routing Mode' is configured to <b>QoS</b> or <b>Both</b>.</li> <li>The parameter is reset if two minutes elapse without a call to the destination.</li> </ul>
<b>DNS Status</b>	<p>DNS status:</p> <ul style="list-style-type: none"> <li>"DNS Disable"</li> <li>"DNS Resolved"</li> <li>"DNS Unresolved"</li> </ul>

## Viewing Gateway CDR History

You can view historical Call Detail Records (CDR) of Gateway calls in the Gateway CDR History table. The table displays the last 4,096 CDRs. CDR history information is stored on the device's memory. When a new CDR is generated, the device adds it to the top of the table and all existing entries are shifted one down in the table. If the table has reached maximum capacity of entries and a new CDR is added, the last CDR entry is removed from the table.

- The CDR fields in the table cannot be customized.
- If the device restarts, all CDRs are deleted from memory and from the table.
- You can mask (hide) values of certain CDR fields, as described in [Masking PII in CDRs](#) on page 209.

### ➤ To view Gateway CDR history:

- Web: Open the Gateway CDR History table (**Monitor** menu > **Monitor** tab > **VoIP Status** folder > **Gateway CDR History**).

CALL END TIME	END POINT	CALLER	CALLEE	DIRECTION	REMOTE IP	DURATION	TERMINATION REASON	SESSION ID
03:05:44.506	FXS-3/50	20049	20193	Incoming	10.8.128.82	00:01:03	NORMAL_C	8bd531:46:7570959
03:05:44.503	FXS-1/50	20049	20193	Outgoing	10.8.128.82	00:01:03	NORMAL_C	8bd531:46:7570889
03:05:43.803	FXS-4/5	20076	20220	Incoming	10.8.128.82	00:01:03	NORMAL_C	8bd531:46:7570954
03:05:43.797	FXS-2/5	20076	20220	Outgoing	10.8.128.82	00:01:03	NORMAL_C	8bd531:46:7570887

■ CLI:

- All CDR history:

```
# show voip calls history gw
```

- CDR history for a specific SIP session ID:

```
# show voip calls history gw <session ID>
```

**Table 57-5: Gateway CDR History Table**

Field	Description
<b>Call End Time</b>	Displays the time at which the call ended. The time is displayed in the format, hh:mm:ss, where <i>hh</i> is the hour, <i>mm</i> the minutes and <i>ss</i> the seconds (e.g., 15:06:36).
<b>End Point</b>	Displays the device's endpoint involved in the call, displayed in the format: <ul style="list-style-type: none"> <li>■ Analog: <i>&lt;interface&gt;-&lt;module&gt;/&lt;port&gt;</i>. For example, "FXS-3/1" denotes FXS module 3, port 1.</li> <li>■ Digital: <i>&lt;interface&gt;-&lt;module&gt;/&lt;Trunk ID&gt;/&lt;B-channel&gt;</i>. For example, "ISDN-1/2/3" denotes ISDN module 1, Trunk ID 2, B-channel 3.</li> </ul>
<b>Caller</b>	Displays the phone number (source number) of the party who made the call.
<b>Callee</b>	Displays the phone number (destination number) of the party to whom the call was made.
<b>Direction</b>	Displays the direction of the call with regards to IP and Tel sides: <ul style="list-style-type: none"> <li>■ "Incoming": IP-to-Tel call</li> <li>■ "Outgoing": Tel-to-IP call</li> </ul>
<b>Remote IP</b>	Displays the IP address of the call party. For an "Incoming" call, this is the source IP address; for an "Outgoing" call, this is the destination IP address.

Field	Description
<b>Duration</b>	Displays the duration of the call, displayed in the format hh:mm:ss, where <i>hh</i> is hours, <i>mm</i> minutes and <i>ss</i> seconds. For example, 00:01:20 denotes 1 minute and 20 seconds.
<b>Termination Reason</b>	Displays the reason for the call being released (ended). For example, "NORMAL_CALL_CLEAR" indicates a normal off-hook (hang up) of the call party.
<b>Session ID</b>	Displays the SIP session ID of the call.

## Viewing CDR History of SBC and Test Calls

You can view historical Call Detail Records (CDR) of SBC calls and Test calls in the SBC CDR History table. History CDRs are stored on the device's memory. When a new CDR is generated, the device adds it to the top of the table and all existing entries are shifted one down in the table. The table displays the last 2,048 CDRs. If the table reaches maximum capacity of entries and a new CDR is added, the last CDR entry is removed from the table.

- The CDR fields in the table cannot be customized.
- If the device restarts, all CDRs are deleted from memory and from the table.
- You can mask (hide) certain values, as described in [Masking PII in CDRs](#) on page 209.

### ➤ To view SBC and Test Call CDR history:

- **Web:** Open the SBC CDR History table (**Monitor** menu > **Monitor** tab > **VoIP Status** folder > **SBC CDR History**).

CALL END TIME	ENDPOINT TYPE	IP GROUP	CALLER	CALLEE	DIRECTION	REMOTE IP	DURATION	TERMINATION REASON	SESSION ID
11:53:30.140 UTC Sui	TEST	IPGroup_1	200	200	Incoming	10.33.8.52	00:00:41	NORMAL_CALL_CLEAR	f0000d:1:228
11:52:39.415 UTC Sui	TEST	IPGroup_2	201	100	Outgoing	10.33.8.52	00:00:20	NORMAL_CALL_CLEAR	f0000d:1:227
11:52:04.458 UTC Sui	SBC	IPGroup_2	200	236	Incoming	10.33.8.52	00:00:02	NORMAL_CALL_CLEAR	f0000d:1:226
11:52:04.444 UTC Sui	SBC	IPGroup_2	200	236	Outgoing	10.33.8.52	00:00:02	NORMAL_CALL_CLEAR	f0000d:1:226

- **CLI:**

- All CDR history:

```
# show voip calls history sbc
```

- CDR history for a specific SIP session ID:

```
# show voip calls history sbc <session ID>
```

Table 57-6: SBC CDR History Table

Field	Description
<b>Call End Time</b>	Displays the time at which the call ended. The time is displayed in the format, hh:mm:ss, where <i>hh</i> is the hour, <i>mm</i> the minutes and <i>ss</i> the seconds (e.g., 15:06:36).
<b>Endpoint Type</b>	Indicates the type of CDR: <ul style="list-style-type: none"> <li>■ "SBC": CDR belongs to an SBC call.</li> <li>■ "TEST": CDR belongs to a Test call.</li> </ul>
<b>IP Group</b>	Displays the IP Group of the leg for which the CDR was generated.
<b>Caller</b>	Displays the phone number (source URI user@host) of the party who made the call.
<b>Callee</b>	Displays the phone number (destination URI user@host) of the party to whom the call was made.
<b>Direction</b>	Displays the direction of the call: <ul style="list-style-type: none"> <li>■ "Incoming"</li> <li>■ "Outgoing"</li> </ul>
<b>Remote IP</b>	Displays the IP address of the call party. For an "Incoming" call, this is the source IP address; for an "Outgoing" call, this is the destination IP address.
<b>Duration</b>	Displays the duration of the call, displayed in the format hh:mm:ss, where <i>hh</i> is hours, <i>mm</i> minutes and <i>ss</i> seconds. For example, 00:01:20 denotes 1 minute and 20 seconds.
<b>Termination Reason</b>	Displays the reason for the call being released (ended). For example, "NORMAL_CALL_CLEAR" indicates a normal termination.
<b>Session ID</b>	Displays the SIP session ID of the call.

## 58 Viewing PSTN Status

This section describes how to view PSTN-related status.

### Viewing Trunks & Channels Status

You can view the status of the device's PSTN trunks and corresponding channels in the Web interface. It also enables you to view trunk configuration and channel information.

➤ **To view trunk and channel status:**

■ Open the Trunks & Channels Status page:

- **Navigation tree:** Monitor menu > Monitor tab > PSTN Status folder > Trunks & Channels Status.
- **Monitor home page:**
  - i. Open the Monitor home page (see [Viewing Device Status on Monitor Page](#) on page 1443).
  - ii. Click a PSTN port.

Trunks		Channels																															
Status		0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
 Trunk 1																																	

Trunks		Channels																															
Status		0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20	21	22	23	24	25	26	27	28	29	30	31
 Trunk 1																																	
 Trunk 2																																	
 Trunk 3																																	
 Trunk 4																																	
 Trunk 5																																	
 Trunk 6																																	
 Trunk 7																																	
 Trunk 8																																	
 Trunk 9																																	
 Trunk 10																																	
 Trunk 11																																	

Icon	Color	Trunk
		Label
	Yellow	RAI Alarm
	Red	LOS / LOF Alarm
	Blue	AIS Alarm
	Light Orange	D-Channel Alarm
	Dark Orange	NFAS Alarm

Channel status within a trunk is depicted by color-coded icons, as described in the table below:

**Table 58-2: Description of Color-Coded Icons for Channel Status**

Icon	Color	Label	Description
	Light blue	<b>Inactive</b>	Channel is configured, but currently has no calls
	Green	<b>Active</b>	Call in progress (RTP traffic) and no alarms
	Gray	<b>Non Voice</b>	Channel is not configured
	Blue	<b>ISDN Signaling</b>	Channel is configured as a D-channel
	Yellow	<b>CAS Blocked</b>	-
	Dark Orange	<b>Maintenance</b>	B-channel has been intentionally taken out of service due to maintenance
	Red	<b>Out Of Service</b>	B-channel is out of service

The Trunks & Channels Status page also allows you to do the following:

- **To view configuration settings of a trunk:** Click the trunk's icon, and then from the shortcut menu, choose **Trunk Settings**; the Trunk Settings page opens, displaying the trunk's settings. For more information, see [Configuring Trunk Settings](#) on page 878.
- **To view or provide a description of a trunk:**
  - a. Click the trunk's icon, and then from the shortcut menu, choose **Trunk Description**; the following appears:

## Trunk 15 Description

- b. Enter a description, and then click **Apply**.

The description can only include alphanumeric characters (without spaces).

- **To view detailed information of a trunk's channel:** Click the channel icon; a page appears with various tabs, displaying the information. For more information, see [Viewing Voice Channel Information](#) on page 1448.

## Viewing NFAS Groups and D-Channel Status

You can view the status of the device's D-channels and NFAS groups, if configured. The status of a D-channel and NFAS group can be "In Service" or "Out of Service" and the D-channel can be "Primary" or "Backup".

You can also perform a switchover from active and to standby D-channel belonging to the same NFAS group. This is done using the **Switch Activity** button. For more information, see [Performing Manual D-Channel Switchover in NFAS Group](#) on page 929.

This page is applicable only to T1 ISDN protocols supporting NFAS, and only if the NFAS group is configured with two D-channels.

### ➤ To view the status of the D-channels and NFAS groups:

- Open the NFAS Group & D-Channel Status page (**Monitor** menu > **Monitor** tab > **PSTN Status** folder > **NFAS Group & D-Channel Status**).

▼ NFAS Group #2

Status: **In Service**

D-Channels:

- Trunk#1
  - Configuration: Primary
  - Status: **In Service**
  - NFAS Status: Active
- Trunk#2
  - Configuration: Backup
  - Status: **Out Of Service**
  - NFAS Status: Not Applicable

[Switch Activity Group #2](#)

## 59 Viewing Network Status

This section describes how to view network-related status.

### Viewing Active IP Interfaces

You can view the device's active IP interfaces that are configured in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).

➤ **To view active IP network interfaces:**

- Open the IP Interface Status page (**Monitor** menu > **Monitor** tab > **Network Status** folder > **IP Interface Status**).

INDEX	APPLICATION TYPE	IP ADDRESS	INTERFACE MODE	PREFIX LENGTH	DEFAULT GATEWAY	INTERFACE NAME	PRIMARY DNS SERVER IP ADDRESS	SECONDARY DNS SERVER IP ADDRESS	UNDERLYING DEVICE	ADDRESS STATE
0	O+M+C	10.15.7.96	IPv4 Manual	16	10.15.0.1	O+M+C	0.0.0.0	0.0.0.0	vlan 1	Permanent
NA	Internal	169.253.254.254	IPv4 Manual	16	0.0.0.0	Internalif 2	0.0.0.0	0.0.0.0	Internalif 2	Permanent

### Viewing Ethernet Device Status

You can view the status of configured Ethernet Devices that have been successfully applied. To configure Ethernet Devices, see [Configuring Underlying Ethernet Devices](#) on page 156.

➤ **To view Ethernet Device status:**

- Open the Ethernet Device Status page (**Monitor** menu > **Monitor** tab > **Network Status** folder > **Ethernet Device Status**).

INDEX	VLAN ID	UNDERLYING INTERFACE	NAME
0	1	GROUP_1	vlan 1
1	2	GROUP_2	vlan 2

### Viewing Ethernet Port Information

You can view status information of the device's Ethernet ports. To configure Ethernet ports, see [Configuring Underlying Ethernet Devices](#) on page 156

If the device is operating in High-Availability mode, you can also view Ethernet port information of the redundant device, by opening the Redundant Ethernet Port Information page (**Monitor** menu > **Monitor** tab > **Network Status** folder > **Redundant Ethernet Port Information**).

➤ **To view Ethernet port information:**

- Open the Ethernet Port Information table, by doing one of the following:

- Navigation tree: **Monitor** menu > **Monitor** tab > **Network Status** folder > **Ethernet Port Information**.
- Monitor home page: Click an Ethernet port on the graphical display of the device (see [Viewing Device Status on Monitor Page](#) on page 1443).

	PORT NAME	ACTIVE	SPEED	DUPLEX MODE	STATE	GROUP MEMBER
1	GE_4_1	Yes	1 Gbps	Full Duplex	Forwarding	GROUP_1
2	GE_4_2	No	10 Mbps	Half Duplex	Disabled	GROUP_1

Table 59-1: Ethernet Port Information Table Description

Parameter	Description
Port Name	Displays the user-defined name of the port.
Active	Displays if the port is active ("Yes") or not ("No").
Speed	Displays the speed of the Ethernet port.
Duplex Mode	Displays if the port is half- or full-duplex mode.
State	<p>Displays the status of the port.</p> <p>If the Ethernet Group contains a single port, the port status is always "Forwarding" (i.e., data is being transmitted and received on the port).</p> <p>If the Ethernet Group contains two ports (for 1+1 port redundancy):</p> <ul style="list-style-type: none"> <li>■ If the 'Mode' of the port is <b>REDUN_1RX_1TX</b>, one port is "Forwarding" (i.e., active port) and one port is "Disabled" (i.e., standby port).</li> <li>■ If the 'Mode' of the port is <b>REDUN_2RX_1TX</b> or <b>REDUN_2RX_2TX</b>, both ports are "Forwarding".</li> </ul>
Group Member	Displays the Ethernet Group to which the port belongs.

## Viewing Static Routes Status

You can view the status of static IP routes, configured in the Static Routes table (see [Configuring Static IP Routes](#) on page 176) and routes through the Default Gateway.

The status of the static routes can be one of the following:

- "Active": Static route is used by the device.
- "Inactive": Static route is not used. When the destination IP address is not on the same segment with the next hop, or the interface doesn't exist, the route state changes to "Inactive".

➤ **To view the status of static IP routing:**

- Open the Static Route Status table (**Monitor** menu > **Monitor** tab > **Network Status** folder > **Static Route Status**).

INDEX	DESTINATION IP ADDRESS	PREFIX LENGTH	GATEWAY IP ADDRESS	METRIC	DEVICE NAME	STATUS	DESCRIPTION
NA	10.15.0.0	16	0.0.0.0	0	vlan 1	Active	
NA	10.13.0.0	16	0.0.0.0	0	vlan 2	Active	
NA	0.0.0.0	0	10.15.0.1	1	vlan 1	Active	

## Viewing IDS Active Blocked List

The IDS Active Blocked List table displays the remote hosts that are currently blocked by the device's Intrusion Detection System (IDS).

For more information on IDS configuration, see [Intrusion Detection System](#) on page 262

For devices in High-Availability (HA) mode, all the table's entries are deleted upon an HA switchover.

The following procedure describes how to view the IDS Active Blocked List table through the Web interface. You can also view the table through CLI using the command, `show voip ids blacklist active`.

➤ **To view the active IDS blocked list:**

- Open the IDS Active Blocked List page (**Monitor** menu > **Monitor** tab > **Network Status** folder > **IDS Active Blocked List**).

<div> <div> <div></div> <div></div> <div></div> <div></div> </div> <div>Page 1 of 1</div> <div> <div></div> <div></div> <div></div> <div></div> </div> <div>10</div> <div>No records to view</div> </div>						
REMAINING TIME (SECONDS)	NETWORK INTERFACE	IP ADDRESS	PORT	TRANSPORT TYPE	REMOVAL KEY	

**Table 59-2: IDS Active Blocked List Table Description**

Field	Description
Remaining Time	The duration left until the device deletes the attacker (remote host) from the table and takes it off the IDS blocked list. The blocked period is configured by the 'Deny Period' (IDSRule_DenyPeriod) parameter.
Network Interface	The device's IP Interface on which the malicious attack was detected.
IP Address	The IP address of the attacker (remote host).

Field	Description
Port	The port of the attacker (remote host). <b>Note:</b> The field is applicable only if the 'Threshold Scope' (IDSRule_ThresholdScope) parameter of the associated IDS rule is configured to <b>IP+Port</b> .
Transport Type	The transport type used for the attack.
Removal Key	A unique number (key) that the device assigns to the listed blocked entry. This is used if you want to remove a specific blocked entry from the table, which is done through the CLI command, <code>clear voip ids blacklist &lt;Removal Key&gt;</code> .

## 60 Reporting Information to External Party

This section describes features for reporting various information to an external party.

### Configuring RTCP XR

RTP Control Protocol Extended Reports (RTCP XR) is a VoIP management control that defines a set of metrics containing information for assessing VoIP call quality and for diagnosing problems. RTCP XR (RFC 3611) extends the RTCP reports defined in RFC 3550 by providing additional VoIP metrics (Quality of Experience). RTCP XR information publishing is implemented in the device according to RFC 6035. The draft defines how a SIP User Agent (UA) publishes the detailed information to a defined collector. RTCP XR measures VoIP call quality such as packet loss, delay, signal / noise / echo levels, estimated R-factor, and mean opinion score (MOS). RTCP XR measures these parameters using metrics as listed in the table below. RTCP XR messages containing key call-quality-related metrics are exchanged periodically (user-defined) between the device and the SIP UA. This allows an analyzer to monitor these metrics midstream, or a device to retrieve them through SNMP.

- The RTCP XR feature is available only if the device is installed with a License Key that includes this feature. For installing a License Key, see [License Key](#) on page 1362.
- If the RTCP XR feature is unavailable (not licensed or disabled), the R-factor VoIP metrics are not provided in CDRs (CDR fields, Local R Factor and Remote R Factor) generated by the device. Instead, these CDR fields are sent with the value 127, meaning that information is unavailable.
- While the device attempts to determine the signal level, it reports a MOS value of "127 (NA)". Once it has determined the signal level, it reports the estimated MOS.
- Packet loss effects voice quality estimation only during periods of voice. During periods of silence, packet loss doesn't effect or degrade voice quality.

You can configure the device to send RTCP XR to a specific IP Group. The device sends RTCP XR in SIP PUBLISH messages. The PUBLISH message contains the following RTCP XR related header values:

- From and To: Telephone extension number of the user
- Request-URI: IP Group name to where RTCP XR is sent
- Event: "vq-rtcpxr"
- Content-Type: "application/vq-rtcpxr"

You can also configure the stage of the call at which you want the device to send RTCP XR:

- End of the call.
- Periodically, according to a user-defined interval between consecutive reports.
- (Gateway Application Only) End of a media segment. A media segment is a change in media, for example, when the coder is changed or when the caller toggles between two

called parties (using call hold/retrieve). The RTCP XR sent at the end of a media segment contains information only of that segment. For call hold, the device sends RTCP XR each time the call is placed on hold and each time it is retrieved. In addition, the Start timestamp in the RTCP XR indicates the start of the media segment; the End timestamp indicates the time of the last sent periodic RTCP XR (typically, up to 5 seconds before reported segment ends).

The type of RTCP XR report event (VQReportEvent) supported by the device is VQSessionReport (SessionReport). The device can include local and remote metrics in the RTCP XR. Local metrics are generated by the device while remote metrics are provided by the remote endpoint. The following table lists the supported voice metrics (parameters) published in the RTCP XR.

**Table 60-1: RTCP XR Published VoIP Metrics**

Metric	Parameter	Description
<b>CallID</b>	-	Call ID - call ID from the SIP dialog
<b>LocalID</b>	-	Local ID - identifies the reporting endpoint for the media session
<b>RemoteID</b>	-	Remote ID - identifies the remote endpoint of the media session
<b>OrigID</b>	-	Originating ID - Identifies the endpoint which originated the session
<b>LocalAddr</b>	-	Local Address - IP address, port, and SSRC of the endpoint/UA which is the receiving end of the stream being measured
<b>RemoteAddr</b>	-	Remote Address - IP address, port, and SSRC of the source of the stream being measured
<b>LocalGroup</b>	-	Local Group ID - identification for the purposes of aggregation for the local endpoint
<b>RemoteGroup</b>	-	Remote Group ID - identification for the purposes of aggregation for the remote endpoint
<b>LocalMAC</b>	-	Media Access Control (MAC) address of the local SIP device
<b>Timestamps</b>	START	Start time of the media session, or of the media segment for the Gateway application.
	STOP	End time of the media session, or media segment (last sent RTCP XR packet) for the Gateway

Metric	Parameter	Description
		application.
<b>SessionDesc</b>	PT	Payload Type - 'payload type' parameter in the RTP packets (i.e., the codec).
	PD	Payload Description - description of the codec
	SR	Sample Rate - rate at which the voice was sampled
	FD	Frame Duration (msec) - packetization rate
	FO	Frame Octets - number of octets in each frame per RTP packet
	FPP	Frames per Packets - number of frames per RTP packet
	PLC	Packet Loss Concealment - indicates whether a PLC algorithm was used for the session ("0" - unspecified; "1" - disabled; "2" - enhanced; "3" - standard)
	SSUP	Silence Suppression State - indicates whether silence suppression, also known as Voice Activity Detection (VAD) is enabled ("on" or "off")
<b>JitterBuffer</b>	JBA	Jitter Buffer Adaptive - indicates the jitter buffer in the endpoint ("0" - unknown; "1" - reserved; "2" - non-adaptive; "3" - adaptive)
	JBR	Jitter Buffer Rate
	JBN	Jitter Buffer Nominal
	JBM	Jitter Buffer Max
	JBX	Jitter Buffer Abs Max
<b>PacketLoss</b>	NLR	Network Packet Loss Rate
	JDR	Jitter Buffer Discard Rate

Metric	Parameter	Description
<b>BurstGapLoss</b>	BLD	Burst Loss Density
	BD	Burst Duration
	GLD	Gap Loss Density
	GD	Gap Duration
	GMIN	Minimum Gap Threshold
<b>Delay</b>	RTD	Round Trip Delay (msec)
	ESD	End System Delay (msec)
	OWD	One Way Delay (msec)
	IAJ	Inter-Arrival Jitter (msec)
	MAJ	Mean Absolute Jitter (msec)
<b>Signal</b>	SL	Signal Level (dB) - ratio of the signal level to a 0 dBm0 reference
	NL	Noise Level (dB) - ratio of the silent period background noise level to a 0 dBm0 reference
	RERL	Residual Echo Return Noise (dB) - ratio between the original signal and the echo level as measured after echo cancellation or suppression has been applied
<b>QualityEst</b>	RLQ	Listening Quality R - listening quality expressed as an R factor (0-95 for narrowband calls and 0-120 for wideband calls)
	RLQEstAlg	RLQ Est. Algorithm - name (string) of the algorithm used to estimate RLQ
	RCQ	Conversational Quality R - cumulative measurement of voice quality from the start of the session to the reporting time (R is 0-95 for narrowband calls and 0-120 for wideband calls)
	RCQEstAlg	RCQ Est. Algorithm - name (string) of the algorithm used to estimate RCQ

Metric	Parameter	Description
	EXTRI	External R In - voice quality as measured by the local endpoint for incoming connection on "other" side (R is 0-95 for narrowband calls and 0-120 for wideband calls)
	ExtRIEstAlg	Ext. R In Est. Algorithm - name (string) of the algorithm used to estimate EXTRI
	EXTRO	External R Out - value is copied from RTCP XR received from the remote endpoint on the "other" side of this endpoint (R is 0-95 for narrowband calls and 0-120 for wideband calls)
	ExtROEstAlg	Ext. R Out Est. Algorithm - name (string) of the algorithm used to estimate EXTRO
	MOSLQ	MOS-LQ - estimated mean opinion score for listening voice quality on a scale from 1 to 5, in which 5 represents excellent and 1 represents unacceptable
	MOSLQEstAlg	MOS-LQ Est. Algorithm - name (string) of the algorithm used to estimate MOSLQ
	MOSCQ	MOS-CQ - estimated mean opinion score for conversation voice quality on a scale from 1 to 5, in which 5 represents excellent and 1 represents unacceptable
	MOSCQEstAlg	MOS-CQ Est. Algorithm - name (string) of the algorithm used to estimate MOSCQ
	QoEEstAlg	QoE Est. Algorithm - name (string) of the algorithm used to estimate all voice quality metrics
<b>DialogID</b>	-	Identification of the SIP dialog with which the media session is related

Below shows an example of a SIP PUBLISH message sent with RTCP XR and QoE information:

```
PUBLISH sip:172.17.116.201 SIP/2.0

➤ **To configure RTCP XR:**

1. Open the RTP/RTCP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **RTP/RTCP Settings**).
2. Under the RTCP-XR group, configure the following:
  - From the 'Enable RTCP XR' drop-down list (*VQMonEnable*), select the required option for voice quality monitoring and RTCP XR.
  - In the 'Tx RTCP Packets Interval' field (*RTCPInterval*), type the time interval between consecutive RTCP reports.
  - Select the 'Disable RTCP XR Interval Randomization' check box (*DisableRTCPRandomize*) to disable randomization of RTCP report intervals, or clear the check box so that each report interval accords exactly to the parameter [RTCPInterval].
  - In the 'Burst Threshold' field (*VQMonBurstTHR*), type the voice quality monitoring excessive burst alert threshold.
  - In the 'Delay Threshold' field (*VQMonDelayTHR*), type the voice quality monitoring excessive delay alert threshold.
  - In the 'R-Value Delay Threshold' field (*VQMonEOCRValTHR*), type the voice quality monitoring end of call low quality alert threshold.
  - In the 'Minimum Gap Size' field (*VQMonGMin*), type the voice quality monitoring minimum gap size (number of frames).

#### RTCP-XR

Enable RTCP XR	• <span>Enable Fully</span> ▼
Tx RTCP Packets Interval (in msec)	<input type="text" value="5000"/>
Disable RTCP XR Interval Randomization	• <input checked="" type="checkbox"/>

R-Value Delay Threshold	<input type="text" value="-1"/>
Minimum Gap Size	<input type="text" value="16"/>

3. Under the RTCP-XR Collection Server group, configure the following:

- (Gateway Application Only) From the 'Gateway RTCP XR Report Mode' drop-down list (RTCPXRReportMode), select the required option for sending RTCP XR reports and the stage of the call to send.
- From the 'Publication IP Group ID' drop-down list (PublicationIPGroupID), select the IP Group to where you want the device to send the RTCP XR reports.
- (SBC Application Only) From the 'SBC RTCP XR Report Mode' drop-down list (SBCRtcpXrReportMode), select the option to enable the sending of RTCP XR reports of QoE metrics at the end of each call session (i.e., after a SIP BYE).

#### RTCP-XR COLLECTION SERVER

Gateway RTCP XR Report Mode	•	End Call & Periodic	▼
Publication IP Group ID	•	#0 [Default_IPG]	▼ View
SBC RTCP XR Report Mode	•	End of Call	▼

4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Call Detail Records

Call Detail Records (CDR) contain vital statistics and information on calls processed by the device. The device can generate and report CDRs at various stages of the call (e.g., start of call or end of call). CDRs can be generated for SIP signaling and media.

The device can send CDRs to any of the following:

- **Syslog server:** The CDR Syslog message complies with RFC 3164 and is identified by Facility 17 ("local1") and Severity 5 (Notice).
- **RADIUS server:** For CDR in RADIUS format, see [Configuring RADIUS Accounting](#) on page 1588. To configure RADIUS servers for CDR reporting, see [Configuring RADIUS Servers](#) on page 369.
- **REST server:** The device can send signaling-related CDRs to a REST server using AudioCodesREST API (see [Configuring CDR Reporting to REST Server](#) on page 1515).
- **Locally on the device:** CDRs can be stored locally on the device (see [Storing CDRs Locally on the Device](#) on page 1516).

- To view Gateway CDRs stored in the device's memory, see [Viewing Gateway CDR History](#) on page 1493.
- To view SBC and Test Call CDRs stored on the device's memory, see [Viewing CDR History of SBC and Test Calls](#) on page 1495.

## Enabling CDR Generation and Configuring the CDR Server Address

For the device to generate CDRs, you need to enable the syslog feature and configure a collecting server address. The collecting server can be a dedicated CDR server or the server used for syslog messages.

### ➤ To enable CDR generation and configure the CDR server address:

1. Enable the syslog feature (see [Enabling Syslog](#) on page 1622).
2. Open the Call Detail Record Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Call Detail Record Settings**).
3. In the 'CDR Syslog Server IP Address' [CDRSyslogServerIP] field, enter the address (IPv4 or IPv6, or FQDN) of the server to where you want the CDRs sent.

CDR Syslog Server IP Address

14.7.8.9

4. Click **Apply**.

- If you don't configure an address for the CDR server, the device sends the CDRs to the address that you configured for the syslog servers in [Configuring the Primary Syslog Server Address](#) on page 1622 and [Configuring Secondary Syslog Servers](#) on page 1624.
- The IP Interface, port configured for the syslog server in [Configuring the Primary Syslog Server Address](#) on page 1622 are also used for the CDR server.

## Configuring CDR Filters and Report Level

You can configure various CDR filters and the stage of the call at which you want the device to generate and send CDRs. For a detailed description of the parameters described in this section, see [Syslog, CDR and Debug Parameters](#) on page 1766.

### ➤ To configure CDR filters and report level:

1. Open the Call Detail Record Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Call Detail Record Settings**).
2. Configure CDR filters:
  - In the 'Call-End CDR SIP Reasons Filter' [CallEndCDRSIPReasonsFilter] field, configure the SIP release cause codes that if received for calls, the device doesn't generate and send Call-End CDRs:

Call-End CDR SIP Reasons Filter

• 300,4xx

- Select the 'Call-End CDR Zero Duration Filter' check box [CallEndCDRZeroDurationFilter] if you want the device to not generate and send Call-End CDRs for calls of zero (0) duration:

Call-End CDR Zero Duration Filter ☒

3. Configure the call stage at which CDRs are generated and sent:

- From the 'CDR Report Level' [CDRReportLevel] drop-down list, select the stage of the call at which you want signaling-related CDRs to be generated and sent.
- (SBC Application Only) From the 'Media CDR Report Level' [MediaCDRReportLevel] drop-down list, select the stage of the call at which you want media-related CDRs to be generated and sent.

CDR Report Level

None

Media CDR Report Level

None

4. Click **Apply**.

## Configuring CDR Reporting to REST Server

You can configure the device to send signaling-related CDRs to a REST server using AudioCodes REST API. The device sends the CDRs in JSON format.

You can customize the CDRs that are sent to the REST server, by adding CDR fields or changing their names. For more information, see [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578 for SBC calls and [Customizing CDRs for Gateway Calls](#) on page 1572 for Gateway calls.

### ➤ To configure CDR reporting to a REST server:

1. Enable the syslog feature for sending log messages (CDRs) generated by the device to a collecting log message server. For more information, see [Enabling Syslog](#) on page 1622.
2. Configure the REST server:
  - a. Open the Remote Web Services table (see [Configuring Remote Web Services](#) on page 438).
  - b. Click **New**, and then configure an HTTP/S-based server to represent the REST server. Make sure that you configure the 'Type' parameter to **General**. Configure the remaining HTTP/S server parameters according to your requirements.
  - c. Click **Apply**.
3. Open the Call Detail Record Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Call Detail Record Settings**), and then do the following:

- a. From the 'REST CDR Report Level' drop-down list, select the stage of the call at which you want the CDRs to be generated and sent.
- b. From the 'REST CDR HTTP Server Name' drop-down list, select the REST server that you configured in the Remote Web Services table (see Step 2) to where you want the device to send the CDRs.

- c. Click **Apply**.

## Miscellaneous CDR Configuration

Miscellaneous but important CDR configuration parameters are listed below:

- To enable or disable the inclusion of the sequence number (S=) in CDR Syslog messages, use the 'CDR Syslog Sequence Number' [CDRSyslogSeqNum] parameter.
- The device sends CDRs only for dialog-initiating INVITE messages (call start), 200 OK responses (call connect) and BYE messages (call end). For SBC calls only: If you want to enable the generation of CDRs for non-call SIP dialogs (such as SUBSCRIBE, OPTIONS, and REGISTER), use the [EnableNonCallCdr] parameter.
- To configure the units of measurement for the call duration in CDRs ("Duration" CDR field), use the [CallDurationUnits] parameter.
- To configure the time zone (e.g., GMT+1) that is displayed with the timestamp in CDRs ("Connect Time", "Release Time", and "Setup Time" CDR fields), use the [TimeZoneFormat] parameter

## Storing CDRs Locally on the Device

CDRs generated by the device can be stored locally on the device (RAM).

You can specify the calls for which you wish to create locally stored CDRs. This is done using Logging Filter rules in the Logging Filters table. For example, you can configure a rule to create locally stored CDRs for traffic belonging only to IP Group #2.

Locally stored CDRs are saved in a comma-separated values file (\*.csv), where each CDR is on a dedicated row or line. An example of a CSV file with two CDRs are shown below :

- CSV file viewed in Excel:

	A	B	C	D	E	F	G	H
1	3b463e:215:1	CALL_END	4	14:34:40.000 UTC Wed Dec 16 2015	14:34:35.000 UTC Wed Dec 16 2015	14:34:33.000 UTC Wed Dec 16 2015	RMT	GWAPP_NORMAL
2	3b463e:215:1	CALL_END	4	14:34:40.000 UTC Wed Dec 16 2015	14:34:35.000 UTC Wed Dec 16 2015	14:34:33.000 UTC Wed Dec 16 2015	LCL	GWAPP_NORMAL
3								

- CSV file viewed in a text editor (Notepad):

1	3b463e:215:1,CALL_END,4,14:34:40.000	UTC Wed Dec 16 2015,14:34:35.000	UTC Wed Dec 16 2015,14:34:33.000	UTC Wed Dec 16 2015,RMT,GWAPP_NORMAL_I
2	3b463e:215:1,CALL_END,4,14:34:40.000	UTC Wed Dec 16 2015,14:34:35.000	UTC Wed Dec 16 2015,14:34:33.000	UTC Wed Dec 16 2015,LCL,GWAPP_NORMAL_I
3				

The device's CLI provides enhanced support for performing various actions on locally stored CDRs:

- To view the CDR column headers corresponding to the CDR data in the CSV file:

- SBC CDRs:

```
(config-system)# cdr
(cdr)# cdr-format show-title local-storage-sbc
session id,report type,call duration, call end time, call connect time,call
start time, call originator, termination reason, call id, srce uri, dest uri
```

- Gateway CDRs:

```
(config-system)# cdr
(cdr)# cdr-format show-title local-storage-gw
```

- To view stored CDR files:

- View all stored CDR files:

```
# show storage-history
```

- View all stored, unused CDR files:

```
# show storage-history unused
```

- To copy stored CDR files to a remote destination:

```
# copy storage-history cdr-storage-history <filename> to
<protocol://destination>
```

Where:

- *filename*: name you want to assign the file. Any file extension name can be used, but as the file content is in CSV format, it is recommended to use the .csv file extension.
- *protocol*: protocol over which the file is sent (tftp, http, or https).

For example:

```
copy storage-history cdr-storage-history my_cdrs.csv to
tftp://company.com/cdrs
```

- To delete stored CDR files, see [Deleting Locally Stored CDRs](#) on page 212.

- If the device restarts or powers off, locally stored CDRs are deleted.
- Locally stored CDRs are applicable only to "CALL\_END" CDR Report Types and to SBC signaling and Gateway CDRs.
- When the device operates in High-Availability (HA) mode, active and redundant devices maintain their own stored CDRs. In other words, upon an HA switchover the stored CDRs on the active device are not copied to the redundant device (which becomes the new active device). However, you can view the stored CDRs on the redundant device without performing a switchover, by accessing the redundant device from the active device through SSH (or SFTP), as described in [Accessing Files on Redundant Device from Active through SSH](#) on page 1326.
- You can customize the CDR fields for local storage. See [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578 for SBC calls. For Gateway calls, see [Customizing CDRs for Gateway Calls](#) on page 1572.

➤ **To configure local CDR storage:**

1. Open the Logging Filters table (see [Configuring Logging Filter Rules](#) on page 1602), and then enable CDR local storage by configuring a log filtering rule with the following settings:
  - 'Filter Type' and 'Value': (as desired)
  - 'Log Destination': **Local Storage**
  - 'Log Type': **CDR**
  - 'Mode': **Enable**
2. Open the Call Detail Record Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Call Detail Record Settings**), and then configure the following parameters:
  - 'File Size' [CDRLocalMaxFileSize]: Enter the maximum size (in kilobytes) of the CDR file. When the Current file reaches this size, the device creates a CDR file. However, if the 'Rotation Period' is reached before the file has reached this maximum size, the CDR file is created.
  - 'Number of Files' [CDRLocalMaxNumOfFiles]: Enter the maximum number of CDR files. If this maximum is reached, any new CDR file replaces the oldest CDR file (i.e., FIFO).
  - 'Rotation Period' [CDRLocalInterval]: Enter the periodic duration (in minutes) of how often a CDR file is created from the Current file (even if empty). For example, if configured to 60, a file is created every hour (or before, if the maximum size has been reached).

For a detailed description of each parameter, see [Syslog, CDR and Debug Parameters](#) on page 1766.

File Size (KBytes)

1024

Number Of Files

5

Rotation period (min)

60

If the CDR storage feature is enabled and you later change the maximum number of files (using the [CDRLocalMaxNumOfFiles] parameter) to a lower value (e.g., from 50 to 10), the device stores the remaining files (e.g., 40) in its memory as *unused* files.

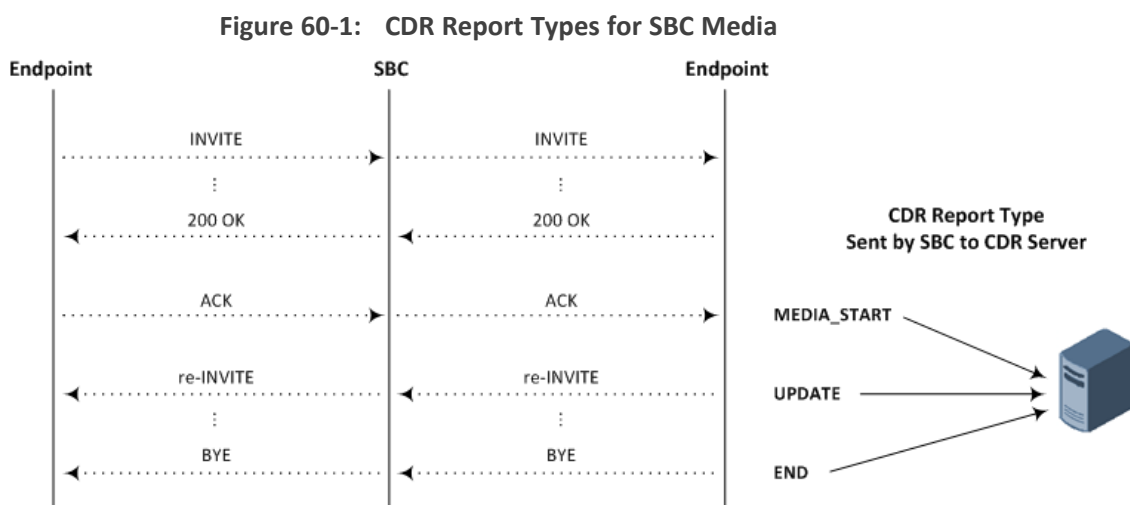

## CDR Field Description

This section describes the CDR fields that can be generated by the device. Some are generated by default, while others are generated only if you customize the CDR to include them, as described in [Customizing CDRs for Gateway Calls](#) on page 1572 and [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578.

■ For SBC calls, the device generates a signaling CDR and a media CDR:

- **Media CDR:** This CDR is published per active media stream. Each media CDR has a unique call ID that corresponds to its signaling CDR. There are three different CDR Report Types (CDRReportType), which the device sends to the CDR server at different stages of the SIP dialog session:
  - ◆ "MEDIA\_START": This CDR is sent upon an INVITE message.
  - ◆ "MEDIA\_UPDATE": This CDR is sent upon a re-INVITE message (e.g., the established call is placed on hold by one of the call parties).
  - ◆ "MEDIA\_END": This CDR is sent upon a BYE message (i.e., call ends).

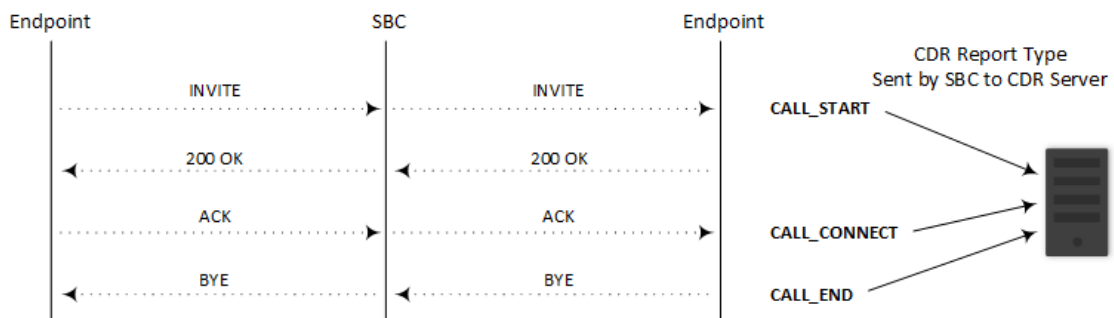

The CDR Report Types for SBC media and the SIP dialog stages at which they are sent are shown in the following figure:

- **Signaling CDR:** This CDR contains SIP signaling information. A typical SBC session consists of two SBC legs. Each leg generates its own signaling CDRs. Each leg generates three different CDR Report Types (CDRReportType), which the device sends to the CDR server at different stages of the SIP dialog:
  - ◆ "CALL\_START": This CDR is sent upon an INVITE message.
  - ◆ "CALL\_CONNECT": This CDR is sent upon an ACK message (i.e., call is established).
  - ◆ "CALL\_END": This CDR is sent upon a BYE message (i.e., call ends).

The CDR Report Types for SBC signaling and the SIP dialog stages at which they are sent are shown in the following figure:

**Figure 60-2: CDR Report Types for SBC Signaling**

You can customize the signaling CDR that is sent at the end of the SBC call ("CALL\_END") to also include media-related CDR fields. This is applicable only to syslog CDRs, local storage CDRs, and RADIUS CDRs. For customizing SBC CDRs, see [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578. When there is more than one media stream in the SBC session, the added media-related fields only represent the first audio media.

CDRs belonging to the same SBC session (both incoming and outgoing legs) have the same Session ID (SessionId CDR field). CDRs belonging to the same SBC leg have the same Leg ID (LegId CDR field).

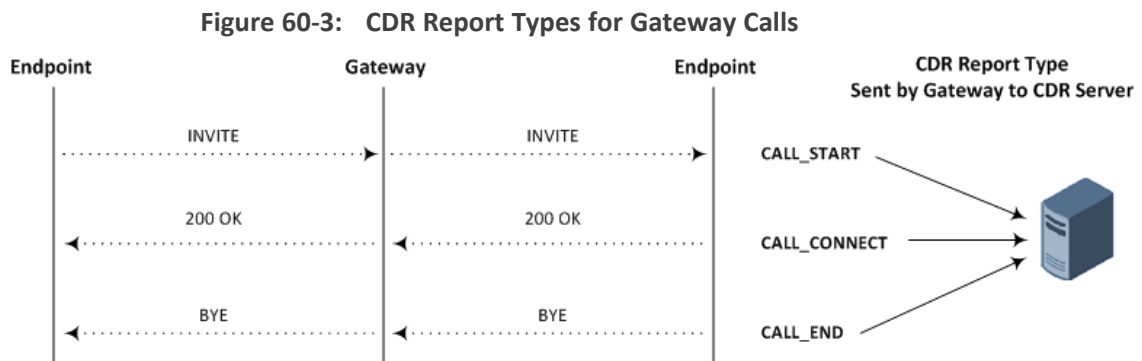

For billing applications, the CDR that the device sends at the end of the call ("CALL\_END" CDR Report Type) is usually sufficient. This CDR may be based on the following CDR fields:

- Leg ID
- Source URI
- Destination URI
- Call originator (i.e., caller)
- Call duration
- Call time

- For Gateway calls, the CDR includes both media and signaling CDR fields. The CDR can be one of the following report types (CDRReportType field), depending at which stage of the SIP dialog it was sent:

- "CALL\_START": This CDR is sent upon an INVITE message.
- "CALL\_CONNECT": This CDR is sent upon a 200 OK response (i.e., call is established).
- "CALL\_END": This CDR is sent upon a BYE message (i.e., call ends).

The CDR Report Types and the SIP dialog stages at which they are sent are shown in the following figure:

The syslog displays CDRs in tabular format, whereby the CDR field names (titles) are displayed on the first lines and their corresponding values on the subsequent lines. Below shows an example of an SBC signaling CDR sent at the end of a normally terminated call:

```
[S=40] |CDRReportType |EPTyp |SIPCallId |SessionId |Orig |SourceIp |SourcePort
|DestIp |DestPort |TransportType |SrcURI |SrcURIBeforeMap |DstURI
|DstURIBeforeMap |Durat |TrmSd |TrmReason |TrmReasonCategory |SetupTime

If all CDR field values are within a specific number of characters, they appear aligned under their corresponding field names. However, if some of the values exceed their specific number of characters for syslog tabular alignment, the values do not appear fully aligned with their corresponding field names. If you customize the title of a CDR field and it contains more

characters than the default title, the maximum number of characters to ensure syslog tabular alignment will be updated accordingly to fit the customized title. For example, if you customize the default CDR field title "Duration" (8 characters) to "Duration in Sec" (15 characters), the tabular alignment of field names to corresponding values will be updated to 15 as well. The maximum number of characters for syslog tabular alignment when CDR field titles are not customized are given in the table below.

**Table 60-2: CDR Field Descriptions**

Field	Description
Accounting Status Type [305]	<p>Displays the CDR Report Type in numeric representation (integer), used mainly for the RADIUS Accounting Status Type attribute (40):</p> <ul style="list-style-type: none"> <li>■ "1" = "Accounting Start" for "CALL_START" or "CALL_CONNECT"</li> <li>■ "2" = "Accounting Stop" for "CALL_END"</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable to SBC media and signaling, and Gateway CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Alerting Time [443]	<p>Displays the duration (in milliseconds) between ringing (SIP 180 Ringing) and call answered (SIP 200 OK) or unanswered (CANCEL).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling, and Gateway CDRs ("CALL_CONNECT" and "CALL_END" Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
AMD Decision Probability [630]	<p>Displays the success (in percentage) that the answering type (probability) was correctly detected for the Answering Machine Detection (AMD) feature.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "%" for syslog.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 3.</li> </ul>
AMD Decision [629]	<p>Displays the detected answering type for the AMD feature:</p> <ul style="list-style-type: none"> <li>"V": voice</li> <li>"A": answer machine</li> <li>"S": silence</li> <li>"U": unknown</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>The default field title is "AMD" for syslog.</li> <li>The maximum number of characters for syslog tabular alignment is 3.</li> </ul>
AOC Amount [523]	<p>Displays the total amount charged for the call for the Advice of Charge (AOC) feature. The field is an integer from 0 to 999999.</p> <p>Data is stored per call and sent in the syslog as follows:</p> <ul style="list-style-type: none"> <li>currency-type: amount multiplier for currency charge (euro or usd)</li> <li>recorded-units: for unit charge (1-999999)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>The default field title is "Amount" for syslog.</li> <li>The maximum number of characters for syslog tabular alignment is 9.</li> </ul>
AOC Currency [522]	<p>Displays the currency of the AOC (e.g., "EUR").</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the Gateway CDR Format table.</li> <li>The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Type).</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 3.</li> </ul>
AOC Multiplier [524]	<p>Displays the AOC multiplier information. The field is an integer from 0,001 to 1000 (in steps of 10).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>The default field title is "Mult" for syslog.</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
B-Channel [501]	<p>Displays the B-channel.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>The default field title is "BChan" for syslog.</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Blank [308]	<p>Displays an empty string value " " and 0 for an integer value. This is typically used for RADIUS CDRs.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>The field is applicable to all CDR Report Types.</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Call Duration [408]	<p>Displays the duration of the call. The field is an integer.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>To configure the units of measurement (seconds - default, deciseconds, centiseconds, or milliseconds), use the [CallDurationUnits] parameter.</li> <li>By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "Duration" for syslog and Local Storage, and none for RADIUS (ACCT_SESSION_TIME standard ID 46).</li> <li>■ The maximum number of characters for syslog tabular alignment is 8.</li> </ul>
Call End Sequence Number [442]	<p>Displays the sequence number of the call. The field is an integer. For each call-end CDR, the field is assigned the next consecutive number. For example, for the first terminated call processed by the device, the field is assigned the value "1"; for the second terminated call, the field is assigned the value "2", and so on. The field value resets to 1 upon a device restart, an HA switchover (for HA-supporting products), or when it reaches the value FFFFFFFF (hexadecimal).</p> <p>As the field is consecutive, you can use this field to check whether there are any missing CDRs.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Call ID [301]	<p>Displays the unique ID of the call, which appears in the SIP Call-ID header. The field is a string of up to 130 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable to SBC media and signaling, and Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "SIPCallId" for syslog and Local Storage, and "call-id=" for RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 50.</li> </ul>
Call Orig RADIUS [434]	<p>Displays the originator of the call:</p> <ul style="list-style-type: none"> <li>■ "answer": Call originated from the IP side (Gateway) or incoming leg</li> </ul>

Field	Description
	<p>(SBC)</p> <ul style="list-style-type: none"> <li>■ "originate": Call originated from the Tel side (Gateway) or outgoing leg (SBC)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable to CDR Report Types "Start Acc" and "Stop Acc".</li> <li>■ The field is applicable to all types, but mainly to RADIUS (SBC and GatewayCDRs).</li> <li>■ The default field title is "h323-call-origin=" for RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Call Orig [401]	<p>Displays which side originated the call for the specific leg.</p> <ul style="list-style-type: none"> <li>■ "LCL": SBC Outgoing leg (called party side) or Tel side</li> <li>■ "RMT": SBC Incoming leg (i.e., caller party side) or IP side</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "Orig" for syslog and "Direction" in the Web SBC CDR History table and Web Gateway CDR History table.</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Callee Display ID [432]	<p>Displays the name of the called party. The field is a string of up to 36 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "Callee" in the sent CDR.</li> <li>■ The maximum number of characters for syslog tabular alignment is 37.</li> </ul>

Field	Description
Caller Display ID [431]	<p>Displays the name of the caller (caller ID). The field is a string of up to 50 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "Caller" in the CDR.</li> <li>■ The maximum number of characters for syslog tabular alignment is 51.</li> </ul>
CDR Type [300]	<p>Displays the application type of the CDR. The field is an integer:</p> <ul style="list-style-type: none"> <li>■ "2": Gateway CDR</li> <li>■ "3": SBC signaling CDR</li> <li>■ "4": SBC media CDR</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media and signaling, and Gateway CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 6.</li> </ul>
Channel ID [600]	<p>Displays the port (channel) ID.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_START", "CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "Cid" in the CDR.</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Coder Type [601]	<p>Displays the coder used for the call. The field is a string, for example, "g711Alaw64k", "g711Ulaw64k" and "g729".</p> <p><b>Note:</b></p>

Field	Description
	<ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "Coder" in the CDR.</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Conn ID [502]	<p>Displays the Digital Connection ID.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "ConId" in the CDR.</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Connect Time [412]	<p>Displays the date and time that the call was connected. The field is a string of up to 35 characters and in the following format: &lt;hh:mm:ss:ms&gt; UTC &lt;DDD&gt; &lt;MMM&gt; &lt;DD&gt; &lt;YYYY&gt;. For example, "17:00:49.053 UTC Thu Dec 14 2017"</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To configure the time zone string (e.g., "UTC" - default, "GMT+1" and "EST"), use the TimeZoneFormat parameter.</li> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "ConnectTime" for syslog and Local Storage, and "h323-connect-time=" for RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 35.</li> </ul>
Dest Port [406]	<p>Displays the SIP signaling destination UDP port. The field is an integer of up to 10 digits.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and Gateway CDRs (all CDR Report Types).</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The default field title is "SigDestPort" for Gateway syslog and Local Storage, and "DestPort" for SBC syslog and Local Storage.</li> <li>■ The maximum number of characters for syslog tabular alignment is 11.</li> </ul>
Destination Host Before Manipulation [815]	<p>Displays the original destination hostname (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Host Name Before Manipulation [518]	<p>Displays the original destination hostname (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "DstHostBeforeMap".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Host Name [519]	<p>Displays the destination hostname (after manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "DstHost".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Host [813]	<p>Displays the destination hostname (after manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC CDRs (all CDR Report Types).</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination IP [403]	<p>Displays the destination IP address. The field is a string of up to 20 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>The default field title is "DestIp".</li> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Number Before Manipulation [510]	<p>Displays the original destination number (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>The default field title is "DstNumBeforeMap".</li> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Number Plan [513]	<p>Displays the destination Numbering Plan Identification (NPI).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>The default field title is "NPI".</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Destination Number Type [512]	<p>Displays the destination Type of Number (TON).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>The default field title is "TON".</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>

Field	Description
Destination Number [511]	<p>Displays the destination phone number.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "DstPhoneNum" for syslog, "" (empty string) for RADIUS (CALLED_STATION_ID standard ID 31), and "Callee" in the Web Gateway CDR History table.</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Tags [441]	<p>Displays destination tags.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
Destination URI Before Manipulation [803]	<p>Displays the original destination URI (username@host) before manipulation, if any. The field is a string of up to 150 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The default field title is "DstURIBeforeMap".</li> <li>■ The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Destination URI [801]	<p>Displays the destination URI (username@host) after manipulation, if any. The field is a string of up to 150 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The default field title is "DstURI".</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Destination Username Before Manipulation [811]	<p>Displays the original destination username (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format tables.</li> <li>The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Destination Username [809]	<p>Displays the destination username (after manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format tables.</li> <li>The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Direct Media [807]	<p>Displays whether the call session flowed directly between the endpoints (i.e., Direct Media). The field is a string:</p> <ul style="list-style-type: none"> <li>"yes": The call is a direct media call session.</li> <li>"no": The call traversed the device.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>The default field title is "DirectMedia".</li> <li>The maximum number of characters for syslog tabular alignment is 11.</li> </ul>
Endpoint Type [400]	<p>Displays the endpoint type. The field is a string:</p> <ul style="list-style-type: none"> <li>"NONE"</li> <li>"FXO"</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ "FXS"</li> <li>■ "ISDN"</li> <li>■ "CAS"</li> <li>■ "TRANSPARNT" (E1/T1 calls without D-channel / signaling)</li> <li>■ "SBC" (SBC calls)</li> <li>■ "TEST" (for Test Call calls)</li> <li>■ "3WCONF" (three-way conferencing calls)</li> <li>■ "SIPREC" (SIPREC calls)</li> <li>■ "MOH" (Music-on-Hold calls)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "EPTyp".</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Fax On Call [505]	<p>Displays whether a fax transaction was detected during the call. The field is an integer:</p> <ul style="list-style-type: none"> <li>■ "0": No</li> <li>■ "1": Yes</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "Fax".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Global Session ID [309]	<p>Displays the global session ID.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable to SBC signaling and media, and Gateway CDRs.</li> <li>■ The default field title is "h323-gw-id=" for RADIUS (A_ACCT_SESSION_TIME).</li> <li>■ The maximum number of characters for syslog tabular alignment is 16.</li> <li>■ For more information on the global session ID, see <a href="#">Enabling Same Call Session ID over Multiple Devices</a> on page 1665.</li> </ul>
H323 ID [306]	<p>Displays the device ID which can configured by the H323IDString parameter. It is typically used for RADIUS CDRs. The field is a string.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is included in the default RADIUS CDR.</li> <li>■ The field is applicable only to RADIUS SBC and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "h323-gw-id for RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 33.</li> </ul>
IP Group ID [416]	<p>Displays the IP Group ID. The field is an integer.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
IP Group Name [417]	<p>Displays the IP Group name. The field is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "IPG (name)" for Gateway syslog and Local Storage, "IPGroup (name)" for SBC syslog and Local Storage, and "IP Group" in the Web SBC CDR History table.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
IP Profile ID [425]	<p>Displays the IP Profile ID. The field is an integer.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
IP Profile Name [426]	<p>Displays the IP Profile name. The field is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>The default field title is "IpProfileId (name)".</li> <li>The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
Is Recorded [822]	<p>Displays if the SBC leg was recorded (SIPREC) or not.</p> <p>The field is a string:</p> <ul style="list-style-type: none"> <li>"yes"</li> <li>"no"</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format tables.</li> <li>The field is applicable only to SBC signaling CDRs ("CALL_END" CDR Report Type; other Report Types will display "no").</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
ISDN Line Type [525]	<p>Displays the ISDN line type. The field is an integer:</p> <ul style="list-style-type: none"> <li>"10": E1</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ "11": T1</li> <li>■ "12": BRI</li> <li>■ "21": Unknown</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the Gateway CDR Format table.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Latched RTP IP [631]	<p>Displays the remote IP address of the incoming RTP stream that the device "latched" onto as a result of the RTP latching mechanism for NAT traversal.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "LatchedRtpIp".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Latched RTP Port [632]	<p>Displays the remote RTP port of the incoming RTP stream that the device "latched" onto as a result of the RTP latching mechanism for NAT traversal. The field is an integer 0 to 0xFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "LatchedRtpPort".</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Latched T38 IP [633]	<p>Displays the latching of a new T.38 stream (new IP address).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR</li> </ul>

Field	Description
	<p>Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</p> <ul style="list-style-type: none"> <li>■ The default field title is "LatchedT38Ip".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Latched T38 Port [634]	<p>Displays the latching of a new T.38 stream (new port). The field is an integer 0 to 0xFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "LatchedT38Port".</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Leg ID [310]	<p>Displays the unique ID of the call leg within a specific call session. The field is an integer.</p> <p>A basic SBC call consists of two legs (incoming and outgoing) and thus, two leg IDs are generated for the session, one for each leg.</p> <p>A basic Gateway call consists of only one leg ID.</p> <p>For each new call, the device assigns leg ID "1" to the first leg. The device then increments the leg ID for subsequent legs according to the leg sequence in the call session.</p> <p>For example, the device generates leg ID "1" for the SBC incoming leg and leg ID "2" for the SBC outgoing leg. If the call is transferred, the device generates leg ID "3" for the leg belonging to the call transfer target. Another example is a call forking session where the leg ID sequence may be as follows: incoming leg is "1", outgoing leg to user's office phone is "2" and outgoing leg to the user's mobile phone is "3". If the call is then transferred, the leg ID for the transfer leg is "4".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and media, and Gateway CDRs ("CALL_START", "CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "LegId".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>

Field	Description
Local Input Octets [606]	<p>Displays the local input octets (bytes).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is empty for RADIUS (ACCT_INPUT_OCTETS standard ID 42).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Local Input Packets [604]	<p>Displays the number of packets received by the device. The field is an integer from 0 to 0xFFFFFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "InPackets" for syslog and Local Storage, and empty for RADIUS (ACCT_INPUT_PACKETS).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Local Jitter [610]	<p>Displays the RTP jitter. The field is an integer from 0 to 40000 samples (-1 if unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "RTPjitter".</li> <li>■ The maximum number of characters for syslog tabular alignment is 9.</li> </ul>
Local MOS CQ [627]	<p>Displays the local MOS for conversation quality. The field is an integer from 10 to 46 (127 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "LocalMosCQ".</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Local Output Octets [607]	<p>Displays the local output octets (bytes).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is empty for RADIUS (ACCT_OUTPUT_OCTETS standard ID 43).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Local Output Packets [605]	<p>Displays the number of packets sent by the device. The field is an integer from 0 to 0xFFFFFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "OutPackets" for syslog and Local Storage, and empty for RADIUS (ACCT_OUTPUT_PACKETS standard ID 48).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Local Packet Loss [608]	<p>Displays the number of packets lost of the entire stream. The field is an integer from 0 to 0xFFFFFFFF (-1 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "PackLoss" for Gateway syslog and Local Storage, and "LocalPackLoss" for SBC syslog.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Local R Factor [625]	<p>Displays the local R-factor conversation quality. The field is an integer from 0 to 120 (127 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>The default field title is "LocalRFactor".</li> <li>If the RTCP XR feature is unavailable (not licensed or disabled), this R-factor VoIP metric is not provided. Instead, the device sends the CDR field with the value 127, meaning that information is unavailable.</li> <li>The maximum number of characters for syslog tabular alignment is 12.</li> </ul>
Local Round Trip Delay [609]	<p>Displays the average round-trip delay time of the entire RTP stream. The field is an integer from 0 to 10000 ms (-1 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>The default field title is "RTPdelay".</li> <li>The maximum number of characters for syslog tabular alignment is 9.</li> </ul>
Local RTP IP [620]	<p>Displays the local RTP IP address.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC media CDRs ("MEDIA_START" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>The default field title is "LocalRtpIp".</li> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>

Field	Description
Local RTP Port [621]	<p>Displays the local RTP port. This field is an integer from 0 to 0xFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "LocalRtpPort".</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Local SSRC Sender [611]	<p>Displays the local RTP synchronization source (SSRC). The field is an integer from 0 to 0xFFFFFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "RTPssrc" for Gateway syslog and Local Storage, and "TxRTPssrc" for SBC syslog.</li> <li>■ The maximum number of characters for syslog tabular alignment is 14.</li> </ul>
Media List [819]	<p>Displays all the media types (e.g., "audio", "text", "msrp", and "video") that was used for the call session. The field is a string.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC signaling CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 40.</li> </ul>
Media Realm ID [427]	<p>Displays the Media Realm ID. The field is an integer.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all</li> </ul>

Field	Description
	<p>CDR Report Types).</p> <ul style="list-style-type: none"> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Media Realm Name [428]	<p>Displays the Media Realm name. The field is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "MediaRealmId (name)".</li> <li>■ The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
Media Type [304]	<p>Displays the media type (e.g., "audio", "text", or "video").</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media and GatewayCDRs ("CALL_END" and "MEDIA_END" CDR Report Type).</li> <li>■ The default field title is "MediaType".</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Metering Pulses Generated [504]	<p>Displays the number of generated metering pulses.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "MeteringPulses".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Module And Port [521]	<p>Displays the module and port used.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the Gateway CDR Format table.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "End Point" in the Web Gateway CDR History table.</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Packet Interval [602]	<p>Displays the coder packet interval. The field is an integer from 10 to 200 ms.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START", "MEDIA_UPDATE" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "Intrv".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Payload Type [603]	<p>Displays the RTP payload type. The field is an integer, for example:</p> <ul style="list-style-type: none"> <li>■ "0" for G.711 U-law</li> <li>■ "8" for G.711 A-law</li> <li>■ "18" for G.729</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START", "MEDIA_UPDATE" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Proxy Set ID [424]	<p>Displays the Proxy Set ID.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR</li> </ul>

Field	Description
	<p>Format table.</p> <ul style="list-style-type: none"> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Proxy Set Name [438]	<p>Displays the Proxy Set name. The field is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "ProxySetId (name)".</li> <li>■ The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
PSTN Termination Reason [520]	<p>Displays the Q.850 protocol termination reason. The field is an integer from 0 to 127.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "PstnTermReason".</li> <li>■ The maximum number of characters for syslog tabular alignment is 14.</li> </ul>
RADIUS Call ID [307]	<p>Displays the RADIUS call ID.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC and GatewayRADIUS CDRs (all CDR Report Types).</li> <li>■ The default field title is "h323-conf-id=" in RADIUS CDRs.</li> <li>■ The maximum number of characters for syslog tabular alignment is 50.</li> </ul>
Redirect	<p>Displays the redirect phone number before manipulation, if any.</p>

Field	Description
Number Before Manipulation [514]	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the Gateway CDR Format table.</li> <li>■ The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "RedirectNumBeforeMap".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Redirect Number Plan [527]	<p>Displays the redirect Numbering Plan Identification (NPI).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the Gateway CDR Format table.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Redirect Number Type [526]	<p>Displays the redirect Type of Number (TON).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the Gateway CDR Format table.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Redirect Number [515]	<p>Displays the original redirect number (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "RedirectPhonNum".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Redirect Reason [414]	<p>Displays the reason for the call redirection. The field is an integer of up to 15 digits:</p>

Field	Description
	<ul style="list-style-type: none"> <li>■ "-1": Not relevant</li> <li>■ "0": Unknown reason</li> <li>■ "1": Call forward busy (CFB)</li> <li>■ "2": Call forward no reply (CFNR)</li> <li>■ "3": Call forward network busy</li> <li>■ "4": Call deflection</li> <li>■ "5": Immediate call deflection</li> <li>■ "6": Mobile subscriber not reachable</li> <li>■ "9": DTE out of order</li> <li>■ "10": Call forwarding DTE</li> <li>■ "13": Call transfer</li> <li>■ "14": Call pickup</li> <li>■ "15": Call systematic or call forward unconditional (CFU)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "RedirectReason".</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Redirect URI Before Manipulation [805]	<p>Displays the original call redirect URI (username@host) before manipulation, if any. The field is a string of up to 150 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling CDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "RedirectURINumBeforeMap".</li> <li>■ The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Redirect URI [804]	<p>Displays the original call redirect URI (username@host) after manipulation, if any. The field value is a string of up to 150 characters.</p>

Field	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling CDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "RedirectURINum".</li> <li>■ The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Release Time [413]	<p>Displays the date and time the call ended (disconnected). The field is a string of up to 35 characters and presented in the following format: &lt;hh:mm:ss.ms&gt; UTC &lt;DDD&gt; &lt;MMM&gt; &lt;DD&gt; &lt;YYYY&gt;. For example, "17:00:55.002 UTC Thu Dec 14 2017".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To configure the time zone string (e.g., "UTC" - default, "GMT+1" and "EST"), use the TimeZoneFormat parameter.</li> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "ReleaseTime" for syslog, "h323-disconnect-time=" for RADIUS, and "Call End Time" in the Web SBC CDR History table and Web Gateway CDR History table.</li> <li>■ The maximum number of characters for syslog tabular alignment is 35.</li> </ul>
Remote Input Octets [614]	<p>Displays the remote input octets (bytes).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Remote Input Packets [612]	<p>Displays the number of packets that the remote side reported it received. The field is an integer from 0 to 0xFFFFFFFF.</p> <p><b>Note:</b></p>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Remote IP [404]	<p>Displays the remote SIP IP address.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_START", "CALL_CONNECT", and "CALL_END" CDR Report Types).</li> <li>■ The field is applicable to syslog, RADIUS, Local Storage, and Web History CDRs.</li> <li>■ The default CDR title is "Remote IP" in the Web SBC CDR History table and Web Gateway CDR History table.</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Remote Jitter [618]	<p>Displays the remote RTP jitter. The field is an integer from 0 to 40000 samples (-1 if unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 9.</li> </ul>
Remote MOS CQ [628]	<p>Displays the remote MOS for conversation quality. The field is an integer from 10 to 46 (127 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "RemoteMosCQ".</li> <li>■ The maximum number of characters for syslog tabular alignment is 11.</li> </ul>
Remote Output Octets [615]	<p>Displays the remote output octets (bytes).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Remote Output Packets [613]	<p>Displays the number of packets received by the device. The field is an integer from 0 to 0xFFFFFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Remote Packet Loss [616]	<p>Displays the number of packets lost of the entire remote stream. The field is an integer from 0 to 0xFFFFFFFF (-1 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "RemotePackLoss".</li> <li>■ The maximum number of characters for syslog tabular alignment is 14.</li> </ul>
Remote Port	Displays the remote SIP port. This field is an integer from 0 to 0xFFFF.

Field	Description
[407]	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_START", "CALL_CONNECT", and "CALL_END" CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Remote R Factor [626]	<p>Displays the remote R-factor conversation quality. The field is an integer from 0 to 120 (127 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "RemoteRFactor".</li> <li>■ If the RTCP XR feature is unavailable (not licensed or disabled), this R-factor VoIP metric is not provided. Instead, the device sends the CDR field with the value 127, meaning that information is unavailable.</li> <li>■ The maximum number of characters for syslog tabular alignment is 13.</li> </ul>
Remote Round Trip Delay [617]	<p>Displays the average round-trip delay time of the remote RTP stream. The field is an integer from 0 to 10000 ms (-1 if information is unavailable).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The maximum number of characters for syslog tabular alignment is 9.</li> </ul>
Remote RTP IP [622]	<p>Displays the remote RTP IP address.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START", "MEDIA_UPDATE" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "RtPlp" for syslog Signaling and Local Storage, "RemoteRtPlp" for syslog Media, and "h323-remote-address=" for RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Remote RTP Port [623]	<p>Displays the remote RTP port. This field is an integer from 0 to 0xFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START", "MEDIA_UPDATE" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is ""Port" for syslog Signaling and "RemoteRtpPort" for syslog Media.</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Remote SIP User Agent [818]	<p>Displays the remote SIP User-Agent header value.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC signaling ("CALL_START", "CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Remote SSRC Sender [619]	<p>Displays the remote (sender) RTP synchronization source (SSRC). The field is an integer from 0 to 0xFFFFFFFF.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Type) and Gateway CDRs ("CALL_END" CDR Report Type).</li> <li>■ The default field title is "RemoteRTPssrc" for Gateway syslog and</li> </ul>

Field	Description
	<p>"RxRTPssrc" for SBC syslog Media.</p> <ul style="list-style-type: none"> <li>■ The maximum number of characters for syslog tabular alignment is 14.</li> </ul>
Report Type [303]	<p>Displays the type of CDR report. The field is a string:</p> <ul style="list-style-type: none"> <li>■ "CALL_START": The CDR is sent upon an INVITE message.</li> <li>■ "CALL_CONNECT": The CDR is sent upon a 200 OK response.</li> <li>■ "CALL_END": The CDR is sent upon a BYE message.</li> <li>■ "DIALOG_START": The CDR is sent upon the start of a non-INVITE session (only when enabled, using the EnableNonCallCdr parameter).</li> <li>■ "DIALOG_END": The CDR is sent upon the end of a non-INVITE session (only when enabled, using the EnableNonCallCdr parameter).</li> <li>■ "DIALOG_CONNECT ": The CDR is sent upon establishment of a non-INVITE session (only when enabled, using the EnableNonCallCdr parameter).</li> <li>■ "MEDIA_START": The CDR is sent upon 200 OK response or early media</li> <li>■ "MEDIA_UPDATE": The CDR is sent upon a re-INVITE message</li> <li>■ "MEDIA_END": The CDR sent is upon a BYE message</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable to SBC media and signaling, and Gateway CDRs.</li> <li>■ The default field title is "GWReportType" for Gateway syslog and Local Storage, "SBCReportType" for SBC syslog and Local Storage, and "MediaReportType" for SBC syslog Media.</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
RTP IP DiffServ [624]	<p>The field displays the RTP IP DiffServ. The valid value is an integer from 0 to 63.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_START", "MEDIA_UPDATE" and "MEDIA_END" CDR Report Types) and Gateway CDRs ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>■ The default field title is "TxRTPIPDiffServ".</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
Session ID [302]	<p>Displays the unique session ID. The field value is a string of up to 24 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable to SBC media and signaling, and Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "SessionId".</li> <li>■ The maximum number of characters for syslog tabular alignment is 24.</li> </ul>
Setup Time [411]	<p>Displays the date and time that the call was setup. The field value is a string of up to 35 characters and presented in the following format: &lt;hh:mm:ss:ms&gt; UTC &lt;DDD&gt; &lt;MMM&gt; &lt;DD&gt; &lt;YYYY&gt;. For example, "17:00:49.052 UTC Thu Dec 14 2017"</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To configure the time zone string (e.g., "UTC" - default, "GMT+1", and "EST"), use the TimeZoneFormat parameter.</li> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "SetupTime"" for syslog and Local Storage, and "h323-setup-time=" for RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 35.</li> </ul>
Signaling IP DiffServ [422]	<p>Displays the signaling IP DiffServ. The field value is an integer of up to 15 digits.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "TxSigIPDiffServ".</li> <li>■ The maximum number of characters for syslog tabular alignment is 15.</li> </ul>
SIP Interface ID [420]	<p>Displays the SIP Interface table row index (integer).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
SIP Interface Name [433]	<p>Displays the SIP Interface name. The field value is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "SIPInterfaceId (name)".</li> <li>■ The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
SIP Local Tag [445]	<p>Displays the 'tag' parameter of the SIP From / To headers that is generated by the device in the outgoing SIP message. The field value is a string of up to 100 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable to all CDR Report Types, but it may not be added to some Report Types in all call scenarios.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs.</li> <li>■ The maximum number of characters for syslog tabular alignment is</li> </ul>

Field	Description
	20.
SIP Method [806]	<p>Displays the SIP message type (method). The field value is a string of up to 10 characters:</p> <ul style="list-style-type: none"> <li>■ "INVITE"</li> <li>■ "OPTIONS"</li> <li>■ "REGISTER"</li> <li>■ "NOTIFY"</li> <li>■ "INFO"</li> <li>■ "SUBSCRIBE"</li> <li>■ "MESSAGE"</li> <li>■ "BENOTIFY"</li> <li>■ "SERVICE"</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The default field title is "SIPMethod".</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
SIP Remote Tag [446]	<p>Displays the 'tag' parameter of the SIP From / To headers that is received by the device in the incoming SIP message. The field value is a string of up to 100 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable to all CDR Report Types, but it may not be added to some Report Types in all call scenarios.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs.</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
SIP Termination	Displays the description of the SIP call termination reason. The field

Field	Description
Description [430]	<p>value is a string of up to 70 characters and is set to one of the following:</p> <ul style="list-style-type: none"> <li>■ SIP Reason header, if exists, for example: SIP ;cause=200 ;text="Call completed elsewhere".</li> <li>■ If no SIP Reason header exists, the description is taken from the reason text, if exists, of the SIP response code, for example: "417 Unknown Resource-Priority".</li> <li>■ If no reason text exists in the SIP response code, the description is taken from an internal SIP response mapping mechanism. For example, if the device receives a SIP response "422", it sends in the CDR "422 Session Interval Too Small method" as the description.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "SipTermDesc".</li> <li>■ The maximum number of characters for syslog tabular alignment is 26.</li> </ul>
SIP Termination Reason [429]	<p>Displays the SIP reason for call termination. The field value is a string of up to 12 characters and is set to one of the following:</p> <ul style="list-style-type: none"> <li>■ "BYE"</li> <li>■ "CANCEL"</li> <li>■ SIP error codes (e.g., "404")</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "SIPTrmReason".</li> <li>■ The maximum number of characters for syslog tabular alignment is 12.</li> </ul>
Source Host Before Manipulation [814]	<p>Displays the original source hostname (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Host Name Before Manipulation [516]	<p>Displays the original source hostname (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "SrcHostBeforeMap".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Host Name [517]	<p>Displays the source hostname (after manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "SrcHost".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Host [812]	<p>Displays the source hostname (after manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source IP [402]	<p>Displays the source IP address. The field value is a string of up to 20 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The default field title is "SourceIp".</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Number Before Manipulation [506]	<p>Displays the source number (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "SrcNumBeforeMap" for syslog, and "Caller" for Web CDR History.</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Number Plan [509]	<p>Displays the source Numbering Plan Identification (NPI).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "NPI".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Source Number Type [508]	<p>Displays the source Type of Number (TON).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "TON".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Source Number [507]	<p>Displays the source number (after manipulation).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "SrcPhoneNum" for syslog and Local Storage, and "" for RADIUS (A_CALLING_STATION_ID).</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Port [405]	<p>Displays the SIP signaling source UDP port. The field value is an integer of up to 10 digits.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>The default field title is "SigSourcePort" for Gateway syslog, and "SourcePort" for SBC syslog and Local Storage.</li> <li>The maximum number of characters for syslog tabular alignment is 13.</li> </ul>
Source Tags [440]	<p>Displays source tags.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
Source URI Before Manipulation [802]	<p>Displays the source URI (username@host) before manipulation. The field value is a string of up to 150 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> <li>The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>The default field title is "SrcURIBeforeMap".</li> <li>The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Source URI [800]	<p>Displays the source URI (username@host). The field value is a string of up to 150 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>By default, the field is included in the CDR.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The default field title is "SrcURI".</li> <li>■ The maximum number of characters for syslog tabular alignment is 41.</li> </ul>
Source Username Before Manipulation [810]	<p>Displays the original source username (before manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format tables.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The default field title is "Caller" in the Web SBC CDR History table.</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
Source Username [808]	<p>Displays the source username (after manipulation, if any).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format tables.</li> <li>■ The field is applicable only to SBC signaling CDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 20.</li> </ul>
SRD ID [418]	<p>Displays the SRD table row index.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
SRD Name [419]	<p>Displays the SRD name. The field value is a string of up to 40 characters.</p> <p><b>Note:</b></p>

Field	Description
	<ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "SrdId (name)".</li> <li>■ The maximum number of characters for syslog tabular alignment is 32.</li> </ul>
Call Success [447]	<p>Displays whether the call succeeded ("yes") or failed ("no").</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> </ul>
Termination Reason Category [423]	<p>Displays the category of the call termination reason. The field value is up to 17 characters and is set to one of the following:</p> <p><b>Calls with duration 0 (i.e., not connected):</b></p> <ul style="list-style-type: none"> <li>■ "NO_ANSWER": <ul style="list-style-type: none"> <li>✓ "GWAPP_NORMAL_CALL_CLEAR"</li> <li>✓ "GWAPP_NO_USER_RESPONDING"</li> <li>✓ "GWAPP_NO_ANSWER_FROM_USER_ALERTED"</li> </ul> </li> <li>■ "BUSY": <ul style="list-style-type: none"> <li>✓ "GWAPP_USER_BUSY"</li> </ul> </li> <li>■ "NO_RESOURCES": <ul style="list-style-type: none"> <li>✓ "GWAPP_RESOUUCE_UNAVAILABLE_UNSPECIFIED"</li> <li>✓ "RELEASE_BECAUSE_NO_CONFERENCE_RESOURCES_LEFT"</li> <li>✓ "RESOURCE_BECAUSE_NO_TRANSCODING_RESOURCES_LEFT"</li> <li>✓ "RELEASE_BECAUSE_GW_LOCKED"</li> </ul> </li> <li>■ "NO_MATCH": <ul style="list-style-type: none"> <li>✓ "RELEASE_BECAUSE_UNMATCHED_CAPABILITIES"</li> </ul> </li> <li>■ "FORWARDED":</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>✓ "RELEASE_BECAUSE_FORWARD"</li> <li>■ "GENERAL_FAILED": Any other reason</li> </ul> <p><b>Calls with duration:</b></p> <ul style="list-style-type: none"> <li>■ "NORMAL_CALL_CLEAR":</li> <li>✓ "GWAPP_NORMAL_CALL_CLEAR"</li> <li>■ "ABNORMALLY_TERMINATED": Anything else</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "TrmReasonCategory" for syslog and Local Storage, and "Termination Reason" for Web CDR History.</li> <li>■ The maximum number of characters for syslog tabular alignment is 17.</li> </ul>
Termination Reason Value [437]	<p>Displays the Q.850 reason codes (1-127) for call termination. For example, "16" for Normal Termination.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR for RADIUS CDRs.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "h323-disconnect-cause=" (e.g., "h323-disconnect-cause=16").</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Termination Reason [410]	<p>Displays the reason for the call termination. The field value is a string of up to 40 characters and is set to one of the following:</p> <ul style="list-style-type: none"> <li>■ Standard Call Termination Reasons: <ul style="list-style-type: none"> <li>✓ "GWAPP_REASON_NOT_RELEVANT" (0)</li> <li>✓ "GWAPP_ALL_RELEASE_REASONS" (0)</li> <li>✓ "GWAPP_UNASSIGNED_NUMBER" (1)</li> <li>✓ "GWAPP_NO_ROUTE_TO_TRANSIT_NET" (3)</li> <li>✓ "GWAPP_NO_ROUTE_TO_DESTINATION" (3)</li> </ul> </li> </ul>

Field	Description
	✓ "GWAPP_SEND_SPECIAL_INFORMATION_TONE" (4)
	✓ "GWAPP_MISDIALED_TRUNK_PREFIX" (5)
	✓ "GWAPP_CHANNEL_UNACCEPTABLE" (6)
	✓ "GWAPP_CALL_AWARDED_AND" (7)
	✓ "GWAPP_PREEMPTION" (8)
	✓ "GWAPP_PREEMPTION_CIRCUIT_RESERVED_FOR_REUSE" (9)

Termination Side RADIUS [435]	<p>Displays the party that terminated the call. The field value is a string:</p> <ul style="list-style-type: none"> <li>■ "originate": SBC incoming leg or IP side for Gateway calls</li> <li>■ "answer": SBC outgoing leg or Tel side for Gateway calls</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is mainly relevant to RADIUS CDRs, but can also be used in syslog and Local Storage.</li> <li>■ The default field title is "terminator=".</li> <li>■ The maximum number of characters for syslog tabular alignment is 10.</li> </ul>
Termination Side Yes No [436]	<p>Displays the party that terminated the call. The field value is a string:</p> <ul style="list-style-type: none"> <li>■ "yes": SBC outgoing leg or Tel side for Gateway calls</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>■ "no": SBC incoming leg or IP side for Gateway calls</li> </ul> <p>The field is applicable to RADIUS CDRs</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is mainly relevant to RADIUS CDRs, but can also be used in syslog and Local Storage.</li> <li>■ The default field title is "terminator=" (e.g., "terminator=yes").</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Termination Side [409]	<p>Displays the party that terminated the call. The field value is a string:</p> <ul style="list-style-type: none"> <li>■ "LCL": SBC Outgoing leg or Tel side.</li> <li>■ "RMT": SBC Incoming leg or IP side.</li> <li>■ "UNKN": Unknown</li> </ul> <p>For example, if the Orig field is "RMT" and this Termination Side field is "LCL", then the called party ended the call.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs ("CALL_END" CDR Report Types).</li> <li>■ The default field title is "TrmSd".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Transport Type [421]	<p>Displays the SIP signaling transport type protocol. The field value is a string:</p> <ul style="list-style-type: none"> <li>■ "UDP"</li> <li>■ "TCP"</li> <li>■ "TLS"</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "SigTransportType" for Gateway syslog and</li> </ul>

Field	Description
	<p>Local Storage, and "TransportType" for SBC syslog and Local Storage.</p> <ul style="list-style-type: none"> <li>■ The maximum number of characters for syslog tabular alignment is 16.</li> </ul>
Trigger [439]	<p>Displays the reason for the call (i.e., what triggered it):</p> <ul style="list-style-type: none"> <li>■ "Normal": regular call</li> <li>■ "Refer": call transfer</li> <li>■ "AltRoute": alternative routing</li> <li>■ "Forward": call forward</li> <li>■ "Reroute": When a broken connection on the outgoing leg occurs, the call is rerouted to another destination according to the IP-to-IP Routing table (where matching characteristics includes the trigger for reroute).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling and GatewayCDRs (all CDR Report Types).</li> <li>■ The default field title is "Trigger".</li> <li>■ The maximum number of characters for syslog tabular alignment is 8.</li> </ul>
Trunk Group ID [503]	<p>Displays the Trunk Group ID (integer).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "TG".</li> <li>■ The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Trunk ID [500]	<p>Displays the physical trunk number (integer).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to Gateway CDRs (all CDR Report Types).</li> <li>■ The default field title is "Trunk".</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>
Var Call User Defined 1-5 [448-452]	<p>Displays the SIP header data obtained from using call variables (Var.Call.Src/Dst.UserDefined1-5) in Message Manipulation rules.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>The field is applicable only to SBC signaling and Gateway CDRs (all CDR Report Types).</li> <li>The field is applicable only to syslog, RADIUS, Local Storage, and JSON.</li> <li>For each variable-based field, the maximum number of characters for syslog tabular alignment is 20.</li> <li>The maximum characters for all five variable-based CDR fields combined is 200. For example, if the summation of Var Call User Defined 1 and Var Call User Defined 2 is 1,024 characters, no characters are displayed for the other variables.</li> </ul>
Was Call Started [415]	<p>Displays if the call was started or not (i.e., if a "CALL_START" CDR Report was generated).</p> <ul style="list-style-type: none"> <li>"0": No INVITE was sent to the IP side for the Tel-to-IP call, or no Setup message was sent to the Tel side for the IP-to-Tel call. Note that the first "CALL_START" CDR report type of a new signaling leg has value "0".</li> <li>"1": The call was started – an INVITE was sent to the IP side for the Tel-to-IP call, or a Setup message was sent to the Tel side for the IP-to-Tel call.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table and Gateway CDR Format table.</li> <li>The field is applicable only to SBC signaling and Gateway CDRs ("CALL_END" CDR Report Types).</li> <li>The field is applicable only to syslog, RADIUS, and Local Storage.</li> <li>The maximum number of characters for syslog tabular alignment is 5.</li> </ul>

Field	Description
Coder Transcoding [635]	<p>Displays whether there was coder transcoding for the SBC call. The field is a string:</p> <ul style="list-style-type: none"> <li>■ "TRANSCODING"</li> <li>■ "NO_TRANSCODING"</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC media CDRs ("MEDIA_END" CDR Report Types).</li> <li>■ The field is applicable only to syslog and RADIUS.</li> <li>■ The maximum number of characters for syslog tabular alignment is 17.</li> </ul>
Voice AI Connector ID [820]	<p>Displays the ID of the VoiceAI Connect when the device is used as a VoiceAI Connect Gateway.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>■ The field is applicable only to SBC signaling (all CDR Report Types).</li> <li>■ The default field title is "VoiceAIConnectorName".</li> <li>■ For more information on the VoiceAI Connect, click <a href="#">here</a>.</li> </ul>
Voice AI Connector Name [821]	<p>Displays the name of the VoiceAI Connect when the device is used as a VoiceAI Connect Gateway.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, the field is included in the CDR.</li> <li>■ The field is applicable only to SBC signaling (all CDR Report Types).</li> <li>■ The default field title is "VoiceAIConnectorName".</li> <li>■ For more information on the VoiceAI Connect, click <a href="#">here</a>.</li> </ul>
Tenant ID [823]	<p>Displays the Tenant ID, which is typically used by OVOC. The value is obtained from the SIP message (header data) using Message Manipulation rules with the call variable <i>Var.Call.Src/Dst.TenantId</i>.</p> <ul style="list-style-type: none"> <li>■ The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> </ul>

Field	Description
	<ul style="list-style-type: none"> <li>The field is applicable only to SBC signaling ("CALL_CONNECT" and "CALL_END" CDR Report Types).</li> <li>The maximum number of characters for syslog tabular alignment is 71.</li> </ul>
Released From IP [824]	<p>Displays if the call was terminated by the device (i.e., internal reason, for example, register user not found), or by the callee or called party. The field is a string:</p> <ul style="list-style-type: none"> <li>"Yes" = Call was terminated by the callee or called party.</li> <li>"No" = Call was terminated by the device.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The field is optional. You can include it in the CDR by CDR customization using the SBC CDR Format table.</li> <li>The field is applicable only to SBC signaling CDRs ("CALL_END" CDR Report Type).</li> </ul>

## Customizing CDRs for Gateway Calls

The Gateway CDR Format table lets you configure CDR customization rules for Gateway-related CDRs that are generated by the device for the following:

- CDRs (media and SIP signaling) sent in syslog messages. For CDRs sent in syslog messages, you can customize the name of CDR fields. You can configure up to 128 Syslog CDR customization rules.
- CDRs related to RADIUS accounting and sent in RADIUS accounting request messages. For RADIUS accounting CDRs, you can customize the RADIUS Attribute's prefix name and ID, for standard RADIUS Attributes and vendor-specific RADIUS Attributes (VSA). For example, instead of the default VSA name, "h323-connect-time" with RADIUS Attribute ID 28, you can change the name to "Call-Connect-Time" with ID 29. You can configure up to 40 RADIUS-accounting CDR customization rules. For more information on RADIUS accounting, see [Configuring RADIUS Accounting](#) on page 1588.
- CDRs stored locally on the device. For local storage of CDRs, you can customize the name of CDR fields. You can configure up to 64 locally-stored CDR customization rules. For more information on local storage of CDRs, see [Storing CDRs Locally on the Device](#) on page 1516.
- CDRs (signaling only) sent to the REST server in JSON format using the device's REST API. You can configure up to 64 JSON CDR customization rules. For more information on CDRs and REST, see [Configuring CDR Reporting to REST Server](#) on page 1515.

Customizing the CDR means the following:

- Defining which CDR fields are included in the CDR. For example, if you configure only one customization rule for the Syslog CDR type with the Call Duration CDR field, the device generates these CDR types with only this single CDR field.

You can also customize the CDR to include the User-Defined CDR fields whose value is obtained from SIP messages (e.g., a specific header), using Message Manipulation rules with call variables. The call variables store the value and then the device adds the stored value to these special CDR fields when the CDR is generated. You can configure up to five User-Defined CDR fields, titled "Var Call User Defined <1-5>", which you can optionally include in the CDR.

To obtain the values from the SIP message for these CDR fields, use the following call variable syntax in your Message Manipulation rules:

```
Var.Call.Dst.UserDefined<1-5>
```

To apply the Message Manipulation rule (set) to the incoming or outgoing SIP message, using the [GWInboundManipulationSet] or [GWOOutboundManipulationSet] parameter, respectively.

For a configuration example, see [CDR Customization using Call Variables Example](#) on page 1585.

- Changing the default name (`title`) of the CDR field. For example, you can change the title of the Call Duration CDR field to "Call Length".
- (RADIUS Only) Changing the RADIUS Attribute's prefix name and ID, for standard RADIUS Attributes and vendor-specific RADIUS Attributes (VSA).

- If you don't customize the CDR for a specific CDR type, the device generates the CDR in a default format (fields and titles). For a detailed description of the fields that can be included in the CDR (customized and default), see [CDR Field Description](#) on page 1519.
- To return to the default CDR format for a specific CDR type, remove all your customization rules of that CDR type.

- To view Gateway CDRs in the Web interface, see [Viewing Gateway CDR History](#) on page 1493.
- The following standard RADIUS Attributes cannot be customized: 1 through 6, 18 through 20, 22, 23, 27 through 29, 32, 34 through 39, 41, 44, 52, 53, 55, 60 through 85, 88, 90, and 91.
- If the RTCP XR feature is unavailable (not licensed or disabled), the R-factor VoIP metrics are not provided in CDRs (CDR fields, Local R Factor and Remote R Factor) generated by the device. Instead, these CDR fields are sent with the value 127, meaning that information is unavailable.
- To customize CDRs for Test Calls, use the SBC CDR Format table (see [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578).

The following procedure describes how to customize Gateway CDRs through the Web interface. You can also configure it through ini file [GWCDRFormat] or CLI (configure troubleshoot > cdr > cdr-format gw-cdr-format).

➤ **To customize Gateway CDRs:**

1. Open the Gateway CDR Format table (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Gateway CDR Format**).
2. Click **New**; the following dialog box appears:

3. Configure CDR format rules according to the parameters described in the table below.
4. Click **Apply**.

An example of CDR customization rules configured in the table is shown below:

INDEX ↕	CDR TYPE	FIELD TYPE	TITLE	RADIUS ATTRIBUTE TYPE	RADIUS ATTRIBUTE ID
0	Syslog Gateway	Call Orig	Caller	Standard	0
1	Syslog Gateway	Destination IP	"Destination IP Address"	Vendor Specific	0
2	Syslog Gateway	Setup Time	setup-time=	Standard	0
3	Local Storage Gateway	Call Duration	call-duration=	Standard	0

- Index 0: The default CDR field "Call Orig" for syslog is changed to "Caller".
- Index 1: The default CDR field "Destination IP" for syslog is changed to "Destination IP Address" (enclosed by quotation marks).
- Index 2: The default CDR field "Setup Time" for syslog is changed to "setup-time=".
- Index 3: The default CDR field "Call Duration" for local CDR storage is changed to "call-duration=".

**Table 60-3: Gateway CDR Format Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'CDR Type' cdr-type [CDRType]	Defines the application type for which you want to customize CDRs.  <ul style="list-style-type: none"> <li>■ [0] <b>Syslog Gateway</b> = (Default) Customizes CDR field names for CDRs (media and signaling) sent in syslog messages.</li> <li>■ [6] <b>RADIUS Gateway</b> = Customizes CDR field names (RADIUS Attribute prefix names) for CDRs (media and signaling) sent in RADIUS accounting requests.</li> <li>■ [9] <b>Local Storage Gateway</b> = Customizes CDR fields (media and signaling) that are stored locally on the device.</li> <li>■ [10] <b>JSON Gateway</b> = Customizes CDR field names for CDRs (signaling only) that are sent in JSON format to the REST server using the device's REST API.</li> </ul>
'Field Type' col-type [FieldType]	Defines the CDR field (column) that you want to customize. [300] <b>CDR Type</b> (default); [301] <b>Call ID</b> ; [302] <b>Session ID</b> ; [303] <b>Report Type</b> ; [304] <b>Media Type</b> ; [305] <b>Accounting Status Type</b> ; [306] <b>H323 ID</b> ; [307] <b>RADIUS Call ID</b> ; [308] <b>Blank</b> ; [309] <b>Global Session ID</b> ; [310] <b>Leg ID</b> ; [400] <b>Endpoint Type</b> ; [401] <b>Call Orig</b> ; [402] <b>Source IP</b> ; [403] <b>Destination IP</b> ; [404] <b>Remote IP</b> ; [405] <b>Source Port</b> ; [406] <b>Dest Port</b> ; [407] <b>Remote Port</b> ; [408] <b>Call Duration</b> ; [409] <b>Termination Side</b> ; [410] <b>Termination Reason</b> ; [411] <b>Setup Time</b> ; [412] <b>Connect Time</b> ; [413] <b>Release Time</b> ; [414] <b>Redirect Reason</b> ; [415] <b>Was Call Started</b> ; [416] <b>IP Group ID</b> ; [417] <b>IP Group Name</b> ; [418] <b>SRD ID</b> ; [419] <b>SRD Name</b> ; [420] <b>SIP Interface ID</b> ; [421] <b>Transport Type</b> ; [422] <b>Signaling IP DiffServ</b> ; [423] <b>Termination Reason Category</b> ; [424] <b>Proxy Set ID</b> ; [425] <b>IP Profile ID</b> ; [426] <b>IP Profile Name</b> ; [427] <b>Media Realm ID</b> ; [428] <b>Media Realm Name</b> ; [429] <b>SIP Termination Reason</b> ; [430] <b>SIP Termination Description</b> ; [431] <b>Caller Display ID</b> ; [432] <b>Callee Display ID</b> ; [433] <b>SIP Interface Name</b> ; [434] <b>Call Orig RADIUS</b> ; [435] <b>Termination Side RADIUS</b> ; [436] <b>Termination Side Yes No</b> ; [437]

Parameter	Description
	<p>Termination Reason Value; [438] Proxy Set Name; [439] Trigger; [442] Call End Sequence Number; [443] Alerting Time; [445] SIP Local Tag; [446] SIP Remote Tag; [447] Call Success; [448] Var Call User Defined 1; [449] Var Call User Defined 2; [450] Var Call User Defined 3; [451] Var Call User Defined 4; [452] Var Call User Defined 5; [500] Trunk ID; [501] B-Channel; [502] Conn ID; [503] Trunk Group ID; [504] Metering Pulses Generated; [505] Fax On Call; [506] Source Number Before Manipulation; [507] Source Number; [508] Source Number Type; [509] Source Number Plan; [510] Destination Number Before Manipulation; [511] Destination Number; [512] Destination Number Type; [513] Destination Number Plan; [514] Redirect Number Before Manipulation; [515] Redirect Number; [526] Redirect Number Type; [527] Redirect Number Plan; [516] Source Host Name Before Manipulation; [517] Source Host Name; [518] Destination Host Name Before Manipulation; [519] Destination Host Name; [520] PSTN Termination Reason; [521] Module And Port; [522] AOC Currency; [523] AOC Amount; [524] AOC Multiplier; [525] ISDN Line Type; [600] Channel ID; [601] Coder Type; [602] Packet Interval; [603] Payload Type; [604] Local Input Packets; [605] Local Output Packets; [606] Local Input Octets; [607] Local Output Octets; [608] Local Packet Loss; [609] Local Round Trip Delay; [610] Local Jitter; [611] Local SSRC Sender; [612] Remote Input Packets; [613] Remote Output Packets; [614] Remote Input Octets; [615] Remote Output Octets; [616] Remote Packet Loss; [617] Remote Round Trip Delay; [618] Remote Jitter; [619] Remote SSRC Sender; [620] Local RTP IP; [621] Local RTP Port; [622] Remote RTP IP; [623] Remote RTP Port; [624] RTP IP DiffServ; [625] Local R Factor; [626] Remote R Factor; [627] Local MOS CQ; [628] Remote MOS CQ; [629] AMD Decision; [630] AMD Decision Probability; [631] Latched RTP IP; [632] Latched RTP Port; [633] Latched T38 IP; [634] Latched T38 Port.</p>
<p>'Title'</p> <p>title</p> <p>[Title]</p>	<p>Defines a new name for the CDR field (for syslog) or for the RADIUS Attribute prefix name (for RADIUS accounting) that you selected in the 'Column Type' parameter.</p> <p>The valid value is a string of up to 31 characters.</p> <p>You can configure the name to be enclosed by quotation marks (single or double). For example, if you want the CDR</p>

Parameter	Description
	<p>field name to appear as 'Phone Duration', you must configure the parameter to 'Phone Duration'. You can also configure the CDR field name with an equals (=) sign, for example "call-connect-time=".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For RADIUS Attributes that do not require a prefix name, leave the parameter undefined.</li> <li>■ The parameter's value is case-sensitive. For example, if you want the CDR field name to be Phone-Duration, you must configure the parameter to "Phone-Duration" (i.e., uppercase "P" and "D").</li> </ul>
'RADIUS Attribute Type' radius-type [RadiusType]	<p>Defines whether the RADIUS Attribute of the CDR field is a standard or vendor-specific attribute.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Standard</b> = (Default) For standard RADIUS Attributes.</li> <li>■ [1] <b>Vendor Specific</b> = For vendor-specific RADIUS Attributes (VSA).</li> </ul> <p><b>Note:</b> The parameter is applicable only for RADIUS accounting (i.e., 'CDR Type' parameter configured to <b>RADIUS Gateway</b>).</p>
'RADIUS Attribute ID' radius-id [RadiusID]	<p>Defines an ID for the RADIUS Attribute. For vendor-specific Attributes, this represents the VSA ID; for standard attributes, this represents the Attribute ID (first byte of the Attribute).</p> <p>The valid value is 0 to 255 (one byte). The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only for RADIUS accounting (i.e., 'CDR Type' parameter configured to <b>RADIUS Gateway</b>).</li> <li>■ For VSA's (i.e., 'RADIUS Attribute Type' parameter configured to <b>Vendor Specific</b>), the parameter must be configured to any value other than 0.</li> <li>■ For standard RADIUS Attributes (i.e., 'RADIUS Attribute Type' parameter configured to <b>Standard</b>), the value <b>must</b> be a "known" RADIUS ID (per RFC for RADIUS). However, if you configure the ID to 0 (default) for any of the RADIUS Attributes (configured in the 'Column Type'</li> </ul>

Parameter	Description
	<p>parameter) listed below and then apply your rule (Click <b>Apply</b>), the device automatically replaces the value with the RADIUS Attribute's ID according to the RFC:</p> <ul style="list-style-type: none"> <li>✓ <b>Destination Number:</b> 30</li> <li>✓ <b>Source Number:</b> 31</li> <li>✓ <b>Accounting Status Type:</b> 40</li> <li>✓ <b>Local Input Octets:</b> 42</li> <li>✓ <b>Local Output Octets:</b> 43</li> <li>✓ <b>Call Duration:</b> 46</li> <li>✓ <b>Local Input Packets:</b> 47</li> <li>✓ <b>Local Output Packets:</b> 48</li> </ul> <p>If you configure the value to 0 and the RADIUS Attribute is not any of the ones listed above, the configuration is invalid.</p>

## Customizing CDRs for SBC Calls and Test Calls

The SBC CDR Format table lets you customize CDRs for SBC calls and CDRs for Test Calls that are generated by the device for the following CDR types:

- CDRs for SIP signaling or media sent in syslog messages. For CDRs sent in syslog messages, you can customize the name of the CDR field. You can configure up to 128 Syslog CDR customization rules.
- CDRs for RADIUS accounting and sent in RADIUS accounting request messages. For RADIUS accounting CDRs, you can customize the RADIUS Attribute's prefix name and RADIUS Attribute's ID, for standard RADIUS Attributes and vendor-specific RADIUS Attributes (VSA). For example, instead of the default VSA name "h323-connect-time" with RADIUS Attribute ID 28, you can change the name to "Call-Connect-Time" with ID 29. You can configure up to 70 RADIUS-Accounting CDR customization rules (i.e., maximum number of RADIUS Attributes that the device can include in the CDR). For more information on RADIUS accounting, see [Configuring RADIUS Accounting](#) on page 1588.
- CDRs stored locally on the device. For local storage of CDRs, you can customize the name of the CDR field. You can configure up to 64 locally-stored CDR customization rules. For more information on storing CDRs on the device, see [Storing CDRs Locally on the Device](#) on page 1516.
- CDRs (signaling only) sent to the REST server in JSON format using the device's REST API. You can configure up to 64 JSON CDR customization rules. For more information on CDRs and REST, see [Configuring CDR Reporting to REST Server](#) on page 1515.

Customizing the CDR means the following:

- Defining which CDR fields are included in the CDR. For example, if you configure only one customization rule for the syslog signaling (SBC) CDR type with the 'Call Duration' CDR field, the device generates these CDR types with only this single CDR field.

You can also customize the CDR to include the following CDR fields whose value is obtained from the SIP message, using Message Manipulation rules with call variables that store the value. The device adds the stored value to these special CDR fields when the CDR is generated:

- **User-defined CDR Fields:** The device provides up to five user-defined CDR fields titled "Var Call User Defined <1-5>", which you can optionally include in the generated CDR. To obtain the values from the SIP message for these CDR fields, use the following call variable syntax in your Message Manipulation rules:

```
Var.Call.Src|Dst.UserDefined<1-5>
```

For an example, see [CDR Customization using Call Variables Example](#) on page 1585.

- **Tenant ID CDR Field:** You can customize the CDR to include the 'Tenant ID' CDR field, which is typically used by OVOC. To obtain the value from the SIP message for this CDR field, use the following call variable syntax in your Message Manipulation rule:

```
Var.Call.Src|Dst.TenantId
```

For more information on SIP Message Manipulation, see [Configuring SIP Message Manipulation](#) on page 856.

- Changing the default name (`title`) of the CDR field. For example, you can change the title of the Call Duration CDR field to "Call Length".
- Changing the RADIUS Attribute's prefix name and ID, for standard RADIUS Attributes and vendor-specific RADIUS Attributes (VSA).

- If you don't customize the CDR, the device generates the CDR in a default format (fields and titles). For a detailed description of the fields that can be included in the CDR (customized and default), see [CDR Field Description](#) on page 1519.
- To return to the default CDR format for a specific CDR type, remove all the customization rules of that CDR type.
- When customizing the RADIUS CDR:
  - ✓ The following standard RADIUS Attributes cannot be customized: 1 through 6, 18 through 20, 22, 23, 27 through 29, 32, 34 through 39, 41, 44, 52, 53, 55, 60 through 85, 88, 90, and 91.
  - ✓ You must add the following RADIUS Attribute as the **first** rule in the SBC CDR Format table to ensure uniqueness (and to differentiate) between Call Connect (START) and Call End (STOP) RADIUS packets:

GENERAL	
Index	0
CDR Type	RADIUS SBC
Field Type	Accounting Status Type
Title	
RADIUS Attribute Type	Standard
RADIUS Attribute ID	40

- If the RTCP XR feature is unavailable (not licensed or disabled), the R-factor VoIP metrics are not provided in CDRs (CDR fields, Local R Factor and Remote R Factor) generated by the device. Instead, these CDR fields are sent with the value 127, meaning that information is unavailable.
- Test Call CDRs include "CALL\_START", "CALL\_CONNECT" and "CALL\_END" CDR Report Types.
- By default, SBC signaling CDRs that are sent at the end of the call ("CALL\_END" CDR Report Type) include only signaling-related CDR fields. However, by using the SBC CDR Format table, you can customize this CDR to also include media-related fields.
- To view historical CDRs stored on the device see [Viewing CDR History of SBC and Test Calls](#) on page 1495.

The following procedure describes how to customize SBC and Test Call CDRs through the Web interface. You can also configure it through ini file [SBCCDRFormat] or CLI (`configure troubleshoot > cdr > cdr-format sbc-cdr-format`).

#### ➤ To customize SBC and Test Call CDRs:

1. Open the SBC CDR Format table (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **SBC CDR Format**).
2. Click **New**; the following dialog box appears:

3. Configure the CDR according to the parameters described in the table below.

4. Click **Apply**.

Examples of configured CDR customization rules are shown below:

INDEX	CDR TYPE	FIELD TYPE	TITLE	RADIUS ATTRIBUTE TYPE	RADIUS ATTRIBUTE ID
0	Syslog SBC	Source IP	"Source IP Address"	Standard	0
1	RADIUS SBC	Release Time	disconnect-time=	Vendor Specific	29
2	Local Storage SBC	Call Duration	Lenght of Call	Standard	0

**Table 60-4: SBC CDR Format Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'CDR Type' cdr-type [CDRType]	Defines the application type for which you want to customize CDRs. <ul style="list-style-type: none"> <li>[1] <b>Syslog SBC</b> = (Default) Customizes CDR fields for SIP signaling-related CDRs sent in syslog messages. However, for SBC signaling "CALL_END" CDR Report Types (sent at the end of the call), you can also customize the CDR to include media-related CDR fields (e.g., Local Packet Loss).</li> <li>[3] <b>Syslog Media</b> = Customizes CDR fields for media-related CDRs sent in syslog messages.</li> <li>[5] <b>Local Storage SBC</b> = Customizes CDR fields that are stored locally on the device. Only signaling-related CDRs are stored locally on the device. However, for SBC signaling "CALL_END" CDR Report Types (sent at the end of the call), you can also customize the CDR to include media-related CDR fields (e.g., Local Packet Loss).</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [7] <b>RADIUS SBC</b> = Customizes CDR fields (i.e., RADIUS Attributes) for CDRs sent in RADIUS accounting request messages.</li> <li>■ [11] <b>JSON SBC</b> = Customizes CDR fields for SIP signaling-related CDRs that are sent in JSON format to the REST server using the device's REST API.</li> </ul>
'Field Type' col-type [FieldType]	<p>Defines the CDR field (column) that you want to customize. The applicable CDR field depends on the settings of the 'CDR Type' parameter:</p> <ul style="list-style-type: none"> <li>■ For all types: [300] <b>CDR Type</b> (default); [301] <b>Call ID</b>; [302] <b>Session ID</b>; [303] <b>Report Type</b>; [304] <b>Media Type</b>; [305] <b>Accounting Status Type</b>; [306] <b>H323 ID</b>; [307] <b>RADIUS Call ID</b>; [308] <b>Blank</b>; [309] <b>Global Session ID</b>; [310] <b>Leg ID</b></li> <li>■ <b>Syslog SBC</b> (signaling), <b>Local Storage SBC</b>, <b>RADIUS SBC</b>, and <b>JSON SBC</b>: <ul style="list-style-type: none"> <li>[400] <b>Endpoint Type</b>; [401] <b>Call Orig</b>; [402] <b>Source IP</b>; [403] <b>Destination IP</b>; [404] <b>Remote IP</b>; [405] <b>Source Port</b>; [406] <b>Dest Port</b>; [407] <b>Remote Port</b>; [408] <b>Call Duration</b>; [409] <b>Termination Side</b>; [410] <b>Termination Reason</b>; [411] <b>Setup Time</b>; [412] <b>Connect Time</b>; [413] <b>Release Time</b>; [414] <b>Redirect Reason</b>; [415] <b>Was Call Started</b>; [416] <b>IP Group ID</b>; [417] <b>IP Group Name</b>; [418] <b>SRD ID</b>; [419] <b>SRD Name</b>; [420] <b>SIP Interface ID</b>; [421] <b>Transport Type</b>; [422] <b>Signaling IP DiffServ</b>; [423] <b>Termination Reason Category</b>; [424] <b>Proxy Set ID</b>; [425] <b>IP Profile ID</b>; [426] <b>IP Profile Name</b>; [427] <b>Media Realm ID</b>; [428] <b>Media Realm Name</b>; [429] <b>SIP Termination Reason</b>; [430] <b>SIP Termination Description</b>; [431] <b>Caller Display ID</b>; [432] <b>Callee Display ID</b>; [433] <b>SIP Interface Name</b>; [434] <b>Call Orig RADIUS</b>; [435] <b>Termination Side RADIUS</b>; [436] <b>Termination Side Yes No</b>; [437] <b>Termination Reason Value</b>; [438] <b>Proxy Set Name</b>; [439] <b>Trigger</b>; [442] <b>Call End Sequence Number</b>; [443] <b>Alerting Time</b>; [445] <b>SIP Local Tag</b>; [446] <b>SIP Remote Tag</b>; [447] <b>Call Success</b>; [448] <b>Var Call User Defined 1</b>; [449] <b>Var Call User Defined 2</b>; [450] <b>Var Call User Defined 3</b>; [451] <b>Var Call User Defined 4</b>; [452] <b>Var Call User Defined 5</b></li> </ul> </li> <li>■ <b>Syslog Media</b>, <b>RADIUS SBC</b>, <b>Local Storage SBC</b>, and <b>Syslog SBC</b>: <ul style="list-style-type: none"> <li>[600] <b>Channel ID</b>; [601] <b>Coder Type</b>; [602] <b>Packet Interval</b>; [603] <b>Payload Type</b>; [604] <b>Local Input Packets</b>; [605] <b>Local Output Packets</b>; [606] <b>Local Input Octets</b>; [607] <b>Local Output Octets</b>; [608] <b>Local Packet Loss</b>; [609] <b>Local Round Trip Delay</b>; [610] <b>Local Jitter</b>; [611] <b>Local SSRC Sender</b>; [612] <b>Remote Input Packets</b>; [613] <b>Remote Out-</b></li> </ul> </li> </ul>

Parameter	Description
	<p><b>put Packets; [614] Remote Input Octets; [615] Remote Output Octets; [616] Remote Packet Loss; [617] Remote Round Trip Delay; [618] Remote Jitter; [619] Remote SSRC Sender; [620] Local RTP IP; [621] Local RTP Port; [622] Remote RTP IP; [623] Remote RTP Port; [624] RTP IP DiffServ; [625] Local R Factor; [626] Remote R Factor; [627] Local MOS CQ; [628] Remote MOS CQ; [629] AMD Decision; [630] AMD Decision Probability; [631] Latched RTP IP; [632] Latched RTP Port; [633] Latched T38 IP; [634] Latched T38 Port; [635] Coder Transcoding</b></p> <p><b>Note:</b> For 'CDR Types' <b>Syslog SBC</b>, <b>Local Storage SBC</b>, and <b>RADIUS SBC</b>, the above media-related CDR fields are added only to "CALL_END" SBC signaling CDR report Types (which by default, include only signaling CDR fields).</p> <p>■ <b>Syslog SBC (signaling), Local Storage SBC, RADIUS SBC, and JSON SBC:</b></p> <p>[800] <b>Source URI</b>; [801] <b>Destination URI</b>; [802] <b>Source URI Before Manipulation</b>; [803] <b>Destination URI Before Manipulation</b>; [804] <b>Redirect URI</b>; [805] <b>Redirect URI Before Manipulation</b>; [806] <b>SIP Method</b>; [807] <b>Direct Media</b>; [808] <b>Source Username</b>; [809] <b>Destination Username</b>; [810] <b>Source Username Before Manipulation</b>; [811] <b>Destination Username Before Manipulation</b>; [812] <b>Source Host</b>; [813] <b>Destination Host</b>; [814] <b>Source Host Before Manipulation</b>; [815] <b>Destination Host Before Manipulation</b>; [816] <b>Source Dial Plan Tags</b>; [817] <b>Destination Dial Plan Tags</b>; [818] <b>Remote SIP User Agent</b>; [819] <b>Media List</b>; [820] <b>Voice AI Connector ID</b>; [821] <b>Voice AI Connector Name</b>; [822] <b>Is Recorded</b>; [823] <b>Tenant ID</b>; [824] <b>Released From IP</b>.</p>
'Title' title [Title]	<p>Defines a new name for the CDR field (for Syslog or local storage) or for the RADIUS Attribute prefix name (for RADIUS accounting) that you selected in the 'Column Type' parameter.</p> <p>The valid value is a string of up to 31 characters. You can also configure the name to be enclosed by quotation marks (single or double). For example, if you want the CDR field name to appear as 'Phone Duration', you must configure the parameter to 'Phone Duration'. You can also configure the CDR field name with an equals (=) sign, for example "call-connect-time=".</p> <p><b>Note:</b></p> <p>■ For VSA's that do not require a prefix name, leave the parameter undefined.</p> <p>■ The parameter's value is case-sensitive. For example, if you want the</p>

Parameter	Description
	CDR field name to be Phone-Duration, you must configure the parameter to "Phone-Duration" (i.e., uppercase "P" and "D").
'RADIUS Attribute Type' radius-type [RadiusType]	<p>Defines whether the RADIUS Attribute of the CDR field is a standard or vendor-specific attribute.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Standard</b> = (Default) For standard RADIUS Attributes.</li> <li>■ [1] <b>Vendor Specific</b> = For vendor-specific RADIUS Attributes (VSA).</li> </ul> <p><b>Note:</b> The parameter is applicable only to RADIUS accounting (i.e., 'CDR Type' parameter configured to <b>RADIUS SBC</b>).</p>
'RADIUS Attribute ID' radius-id [RadiusID]	<p>Defines an ID for the RADIUS Attribute. For VSAs, this represents the VSA ID; for standard Attributes, this represents the Attribute ID (first byte of the Attribute).</p> <p>The valid value is 0 to 255 (one byte). The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to RADIUS accounting (i.e., 'CDR Type' parameter configured to <b>RADIUS SBC</b>).</li> <li>■ For VSA's (i.e., 'RADIUS Attribute Type' parameter configured to <b>Vendor Specific</b>), the parameter must be configured to any value other than 0.</li> <li>■ For standard RADIUS Attributes (i.e., 'RADIUS Attribute Type' parameter configured to <b>Standard</b>), the value <b>must</b> be a "known" RADIUS ID (per RFC for RADIUS). However, if you configure the ID to 0 (default) for any of the RADIUS Attributes (configured in the 'Column Type' parameter) listed below and then apply your rule (Click <b>Apply</b>), the device automatically replaces the value with the RADIUS Attribute's ID according to the RFC: <ul style="list-style-type: none"> <li>✓ <b>Destination Username:</b> 30</li> <li>✓ <b>Source Username:</b> 31</li> <li>✓ <b>Accounting Status Type:</b> 40</li> <li>✓ <b>Local Input Octets:</b> 42</li> <li>✓ <b>Local Output Octets:</b> 43</li> <li>✓ <b>Call Duration:</b> 46</li> <li>✓ <b>Local Input Packets:</b> 47</li> <li>✓ <b>Local Output Packets:</b> 48</li> </ul> </li> </ul> <p>If you configure the value to 0 and the RADIUS Attribute is not any of</p>

Parameter	Description
	the ones listed above, the configuration is invalid.

## CDR Customization using Call Variables Example

This section provides an example of customizing the CDR to include the 'Var Call User Defined <1-5>' field, whose value is obtained using call variables in Message Manipulation rules.

The example includes the following:

- Uses the call variable `Var.Call.Src.UserDefined1` (for SBC calls) or `Var.Call.Dst.UserDefined1` (for Gateway calls) in a Message Manipulation rule to store the value of the SIP header "X-AccountNumber" received in a 200 OK response.
- Customizes the CDR format to add the CDR field "Var Call User Defined 1", renames it "Account", and obtains its value from the call variable above.

### ➤ To customize CDR using call variable:

1. In the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856), configure the following rule:
  - 'Index': **0**
  - 'Name': **Store X-AccountNumber header**
  - 'Manipulation Set ID': **5**
  - 'Message Type': **Invite.Response.2xx**
  - 'Action Subject': **Var.Call.Src.UserDefined1** (for SBC calls) or **Var.Call.Dst.UserDefined1** (for Gateway calls)
  - 'Action Type': **Modify**
  - 'Action Value': **Header.X-AccountNumber**
2. In the SBC CDR Format table or Gateway CDR Format table, configure the following rule:
  - 'Index': **0**
  - 'CDR Type': **Syslog SBC** (SBC CDR Format table) or **Syslog Gateway** (Gateway CDR Format table)
  - 'Field Type': **Var Call User Defined 1**
  - 'Title': **Account**
3. (Gateway calls only) Configure the [GWInboundManipulationSet] parameter to "5" (i.e., value of 'Manipulation Set' parameter, above).

The following shows an example of a received SIP 200 OK response message with the X-InContact-BusNo header:

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 172.28.244.31:5060;branch=z9hG4bKac166782921
Contact: <sip:Stack@10.21.19.151:5060>
To: <sip:+18017155444@abc.com>;tag=87245f3d
From: "usera"<sip:usera@abc.com>;tag=1c1187059515
Call-ID: 628022773122202022133@172.28.244.31
CSeq: 1 INVITE
Session-Expires: 1200;refresher=uas
Content-Type: application/sdp
Supported: timer
X-AccountNumber: 87654321
```

The following shows the generated CDR:

```
|Orig |Account|
|LCL |87654321|
```

## Customizing CDR Indication for Call Success or Failure based on Responses

The CDR can indicate if a call was a success ("yes") or failure ("no"), using the 'Call Success' CDR field. This is an optional field that you can include in CDRs, by customizing the CDR format (as described in [Customizing CDRs for Gateway Calls](#) on page 1572 [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578).

The device determines if a call is a success or failure based on the release (termination) reason of the call, which can be a SIP response code received from the SIP User Agent or an internal response generated by the device. However, you can change the device's default mapping of call success and failure with these responses. For example, by default, the device considers a call that is released with a SIP 404 (Not Found) response as a call failure (i.e., 'Call Success' CDR field displays "no"). Using this feature, you can configure the device to consider SIP 404 responses as a call success.

### ➤ To customize CDR indication for call success and failure:

1. Open the Call Detail Record Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Call Detail Record Settings**).
2. To customize call success or failure indication for SIP reasons:
  - In the 'Call Success SIP Reasons' [CallSuccessSIPReasons] field, configure the SIP response codes that you want the device to consider as call success.
  - In the 'Call Failure SIP Reasons' [CallFailureSIPReasons] field, configure the SIP response codes that you want the device to consider as call failure.

Call Success SIP Reasons

Call Failure SIP Reasons

- If your configuration results in overlapping reasons between the two parameters above, preference is given to the parameter with the specific response code instead of the parameter with the range ("xx"). For example, if 'Call Success SIP Reasons' is configured to "404,5xx" and 'Call Failure SIP Reasons' to "502", a call with SIP response code 502 is considered a call failure, as the 'Call Failure SIP Reasons' parameter is configured with the specific code while the 'Call Success SIP Reasons' is configured with the code range (5xx).
- By default, the device considers these SIP response codes as a call success:
  - ✓ No answer (452 and 487)
  - ✓ Busy (486 and 600)
  - ✓ Forwarded (300, 301, 302, 303, and 305)For all other SIP failure response codes, the device considers them as call failure.

3. To customize call success or failure indication for internal reasons:

- In the 'Call Success Internal Reasons' [CallSuccessInternalReasons] field, configure the internal response codes that you want the device to consider as call success.
- In the 'Call Failure Internal Reasons' [CallFailureInternalReasons] field, configure the internal response codes that you want the device to consider as call failure.

Call Success Internal Reasons

Call Failure Internal Reasons

For a list of the internal response codes, see the 'Termination Reason' [410] CDR field in [CDR Field Description](#) on page 1519.

4. To customize call success or failure indication for the internal response "GWAPP\_NO\_USER\_RESPONDING" (18) before or after call connect (SIP 200 OK):

- From the 'No User Response Before Connect' [NoUserResponseBeforeConnectSuccess] drop-down list, select **Call Failure** if you want the device to consider a call as a failure when this response is received before call connect.
- From the 'No User Response After Connect' [NoUserResponseAfterConnectSuccess] drop-down list, select **Call Success** if you want the device to consider a call as a success when this response is received after call connect.

No User Response Before Connect

No User Response After Connect

5. To customize call success or failure indication for the internal response 'RELEASE\_BECAUSE\_CALL\_TRANSFERRED' (807) before or after call connect (SIP 200 OK):
  - From the 'Call Transferred before Connect' [CallTransferredBeforeConnectSuccess] drop-down list, select **Call Success** if you want the device to consider the call as a success when this response is received before call connect (SIP 200 OK).
  - From the 'Call Transferred after Connect' [CallTransferredAfterConnectSuccess] drop-down list, select **Call Failure** if you want the device to consider the call as a failure when this response is received after call connect (SIP 200 OK).

**Call Transferred Before Connect**

Call Failure

**Call Transferred After Connect**

Call Success

## Configuring RADIUS Accounting

The device supports RADIUS Accounting (per RFC 2866) and sends accounting data of SIP calls as call detail records (CDR) to a RADIUS Accounting server. CDR-based accounting messages can be sent upon call release, call connection and release, or call setup and release. This section lists the CDR attributes for RADIUS accounting.

The following figure shows the interface between the device and the RADIUS server, based on the RADIUS Accounting protocol. For each CDR that the device sends to the RADIUS server, it sends an Accounting-Request Stop with all the CDR attributes. When the RADIUS server successfully receives all the CDR attributes, it responds with an Accounting-Response Stop ACK message to the device. If the device doesn't receive the Accounting-Response ACK message, it can resend the Accounting-Request Stop with all CDR attributes again, up to a user-defined number of re-tries (see [Configuring RADIUS Packet Retransmission](#) on page 373).

There are two types of data that can be sent to the RADIUS server. The first type is the accounting-related attributes and the second type is the vendor specific attributes (VSA):

- **Standard RADIUS Attributes (per RFC):** A typical standard RADIUS attribute is shown below. The RADIUS attribute ID depends on the attribute.

```

2e 06 00 00 00 03 --- Data
|  |
|  Length (including header)
RADIUS ID
  
```

The following figure shows a standard RADIUS attribute collected by Wireshark. The bottom pane shows the RADIUS attribute information as sent in the packet; the upper pane is Wireshark's interpretation of the RADIUS information in a more readable format. The example shows the attribute in numeric format (32-bit number in 4 bytes).

- Vendor-specific RADIUS Attributes:** RADIUS attributes that are specific to the device (company) are referred to as Vendor-specific attributes (VSA). The CDR of VSAs are sent with a general RADIUS ID of 26 to indicate that they are vendor-specific (non-standard). In addition, the company's registered vendor ID (as registered with the Internet Assigned Numbers Authority or IANA) is also included in the packet. The device's default vendor ID is 5003, which can be changed (see [Configuring the RADIUS Vendor ID](#) on page 373). The VSA ID is also included in the packet.

```

1a 13 00 00 13 8b 21 0d 68 33 32 33 2d 67 77 2d 69 64 3d --- Data
| | | | | | | |
| | Vendor ID | Vendor part length
| | (5003) | Vendor-Specific Attribute (VSA) ID
| Length (including header)
RADIUS ID indicating vendor-specific (26)
  
```

The following figure shows a vendor-specific RADIUS attribute collected by Wireshark. The bottom pane shows the RADIUS attribute information as sent in the packet; the upper pane is Wireshark's interpretation of the RADIUS information in a more readable format. The example shows the attribute in string-of-characters format.

You can customize the prefix title of the RADIUS attribute name and ID. For more information, see [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578 and [Customizing CDRs for Gateway Calls](#) on page 1572.

To configure the address of the RADIUS Accounting server, see [Configuring RADIUS Servers](#) on page 369. For all RADIUS-related configuration, see [RADIUS-based Services](#) on page 369.

➤ **To configure RADIUS accounting:**

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).
2. Select the 'Enable RADIUS Access Control' check box [EnableRADIUS]:

Enable RADIUS Access Control

3. Click **Apply**.
4. Open the Call Detail Record Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Call Detail Record** folder > **Call Detail Record Settings**).
5. From the 'RADIUS Accounting Type' [RADIUSAccountingType] drop-down list, select the stage of the call that RADIUS accounting messages are sent to the RADIUS accounting server.
6. From the 'AAA Indications' [AAAIndications] drop-down list, select whether you want Authentication, Authorization and Accounting (AAA) indications.

For a detailed description of the parameters, see [RADIUS Parameters](#) on page 2142.

#### RADIUS ACCOUNTING SETTING

RADIUS Accounting Type

At Call Release

AAA Indications

Accounting Only

7. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

The table below lists the RADIUS Accounting CDR attributes included in the communication packets transmitted between the device and a RADIUS server.

**Table 60-5: Default RADIUS Accounting CDR Attributes**

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
<b>Request Attributes</b>						
1	user-name	(Standard)	Account number or calling party	String up to	5421385747	Start

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
			number or blank	15 digits long		Acc Stop Acc
4	nas-ip-address (for IPv4) nas-ipv6-address (for IPv6)	(Standard)	IP address (IPv4 or IPv6) of the requesting device	Numeric	192.168.14.43 (IPv4)	Start Acc Stop Acc
6	service-type	(Standard)	Type of service requested	Numeric	1: login	Start Acc Stop Acc
26	h323-incoming-conf-id	1	SIP call identifier	Up to 32 octets	h323-incoming-conf-id=38393530	Start Acc Stop Acc
26	h323-remote-address	23	IP address of the remote gateway	Numeric	-	Stop Acc
26	h323-conf-id	24	H.323/SIP call identifier	Up to 32 octets	-	Start Acc Stop Acc
26	h323-setup-time	25	Setup time in NTP format 1	String	h323-setup-time=09:33:26.621 Mon Dec	Start Acc

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
					2014	Stop Acc
26	h323-call-origin	26	<p>Originator of call:</p> <ul style="list-style-type: none"> <li>■ "answer": Call originated from the IP side (Gateway) or incoming leg (SBC)</li> <li>■ "originate": Call originated from the Tel side (Gateway) or outgoing leg (SBC)</li> </ul>	String	h323-call-origin=answer	Start Acc Stop Acc
26	h323-call-type	27	Protocol type or family used on this leg of the call. The value is always "VOIP".	String	h323-call-type=VOIP	Start Acc Stop Acc
26	h323-connect-time	28	Connect time in NTP format	String	h323-connect-time=09:33:37.657 UTC Mon Dec 08 2015	Stop Acc
26	h323-disconnect-time	29	Disconnect time in NTP format	String	-	Stop Acc
26	h323-disconnect-cause	30	Disconnect cause code (Q.850)	Numeric	h323-disconnect-cause=16	Stop Acc
26	h323-	33	Name of the	String	h323-gw-	Star

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
	gw-id		gateway		id=<SIP ID string>	t Acc Stop Acc
26	sip-call-id	34	SIP Call ID	String	sip-call-id=abcde@ac.com	Star t Acc Stop Acc
26	call-terminator	35	Terminator of the call: <ul style="list-style-type: none"> <li>■ "yes": Call terminated by the Tel side (Gateway) or outgoing leg (SBC)</li> <li>■ "no": Call terminated by the IP side (Gateway) or incoming leg (SBC)</li> </ul>	String	call-terminator=yes	Stop Acc
26	terminator	37	Terminator of the call: <ul style="list-style-type: none"> <li>■ "answer": Call originated from the IP side (Gateway) or incoming leg (SBC)</li> <li>■ "originate":</li> </ul>	String	terminator=originate	Stop Acc

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
			Call originated from the Tel side (Gateway) or outgoing leg (SBC)			
30	called-station-id	(Standard)	Gateway call: Called (destination) phone number  SBC call: Destination URI	String	8004567145	Start Acc
31	calling-station-id	(Standard)	Calling Party Number (ANI) (Gateway call) or Source URI (SBC call)	String	5135672127	Start Acc Stop Acc
40	acct-status-type	(Standard)	Account Request Type: <ul style="list-style-type: none"> <li>■ "1" (start): Sent in Call Start or Call Connect CDRs</li> <li>■ "2" (stop): Sent in Call End CDRs only.</li> </ul> <p><b>Note:</b> It is highly recommended to add this attribute if you are customizing the RADIUS CDR format (see <a href="#">Customizing CDRs for SBC Calls and</a></p>	Numeric	1	Start Acc Stop Acc

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
			<a href="#">Test Calls</a> on page 1578 for SBC calls and <a href="#">Customizing CDRs for Gateway Calls</a> on page 1572 for Gateway calls).			
41	acct-delay-time	(Standard)	No. of seconds tried in sending a particular record	Numeric	5	Start Acc Stop Acc
42	acct-input-octets	(Standard)	Number of octets received for that call duration (for SBC calls, applicable only if media anchoring)	Numeric	-	Stop Acc
43	acct-output-octets	(Standard)	Number of octets sent for that call duration (for SBC calls, applicable only if media anchoring)	Numeric	-	Stop Acc
44	acct-session-id	(Standard)	A unique accounting identifier that corresponds to the acct-status-type attribute and thus, the identifier of the start CDR is identical to the stop CDR ID of the same call.	String	34832	Start Acc Stop Acc

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
			This attribute is composed of the Session ID of the call (e.g., [SID=9be7fc:152:99757]) followed by a colon (:) and the leg ID (e.g., 9be7fc:152:99757:1 for the SBC incoming leg or Gateway call, and 9be7fc:152:99757:2 for the SBC outgoing leg).			
46	acct-session-time	(Standard)	For how many seconds the user received the service	Numeric	-	Stop Acc
47	acct-input-packets	(Standard)	Number of packets received during the call	Numeric	-	Stop Acc
48	acct-output-packets	(Standard)	Number of packets sent during the call	Numeric	-	Stop Acc
61	nas-port-type	(Standard)	Physical port type of device on which the call is active	String	0: Asynchronous	Start Acc Stop Acc
<b>Response Attributes</b>						
26	h323-	103	The reason for	Numeric	0 Request	Stop

Attribute ID	Attribute Name	Vendor-Specific Attribute (VSA) ID	Description	Value Format	Example	AAA
	return-code		failing authentication (0 = ok, other number failed)	ic	accepted	p Acc
44	acct-session-id	(Standard)	A unique accounting identifier – match start & stop	String	-	Sto p Acc

Below is an example of RADIUS Accounting, where non-standard parameters are preceded with brackets:

#### Accounting-Request (4)

```

user-name = 111
acct-session-id = 1
nas-ip-address = 212.179.22.213
nas-port-type = 0
acct-status-type = 2
acct-input-octets = 4841
acct-output-octets = 8800
acct-session-time = 1
acct-input-packets = 122
acct-output-packets = 220
called-station-id = 201
calling-station-id = 202

```

#### // Accounting non-standard parameters:

```

(4923 33) h323-gw-id =
(4923 23) h323-remote-address = 212.179.22.214
(4923 1) h323-ivr-out = h323-incoming-conf-id:02102944 600a1899 3fd61009
0e2f3cc5
(4923 30) h323-disconnect-cause = 22 (0x16)
(4923 27) h323-call-type = VOIP
(4923 26) h323-call-origin = Originate
(4923 24) h323-conf-id = 02102944 600a1899 3fd61009 0e2f3cc5

```

## Querying Device Channel Resources using SIP OPTIONS

The device reports its maximum and available channel resources in SIP 200 OK responses upon receipt of SIP OPTIONS messages. The device sends this information in the SIP X-Resources header with the following parameters:

- **telchs:** Specifies the total telephone channels and the number of free (available) telephone channels.
- **mediachs:** Not applicable

Below is an example of the X-Resources:

```
X-Resources: telchs= 12/4;mediachs=0/0
```

In the example above, "telchs" specifies the number of available channels and the number of occupied channels (4channels are occupied and 12channels are available).

This feature is applicable only to the Gateway application.

## 61 Remote Monitoring of Device behind NAT

When the device is located behind a NAT, you can configure it to periodically send monitoring reports to a third-party, remote HTTP-based monitoring server. This third-party server is configured on the device as a Remote Web Service (HTTP host), where the 'Type' parameter is set to **Remote Monitoring**. The device sends the reports over HTTP/S using RESTful API (in JSON format), where the device acts as the client.

You can choose to send various reports to the monitoring server:

- **Status reports:** These reports contain status information of the device, for example, software version, network configuration (IP network interfaces, Ethernet port interfaces, and proxy addresses), IP Groups, Trunk Groups, PSTN trunks, analog ports, and serial number).
- **Active alarms reports:** These reports contain currently active alarms.
- **Key performance indicators reports:** These reports contain performance monitoring statistics, for example, number of active SBC sessions, average call duration, and number of established inbound calls.
- **Registration status reports:** These reports contain status information of SIP User Agents (UA) currently registered with the device.

If the device receives an HTTP failure response (4xx/5xx/6xx) from the Remote Web Service when it attempts to send it a monitoring report, the device raises the SNMP alarm, `acRemoteMonitoringAlarm` (with Warning severity level). This alarm is cleared only when it receives an HTTP successful response (2xx) from the server.

- Currently, you can configure the device to send monitoring reports to only one Remote Web Service.
- If the report contains the **more** attribute with value "True", it means that the report has reached its maximum file size and the device will send another report with more information. The last report doesn't contain this attribute.

### ➤ To enable remote monitoring of device behind NAT:

1. In the Remote Web Services table (see [Configuring Remote Web Services](#) on page 438), configure a Remote Web Service with the 'Type' parameter set to **Remote Monitoring**.
2. Open the Web Service Settings page (**Setup** menu > **IP Network** tab > **Web Services** folder > **Web Service Settings**).

REMOTE MONITORING	
Remote Monitoring	<input checked="" type="checkbox"/>
Reporting Period (sec)	<input type="text" value="60"/>
Device Status	<input type="checkbox"/>
Active Alarms	<input checked="" type="checkbox"/>
Performance Indicators	<input type="checkbox"/>
Registration Status	<input checked="" type="checkbox"/>

3. Select the 'Remote Monitoring' check box to enable the feature.
4. In the 'Reporting Period' field, configure the interval (in seconds) between each sent report.
5. Select the check boxes of the corresponding report types (information) that you want the device to send:
  - 'Device Status': Report contains status information of the device
  - 'Active Alarms': Report contains currently active alarms
  - 'Performance Indicators': Report contains performance monitoring statistics
  - 'Registration Status': Report contains information of users registered with the device
6. Click **Apply**.

# Part X

## Diagnostics

## 62 Syslog and Debug Recording

For debugging and troubleshooting, you can use the device's syslog and/or Debug Recording capabilities:

- **Syslog:** Syslog is an event notification protocol that enables a device to send event notification messages across IP networks to event message collectors, also known as syslog servers. The device contains an embedded syslog client, which sends error reports / events that it generates to a remote syslog server using the IP / UDP protocol. This information is a collection of error, warning, and system messages that records every internal operation of the device.
- **Debug Recording:** The device can send debug recording packets to a debug capturing server. When the debug recording is activated, the device duplicates all messages that are sent and/or received by it and then sends them to an external server defined by IP address. The debug recording can be done for different types of traffic such as RTP/RTCP, T.38, ISDN, CAS, and SIP. Debug recording is used for advanced debugging when you need to analyze internal messages and signals. Debug recording is also useful for recording network traffic in environments where hub or port mirroring is unavailable and for recording internal traffic between two endpoints on the same device.

You can include syslog messages in debug recording (see [Configuring Logging Filter Rules](#) below).

### Configuring Logging Filter Rules

The Logging Filters table lets you configure up to 60 rules for filtering debug recording packets, syslog messages, and Call Detail Records (CDR). The logging filter determines the calls for which you want to generate the log. For example, you can add a rule to generate syslog messages only for calls belonging to IP Groups 2 and 4, or for calls belonging to all IP Groups except IP Group 3.

You can also configure logging filters for generating CDRs only and saving them on the device (local storage). Debug recording logging filters can include signaling information (such as SIP messages), syslog messages, PSTN traces (ISDN and CAS), CDRs, media (RTP, RTCP, and T.38), and pulse-code modulation (PCM) of voice signals from and to the TDM.

You can configure the following special logging filters for OVOC:

- You can filter logged SIP messages that the device sends to OVOC so that OVOC can display SIP call dialog sessions as SIP call flow diagrams (SIP ladder).
- You can filter Quality of Experience (voice metrics in CDRs) reports that the device sends to OVOC.

If you don't configure any rules in the Logging Filters table and you have globally enabled debug recording (by configuring the Debug Recording server's address - see note below), syslog (global parameter - see note below), and/or CDR generation (global parameter for enabling syslog - see note below), logs are generated for all calls. Therefore, the benefit of logging filters is that it

allows you to create logs per specific calls, eliminating the need for additional device resources (CPU consumption) otherwise required when logs are generated for all calls.

You can enable and disable each of your configured logging filter rules. Enabling rules that are not for debugging recording, activates the rule so that the device generates syslog messages or CDRs. For debug recording rules, you need to explicitly start the debug recording, as described in [Starting and Stopping Debug Recording](#) on page 1644. Disabling a rule is useful, for example, if you currently no longer require the rule, but may need it in the future. Therefore, instead of deleting the rule, you can simply disable it.

- If you want to configure a rule that logs syslog messages to a syslog server (i.e., not to a Debug Recording server), you must enable syslog functionality, using the 'Enable Syslog' (EnableSyslog) parameter (see [Enabling Syslog](#) on page 1622). Enabling syslog functionality is not required for rules that include syslog messages in the debug recording sent to the Debug Recording server.
- To configure the syslog server's address, see [Configuring the Primary Syslog Server Address](#) on page 1622. To configure additional, global syslog settings, see [Configuring Syslog](#) on page 1614.
- To configure the Debug Recording server's address, see [Configuring Debug Recording Server Address](#) on page 1643.
- To configure additional, global CDR settings such as at what stage of the call the CDR is generated (e.g., start and end of call), see [Configuring CDR Filters and Report Level](#) on page 1514.
- To start and stop debug recording rules, see [Starting and Stopping Debug Recording](#) on page 1644.

The following procedure describes how to configure logging filter rules through the Web interface. You can also configure it through ini file [LoggingFilters] or CLI (`configure troubleshoot > logging logging-filters`).

➤ **To configure a logging filter rule:**

1. Open the Logging Filters table (**Troubleshoot** menu > **Troubleshoot** tab > **Logging** folder > **Logging Filters**).
2. Click **New**; the following dialog box appears:

Logging Filters - x

GENERAL	
Index	<input type="text" value="0"/>
Filter Type	<input type="text" value="Any"/>
Value	<input type="text"/>
Log Destination	<input type="text" value="Debug Recording Server"/>
Log Type	<input type="text"/>
Mode	<input type="text" value="Enable"/>

3. Configure a Log Filtering rule according to the parameters described in the table below.

4. Click **Apply**.**Table 62-1: Logging Filters Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Filter Type' filter-type [FilterType]	<p>Defines the filter type criteria.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Any</b>= (Default) Debug recording is done for all calls.</li> <li>■ [2] <b>Trunk ID</b> = Filters the log by Trunk ID.</li> </ul> <p><b>Note:</b> This option is applicable only to the Gateway application.</p> <ul style="list-style-type: none"> <li>■ [3] <b>Trunk Group ID</b> = Filters the log by Trunk Group ID. To configure Trunk Groups, see <a href="#">Configuring Trunk Groups</a> on page 934.</li> </ul> <p><b>Note:</b> Applicable only to the Gateway application.</p> <ul style="list-style-type: none"> <li>■ [4] <b>Trunk &amp; B-channel</b> = Filters the log by Trunk and B-channel.</li> </ul> <p><b>Note:</b> This option is applicable only to the Gateway application.</p> <ul style="list-style-type: none"> <li>■ [5] <b>FXS or FXO</b> = Filters the log by FXS or FXO port.</li> </ul> <p><b>Note:</b> This option is applicable only to the Gateway application.</p> <ul style="list-style-type: none"> <li>■ [6] <b>Tel-to-IP</b> = Filters the log by Tel-to-IP Routing rule. To configure Tel-to-IP Routing rules, see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946.</li> </ul> <p><b>Note:</b> This option is applicable only to the Gateway application.</p> <ul style="list-style-type: none"> <li>■ [7] <b>IP-to-Tel</b> = Filters the log by IP-to-Tel Routing rule. To configure IP-to-Tel Routing rules, see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960.</li> </ul> <p><b>Note:</b> This option is applicable only to the Gateway application.</p> <ul style="list-style-type: none"> <li>■ [8] <b>IP Group</b> = Filters the log by IP Group. To configure IP Groups, see <a href="#">Configuring IP Groups</a> on page 591.</li> <li>■ [9] <b>SRD</b> = Filters the log by SRD. To configure SRDs, see <a href="#">Configuring SRDs</a> on page 558.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [10] <b>Classification</b> = Filters the log by Classification rule. To configure Classification rules, see <a href="#">Configuring Classification Rules</a> on page 1171. <b>Note:</b> This option is applicable only to the SBC application.</li> <li>■ [11] <b>IP-to-IP Routing</b> = Filters the log by IP-to-IP Routing rule. To configure IP-to-IP Routing rules, see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186. <b>Note:</b> This option is applicable only to the SBC application.</li> <li>■ [12] <b>User</b> = Filters the log by user (source and destination). The user is defined by username or username@hostname in the source or destination headers of the SIP request. For example, "2222@10.33.45.201" (without quotation marks) represents the following INVITE request:   <pre>INVITE sip:2222@10.33.45.201;user=phone SIP/2.0 From: sip:2222@10.33.45.201;user=phone</pre> </li> <li>■ [13] <b>IP Trace</b> = Filters the log by an IP network trace, using Wireshark-like expressions. For more information, see <a href="#">Filtering IP Network Traces using Wireshark-Like Expressions</a> on page 1610. For filtering IP traces by Ethernet port, or VLAN, see <a href="#">Filtering IP Network Traces by Ethernet Port or VLAN</a> on page 1612. The device adds an "ACDR" header to IP trace recordings.</li> <li>■ [14] <b>SIP Interface</b> = Filters the log by SIP Interface. To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</li> <li>■ [15] <b>System Trace</b> = Filters the log to include logged information not related to calls, for example, the device's CPU, HA traffic between active and redundant devices, or a disconnection with the LDAP server.</li> <li>■ [16] <b>IP Group Tag</b> = Filters the log by the IP Group's tag (source and destination). The tag is configured by the 'Tags' parameter in the IP Groups table.</li> </ul>
'Value' value [Value]	<p>Defines the value for the filtering type configured in the 'Filter Type' parameter.</p> <p>The value can include the following:</p> <ul style="list-style-type: none"> <li>■ For IP traces ('Filter Type' parameter configured to <b>IP Trace</b>),</li> </ul>

Parameter	Description
	<p>you need to configure the value with Wireshark-like expressions to filter the IP trace, as described in <a href="#">Filtering IP Network Traces using Wireshark-Like Expressions</a> on page 1610. If the parameter is not configured, the IP trace applies to all packets.</p> <ul style="list-style-type: none"> <li>■ For system traces ('Filter Type' parameter configured to <b>System Trace</b>), configure the value to one of the following: <ul style="list-style-type: none"> <li>✓ "syslog": This option includes INFO packet types.</li> <li>✓ "tpncp": This option includes device events and command packets, as displayed when using the Wireshark filter 'tpncp'.</li> <li>✓ "ha": This option includes High Availability (HA) and TPNCPC command packet types (communication between active and redundant devices).</li> </ul> </li> <li>■ A single value.</li> <li>■ A range, using a hyphen "-" between the two values. For example, to specify IP Groups 1, 2 and 3, configure the parameter to "1-3" (without quotation marks).</li> <li>■ Multiple, non-contiguous values, using commas "," between each value. For example, to specify IP Groups 1, 3 and 9, configure the parameter to "1,3,9" (without quotation marks).</li> <li>■ Trunks, FXS, or FXO pertaining to a module, using the syntax module number/port or port, for example: <ul style="list-style-type: none"> <li>✓ "1/2" (without quotation marks) means module 1, port 2</li> <li>✓ "1/[2-4]" (without quotation marks) means module 1, ports 2 through 4</li> </ul> </li> <li>■ To exclude specific configuration entities from the log filter, use the exclamation (!) wildcard character. For example, to include all IP Groups in the filter except IP Group ID 2, configure the 'Filter Type' parameter to <b>IP Group</b> and the 'Value' parameter to "!2" (without quotation marks).</li> </ul> <p><b>Note:</b> For SBC calls, a Logging Filter rule applies to the entire session (i.e., inbound and outbound legs). Therefore, if you want to exclude logging of specific calls, you need to configure the 'Value' parameter with both legs. For example:</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ If you want to exclude logs for calls between IP Group 1 and IP Group 2, configure the parameter to "!1,2" (without quotation marks).</li> <li>✓ If you want to exclude logs for calls between SIP Interface 4 and SIP Interface 9, configure the parameter to "!4,9" (without quotation marks).</li> </ul> <p><b>Note:</b> You can use the index number or string name to specify the configuration entity for the following 'Filter Types': Tel-to-IP, IP-to-Tel, <b>IP Group</b>, <b>SRD</b>, <b>Classification</b>, <b>IP-to-IP Routing</b>, or <b>SIP Interface</b>. For example, to specify IP Group "My SIP Trunk" at Index 2, configure the parameter to either "2" or "My SIP Trunk" (without quotation marks).</p>
'Log Destination' log-dest [LogDestination]	<p>Defines where the device sends the log file.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Syslog Server</b> = The device generates syslog messages for your log filter and sends them to a user-defined syslog server.</li> <li>■ [1] <b>Debug Recording Server</b> = (Default) The device generates debug recording packets for your log filter and sends them to a user-defined Debug Recording server.</li> <li>■ [2] <b>Local Storage</b> = The device generates CDRs for your log filter and stores them locally on the device. For more information on local storage of CDRs, see <a href="#">Storing CDRs Locally on the Device</a> on page 1516.</li> <li>■ [3] <b>OVOC (QoE)</b> = This option is used when the device sends any of the following to OVOC: <ul style="list-style-type: none"> <li>✓ <b>SIP messages:</b> The SIP messages can be used by OVOC to display SIP call dialog sessions as SIP call flow diagrams (SIP ladder). For this functionality, you also need to configure the 'Log Type' parameter to <b>SIP Ladder</b>. For more information on enabling this functionality, see <a href="#">Enabling SIP Call Flow Diagrams in OVOC</a> on page 1663.</li> <li>✓ <b>Quality of Experience (QoE) voice metric reports:</b> To configure reporting and filtering of QoE to OVOC, see <a href="#">Reporting QoE to OVOC</a> on page 523. For this functionality, you also need to configure the 'Log Type' parameter to <b>CDR</b>.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>Syslog Server</b>:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ If you have also configured the debug level to <b>No Debug</b> (see the [GwDebugLevel] parameter in <a href="#">Configuring Syslog Debug Level</a> on page 1633), the syslog messages include only system warnings and errors.</li> <li>✓ The 'Log Type' parameter (below) is not applicable (all syslog messages are sent to the syslog server).</li> <li>■ If you configure the 'Filter Type' parameter to <b>IP Trace</b>, you must configure the parameter to <b>Debug Recording Server</b>.</li> <li>■ For local storage of CDRs, configure the parameter to <b>Local Storage</b> and the 'Log Type' parameter to <b>CDR</b>.</li> <li>■ If you configure the parameter to <b>Debug Recording Server</b>, you can also include syslog messages in the debug recording packets sent to the debug recording server. To include syslog messages, configure the 'Log Type' parameter (see below) to the relevant option.</li> </ul>
'Log Type' log-type [CaptureType]	<p>Defines the type of messages to include in the log file.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Not configured. The option is applicable only for sending syslog messages to a syslog server (i.e., 'Log Destination' parameter is configured to <b>Syslog Server</b>).</li> <li>■ [1] <b>Signaling</b> = The option is applicable only to debug recording (i.e., 'Log Destination' parameter is configured to <b>Debug Recording Server</b>). The debug recording includes signaling information such as SIP signaling messages, syslog messages, CDRs, and the device's internal processing messages.</li> <li>■ [2] <b>Signaling &amp; Media</b> = The option is applicable only to debug recording (i.e., 'Log Destination' parameter is configured to <b>Debug Recording Server</b>). The debug recording includes media (RTP/RTCP/T.38), and only signaling and syslog messages associated with the recorded media.</li> </ul> <p><b>Note:</b> The device requires a lot of resources for media debug recording. The number of media sessions (and associated signaling) that the device records depends on available resources. Therefore, when many media sessions need to be recorded (e.g., when the 'Filter Type' parameter is configured to <b>Any</b>) not all media sessions (and associated signaling) are recorded. If the device has no resources to debug record any media, it doesn't debug record any signaling as well. As</p>

Parameter	Description
	<p>debug recording of signaling requires less resources than media debug recording, if you want to perform debug recording only on signaling, then it is recommended to configure the parameter to <b>Signaling</b>.</p> <ul style="list-style-type: none"> <li>■ [3] <b>Signaling &amp; Media &amp; PCM</b> = The option is applicable only to debug recording (i.e., 'Log Destination' parameter is configured to <b>Debug Recording Server</b>). The debug recording includes signaling, syslog messages, media, and PCM (voice signals from and to TDM).</li> <li>■ [4] <b>PSTN Trace</b> = The option is applicable only to debug recording (i.e., 'Log Destination' parameter is configured to <b>Debug Recording Server</b>) and if the 'Filter Type' parameter is configured to <b>Trunk ID</b>. The debug recording includes ISDN and CAS traces.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>✓ This option is applicable only to digital interfaces.</li> <li>✓ To capture traffic of all trunks, configure the 'Value' parameter (above) to "-1" (without quotation marks).</li> <li>✓ You must configure the trace level for the trunks that you want to trace. This is done using the 'Trace Level' parameter on the Trunk Settings page (see <a href="#">Configuring Trunk Settings</a> on page 878).</li> </ul> <ul style="list-style-type: none"> <li>■ [5] <b>CDR</b> = Only CDRs are generated. This option is applicable only when you configure the 'Log Destination' parameter to <b>Local Storage</b> or <b>OVOC (QoE)</b> for QoE reporting to OVOC.</li> <li>■ [6] <b>SIP Ladder</b> = The device sends SIP messages (in XML format), as they occur in real-time, to OVOC for displaying SIP call dialog sessions as call flow diagrams. For this functionality, you also need to configure the 'Log Destination' parameter to <b>OVOC (QoE)</b>. For enabling this functionality, see <a href="#">Enabling SIP Call Flow Diagrams in OVOC</a> on page 1663.</li> <li>■ [7] <b>SIP Only</b> = The option is applicable only to debug recording (i.e. the 'Log Destination' parameter is configured to <b>Debug Recording Server</b>). The debug recording includes only SIP messages.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This parameter is not applicable if you configure the 'Log Destination' parameter to <b>Syslog Server</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For local storage of CDRs, configure the 'Log Destination' parameter to <b>Local Storage</b> and the 'Log Type' parameter to <b>CDR</b>.</li> <li>■ PSTN debug traces may affect performance.</li> <li>■ The parameter is not applicable when the 'Filter Type' parameter is configured to <b>IP Trace</b>.</li> <li>■ To include syslog messages in debug recording, it is unnecessary to enable syslog functionality.</li> </ul>
'Mode' mode [Mode]	<p>Enables and disables the rule.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b> (Default)</li> </ul> <p><b>Note:</b> For debugging recording rules, you need to explicitly start the debug recording, as described in <a href="#">Starting and Stopping Debug Recording</a> on page 1644.</p>

## Filtering IP Network Traces using Wireshark-Like Expressions

You can filter syslog and debug recording messages for IP network traces, by configuring the 'Filter Type' parameter to **IP Trace** in the Logging Filters table.

IP traces record any IP stream, according to destination and/or source IP address, or port and Layer-4 protocol (UDP, TCP or any other IP type as defined by <http://www.iana.com>). Network traces are typically used to record HTTP.

Using IP traces is only intended for capturing non-media traffic (e.g., SIP and syslog); not media traffic (RTP/RTCP). Capturing only non-media traffic prevents device CPU overload under medium or high traffic. If you want to capture media traffic, configure the 'Filter Type' parameter to a different option (e.g., **Any**) instead of **IP Trace**.

When the **IP Trace** option is selected, only the 'Value' parameter is applicable in the Logging Filters table. This parameter configures Wireshark-like filtering expressions for your IP trace. The following Wireshark-like expressions are supported:

**Table 62-2: Supported Wireshark-like Expressions for 'Value' Parameter**

Expression	Description
and, &&, ==, <, >	Comparison operators used between expressions.
ip.addr	Defines IPv4 addresses (up to two) to capture.

Expression	Description
ip.dst	Defines the destination IPv4 address to capture.
ip.proto	Defines the IP protocol type (PDU) entered as an enumeration value (e.g., 1 is ICMP, 6 is TCP, and 17 is UDP) to capture.
ip.src	Defines the source IPv4 address to capture.
ipv6	Captures all IPv6 packets (source and destination).
ipv6.addr	Defines IPv6 addresses (up to two) to capture.
ipv6.dst	Defines the destination IPv6 address to capture.
ipv6.src	Defines the source IPv6 address to capture.
udp, tcp, icmp, sip, ldap, http, https	Defines single expressions of the protocol type to capture.
udp.dstport, tcp.dstport	Defines the transport layer of the destination port to capture.
udp.port, tcp.port	Defines the transport layer to capture.
udp.srcport, tcp.srcport	Defines the transport layer of the source port to capture.

The following are examples of configured expressions for the 'Value' parameter:

- `udp && ip.addr==10.8.6.55`
- `ip.src==10.8.6.55 && udp.port>=5000 and udp.port<6000`
- `ip.dst==10.8.0.1/16`
- `ip.addr==10.8.6.40`
- `ipv6.addr==2001:0db8:85a3:0000:0000:8a2e:0370:7334`
- `ipv6.src==2001:db8:abcd:0012::0/64`

For conditions requiring the "or" / "||" expression, add multiple rows in the Logging Filters table. For example, the Wireshark condition "ip.src == 1.1.1.1 or ip.src == 2.2.2.2" and "ip.dst == 3.3.3.3" can be done by adding two rows in the table, where the 'Value' parameter of each row has the following value:

- Index #0: 'Value' parameter is configured to "ip.src == 1.1.1.1 and ip.dst == 3.3.3.3" (without apostrophes)
- Index #1: 'Value' parameter is configured to "ip.src == 2.2.2.2 and ip.dst == 3.3.3.3" (without apostrophes)

## Logging Filters (2)

+ New Edit		Page 1 of 1		Show 10 records per page	
INDEX	FILTER TYPE	VALUE	LOG DESTINATION	LOG TYPE	MODE
0	IP Trace	ip.src == 1.1.1.1 and ip.dst == 3.3.3.3	Debug Recording Server		Enable
1	IP Trace	ip.src == 2.2.2.2 and ip.dst == 3.3.3.3	Debug Recording Server		Enable

- If you leave the 'Value' parameter empty, the device records all IP traffic types (IPv4 and IPv6).
- You can't configure the 'Value' parameter with both IPv4 and IPv6 addresses.
- You can't configure the 'Value' parameter with "ip.addr" or "udp/tcp.port" together with "ip.src/dst" or "udp/tcp.srcport/dstport". For example, the following is invalid:  
ip.addr==1.1.1.1 and ip.src==2.2.2.2
- You can't configure the 'Value' parameter with "ipv6.addr" or "udp/tcp.port" together with "ipv6.src/dst" or "udp/tcp.srcport/dstport". For example, the following is invalid:  
ipv6.addr==2001:0db8:85a3:0000:0000:8a2e:0370:7334 and  
ipv6.src==2001:db8:abcd:0012::0/64

## Filtering IP Network Traces by Ethernet Port or VLAN

By default, when you configure a log filter (in the Logging Filters table) for filtering syslog and debug recording messages for IP network traces ('Filter Type' parameter configured to **IP Trace**), the device records (traces) all the packets received and sent on all the device's physical Ethernet ports. However, you can change this by selecting a specific port, or VLAN ID.

### ➤ To filter IP network traces by Ethernet port, Ethernet Group or VLAN:

1. Make sure that you have configured a log filtering rule for IP traces in the Logging Filters table (see [Configuring Logging Filter Rules](#) on page 1602).
2. Open the Debug Recording page (**Troubleshoot** tab > **Troubleshoot** menu > **Logging** folder > **Debug Recording**).

#### IP TRACE

Recording Mode

All Physical Ethernet Port ▼

Physical Ethernet Port

None ▼

VLAN ID

• None ▼

3. From the 'Recording Mode' drop-down list, select one of the following:
  - **All Physical Ethernet Ports:** The log filter for the IP trace is applied on packets received and sent (tagged and untagged) on all the physical Ethernet ports.

- **Physical Ethernet Port:** The log filter for the IP trace is applied on packets received and sent on the specific Ethernet port selected in Step 4.
  - **VLAN ID:** The log filter for the IP trace is applied on packets received and sent on the specific VLAN (underlying Ethernet Device) selected in Step 5.
4. If you selected **Physical Ethernet Port** in Step 3, then from the 'Physical Ethernet Port' drop-down list, select the port. To view the device's Ethernet ports, see [Configuring Physical Ethernet Ports](#) on page 150.

The device has only one Ethernet port into its kernel software and therefore, the 'Physical Ethernet Port' field displays **None**. If you configure tunneling for the device, special tunneling ports are added to the kernel software and these are represented in the field as **Tunnel**.

5. If you selected **VLAN ID** in Step 3, then from the 'VLAN ID' drop-down list, select the VLAN. To configure VLANs (Ethernet Devices), see [Configuring Underlying Ethernet Devices](#) on page 156.

- The recording includes just packets of specific VLAN, but without the VLAN header.
- Untagged packets are not recorded.

6. Click **Apply**.

## Debugging PSTN Calls through CLI

You can also troubleshoot and debug digital (PSTN) calls through the device's CLI.

PSTN traces may affect performance.

- **To configure the debug (trace) level:** The debug (trace) level determines the level of information included in the PSTN trace. For all PSTN traces, the trace level is configured per PSTN interface, using the following command:

```
configure voip > interface {e1-t1|bri} {Slot/Port} > trace-level {full-isdn|full-isdn-
with-duplications|layer3|layer3-no-duplications|no-trace|q921-raw-
data|q931|q931-q921-raw-data|q931-raw-data}
```

For example:

```
# configure voip
(config-voip)# interface e1-t1 1/1
(e1-t1 1/1)# trace-level full-isdn
```

- **To start a PSTN trace:**

- **Per Trunk:** Debugging per trunk is configured in the Logging Filters where there is an option to start and stop the trace:

```
(config-troubleshoot)# logging logging-filters <Table Row Index>
```

For more information on the Logging Filters table, see [Configuring Logging Filter Rules](#) on page 1602.

The trace level is configured using the `interface` command described in the beginning of this section.

- **All Trunks:** You can perform PSTN traces for all trunks for which you have configured trace levels (using the `interface` command described in the beginning of this section). To start the trace for all these trunks, use the following command:

```
# debug debug-recording <IP Address of Debug Recording Server> pstn-trace
```

- **To enable sending traces to syslog:** To send the PSTN traces to a syslog server, use the following command:

```
(config-troubleshoot)# pstn-debug on
```

If you send traces to a syslog server, you must configure the trace level to **q931-raw-data**.

## Configuring Syslog

This section describes how to configure syslog. To filter syslog messages, see [Configuring Logging Filter Rules](#) on page 1602.

### Syslog Message Format

The syslog message is sent from the device to a syslog server as an ASCII (American Standard Code for Information Interchange) message. Syslog uses UDP as its underlying transport layer mechanism. By default, UDP port 514 is assigned to syslog, but this can be changed (see [Enabling Syslog](#) on page 1622).

Syslog includes two types of log messages:

- **SIP Call Session Logs:** Logs relating to call sessions (e.g., call established). These logs are identified by a session ID ("SID"), described in detail in the table below. For example:

```
10:44:11.299 10.15.77.55 local0.notice [S=511941] [SID=50dcb2:31:12079]
(N 483455) ReleaseAddress. IPv4IF=1 IPv6IF=-1 Port=7500 [Time:10-
09@09:42:56.938]
```

- **Board Logs:** Logs relating to the operation of the device (infrastructure) that are non-call (SIP) session related (e.g., device restart or Web login). These logs are identified by a board ID ("BID"), described in detail in the table below. For example:

```
20:05:36.055 10.15.7.96 local0.notice [S=16] [BID=50dcb2:31] Activity Log:
Successful user login at 10.15.7.96:80. User: Admin. Session: Web
(10.13.2.19) [Time:12-03@17:00:58.781] [1108]
```

The format of the syslog message is described in the following table:

**Table 62-3: Syslog Message Format Description**

Message Item	Description
<b>Receive Timestamp</b>	<p>The syslog message includes a timestamp that the syslog server adds to indicate when it received the message.</p> <p>Example (in bold):</p> <pre>20:05:36.055 10.15.7.96 local0.notice [S=16] [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19) [Time:12-03@17:00:58.781] [1108]</pre>
<b>IP Address</b>	<p>The syslog message includes the IP address of the device, which generated the message.</p> <p>Example (in bold):</p> <pre>20:05:36.055 10.15.7.96 local0.notice [S=16] [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19) [Time:12-03@17:00:58.781] [1108]</pre>
<b>Severity Type</b>	<p>The syslog message includes the severity level with which it was generated (in the format &lt;FacilityCode.Severity&gt;).</p> <p>Example (in bold):</p> <pre>20:05:36.055 10.15.7.96 local0.notice [S=16] [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19)</pre>

Message Item	Description
	<p>[Time:12-03@17:00:58.781] [1108]</p> <p>The severity level can be one of the following:</p> <ul style="list-style-type: none"> <li>■ Error: Indicates that a problem has been identified that requires immediate handling.</li> <li>■ Warning: Indicates an error that might occur if measures are not taken to prevent it.</li> <li>■ Notice: Indicates that an unusual event has occurred.</li> <li>■ Info: Indicates an operational message.</li> <li>■ Debug: Messages used for debugging.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The Info and Debug severity messages are required only for advanced debugging. By default, the device doesn't send them.</li> <li>■ Syslog messages displayed in the Web interface (see <a href="#">Viewing Syslog Messages</a> on page 1636) are color coded according to severity level.</li> </ul>
<b>Sequence Number (S=)</b>	<p>By default, the device sequentially numbers generated syslog messages (in the format <i>[S=&lt;number&gt;]</i>). A skip in the number sequence of messages indicates packet loss (i.e., a network issue).</p> <p>The following example shows two missing syslog messages, S=18 and S=19:</p> <p>20:05:36.055 10.15.7.96 local0.notice <b>[S=16]</b>  [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19)  [Time:12-03@17:00:58.781] [1108]</p> <p>20:05:36.055 10.15.7.96 local0.notice <b>[S=17]</b>  [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. Message Item	Description
	<p><b>Note:</b> You can exclude the sequence number from syslog messages, by disabling the 'CDR Syslog Sequence Number' parameter (see <a href="#">Enabling Syslog</a> on page 1622).</p>
<b>Session ID (SID)</b>	<p>The SID is a unique SIP call session and device identifier. The device identifier facilitates debugging by clearly identifying the specific device that sent the log message, which is especially useful in deployments consisting of multiple devices. In addition, the benefit of unique numbering is that it enables you to filter information (such as SIP, syslog, and media) according to device or session ID.</p> <p>The syntax of the session and device identifiers is as follows:</p> <p><i>[SID=&lt;last 6 characters (3 lower bytes) of MAC address&gt;:&lt;number of times device has restarted&gt;:&lt;unique SID counter indicating the call session, which increments consecutively for each new session and resets to 1 after a device restart&gt;]</i></p> <p>Example (in bold):</p> <pre>10:44:11.299 10.15.77.55 local0.notice [S=511941] [SID=<b>50dcb2:31:12079</b>] (N 483455) ReleaseAddress. IPv4IF=1 IPv6IF=-1 Port=7500 [Time:10-09@09:42:56.938]</pre> <p>Where:</p> <ul style="list-style-type: none"> <li>■ <b>50dcb2</b> is the device's MAC address.</li> <li>■ <b>31</b> is the number of times that the device has restarted.</li> <li>■ <b>12079</b> is a unique SID session number (in other words, this is call session 12,079 since the last device restart).</li> </ul> <ul style="list-style-type: none"> <li>✓ Gateway application: A call session is considered as a Tel-to-IP leg or an IP-to-Tel leg, where each leg is assigned a unique session number.</li> <li>✓ SBC application: A session includes both the outgoing and incoming legs, where both legs share the same session number.</li> <li>✓ Forked legs and alternative legs share the same session number.</li> </ul>
<b>Startup Messages</b>	<p>Some syslog messages that are generated during a device restart (startup) include "[SUP]".</p> <p>Example (in bold):</p> <pre>03/19 12:43:43.539 10.4.4.65 local0.debug [S=93] [<b>SUP</b>]</pre>

Message Item	Description
	<pre>[BID=667402:93] CreateTpappSymbolTable(): symbol tables at 0x7f0a3006f038 [Time:19-03@21:44:35.084] [17]</pre>
<b>Board ID (BID)</b>	<p>Some syslog messages include a BID value. The BID is a unique non-SIP session related (e.g., device restart or a Trunk alarm) and device identifier. The BID value is similar to the SID (above), except that it doesn't contain the session ID. The device identifier facilitates debugging by clearly identifying the specific device that sent the log message, which is especially useful in deployments consisting of multiple devices. In addition, the benefit of unique numbering is that it enables you to filter information according to device.</p> <p>The syntax of the BID is as follows:</p> <p><i>[BID=&lt;last 6 characters (3 lower bytes) of MAC address&gt;:&lt;number of times device has restarted&gt;]</i></p> <p>Example (in bold):</p> <pre>20:05:36.055 10.15.7.96 local0.notice [S=16] <b>[BID=50dcb2:31]</b> Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19) [Time:12-03@17:00:58.781] [1108]</pre> <p>Where:</p> <ul style="list-style-type: none"> <li>■ <i>50dcb2</i> is the device's MAC address.</li> <li>■ <i>31</i> is the number of times that the device has restarted.</li> </ul>
<b>Message Body</b>	<p>The syslog message includes a message body which describes the message.</p> <p>For example, the body (in bold) of the following syslog message indicates that the user logged out of the Web interface:</p> <pre>20:05:36.055 10.15.7.96 local0.notice [S=16] <b>[BID=50dcb2:31] Activity Log: Successful user login at</b> <b>10.15.7.96:80. User: Admin. Session: Web (10.13.2.19)</b> [Time:12-03@17:00:58.781] [1108]</pre>
<b>Transmit Timestamp</b>	<p>Some syslog messages include a timestamp that indicates when the device sent the syslog message. This timestamp is typically only included in syslog messages that are related to the device's software application.</p> <p>Example (in bold):</p>

Message Item	Description
	<pre>20:05:36.055 10.15.7.96 local0.notice [S=16] [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19) [Time:12-03@17:00:58.781] [1108]</pre>
<b>Sequence Number per Process</b>	<p>The syslog message includes a sequence number per application process. This number appears at the end of the syslog message. A skip in the number indicates an internal (not network issue) loss of message (s) by the device's application process (i.e., didn't send the message, for whatever reason). This number is typically used by AudioCodes for debugging.</p> <p>Example (in bold):</p> <pre>20:05:36.055 10.15.7.96 local0.notice [S=16] [BID=50dcb2:31] Activity Log: Successful user login at 10.15.7.96:80. User: Admin. Session: Web (10.13.2.19) [Time:12-03@17:00:58.781] [<b>1108</b>]</pre> <p><b>Note:</b> The sequence number only appears in syslog messages that relate to the device's application process.</p>

### Event Representation in Syslog Messages

The device denotes events in syslog message using unique abbreviations, as listed in the following table. For example, if an invalid payload length event occurs, the syslog message uses the abbreviated event string "IP":

```
Apr 4 12:00:12 172.30.1.14 IP:5 [Code:0x5004] [CID:3294] [Time: 20:17:00]
```

For syslog messages sent for packet loss events, see [Packet Loss Indication in Syslog](#) on page 1641.

**Table 62-4: Syslog Error Event Abbreviations**

Error Abbreviation	Error Name Description
<b>AA</b>	Invalid Accumulated Packets Counter
<b>AC</b>	Invalid Channel ID
<b>AL</b>	Invalid Header Length

Error Abbreviation	Error Name Description
<b>AO</b>	Invalid Codec Type
<b>AP</b>	Unknown Aggregation Payload Type
<b>AR</b>	Invalid Routing Flag Received
<b>AT</b>	Simple Aggregation Packets Lost
<b>CC</b>	Command Checksum Error
<b>CE</b>	Invalid Cell Coder Code
<b>CS</b>	Command Sequence Error
<b>ES</b>	8 sec Timeout Before Disconnect
<b>HO</b>	Host Received Overrun
<b>IA</b>	Invalid AMR Payload
<b>IC</b>	Invalid CID Error
<b>IG</b>	Invalid G723 Code
<b>IP</b>	Invalid payload length
<b>IR</b>	Invalid RTCP Packet
<b>IS</b>	Invalid SID Length
<b>LC</b>	Transmitter Received Illegal Command
<b>LF</b>	Lost Fax Frames In High Speed Mode
<b>LM</b>	Lost Modem Frames In High Speed Mode
<b>MI</b>	Misalignment Error
<b>MR</b>	Modem Relay Is Not Supported
<b>PD</b>	RTP Packet Duplicated
<b>OR</b>	DSP JB Overrun
<b>PH</b>	Packet Header Error
<b>RB</b>	Counts the number of BFI Frames Received From The Host

Error Abbreviation	Error Name Description
RD	No Available Release Descriptor
RO	RTP Reorder
RP	Unknown RTP Payload Type
RS	RTP SSRC Error
UF	Unrecognized Fax Relay Command

### Syslog Fields for Answering Machine Detection (AMD)

The syslog message can include information relating to the Answering Machine Detection (AMD) feature. AMD is used to detect whether a human (including a fax machine), an answering machine, silence, or answering machine beeps have answered the call on the remote side.

The syslog message includes the following AMD-related fields:

■ **AMDSignal:** This field can have one of the following values:

- "V" - voice
- "A" - answer machine
- "S" - silence
- "U" - unknown

■ **AMDDecisionProbability:** The probability (in %) success that the correct answering type was detected.

The following shows an example of a syslog message with AMD information:

```
CallMachine:EVENT_DETECTED_EV - AMDSignal = <type - V/A/S/U>,  
AMDDecisionProbability = <percentage> %
```

If there is no AMD detection, the AMDSignal field is shown empty ("AMDSignal = ").

For more information on the AMD feature, see [Answering Machine Detection \(AMD\)](#) on page 311.

### SNMP Alarms in Syslog Messages

SNMP alerts are sent to the syslog server using the following formats:

■ **Raised Alarms:** RAISE-ALARM: <Alarm Name>; Textual Description: <Textual Description>; Severity <Alarm Severity>; Source <Alarm Source>; Unique ID: <Alarm Unique ID >.

If additional information exists in the alarm, then these are also added: Additional Info1:/ Additional Info2:/ Additional Info3

The Messages' Severity is as follows:

**Table 62-5: Syslog Message Severity**

ITU Perceived Severity (SNMP Alarm's Severity)	AudioCodes Syslog Severity
Critical	RecoverableMsg
Major	RecoverableMsg
Minor	RecoverableMsg
Warning	Notice
Indeterminate	Notice
Cleared	Notice

- **Cleared Alarms:** CLEAR-ALARM: <Alarm Name>; Textual Description: <Textual Description>; Severity <Alarm Severity>; Source <Alarm Source>; Unique ID: <Alarm Unique ID >; If exists Additional Info1:/ Additional Info2:/ Additional Info3:

## Enabling Syslog

To use syslog, you first need to enable it.

### ➤ To enable syslog:

1. Open the Logging Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Logging** folder > **Logging Settings**).
2. Select the 'Enable Syslog' check box:

Enable Syslog

3. Click **Apply**.

## Configuring the Primary Syslog Server Address

This section describes how to configure the "primary" syslog server to where you want the device to send its generated syslog messages.

- To enable the device to send syslog messages, you **MUST** also configure the 'VoIP Debug Level' parameter to **Basic** or **Detailed** (see [Configuring Syslog Debug Level](#) on page 1633).
- In addition to configuring a "primary" syslog server, you can configure "secondary" syslog servers (see [Configuring Secondary Syslog Servers](#) on the next page). The device sends the syslog messages to all configured servers ("primary" and "secondary").
- Unless you configure a dedicated CDR server address (see [Enabling CDR Generation and Configuring the CDR Server Address](#) on page 1514), the syslog server is also used as the CDR server. The syslog server's port number, transport protocol and IP Interface settings then also apply to the CDR server.

➤ **To configure the primary syslog server address:**

1. Open the Logging Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Logging** folder > **Logging Settings**).
2. Configure the syslog address parameters:
  - a. From the 'Syslog Network Interface Name' drop-down list, select the IP Interface from the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159) for communication with the syslog server.
  - b. In the 'Server IP Address' field [SyslogServerIP], enter the address (IPv4 or IPv6 address, or FQDN) of the syslog server.
  - c. In the 'Server Port' field, enter the port of the syslog server.

Syslog Network Interface Name	• #0 [O+M+C] ▼	<a href="#">View</a>
Server IP Address	<input type="text" value="0.0.0.0"/>	
Server Port	<input type="text" value="514"/>	

The IP address version (IPv4 or IPv6) of the IP Interface ('Syslog Network Interface Name') and the syslog server's address ('Server IP Address') must be the same.

3. From the 'Syslog Protocol' drop-down list, select the transport protocol. By default, the device uses the UDP transport protocol for communication with the syslog server. You can change this to TCP or TLS.

Syslog Protocol	• TLS ▼
-----------------	---------

4. If you selected **TLS** as the transport protocol in the previous step, you need to select a TLS Context from the 'Syslog TLS Context' drop-down list:

## Syslog TLS Context

To configure TLS Contexts, see [Configuring TLS Certificate Contexts](#) on page 227.

5. Click **Apply**.

## Configuring Secondary Syslog Servers

In addition to (or instead of) configuring a "primary" syslog server (see [Configuring the Primary Syslog Server Address](#) on page 1622), you can use the Syslog Servers table to configure up to four "secondary" syslog servers to where you want the device to send syslog messages. The device sends the syslog messages to all configured servers ("primary" and "secondary").

You can also configure the device's embedded syslog (Rsyslog) client to send event logs (syslog messages) to Apache Kafka, an open-source platform for event streaming. As a Kafka *producer*, the device transmits syslog messages to the remote Kafka *broker*. The broker can be on a local server or hosted on the cloud.

The Kafka broker manages one or more *topics*, which act like categories for classifying syslog messages. Multiple applications or services (Kafka *consumers*) can subscribe to these topics and receive the syslog messages. When multiple Kafka topics exist, you would need to configure multiple Kafka-based syslog servers with the same address for the Kafka broker in the Syslog Servers table. However, each syslog server would be configured with a different Kafka topic name, and different information type and / or severity level.

- To enable the device to send syslog messages, you **MUST** also configure the 'VoIP Debug Level' parameter to **Basic** or **Detailed** (see [Configuring Syslog Debug Level](#) on page 1633).
- The syslog servers are also used as CDR servers, unless you configure a dedicated CDR server address as described in [Enabling CDR Generation and Configuring the CDR Server Address](#) on page 1514.
- Configuring duplicated secondary syslog servers with the same address and port is invalid.
- Configuring duplicated secondary syslog servers with the same address and port as the primary syslog server is invalid.
- The syslog sequence number resets if the device restarts.

The following procedure describes how to configure secondary syslog servers through the Web interface. You can also configure it through ini file [SyslogServers] or CLI (`configure troubleshoot > syslog > syslog-servers`).

### ➤ To configure secondary syslog servers:

1. Open the Syslog Servers table (**Troubleshoot** menu > **Logging** folder > **Syslog Servers**).
2. Click **New**; the following dialog box appears:

Syslog Servers
— x

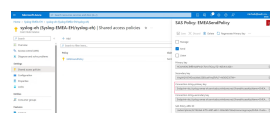

GENERAL

Index	<input type="text" value="1"/>
Address	<input type="text" value="0.0.0.0"/>
Kafka Topic	<input type="text"/>
Kafka Connection String	<input type="text"/>
Port	<input type="text" value="514"/>
Transport Protocol	<input type="text" value="UDP"/>
Interface	<input type="text" value="--"/> <a href="#" style="color: #003366; font-size: small;">View</a>
Information Type	<input type="text" value="All"/>
Severity Level	<input type="text" value="Notice"/>
Mode	<input type="text" value="Enable"/>

3. Configure a secondary syslog server according to the parameters described in the table below.
4. Click **Apply**.

**Table 62-6: Syslog Servers Parameter Descriptions**

Parameter	Description
'Index'	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Address ' ip-address [Address]	<p>Defines the address of the syslog server.</p> <p>The valid value depends on the type of syslog server:</p> <ul style="list-style-type: none"> <li>■ <b>Regular syslog server:</b> IP address (IPv4 or IPv6) or an FQDN.</li> <li>■ <b>Kafka broker:</b> FQDN of the Kafka broker name. When the Kafka broker is hosted on Microsoft Azure, the FQDN</li> </ul>

Parameter	Description
	<p>is the namespace of the Event Hub.</p> <p>The default is 0.0.0.0.</p>
<p>'Kafka Topic'</p> <p>kafka-topic-name</p> <p>[Topic]</p>	<p>Defines the Kafka topic name.</p> <p>When the Kafka broker is hosted on Microsoft Azure, the topic name is the Event Hub namespace.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The parameter is applicable only when the syslog server is a Kafka broker.</p>
<p>'Kafka Connection String'</p> <p>kafka-connection-string</p> <p>[ConnectionString]</p>	<p>Defines the authentication string (password) for connecting to the Kafka broker (topic).</p> <p>When configured, the device encrypts the syslog messages.</p> <p>The figure below shows where you can copy the connection string from for the Kafka broker's topic in Azure Event Hubs:</p>  <p>By default, no value is defined, which means that Kafka communication is over TCP.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only when the syslog server is a Kafka broker.</li> <li>■ The parameter is mandatory if the Kafka broker is hosted on Microsoft Azure (Event Hub).</li> <li>■ If you configure the parameter, you must also select a TLS Context (using the 'Syslog TLS Context' parameter, as described in <a href="#">Configuring the Primary Syslog Server Address</a> on page 1622).</li> </ul>
'Port' port [Port]	<p>Defines the syslog server's port number. The default is 514.</p> <p><b>Note:</b> When the Kafka broker is hosted on Microsoft Azure, configure the port to 9093.</p>
'Transport Protocol' protocol [Protocol]	<p>Defines the transport protocol for communicating with the syslog server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>UDP</b> (default)</li> <li>■ [1] <b>TCP</b></li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>TLS</b></li> <li>■ [3] <b>Kafka</b></li> </ul> <p><b>Note:</b> You also need to select a TLS Context (using the 'Syslog TLS Context' parameter, as described in <a href="#">Configuring the Primary Syslog Server Address</a> on page 1622) for the following settings:</p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>TLS</b>.</li> <li>■ If you configure the parameter to <b>Kafka</b> and you configure a value for the 'Kafka Connection String' parameter.</li> </ul>
'Interface' interface [Interface]	<p>Assigns an IP Interface from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for communication with the syslog server.</p> <p>By default, no value is defined, which means that the device uses the IPv4 OAMP network interface.</p> <p><b>Note:</b> The address version (IPv4 or IPv6) of the IP Interface and the syslog</p>

Parameter	Description
	server's address (see 'Address' parameter above) must be the same.
'Information Type' info-type [InfoType]	<p>Defines the type of information that the device sends in syslog messages to the remote syslog server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>All</b> = (Default) Sends all below options.</li> <li>■ [1] <b>CDR</b> = Sends only CDRs.</li> <li>■ [2] <b>SDR</b> = Sends only SDRs.</li> <li>■ [3] <b>Syslog</b> = Sends only syslogs.</li> </ul>
'Severity Level' severity-level [SeverityLevel]	<p>Defines the minimum severity level of messages included in the syslog message that the device sends to the syslog server.</p> <p>The severity levels in the list below are in descending order (from highest to lowest). Only the selected severity level and all higher severity levels are included in syslog messages. For example, if you configure the parameter to <b>Alert</b>, the syslog includes only alert ("alert") and emergency</p>

Parameter	Description
	<p>("emerg") messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Emergency</b></li> <li>■ [1] <b>Alert</b></li> <li>■ [2] <b>Critical</b></li> <li>■ [3] <b>Error</b></li> <li>■ [4] <b>Warning</b></li> <li>■ [5] <b>Notice</b> (default)</li> <li>■ [6] <b>Info [not recommended]</b></li> <li>■ [7] <b>Debug [not recommended]</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ It's recommended to leave the syslog severity level at default (i.e., <b>Notice</b>) to prevent excessive utilization of the device's resources. Changing severity level is typically done only by AudioCodes Support for debugging.</li> <li>■ Upon a device restart or HA switchover, the parameter restores to default (i.e., <b>Notice</b>).</li> <li>■ To view the corresponding</li> </ul>

Parameter	Description
	strings used in syslog messages for indicating severity levels, see <a href="#">Configuring Syslog Message Severity Level</a> below.
'Mode' mode [Mode]	<p>Activates or deactivates the syslog server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device doesn't send syslog messages to the configured syslog server.</li> <li>■ [1] <b>Enable</b> = The device sends syslog messages to the configured syslog server.</li> </ul>

## Configuring Syslog Message Severity Level

You can configure the minimum severity level of messages that you want to include in syslog messages that are generated by the device. The severity levels are described in the following table.

- It's strongly recommended to leave the syslog severity level at default (i.e., Notice) to prevent excessive utilization of the device's resources. Changing severity level is typically done only by AudioCodes Support for debugging.
- Upon a device restart or HA switchover, the syslog severity level returns to default.
- You can also configure syslog severity levels per syslog server (see [Configuring Secondary Syslog Servers](#) on page 1624).

Severity Level (Lowest to Highest)	Syslog String	Description
[7] <b>Debug</b>	"debug"	Debug message.
[6] <b>Info</b>	"info"	An operational message.
[5] <b>Notice</b> (default)	"notice"	An unusual event has occurred.
[4] <b>Warning</b>	"warning"	An error that might occur if measures are not taken to prevent it.
[3] <b>Error</b>	"error"	An error has been identified.
[2] <b>Critical</b>	"crit"	A problem has been identified that is critical.
[1] <b>Alert</b>	"alert"	A problem has been identified and an action must be taken immediately to resolve it.
[0] <b>Emergency</b>	"emerg"	A panic condition (system is unstable).

The specified severity level and all higher severity levels are included in the syslog message. For example, if you configure the parameter to **Alert**, the syslog includes messages with **Alert** severity level and messages with **Emergency** severity level.

When viewing syslog messages in the Web interface (see [Viewing Syslog Messages](#) on page 1636), each severity level is displayed in a different color.

➤ **To configure the minimum message severity level to include in syslog:**

1. Open the Logging Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Logging** folder > **Logging Settings**).
2. From the 'Log Severity Level' [SyslogLogLevel] drop-down list, select the severity level.

**Log Severity Level**

• Critical ▼

3. Click **Apply**.

## Configuring Syslog Debug Level

You can configure the amount of information (debug level) to include in syslog messages. You can also enable the device to send multiple syslog messages bundled into a single packet, and enable a protection mechanism that automatically lowers the debug level when the device's CPU resources become low, ensuring sufficient CPU resources are available for processing voice traffic.

### ➤ To configure syslog debug level:

1. Open the Logging Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Logging** folder > **Logging Settings**).
2. From the 'VoIP Debug Level' [GwDebugLevel] drop-down list, select the debug level of syslog messages:
  - **No Debug:** Disables syslog and no syslog messages are sent.
  - **Basic:** Sends debug logs of incoming and outgoing SIP messages.
  - **Detailed:** Sends debug logs of incoming and outgoing SIP message as well as many other logged processes.

VoIP Debug Level • Basic ▼

3. Select the 'Optimization' check box [SyslogOptimization] to enable the device to accumulate and bundle multiple debug messages into a single UDP packet before sending it to a syslog server. The benefit of this feature is that it reduces the number of UDP syslog packets, thereby improving (optimizing) CPU utilization. The size of the bundled message is configured by the [MaxBundleSyslogLength] parameter.

Optimization • ☒

4. Select the 'CPU Protection' check box [SyslogCpuProtection] to enable the protection feature for the device's CPU resources during debug reporting, ensuring voice traffic is unaffected. If CPU resources drop (i.e., high CPU usage) to a critical level (user-defined threshold), the device automatically lowers the debug level to free up CPU resources that were required for the previous debug-level functionality. When CPU resources become available again, the device increases the debug level to its' previous setting. For example, if you set the 'Debug Level' to **Detailed** and CPU resources decrease to the defined threshold, the device automatically changes the level to **Basic**, and if that is not enough, it changes the level to **No Debug**. Once CPU resources are returned to normal, the device automatically changes the debug level back to its' original setting (i.e., **Detailed**). The threshold is configured by the [DebugLevelHighThreshold] parameter.

CPU Protection ☒

5. Click **Apply**.

## Reporting Management User Activities

You can enable the device to log various operations (actions) done by management users in the device's management interfaces (e.g., Web and CLI). The actions are logged in the Activity Log and sent in syslog messages. You can also view these logged user activities in the CLI and Web interface (see [Viewing Management User Activity Logs](#) on page 1459).

The logged actions are indicated in syslog messages with the string "Activity Log":

```
14:07:46.300 : 10.15.7.95 : Local 0 :NOTICE : [S=3149] [BID=3aad56:32]
Activity Log: <Message>. User: <User>. Session: <Protocol> (<IP Address>)
[Time:dd-mm@hh:mm:ss.sss]
```

Where:

- **<Message>** describes the performed action.
- **<User>** is the username of the user (e.g., "Admin") that performed the action.
- **<Protocol>** is the protocol that was used to access the management interface (e.g., Web or Telnet).
- **<IP Address>** is the IP address of the client PC from where the user accessed the device's management interface.
- **Time** is the date and time that the action was performed.

The device can report the following types of user activities:

- Modifications of individual parameters, for example:

```
16:19:24.983 10.15.7.96 local0.notice [S=7] [BID=5b1035:7] Activity Log:
No Answer Timeout [sec] was changed from '600' to '550'. User: Admin.
Session: WEB (10.13.2.3) [Time:07-09@16:39:22.736]
```

- Modifications of table fields, and addition and deletion of table rows, for example:

```
16:22:54.287 10.15.7.96 local0.notice [S=16] [BID=5b1035:7] Activity Log:
Classification - remove line 2. User: Admin. Session: HTTP (10.13.2.3)
[Time:07-09@16:39:22.736]
```

```
16:22:54.287 10.15.7.96 local0.notice [S=16] [BID=5b1035:7] Activity Log:
Local Users Table row 1 (MyUser) - 'User Level' was changed from
'Administrator' to 'Security Administrator'. User: Admin. Session: WEB
(10.13.2.3) [Time:07-09@16:39:22.736]
```

- Modifications of parameters due to an incremental ini file upload. If you choose this option, you can also define the maximum number of lines of parameters to log from the ini file, using the 'Incremental INI Activity Logs Max Number' parameter.
- Entered CLI commands (modifications of security-sensitive commands are logged without the entered value).
- Configuration file upload (reported without per-parameter notifications).
- Auxiliary file upload and software update.
- File download (ini file, CLI Script file and Configuration Package file).
- Device restart and save to flash memory.
- Access to unauthorized Web pages according to the Web user's access level.
- Modifications of "sensitive" parameters.
- Log in and log out, for example:

```
16:15:56.946 10.15.7.96 local0.notice [S=3] [BID=5b1035:7] Activity Log:
WEB: Successful login at 10.15.7.96:80. User: Admin. Session: WEB
(10.13.2.3) [Time:07-09@16:39:22.736]
```

```
16:16:14.714 10.15.7.96 local0.notice [S=5] [BID=5b1035:7] Activity Log:
Unauthorized access attempt to Login Page. Reason: bad credentials.
User: Admin. Session: WEB (10.13.2.3) [Time:07-09@16:39:22.736]
```

- Actions not related to parameter changes (for example, file uploads and downloads, file delete, lock-unlock maintenance actions, LDAP clear cache, register-unregister, and start-stop trunk). In the Web, these actions are typically done by clicking a button (e.g., the LOCK button).

For more information on each of the above listed options, see [Syslog, CDR and Debug Parameters](#) on page 1766.

The following procedure describes how to configure management user activity logging through the Web interface. You can also configure it through ini file [ActivityListToLog] or CLI (configure troubleshoot > activity-log).

#### ➤ To configure reporting of management user activities:

1. Open the Logging Settings page (**Troubleshoot** tab > **Troubleshoot** menu > **Logging** folder > **Logging Settings**).
2. Under the Activity Types to Report group, select the actions to report to the syslog server. For all activity types, select the 'Select All' check box.

**ACTIVITY TYPES TO REPORT**Select All ☐Parameters Value Change ☐Auxiliary Files Loading ☐Device Restart ☐Flash Memory Burning ☐Device Software Upgrade ☐Non-Authorized Access ☐Sensitive Parameters Value Change ☐Login and Logout ☐CLI Activity ☐Action Executed ☐Incremental INI ☐Incremental INI Activity Logs Max Number **3. Click Apply.**

- Logging of CLI commands can only be configured through CLI (configure troubleshoot > activity-log) or ini file.
- You can configure the device to send an SNMP trap each time a user performs an action. For more information, see [Enabling SNMP Traps for Web Activity](#) on page 114.
- Passwords are hidden (by asterisks \*) in the Activity Log.

**Viewing Syslog Messages**

You can view syslog messages generated by the device using any of the following syslog server types:

- **Device's Web Interface:** The device provides an embedded syslog server, which is accessed through the Web interface (**Troubleshoot** tab > **Troubleshoot** menu > **Message Log** ). You can select the syslog messages displayed on the page, and then copy-and-paste them into a text editor such as Notepad. This text file (txt) can then be sent to AudioCodes support team for diagnosis and troubleshooting.

Start Stop Clear

The displayed logged messages are color-coded based on message type:

- "notice": Dark green
- "error", "crit", "alert", "emerg": Red
- "debug": Black
- "info": Blue
- "warn": Magenta

The page provides various buttons to do the following actions:

**Table 62-7: Buttons on Message Log Page**

Button	Description
<b>Start</b>	Resumes the message log after it has been stopped (see the <b>Stop</b> button).
<b>Stop</b>	Stops the message log, allowing you to easily scroll through the messages to a specific message.
<b>Clear</b>	<p>Clears the message log. The button can only be clicked after you have stopped the message log (see the <b>Stop</b> button).</p> <p><b>Note:</b> If you navigate away from the Message Log page to another page, the Message Log is stopped and cleared.</p>

- It's not recommended to keep a Message Log session open for a prolonged period. This may cause the device to overload. For prolonged (and detailed) debugging, use an external syslog server.
- The Message Log page provides limited syslog server functionality.

- **Device's Serial Console:** You can enable the device to also send the syslog messages to the serial console (over the device's physical serial interface). This may be useful, for example, if you no longer have network access to the device and you would like to perform

diagnostics. To enable this feature, configure the [EnableConsoleLog] parameter to 1, and then restart the device.

- **Device's CLI:** The device sends error messages (e.g., syslog messages) to the CLI as well as to the configured destination.

- To start debug recording:

```
debug log
```

- To stop debug recording:

```
no debug log
```

- To stop all debug recording:

```
no debug log all
```

- **Wireshark:** Third-party, network protocol analyzer (<http://www.wireshark.org>).

- **AudioCodes Syslog Viewer:** This utility can be used for two major tasks:

- Recording and displaying syslog messages from the device
- Analyzing recorded logs (including support for interactive SIP ladder diagrams)

To obtain the Syslog Viewer installation file, download it from <https://www.audiocodes.com/library/firmware>.

Figure 62-1: Example of Syslog Messages in Syslog Viewer

Figure 62-2: Example of SIP Ladder Diagram in Syslog Viewer

- **Third-party, Syslog Server:** Any third-party, syslog server program that enables filtering of messages according to parameters such as priority, IP sender address, time, and date.

## Syslog Message Description for CPU Overload

Whenever the device detects a CPU overload, it sends a syslog message that shows CPU utilization of the different processes (tasks) per core. This information can help in identifying the cause of the overload. When the device detects a CPU overload, it sends a syslog message every 10 seconds until it returns to normal state.

You can also view CPU utilization through the CLI, by using the following command:  
show system utilization

The figure below shows an example of a syslog message generated because of a CPU overload. CPU utilization information is shown under the "CPUUtilMonitor" section (shown in pink). The subsequent table describes the displayed information.

```

CPUUtilMonitor: System CPU overload condition [Core 0/96] (CPU Util=98%; period=1000 [msec])
CPU utilization task report (monitored period=1000 [msec]; total=1000 [msec]) [File:CPUUtiliz
  Name(TID) Core Usage[ms] Usage[%] ( Total[ms] (%) Peak[ms] #Switch) [File:CPUUtilize.cpp

```

Table 62-8: CPU Overload Fields Description in Syslog Message

Field	Description
First line (shown in pink)	
"Core"	Index of the CPU core.
"CPU Util"	CPU utilization (in percentage).
"period"	Total period (in msec).
Second line	
"monitored period"	Duration (in msec) of CPU overload within the total monitored period.
"total"	Monitored period (in msec).
Statistics per task (process) in overloaded cores only <b>Note:</b> By default, the syslog message only shows the five most used tasks in the last period.	
"Name (TID)"	Name of task (process).
"Core"	Index of the CPU core.
"Usage [ms]"	Total time (msec) of monitored period that the task utilized CPU.
"Usage [%]"	Percentage of time of monitored period that the task utilized

Field	Description
	CPU.
"Total [ms (%)]"	Total time (in msec) and percentage that task utilized CPU during entire period.
"peak [ms]"	Maximum lasting time (msec) that the task utilized CPU during the period.
"#Switch"	Context switch time - number of consecutive periods that were allocated for this task.
Statistics per CPU core	
"CPU#"	Index of the CPU core.
"User"	Percentage of CPU utilization that occurred while executing at the user level (application).
"Nice"	Percentage of CPU utilization that occurred while executing at the user level with nice priority (Linux systems).
"System"	Percentage of CPU utilization that occurred while executing at the system level (kernel).
"Idle"	Percentage of time that the CPU was idle (%) during which no tasks were using the CPU core.
"IOWait"	Percentage of time that the CPU was idle (5) during which tasks were using the CPU core.
"IRQ"	IRQ time (in percentage).
"SoftIRQ"	SoftIRQ time (in percentage%).

## Packet Loss Indication in Syslog

The device reports packet loss (PL) of incoming (Rx) RTP media streams (calls) in 15-second intervals. The device obtains packet loss statistics from the RTCP of the RTP streams. When packet loss occurs in the 15-second interval, at the end of the interval the device sends a syslog message with Warning severity level, indicating this packet loss. The syslog indicates the number of calls that experienced packet loss per packet loss range (in percentage) during the interval. It also indicates the number of calls that didn't have packet loss. If no packet loss occurred in all the RTP streams in the 15-second interval, no syslog message is sent.

Below shows an example of a syslog message sent when packet loss occurred in the 15-second interval. This syslog indicates that 6 calls were active during the interval. One call had no packet loss, 3 calls had 1 to 2% packet loss, and 2 calls had 5 to 100% packet loss:

```
16:47:13.921 192.168.8.70 local0.warn [S=2116] [BID=884772:92] Packets-Loss  
report [PL range]=#media-legs: [No PL]=1, [up to 0.5%]=0, [0.5% - 1%]=0, [1% -  
2%]=3, [2% - 5%]=0, [5% - 100%]=2 [[Time:28-12@00:40:18.550|time:28-  
12@00:40:18.550]]
```

Below shows the default packet-loss ranges in the syslog:

- [No PL]: Indicates the number of calls without packet loss.
- [up to 0.5%]: Indicates the number of calls with up to 0.5% packet loss. This packet loss typically has no effect on voice quality.
- [0.5% - 1%]: Indicates the number of calls with 0.5 to 1% packet loss. This packet loss typically has no effect on voice quality.
- [1% - 2%]: Indicates the number of calls with 1 to 2% packet loss. This packet loss may affect voice quality for calls using certain vocoders.
- [2% - 5%]: Indicates the number of calls with 2 to 5% packet loss. This packet loss affects voice quality and typically indicates a network problem.
- [5% - 100%]: Indicates the number of calls with 5 to 100% packet loss. This packet loss affects voice quality and typically indicates a network problem.

You can change these packet-loss ranges, using the [PLThresholdLevelsPerMille] parameter. For more information, see [Syslog, CDR and Debug Parameters](#) on page 1766.

- The packet loss report in the syslog message should be carefully considered. For example, for calls that are opened and then closed during the 15-second interval, packet loss statistics may be misleading due to insufficient packets for accurate calculation. Therefore, if the syslog message shows very few calls in the high packet-loss ranges, then you should probably ignore them as it might be due to this scenario. On the other hand, if there is a large number of calls falling into these high packet-loss ranges, then it probably indicates network problems.

## Configuring Debug Recording

This section describes how to configure debug recording and how to collect debug recording packets.

- For a detailed description of the debug recording parameters, see [Syslog, CDR and Debug Parameters](#) on page 1766.

## Configuring Debug Recording Server Address

The procedure below describes how to configure the address of the debug recording server to where the device sends captured traffic. Once you configure an address, the device generates debug recording packets for all calls. However, you can configure the device to generate debug recording packets for specific calls, using Logging Filter rules in the Logging Filters table (see [Configuring Logging Filter Rules](#) on page 1602).

You can also save debug recordings to an external USB hard drive that is connected to the device's USB port. For more information, see [USB Storage Capabilities](#) on page 1423.

### ➤ To configure debug recording server's address:

1. Open the Debug Recording page (**Troubleshoot** tab > **Troubleshoot** menu > **Logging** folder > **Debug Recording**).

#### DEBUG RECORDING SERVER

Destination IP Address	<input type="text" value="0.0.0.0"/>
Destination Port	<input type="text" value="925"/>
Interface Name	<input type="text"/>

2. In the 'Destination IP Address' field (DebugRecordingDestIP), configure the IP address (IPv4 or IPv6) of the debug capturing server.
3. In the 'Destination Port' field, configure the port of the debug capturing server.
4. In the 'Interface Name' field (DebugRecordingIpInterfaceName), enter the name of the IP Interface through which you want the device to send captured traffic to the debug server. The value must be the same as the 'Name' field value in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
5. Click **Apply**.

- The IP version (IPv4 or IPv6) of the 'Destination IP Address' and 'Interface Name' fields must be the same.
- You can configure the 'Interface Name' field with any IP Interface type (OAMP, Media, or Control), as long as the IP version is the same as the address configured in the 'Destination IP Address' field. By default, the device uses the IPv4 OAMP interface.
- By default, if you configure an address in the 'Destination IP Address' field without configuring the 'Interface Name' field, the device uses the OAMP interface with the same IP version (IPv4 or IPv6) as the configured address. If no OAMP interface with the same IP version exists, then no debug recording is sent.

## Starting and Stopping Debug Recording

To activate debug recording of debug recording rules configured in the Logging Filters table, you need to manually start the debug recording process, as described in this section. By default, debug recording runs for 60 minutes before automatically stopping (unless you manually stop it before this time). You can modify this debug recording duration if needed.

- The device does debug recording only for rules in the Logging Filters table with the following settings:
  - ✓ 'Mode' parameter is configured to **Enable**.
  - ✓ 'Log Destination' parameter is configured to **Debug Recording Server**.
- If debug recording is currently running (i.e., started), the device resets the debug recording timer to the configured debug recording timeout upon the following:
  - ✓ A new rule is added to, or an existing rule is modified in, the Logging Filters table.
  - ✓ A device restart.
  - ✓ An HA switchover.

### ➤ To start debug recording:

1. Configure a debug recording rule(s) in the Logging Filters table and configure its 'Mode' parameter to **Enable** (see [Configuring Logging Filter Rules](#) on page 1602).
2. Open the Debug Recording page (**Troubleshoot** tab > **Troubleshoot** menu > **Logging** folder > **Debug Recording**).
3. Configure the maximum duration for debug recording:
  - a. In the 'Debug Recording Timeout' field, configure the maximum duration (in minutes) for the debug recording process. When this timer expires, the device automatically stops debug recording (unless you've explicitly stopped it before the timer expires).
  - b. Click **Apply**.
4. Click the **Start Debug Recording** button; the device starts debug recording and the following is displayed in these read-only fields:
  - The 'Debug Recording Status' field displays "Started".

- The 'Debug Recording End Date & Time' field displays the date and UTC time when debug recording will automatically stop:

GENERAL	
Debug Recording Status	Started
Stop Debug Recording	<button>Stop Debug Recording</button>
Debug Recording Timeout	<input type="text" value="60"/>
Debug Recording End Date & Time	25/2/2025 12:29:38

➤ **To stop debug recording:**

1. Click the **Stop Debug Recording** button; the device stops debug recording and the read-only 'Debug Recording Status' field displays "Stopped".

## Collecting Debug Recording Messages

To collect debug recording packets, use the open source packet capturing program, Wireshark. This allows you to analyze AudioCodes debug recording protocol.

- The default debug recording port is 925. You can change the port in Wireshark (**Edit menu > Preferences > Protocols > AC DR**).
- The source IP address of the messages is always the OAMP IP address of the device.
- By default (no filters applied), debug recording doesn't capture media (i.e., RTP/RTCP) but captures only non-media (e.g., SIP, syslog, and Web). This is to prevent CPU overload (and even device crashes) when medium or high traffic exists. Therefore, debug recording is **not** intended to capture media. However, if you need to capture full media packets (all headers) using debug recording, please contact AudioCodes support. If you want to capture media, it's recommended to use the Logging Filters table where you can specify media (see [Configuring Logging Filter Rules](#) on page 1602).

➤ **To view debug recording messages using Wireshark:**

1. Install Wireshark on your computer (which can be downloaded from <https://www.wireshark.org>).

During installation, it's recommended to choose (default) the Npcap packet sniffing library for Windows.

2. Only if you are using a Wireshark version that is earlier than 3.4.0 or you want to do PSTN (NetBricks) traces through Wireshark, you need to download AudioCodes proprietary

Wireshark plug-in files to analyze AudioCodes debug recording protocol. Otherwise, skip to Step 3.

- The Wireshark plug-in files are deprecated. Therefore, it's recommended to use Wireshark Version 3.4.0 or later (unless you want to do PSTN traces, which requires the **acdr.dll** plug-in file).
- The plug-in files are per major software release of Wireshark (excluding 3.4.0 and later). For more information, contact the sales representative of your purchased device.
- Make sure that you download the plug-in files that match your computer's Windows operating system (32-bit or 64-bit processor).

- a. Got to AudioCodes firmware download website page at <https://www.audiocodes.com/library/firmware>, and then navigate to the page for the "Wireshark Plugins":

## Wireshark Plugins

[Click here to download](#)

- b. Click the area shown above; folders containing the plug-in files for different Wireshark versions are displayed, as shown in the example below:

 Wireshark

☐ Select All Sort By Name ▾ ☰ ⋮

			
Wireshark 2.0 91 MB	Wireshark 2.4 12 MB	Wireshark 3.0 2 MB	Wireshark 3.2 2 MB

☐ I agree: [Terms and Conditions](#)

0 Items Selected Download

- c. Click the folder icon of the required Wireshark version; zipped folders of the selected Wireshark version are displayed:

Wireshark > Wireshark 3.2

 Wireshark 3.2

☐ Select All Sort By Name ▾ ☰ ⋮

		
dtds.zip 2 KB	plugins.zip 731 KB	Plugins_x64.zip 896 KB

☐ I agree: [Terms and Conditions](#)

0 Items Selected Download

- d. Select the check box of the required zipped plug-in files, select the **I agree** (to the terms and conditions) check box, and then click **Download**; the zipped folder is downloaded to your computer.

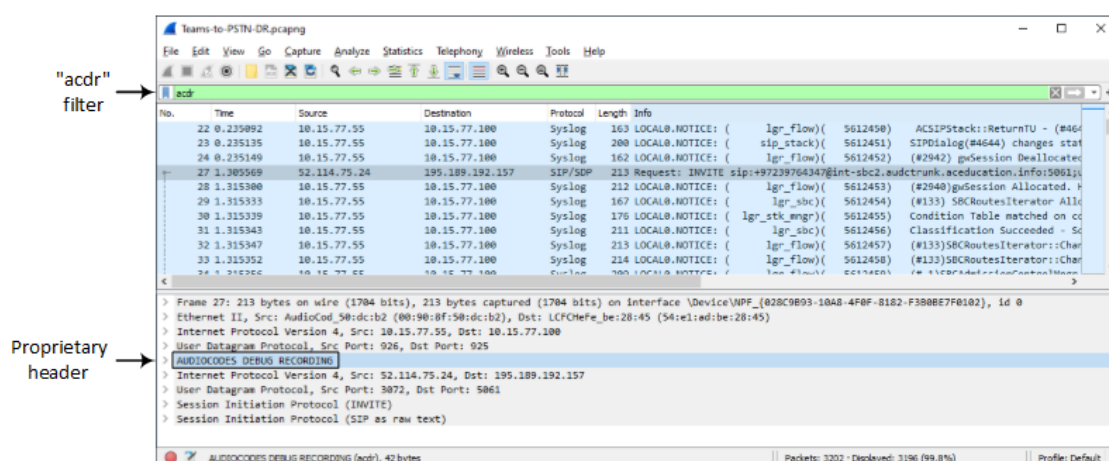

Make sure that you select the zipped plug-in folder that matches your computer's Windows operating system (32-bit or 64-bit processor):

- **plugins.zip**: For 32-bit
- **Plugins\_x64.zip**: for 64-bit

- e. Unzip the downloaded plug-in folder; a folder containing all the plug-in files (.dll) is created.
  - f. Copy all the .dll files to the *plugin* folder (or for Wireshark Version 3.0 or later, to *plugins\<Wireshark version>\epan*) of the Wireshark installation. If the folder already has existing .dll files with the same name, overwrite them.
3. Start your Wireshark program.
  4. In the filter field, type "acdr" to view the debug recording messages.

The device adds the header "AUDIOCODES DEBUG RECORDING" to each debug recording message, as shown below:

## Debug Capturing on Physical VoIP Interfaces

You can capture traffic on the device's physical (Ethernet LAN) VoIP interfaces (Layer-2 VLAN tagged packets). The captured traffic can be saved in a PCAP-format file (suitable for Wireshark) to a TFTP (default) or an FTP server. The generated PCAP file is in the Extensible Record Format (ERF). You can also save the capture to a USB device. The maximum file size of debug captures that can be saved to the device is 20 MB/100 MB.

To capture traffic on physical VoIP interfaces, use the following CLI commands:

- Starts physical VoIP debug capture:

```
# debug capture voip physical eth-lan
# debug capture voip physical start
```

- Captures packets continuously in a cyclical buffer (packets always captured until stop command):

```
# debug capture VoIP physical cyclic buffer
```

- Retrieves latest capture (PCAP file) saved on a specified server:

```
# debug capture VoIP physical get_last_capture <TFTP/FTP server IPv4 / IPv6 address>
```

The file is saved to the device's memory (not flash) and erased after a device restart.

- Marks the captured file (useful for troubleshooting process):

```
# debug capture VoIP physical insert-pad
```

Before running this command, the debug capture must be started.

- Displays debug status and configured rules:

```
# debug capture VoIP physical show
```

- Specifies the destination (FTP, TFTP, or USB) where you want the PCAP file sent:

```
# debug capture VoIP physical target <ftp|tftp|usb>
```

- Stops the debug capture, creates a file named debug-capture-voip-<timestamp>.pcap, and sends it to the TFTP or FTP server:

```
# debug capture voip physical stop <TFTP/FTP server IPv4 / IPv6 address>
```

If no IP address is defined, the capture is saved on the device for later retrieval.

## Debug Capturing on VoIP Interfaces

You can debug capture (record) network traffic on the device's VoIP interfaces per VLAN that is configured in the Ethernet Devices table (see [Configuring Underlying Ethernet Devices](#) on page 156). You can also capture traffic on one of the device's kernel interfaces (e.g., `eth0`, `eth1`, `lo`, or `tun0`). This may be useful, for example, to capture packets on the tunneling interface used for WebSocket traffic.

You can send the captured traffic to the following:

- **CLI terminal screen (tcpdump format):** The captured network packets are displayed in the CLI until you end the capture, by pressing the CTRL + C key combination.
- **Remote server (TFTP or FTP):** The capture is saved as a PCAP file (suitable for Wireshark) and sent to a specified server (default is TFTP) . The generated PCAP file is in the Extensible Record Format (ERF) and is saved on the device during the capture. The maximum file size that can be saved to the device is 10 MB and as long as the capture continues, the packets are written to this 10-MB file in a cyclic manner. When you end the capture (by pressing the CTRL + C key-combination), the device sends the capture file to the server.

The following procedure describes how to configure debug capturing for a specific VLAN. For debug capturing a kernel interface, use the same commands, but instead of `vlan` use `kernel-dev`, as shown below:

```
# debug capture voip interface kernel-dev <Name, e.g., tun0>
```

➤ **To capture traffic on VoIP VLAN interface:**

1. Define the VLAN ID on which you want to do the capture:

```
# debug capture voip interface vlan <VLAN ID>
```

2. Define the protocol that you want to capture (all|arp|icmp|ip|ipv6|tcp|udp):

```
# debug capture voip interface vlan <VLAN ID> proto <Protocol>
```

3. Define a source and/or destination IP address to be captured (any|ipv4\_address|ipv6\_address):

```
# debug capture voip interface vlan <VLAN ID> proto <Protocol> host < IPv4 /  
IPv6 Address>
```

At this stage, you can press Enter to output the capture to the CLI terminal window, or you can continue with the next step to configure additional commands.

4. Define a source and/or destination port number to be captured (any|[1-65535]):

```
# debug capture voip interface vlan <VLAN ID> proto <Protocol> host < IPv4 /  
IPv6 Address> port <Port>
```

At this stage, you can press Enter to output the capture to the CLI terminal window, or you can continue with the next step to configure additional commands.

5. Define the IP address (IPv4) of the server (TFTP or FTP) to where you want the device to send the captured file:

```
# debug capture voip interface vlan <VLAN ID> proto <Protocol> host <IP  
Address> ftp-server|tftp-server < IPv4 / IPv6 Address>
```

6. Press Enter to start debug capturing (and temporarily saves the capture to a file on the device).
7. Press the CTRL+C key-combination to stop the capture and send the file to the defined server.

## Configuring Wireshark Packet Capturing using RPCAP

You can use the device's embedded Remote Capture Protocol (RPCAP) server to capture network packets (IPv4 and IPv6) and then analyze them using the Wireshark tool on your computer. Once you have enabled the device's RPCAP server and then connected (over TCP) your remote Wireshark client to the device, you can use Wireshark to start or stop network capture on a specific device network interface, collect the captured data, and filter the captured data. In other words, control of the packet capturing process is from your Wireshark client. For more information on RPCAP functionality, refer to [Wireshark documentation](#).

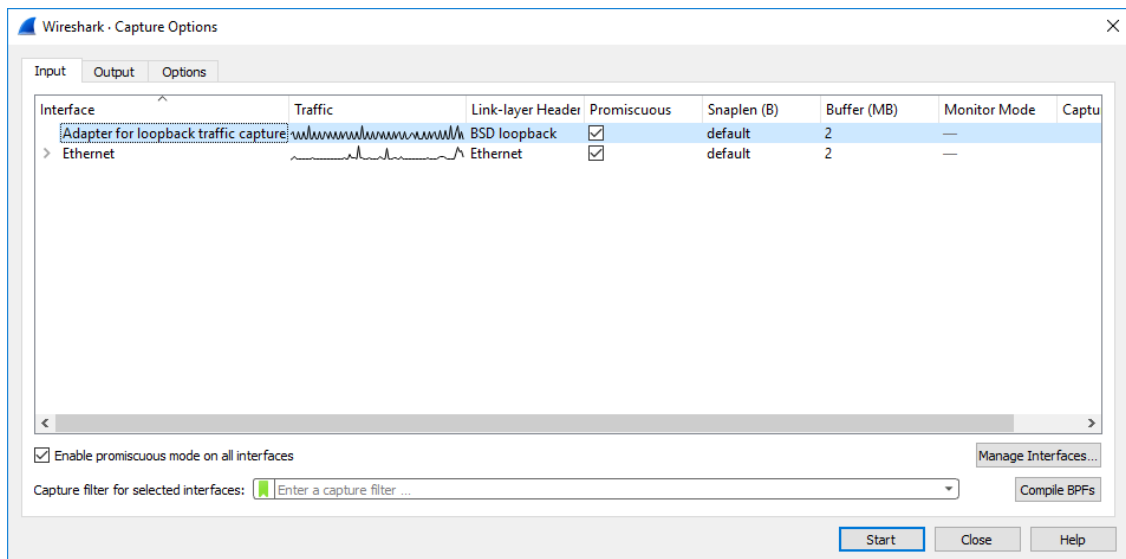

- Wireshark filtering is merely a view filter; the device sends **all** packets to the computer running Wireshark, regardless of Wireshark's filtering settings.
- It's not recommended to use RPCAP during heavy traffic as this may utilize much of the device's CPU and network resources. If you need to capture specific traffic during heavy traffic, it's recommended to use the CLI command `debug capture` or the Logging Filters table for IP traces with the relevant filters (see [Configuring Logging Filter Rules](#) on page 1602).
- To free up the device's CPU resources used by the RPCAP server, after you have finished debugging, it's recommended to stop the RPCAP server, as described at the end of this section.
- By default (no filters applied), RPCAP captures **non-media only** (e.g., SIP, syslog, and Web) and doesn't capture media (i.e., RTP/RTCP). This is to prevent CPU overload under medium or high traffic. Therefore, RPCAP is **not** intended to capture media. If you want to capture media, use the Logging Filters table, as described in [Configuring Logging Filter Rules](#) on page 1602.

### ➤ To start packet capturing through RPCAP:

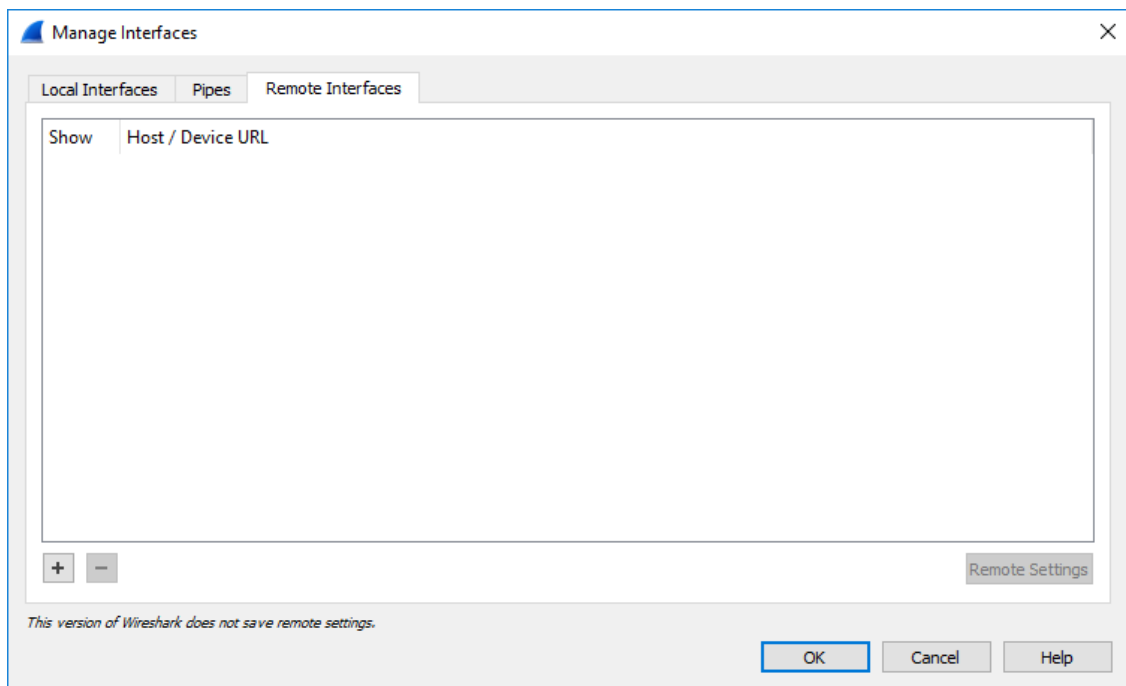

1. Start packet capturing by the device's RPCAP server, using the following CLI command. This command also allows you to configure the first and second ports of the RPCAP server. The first port is an always-open listening port for initial connections. The second port is sent to the client during the initial connection to open a new TCP connection for the captured packets. By default, the first port number is 2002 and the second port number is dynamically allocated by the device.

```
# debug capture rpcap-server start <First Port> <Second Port>
```

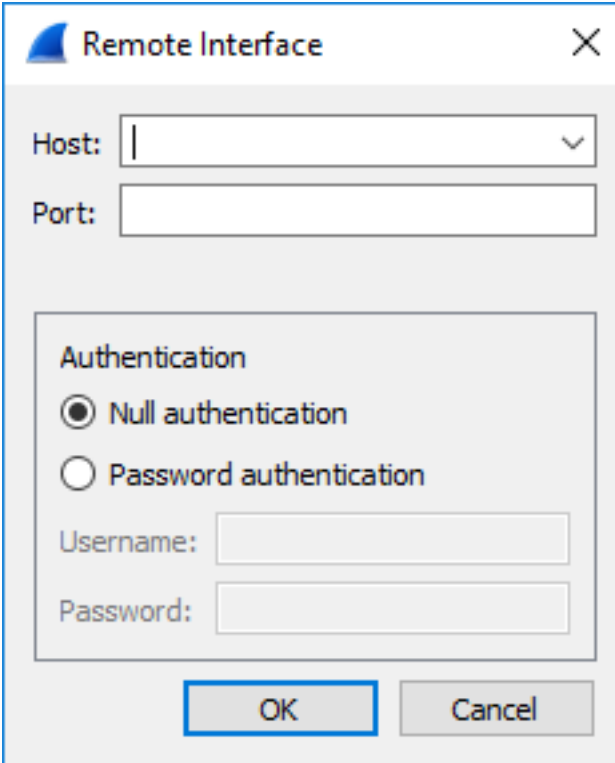

2. On your remote computer, start the Wireshark client.
3. From the Capture menu, choose **Options**; the Capture Options dialog box appears:

4. Click **Manage Interfaces**, and then in the Manage Interfaces dialog box, select the **Remote Interfaces** tab: the following appears:

5. Click the plus button; the following dialog box appears:

The 'Remote Interface' dialog box is used to configure remote device settings. It includes fields for Host and Port, and an Authentication section with radio buttons for Null authentication (selected) and Password authentication. Below the radio buttons are fields for Username and Password. The dialog has OK and Cancel buttons at the bottom.

Host:

Port:

Authentication

☒ Null authentication

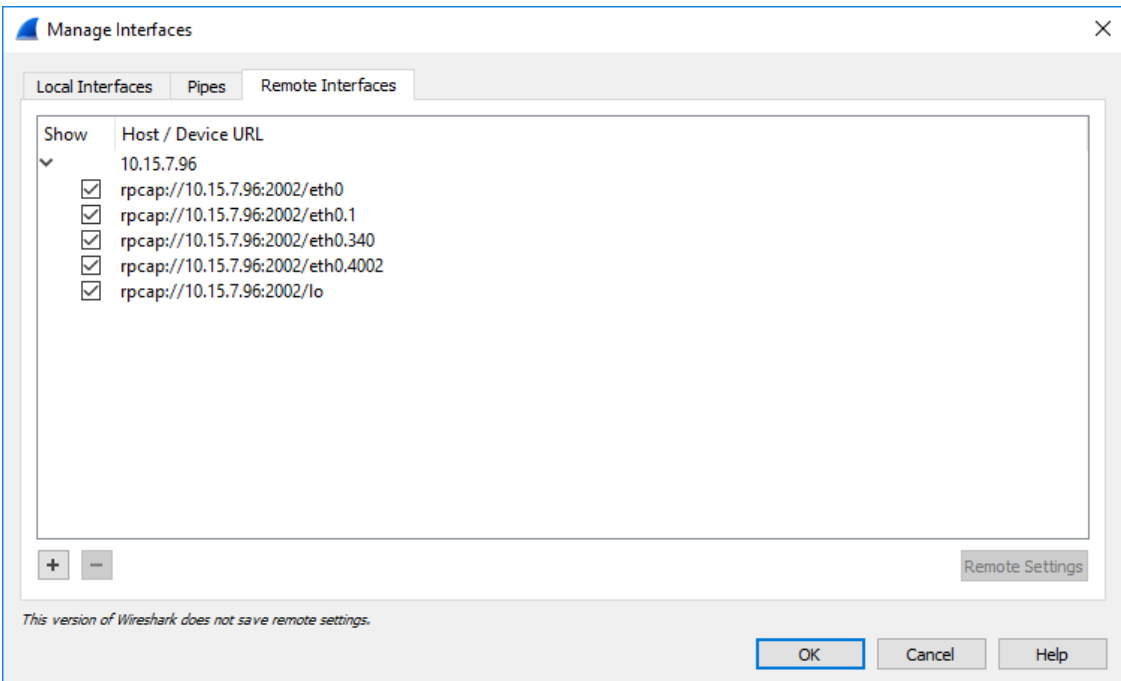

☐ Password authentication

Username:

Password:

OK Cancel

6. Fill in the following fields:
  - In the 'Host' field, enter the IP address of the device.
  - In the 'Port' field, enter the port of the device that is used for the packet capture sessions.
7. Click **OK**; the Manage Interfaces dialog box displays a list of all the device's network interfaces:

The 'Manage Interfaces' dialog box shows a list of network interfaces under the 'Remote Interfaces' tab. The list includes a 'Show' column with a dropdown arrow and a 'Host / Device URL' column. The URLs are listed with checkboxes next to them. At the bottom, there are '+' and '-' buttons, a 'Remote Settings' button, and a note: 'This version of Wireshark does not save remote settings.' The dialog has OK, Cancel, and Help buttons at the bottom right.

Local Interfaces Pipes Remote Interfaces

Show Host / Device URL

10.15.7.96

☒ rpcap://10.15.7.96:2002/eth0

☒ rpcap://10.15.7.96:2002/eth0.1

☒ rpcap://10.15.7.96:2002/eth0.340

☒ rpcap://10.15.7.96:2002/eth0.4002

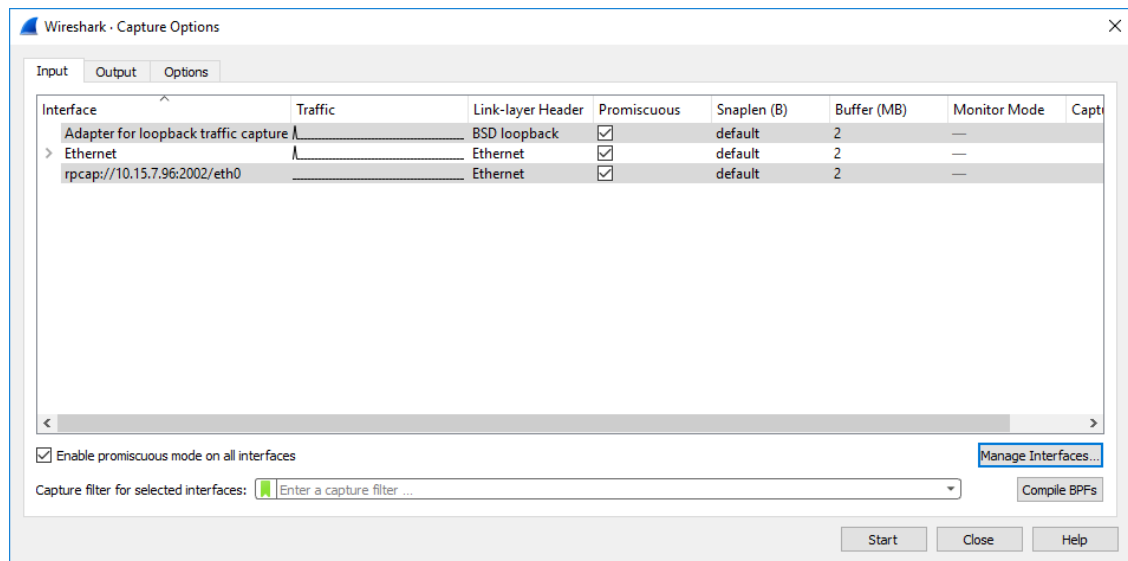

☒ rpcap://10.15.7.96:2002/lo

+ - Remote Settings

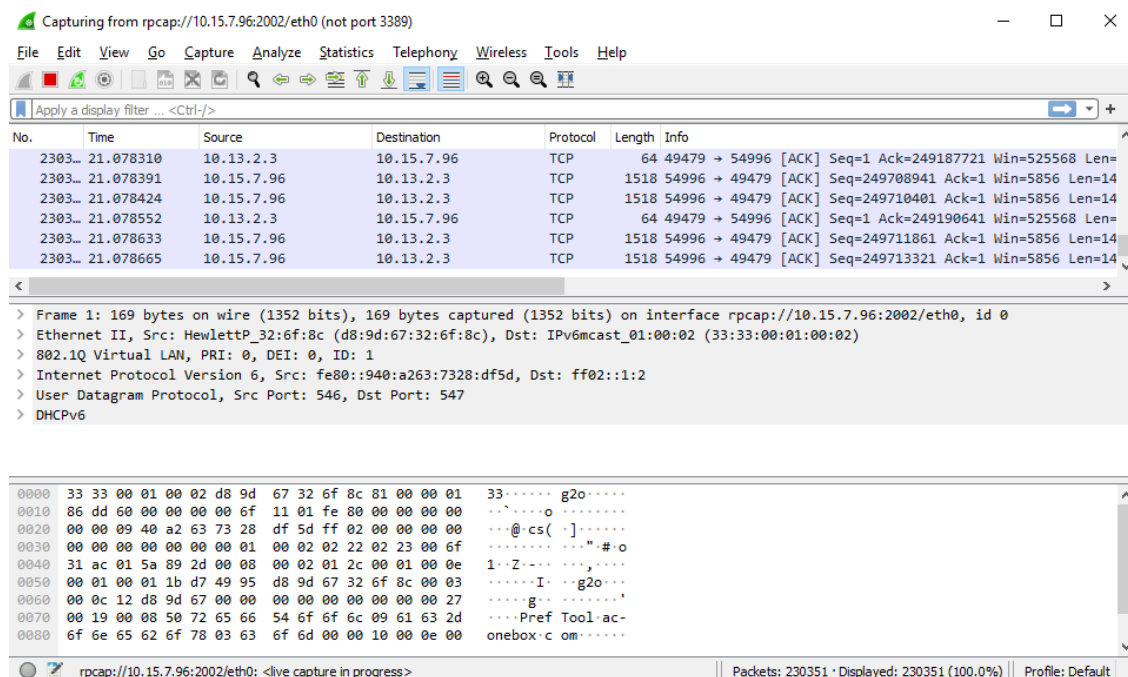

*This version of Wireshark does not save remote settings.*

OK Cancel Help

8. Using the check boxes, select only the network interfaces on which you want to capture packets, and then click **OK**; the Manage Interfaces dialog closes and you are returned to the Capture Options dialog box, which now displays the device's network interfaces that you selected in the previous step:

9. Select the required network interface, and then click **Start**; the Capture Options dialog box closes and the main Wireshark window displays captured packets as they are collected by Wireshark, as shown in the following example:

To stop the packet capturing on Wireshark, from the Capture menu, choose **Stop**. To continue capturing (with or without saving the previous capture), choose **Start**.

To stop the device's RPCAP server, first stop the Wireshark capturing, and then run the following CLI command:

```
# debug capture rpcap-server stop
```

## 63 Creating Core Dump and Debug Files upon Device Crash

For debugging, you can configure the device to create a core dump file and a debug file. These files may assist you in identifying the cause of the crash. The core dump can either be included in or excluded from the debug file, or alternatively, sent separately to a TFTP server. You can then provide the files to AudioCodes support team for troubleshooting.

### Enabling Core Dump File Generation

You can enable the device to automatically generate a core dump file upon a device crash. The core dump is a copy of the device's memory image at the time of the crash. The device generates a new core dump file each time it crashes, replacing the previous core dump file (if exists). The core dump file provides you with a powerful tool for determining the cause of the crash.

You can also configure the device to send the core dump file to a TFTP server (defined by IP address). If you don't configure an address, the core dump file is saved on the device's flash memory (if it has sufficient memory). The core dump file is saved as a binary file, using the following file name format: *core\_<Device Name>\_ver\_<Firmware Version>\_mac\_<MAC Address>\_<Date>\_<Time>*. For example: "core\_acDevice\_ver\_720-8-4\_mac\_00908F099096\_1-02-2015\_3-29-29".

- When downloading the debug file to your computer, you can also include the core dump file, as described in [Downloading the Debug \(and Core Dump\) File](#) on the next page.

#### ➤ To enable core dump file generation:

1. (Optional) Set up a TFTP server where you want the device to send the core dump file.
2. Open the Debug Files page (**Troubleshoot** menu > **Troubleshoot** tab > **Debug** folder > **Debug Files**).
3. Select the 'Enable Core Dump' check box to enable core dump file creation:

Enable Core Dump

4. (Optional) If you want the device to send the core dump file to a remote TFTP server, in the 'Core Dump Destination IP' field, enter the IP address of the remote server. If not configured, the device saves the file in it's local storage memory:

Core Dump Destination IP

0.0.0.0

5. Click **Apply**.

## Downloading the Debug (and Core Dump) File

You can download the debug file from the device (flash memory) and save it to a folder on your local computer.

The device creates the debug file whenever an exception occurs. Each time the device creates a new debug file, it overwrites the existing file. The debug file is saved as a TAR (Tape ARchive) file (.tar), with the following filename format: *debug\_<Device Name>\_ver\_<Firmware Version>\_mac\_<MAC Address>\_<Date>\_<Time>*. For example, *debug\_SBC\_ver\_740-500-966\_mac\_5b-10-35\_13-3-2024\_10-52-37.tar*.

The debug file contains the following:

- Exception information, indicating the specific point in the code where the crash occurred and a list of up to 50 of the most recent SNMP alarms that were raised by the device before it crashed.
- Restart (reset) history, where each restart entry provides the reason of the restart (e.g., triggered by Web interface or was an exception), date and time the restart occurred, device uptime before restart, and software version of the device. This information appears in the reset-history folder.
- Latest syslog messages that were recorded prior to the crash.
- Core dump file if **all** of the following conditions are met:
  - You have enabled core dump generation (see [Enabling Core Dump File Generation](#) on the previous page).
  - You have not configured an IP address to send the core dump to a remote server (see [Enabling Core Dump File Generation](#) on the previous page).
  - The device has sufficient memory on its flash memory.
  - You have enabled the inclusion of the core dump file in the debug file (see below procedure).
- Information on the Floating and Metering licenses (FloatLicense.lzma and MeterLicense.lzma files, respectively, in the system\_logs folder).
- If the device is configured with a Client Defaults ini file, it's included in the debug file in the Device folder (default.ini).
- Configuration Package file (in the Device folder).
- The debug file may include additional application-proprietary debug information.

### ➤ To download debug file:

1. Open the Debug Files page (**Troubleshoot** menu > **Troubleshoot** tab > **Debug** folder > **Debug Files**), and then scroll down to the 'Save The Debug File To The PC' group:

### SAVE THE DEBUG FILE TO THE PC

Save Debug File

Save Redundant Device's Debug File

2. By default, the core dump file is included in the downloaded debug file. If you don't want to include it, clear the 'Attach Core Dump File' check box.
3. Click the **Save Debug File** button; the device downloads the debug file to a folder on your computer. For devices in HA mode, this button downloads the debug file of the active device. To download the redundant device's debug file, click the **Save Redundant Device's Debug File** button.

- Downloading the debug file may take a few minutes. Depending on file size, it may even take more than 10 minutes.

- **Downloading through SFTP:**

You can also download (Get) the debug file from the device through SFTP. The file is located in the device's */debug* folder. Your SFTP client needs to authenticate itself with the SFTP server (i.e., the device). You can access the */debug* folder only if you are a **Security Administrator** user.

For downloading the debug file through SFTP, you need to enable SSH on the device.

The device may take a long time to prepare the debug file for SFTP transfer if it contains much information. Some SFTP clients (for example, WinSCP and FileZilla) have a short default connection timeout and if the file transfer is not started within this timeout, the transfer attempt is aborted. Therefore, it's recommended to configure a longer timeout for your SFTP client application.

## Deleting the Debug (and Core Dump) File

You can delete the debug file that is stored on the device's memory. If you have enabled core dump file generation (see [Enabling Core Dump File Generation](#) on page 1656) without configuring an address of a remote server to send the file to, the core dump file, which is included with the stored debug file is also deleted.

➤ **To delete the debug file (and core dump file):**

1. Establish a CLI session with the device.
2. Type the following command, and then press Enter:

```
# clear debug-file
```

## Debug (and Core Dump) File Contents

The debug file or core dump file contains the following information:

■ **Device:** This folder contains the following file:

- **configuration-package.7z:** This is the Configuration Package file, as described in [Downloading or Uploading Configuration Package File](#) on page 1389.
- **status.tar.gz:** This file contains various status information such as the device's date and available memory. These are some of the files:
  - ◆ **date-u.info** - UTC time
  - ◆ **date.info** - Local time
  - ◆ **uptime.info** - Duration (in seconds) that the device was operational before a restart
  - ◆ **df.info** - Available (free) disk space
  - ◆ **du.info** - Utilized disk space
  - ◆ **HardwareVersionsInfo.txt** - device's hardware version

■ **reset-history:** This folder contains logged device restarts and contains the following:

The *reset-table-of-content.txt* file lists the latest logged device restarts, where each logged restart is sequentially numbered ("Counter"), providing device uptime before the restart, the restart reason, and the date and time that it occurred. If the restart was caused by an error (i.e., crash), "Exception" instead of "Reset" is displayed above the restart counter. Below shows an example of logged device restarts:

```
** Current Reset Counter [84] **

***** Reset *****
Reset Counter:83
Up Time (seconds): 237890
Reset Reason: a hardware reset
Reset Time: 5.3.2025 2:24:18
SwVersion: ramMP500_ESBC_SIP 760A-092-799
*****

***** Reset *****
Reset Counter:82
Up Time (seconds): 890
Reset Reason: Web Reset
Reset Time: 23.2.2025 14:49:12
```

```
SwVersion: ramMP500_ESBC_SIP 760A-092-756
```

```
*****
```

```
**** Exception ****
```

```
Reset Counter:81
```

```
Exception Reason: System crashed due to Kernel Panic
```

```
EXCEPTION TIME : 31.8.2020 10.16.45
```

```
*****
```

Each logged device restart that is listed in the *reset-table-of-content.txt* file has a dedicated subfolder under the *reset-history* folder. For normal restarts, the folder's name is *<Restart Counter>\_Reset* (e.g., "83\_Reset"). For restarts due to errors, the folder's name is *<Restart Counter>\_Exception* (e.g., "81\_Exception").

This subfolder contains system events or messages that were logged immediately prior to the device restart:

- **core.lzma:** This file is generated if Core Dump is enabled and the device restarts (crashes) due to exception event. It is only present in the folder of the latest restart due to an exception.
- **ExceptionInfo.txt:** This file is generated only if device restart was caused by an exception event (error). As mentioned previously, these logged device restarts are displayed in the *reset-table-of-content.txt* file with the title "Exception". The file contains detailed information of the exception.
- **NoSip.lzma:** This file contains the latest syslog messages, but without SIP-related syslog messages.
- **Syslog.lzma:** This file contains all the latest syslog messages.

- To view the debug file in CLI:
  - ✓ Restart history (list of restarts or a specific reset counter): `show debug-file reset-info {list|reset-counter}`
  - ✓ Generated file contents (list of files or a specific file): `show debug-file device-logs list|file`
- The CLI doesn't display the Core Dump file.

## 63 Downloading the DSP Core Dump File

The device automatically creates a DSP Core Dump file whenever a DSP restart occurs. This file captures information about the DSP processes prior to the restart.

You can download the DSP Core Dump file to your computer for debugging. The file is downloaded in 7-Zip archive file format (.7z).

- The Web interface displays the DSP Core Dump file download functionality only when all the following conditions are met:
  - ✓ A DSP Core Dump file has been generated.
  - ✓ You're logged in as an Administrator or a Security Administrator user.
- The DSP Core Dump file is temporarily stored on the device's RAM. Therefore, it's deleted upon a device restart.

### ➤ To download DSP Core Dump file:

1. Open the Debug Files page (**Troubleshoot** menu > **Troubleshoot** tab > **Debug** folder > **Debug Files**).

SAVE THE DSP CORE DUMP FILE TO THE PC

Save DSP Core Dump File

Save

2. Under the **Save the DSP Core Dump File to the PC** group, click the **Save** button; the file is downloaded to a folder on your computer.

## 64 Debugging Web Services

If you have configured remote Web services (see [Remote Web Services](#) on page 438), you can enable debugging of the remote HTTP clients. You can configure the debug level from 1 to 3, where 3 is the most detailed. The debug messages are sent to the syslog server.

➤ **To configure debugging of Web services:**

1. Open the Web Service Settings page (**Setup** menu > **IP Network** tab > **Web Services** folder > **Web Service Settings**).
2. In the 'Debug Level' field (RestDebugMode), enter the debug level (or disable debugging by configuring it to 0):

Debug Level •

3. Click **Apply**.

## 65 Enabling SIP Call Flow Diagrams in OVOC

You can configure the device to send SIP messages (in XML format) of SIP call dialogs to AudioCodes One Voice Operations Centers (OVOC) so that it can display the call dialog as a call flow diagram (ladder). OVOC displays the call flow on the Call Flow page (**Calls** menu > **Calls List** tab > select call > **Show** button > **Call Flow** tab). The call flow is displayed using vertical and horizontal lines. The vertical lines represent the SIP entities (including the device itself) that are involved in the dialog. The horizontal lines represent the SIP requests and responses. An example of a SIP call flow diagram in OVOC is shown below. For more information on OVOC, refer to the document [One Voice Operations Center User's Manual](#).

SIP call flow diagrams may be useful for debugging and for better understanding of the SIP call. The call flow displays all the SIP messages related to the call session, including requests (e.g., INVITES) and responses (e.g., 200 OK). For SBC calls, the call flow reflects messages as sent "over the wire" - incoming messages before manipulation and outgoing messages after manipulation. For Gateway calls, the call flow reflects incoming messages after Pre-Parsing Manipulation (if configured) but before general Message Manipulation, and outgoing messages after manipulation.

### ➤ To configure SIP call flow support:

1. Enable the OVOC call flow feature:
  - a. Open the Logging Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Logging** folder > **Logging Settings**).
  - b. Select the 'Call Flow Report Mode' check box [CallFlowReportMode]:

Call Flow Report Mode ☒

- c. Click **Apply**.
2. To send call flow messages of specific calls only (e.g., for a specific IP Group), configure a Log Filter rule:
  - a. Open the Logging Filters table (see [Configuring Logging Filter Rules](#) on page 1602

- b. Click **New** , and then configure the rule as desired, but with the following parameter settings:

◆ 'Log Destination': **OVOC (QoE)**

◆ 'Log Type': **SIP Ladder**

**Logging Filters** — x

GENERAL

Index	<input type="text" value="0"/>
Filter Type	<input type="text" value="IP Group"/>
Value	<input type="text" value="4"/>
Log Destination	<input type="text" value="OVOC"/>
Log Type	<input type="text" value="SIP Ladder"/>
Mode	<input type="text" value="Enable"/>

- c. Click **Apply**.

- If you have not configured any filtering rule for SIP call flow (**SIP Ladder**) in the Logging Filters table, the device sends call flow messages to OVOC for all calls.
- The device doesn't send OVOC SIP messages that fail authentication (SIP 4xx challenge).
- The feature doesn't support SIPREC messages and REGISTER messages.
- When the device is in HA mode, during a switchover it stops sending SIP call flow messages of current SIP dialogs, and continues sending them after the switchover (even though OVOC doesn't display the continuation of the call after switchover).
- If the device experiences a CPU overload, it stops sending SIP call flow messages to OVOC until the CPU returns to normal levels.

## 66 Enabling Same Call Session ID over Multiple Devices

You can enable the use of a Global Session ID to identify call sessions traversing multiple devices.

The Global Session ID is a randomly assigned ID number that identifies each call session. The ID is unique to the call session and remains the same throughout the session even if the call traverses multiple devices.

The Global Session ID appears in SIP messages using the AudioCodes proprietary SIP header, AC-Session-ID, as shown in the example below:

```
INVITE sip:2000@172.17.113.123;user=phone SIP/2.0
...
AC-Session-ID: 7f6941530b31d715
...
```

If the device receives an incoming SIP message containing the Global Session ID, it sends the same Global Session ID in the outgoing SIP message. If the incoming SIP message doesn't contain a Global Session ID or if a new session is initiated by the device, the device generates a new, unique Global Session ID and adds it to the outgoing SIP message.

To enable the Global Session ID, use the ini file [SendAcSessionIdHeader] parameter or CLI command `configure voip > sip-definition settings > send-acsessionid`.

- The Global Session ID is not included in syslog messages.
- By default, the device doesn't include the Global Session ID in CDRs. However, you can customize CDRs to include it. For more information, see [Customizing CDRs for Gateway Calls](#) on page 1572 and [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578.
- The feature must be enabled on all devices through which the call traverses.
- If you disable this feature, the device sends outgoing SIP messages without a Global Session ID (even if a Global Session ID was received in the incoming SIP message).

## 67 Analog Line Testing

This section describes analog line testing.

### FXO Line Testing

The device can test the telephone lines connected to its FXO ports through SNMP using the `SNMP acAnalogFxoLineTestTable` table. The tests provide various line measurements. In addition to the tests, a keep-alive test is also done every 100 msec on each of the analog ports to detect communication problems with the analog equipment:

- Line Current (mA)
- Line Voltage (V)
- Hook (0 = on-hook; 1 = off-hook)
- Ring (0 - Off; 1 - On)
- Line Connected (0 = Disconnected; 1 = Connected)
- Polarity state (0 = Normal; 1 = Reversed, 2 = N\A)
- Line polarity (0 = Positive; 1 = Negative)
- Message Waiting Indication (0 = Off; 1 = On)

You can also view the above information through the Web interface (see [Viewing Voice Channel Information](#) on page 1448).

Analog line testing is traffic affecting and therefore, do the test only for monitoring and when there are no active calls in progress.

### FXS Line Testing

You can test FXS telephone lines that are connected to the device's FXS ports. The test is done per FXS port and FXS country coefficient type - USA (70) or TBR21 (66). The output of the test displays various line statuses and electrical line measurements. Some of the supported FXS status and line measurements include:

- Hazardous Potential Tests (HPT) - hazardous AC or DC voltage is present on the tip and ring or both.
- Foreign Electromotive Force Tests (FEMT) - foreign voltage is present on the tip, ring or both
- Resistive Fault Tests (RFT) - tip or ring is shorted to ground, or they are shorted to each other
- Receiver Off-hook Tests (ROH) - one or more phones are off hook on phone line during test.
- Ringer Impedance Tests (RIT)

- AC/DC line voltage
- AC/DC line current
- Line resistance
- Line capacity
- Hook status (on or off)
- Message Waiting Indication (MWI) status (on or off)
- Ring status (on or off)
- Reversal polarity status (on or off)

The FXS line test is currently supported only through CLI.

➤ **To run the FXS line test:**

1. Access the VoIP command set:

```
# configure voip
```

2. Access the FXS interface command set:

```
(config-voip)# interface fxs-fxo
```

3. Type the following command:

```
(fxs-fxo)# fxs-line-testing < Module/Port > {66|70}
```

For example, to test FXS port 4 on FXS module1 with coefficient type USA:

```
(fxs-fxo)# fxs-line-testing 1/4 70
```

## FXO Line Impedance Matching Testing

This feature enables you to determine the best impedance value to configure for an analog FXO line. This option tests several impedance values to determine which value returns the best Echo Return Loss (ERL). Once this value is determined, you can configure it on the FXO channel.

Voice quality problems may be experienced in analog lines especially when long physical lines are plugged into the device's FXO ports. Poor quality in analog lines is mostly due to low ERL. These problems may be diminished if the appropriate adjustments are made to best match the FXO interface to the characteristics of the analog line in the particular country in which you have installed the device.

## Running the Line Impedance Test

Line impedance testing for FXO interfaces is done using the `AnalogLineTest` command through the device's Command Shell. The command runs the line test on a specified channel and for every specified impedance level (configured by a range), and then saves the results.

Before performing the line impedance test, you must upload a Voice Prompt file to the device.

### ➤ To run the line impedance test:

1. Access the device's Admin Page, by appending "AdminPage" to the device's IP address in your browser's URL address field (e.g., 10.1.1.1/AdminPage).
2. In the left navigation pane, click **Cmd Shell**; the command shell interface opens.
3. In the 'Command Line' field, type the following:

```
AnalogLineTest <FXO Channel> <Impedance Low Limit> <Impedance High Limit> <Display Syslog>
```

Where:

- *<FXO Channel>*: FXO channel that you want to test and configure.
- *<Impedance Low limit>*: Low level impedance value (0-15) that you want to test
- *<Impedance High limit>*: High level impedance value (0-15) that you want to test
- *<Display Syslog>*: Defines (0/1) if information is sent to syslog during the test

4. Click **Enter**.

The following example runs the test on FXO channel 4 with impedance levels 0 to 5 and sends the output to syslog (1):

```
>/VoiceEngn/AnalogLineTest>AnalogLineTest 4 0 5 1
Starting.....
Check syslog for more information.
This command starts a test on channel 4.
Impedances 0-5 will be tested.
Messages are displayed in syslog during the test.
```

The following describes the sequence of events when you run the impedance matching test:

5. The test is run using the `AnalogLineTest` command.
6. The tested channel is opened with default parameters and set to off-hook state.
7. The channel is configured with the low level impedance value.

8. A call involving the channel is started.
9. A PCM Voice Prompt file is played in the TDM direction.
10. The returned echo is recorded in a second PCM file.
11. Both of these files are scanned simultaneously and an ERL value is obtained.
12. The above steps are repeated for each of the specified impedance levels.
13. When the test completes, the channel is on-hooked and closed.

The figure below shows the correlation between the impedance values in binary (0-15) and the actual impedance values (Ohms).

#### AC Impedance Selection.

The off-hook ac termination is selected from the following:

0000 = 600  $\Omega$

0001 = 900  $\Omega$

0010 = 270  $\Omega$  + (750  $\Omega$  || 150 nF) (TBR21) and 275  $\Omega$  + (780  $\Omega$  || 150 nF)

0011 = 220  $\Omega$  + (820  $\Omega$  || 120 nF) (Australia/New Zealand) and 220  $\Omega$  + (820  $\Omega$  || 115 nF) (Slovakia/South Africa/Germany/Austria/Bulgaria)

0100 = 370  $\Omega$  + (620  $\Omega$  || 310 nF) (New Zealand #2/India)

0101 = 320  $\Omega$  + (1050  $\Omega$  || 230 nF) (England)

0110 = 370  $\Omega$  + (820  $\Omega$  || 110 nF)

0111 = 275  $\Omega$  + (780  $\Omega$  || 115 nF)

1000 = 120  $\Omega$  + (820  $\Omega$  || 110 nF)

1001 = 350  $\Omega$  + (1000  $\Omega$  || 210 nF)

1010 = 0  $\Omega$  + (900  $\Omega$  || 30 nF)

1011 = 600  $\Omega$  + 2.16  $\mu$ F

1100 = 900  $\Omega$  + 1  $\mu$ F

1101 = 900  $\Omega$  + 2.16  $\mu$ F

1110 = 600  $\Omega$  + 1  $\mu$ F

1111 = Global impedance

## Displaying Line Impedance Test Results

After you have run the line impedance test (as described in [Running the Line Impedance Test](#) on the previous page), you can view the test results. The results include a list of impedance values and DC levels relative to the measured ERL values. The higher the ERL, the better the impedance.

### ➤ To view line impedance test results:

1. Access the device's Command Shell.
2. On the command-line prompt, enter the following command:

```
/VoiceEngn/AnalogLineTest>AnalogLineTestResults
```

The following example displays test results of FXO channel 4, where the Impedance 0 (600 Ohms) returns the best (highest) ERL (25.66):

```
/VoiceEngn/AnalogLineTest>AnalogLineTestResults
```

The Analog Line Test Measurements for CID 4:

Impedance	ERL in DB	DC level	Offset
=====	=====	=====	=====
0. 600 OHMS	25.66	-48.48	60.82
1. 900 OHMS	15.87	-46.02	80.71
2. 270 OHMS +(750 OHMS    150 nF)	13.51	-46.56	75.81
3. 220 OHMS +(820 OHMS    120 nF)	12.90	-47.22	70.31
4. 370 OHMS +(620 OHMS    310 nF)	15.16	-45.88	82.04
5. 320 OHMS +(1050 OHMS    230 nF)	11.92	-47.24	70.10

Analog Line Test successfully completed.

The AnalogLineTestResults command only displays the results of the last test that was run.

## Configuring the Best Impedance Level

After you have run the test, you can configure the FXO channel with the best impedance value obtained from the test result.

### ➤ To configure the FXO channel with best impedance value:

1. Access the device's Command Shell.
2. On the command-line prompt, enter the following command:

```
/VoiceEngn/AnalogLineTest>AnalogLineTestConfigureImpedance
```

In our example, where the impedance test of FXO channel 4 resulted in the best ERL (25.66) for 0 to 600 Ohms, the command automatically configures the channel with this ERL:

```
/VoiceEngn/AnalogLineTest>AnalogLineTestConfigureImpedance
```

Best ERL (25.66) was measured with impedance 0. Channel 4 configured with this impedance

## 68 Out-of-Service Physical Reasons for FXS Port

The device takes an FXS physical port out of service when any one of the following occurs:

- The Serial Peripheral Interface (SPI) connection with the port is lost. The device sends the SNMP alarm `acAnalogPortSPIOutOfService` for this out-of-service reason.
- The temperature of the port has exceeded the temperature threshold for normal operation. The device sends the SNMP alarm `acAnalogPortHighTemperature` for this out-of-service reason.
- The port is inactive due to a ground fault. The device sends the SNMP alarm `acAnalogPortGroundFaultOutOfService` for this out-of-service reason.

When the FXS is taken out of service due to any one of the above, the device sends the SNMP alarm `acPortServiceAlarm`.

## 69 Testing SIP Signaling Calls

A simulated endpoint can be configured on the device to test SIP signaling of calls between it and a remote destination. This feature is useful in that it can remotely verify SIP message flow without involving the remote end side in the debug process. The SIP test call simulates the SIP signaling process - call setup, SIP 1xx responses, through to completing the SIP transaction with a 200 OK.

The test call sends syslog messages to a syslog server, showing the SIP message flow, tone signals (e.g., DTMF), termination reasons, as well as voice quality statistics and thresholds (e.g., MOS).

### Configuring Test Call Endpoints

The Test Call Rules table lets you test SIP signaling (setup and registration) and media (DTMF signaling) of calls between a simulated phone on the device and a remote IP endpoint. You can test incoming and outgoing calls, where the test endpoint can be configured as the caller or called party.

The device's simulated phone and the remote endpoints are defined by SIP URIs (user@host). The remote endpoint can be defined as an IP Group or IP address.

Test calls can be dialed automatically at a user-defined interval, or manually when required. When the device initiates a SIP test call, it sends a SIP INVITE towards the remote SIP User Agent (e.g., a SIP proxy server or softswitch). The device simulates the SIP call setup process, managing SIP 1xx responses and completing the SIP transaction with a SIP 200 OK after a user-defined duration.

When the remote SIP UA initiates the call with the device's test call endpoint, the test call ends when the remote UA ends the call (i.e., sends a SIP BYE message). Alternatively, the duration of the test call can be determined by the incoming SIP INVITE message, as described in [Using SIP INVITE to Specify Test Call Duration](#) on page 1684.

- By default, you can configure up to five test call rules. However, you can increase this number by installing a License Key that licenses the required number. For more information, contact the sales representative of your purchased device.
- The device supports up to 400 concurrent test calls with prerecorded tones (PRT) and up to 64 concurrent test calls with DTMF.
- The device's Call Admission Control (CAC) feature (see [Configuring Call Admission Control](#) on page 1164) doesn't apply to Test Calls.
- When the device operates in High-Availability (HA) mode, current Test Calls are disconnected during an HA switchover.
- To configure a Test Call endpoint for measuring and reporting MOS to WebRTC clients, see [Reporting MOS Triggered by WebRTC Client](#) on page 1279
- You can also run a test call using the device's REST API. For more information, refer to the document *REST API for SBC-Gateway-MSBR Device*, by clicking [here](#).
- For testing incoming calls, the device first tries to find a matching rule in the Test Calls Rules table (i.e., SIP INVITE Request-URI user part equals the 'Endpoint URI' parameter value). If there is no matching rule, the device then checks if the prefix of the user part matches the 'Test Call ID' parameter value configured for the Basic Test Call feature (see [Configuring Basic Incoming Test Calls](#) on page 1688).

The following procedure describes how to configure Test Call rules through the Web interface. You can also configure it through ini file [Test\_Call] or CLI (`configure troubleshoot > test-call test-call-table`).

#### ➤ To configure a Test Call:

1. Open the Test Call Rules table (**Troubleshoot** menu > **Troubleshoot** tab > **Test Call** folder > **Test Call Rules**).
2. Click **New**; the following dialog box appears:

COMMON	
Index	0
Endpoint URI	
Called URI	
Route By	IP Group
IP Group	.. <a href="#">View</a>
Destination Address	
SIP Interface	.. <a href="#">View</a>
Application Type	SBC
Destination Transport Type	
QoS Profile	.. <a href="#">View</a>
Bandwidth Profile	.. <a href="#">View</a>

3. Configure a test call according to the parameters described in the table below.

4. Click **Apply**, and then save your settings to flash memory.

**Table 69-1: Test Call Rules Table Parameter Descriptions**

Parameter	Description
Common	
'Index'	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Endpoint URI' endpoint-uri [Test_Call_EndpointURI]	<p>Defines the endpoint's URI. This can be defined as a user or user@host. The device identifies this endpoint only by the URI's user part. The URI's host part is used in the SIP From header in REGISTER requests.</p> <p>The parameter is used as follows:</p> <ul style="list-style-type: none"> <li>■ <b>Incoming test calls:</b> The parameter defines the destination URI in the user part of the incoming INVITE Request-URI.</li> <li>■ <b>Outgoing test calls:</b> The parameter defines the source URI in the user part of the outgoing INVITE request's From header.</li> </ul> <p>The valid value is a string of up to 150 characters. By default, the parameter is not configured.</p> <p><b>Note:</b> The parameter is mandatory.</p>
'Called URI' called-uri [Test_Call_CalledURI]	<p>Defines the destination (called) URI (user@host) in the user part of the outgoing SIP INVITE Request-URI.</p> <p>The valid value is a string of up to 150 characters. By default, the parameter is not configured.</p> <p><b>Note:</b> The parameter is applicable only to outgoing test calls.</p>
'Route By' route-by [Test_Call_RouteBy]	<p>Defines the type of routing method. This applies to incoming and outgoing calls.</p> <ul style="list-style-type: none"> <li>■ [1] <b>IP Group</b> = (Default) Calls are matched by (or routed to) an IP Group. To specify the IP Group, see the 'IP Group' parameter in the table.</li> <li>■ [2] <b>Dest Address</b> = Calls are matched by (or routed to) a destination IP address. To configure the address, see the 'Destination Address' parameter in the table.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If configured to <b>Dest Address</b>: <ul style="list-style-type: none"> <li>✓ You must assign a SIP Interface (see the 'SIP Interface' below).</li> <li>✓ The IP Profile of the default IP Group (ID 0) is used. You can use a different IP Profile, by specifying an IP Group in the 'IP Group' parameter (below).</li> </ul> </li> <li>■ For REGISTER messages, if configured to <b>IP Group</b>, only Server-type IP Groups can be used.</li> </ul>
'IP Group' ip-group-id [Test_Call_IPGroupName]	<p>Assigns an IP Group where the test call is sent to or received from.</p> <p>By default, no value is defined.</p> <p>To configure IP Groups, see <a href="#">Configuring IP Groups</a> on page 591.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable if you configure the 'Route By' parameter to <b>IP Group</b>.</li> <li>■ You can also use this parameter if you configure the 'Route By' parameter to <b>Dest Address</b>. This allows you to associate an IP Profile (that is assigned to the specified IP Group) with the Test Call. The Test Call is not routed to the IP Group, but uses only its IP Profile.</li> <li>■ The IP Group is used for incoming and outgoing calls.</li> </ul>
'Destination Address' dst-address [Test_Call_DestAddress]	<p>Defines the destination host.</p> <p>The valid value is an IP address[:port] in dotted-decimal notation or a DNS name[:port].</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'Route By' parameter to <b>Dest Address</b>.</p>
'SIP Interface' sip-interface-name [Test_Call_SIPInterfaceName]	<p>Assigns a SIP Interface. This is the SIP Interface to which the test call is sent and received from.</p> <p>By default, no value is defined.</p> <p>To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</p>

Parameter	Description
	<b>Note:</b> The parameter is applicable only if the 'Route By' parameter is configured to <b>Dest Address</b> .
'Application Type' application-type [Test_Call_ApplicationType]	<p>Defines the application type for the endpoint. This associates the IP Group and SRD to a specific SIP interface. For example, assume two SIP Interfaces are configured in the SIP Interfaces table where one is set to "GW" and one to "SBC" for the 'Application Type'. If you configure the parameter to <b>SBC</b>, the device uses the SIP Interface set to "SBC".</p> <ul style="list-style-type: none"> <li>■ [0] <b>GW</b> = (Default) Gateway application</li> <li>■ [2] <b>SBC</b> = SBC application</li> </ul>
'Destination Transport Type' dst-transport [Test_Call_DestTransportType]	<p>Defines the transport type for outgoing calls.</p> <ul style="list-style-type: none"> <li>■ [-1] = Not configured (default)</li> <li>■ [0] <b>UDP</b></li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS</b></li> <li>■ [3] <b>SCTP</b></li> </ul> <p><b>Note:</b> The parameter is applicable only if you configure the 'Route By' parameter to <b>Dest Address</b>.</p>
'QoE Profile' qoe-profile [Test_Call_QOEProfile]	<p>Assigns a QoE Profile to the test call.</p> <p>By default, no value is defined.</p> <p>To configure QoE Profiles, see <a href="#">Configuring Quality of Experience Profiles</a> on page 528.</p>
'Bandwidth Profile' bandwidth-profile [Test_Call_BWProfile]	<p>Assigns a Bandwidth Profile to the test call.</p> <p>By default, no value is defined.</p> <p>To configure Bandwidth Profiles, see <a href="#">Configuring Bandwidth Profiles</a> on page 535.</p>
Media	
'Offered Audio Coders Group' offered-audio-coders-group-name [Test_Call_OfferedCodersGroupName]	<p>Assigns a Coder Group, configured in the Coders Groups table, whose coders are added to the SDP Offer in the outgoing Test Call.</p> <p>If not configured, the device uses the Coder Group specified by the 'Extension Coders Group' parameter of the IP Profile associated with the rule's IP Group (see</p>

Parameter	Description
	<p>the 'IP Group' parameter above).</p> <p>To configure Coder Groups, see <a href="#">Configuring Coders Groups</a> on page 661.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter's settings override the corresponding SBC parameter of the IP Profile associated with the rule's IP Group.</li> <li>■ If you don't configure this parameter nor the corresponding parameter of the associated IP Profile, the device uses Coder Group ID 0.</li> </ul>
<p>'Allowed Audio Coders Group'</p> <p>allowed-audio-coders-group-name</p> <p>[Test_Call_AllowedAudioCodersGroupName]</p>	<p>Assigns an Allowed Audio Coders Group, configured in the Allowed Audio Coders Groups table, which defines only the coders that can be used for the test call. For incoming test calls, the device accepts the first offered coder that is supported and allowed.</p> <p>If not configured, the device uses the Allowed Audio Coders Group specified by the 'Allowed Audio Coders' parameter of the IP Profile associated with the rule's IP Group (see the 'IP Group' parameter above).</p> <p>To configure Allowed Audio Coders Groups, see <a href="#">Configuring Allowed Audio Coder Groups</a> on page 669.</p> <p><b>Note:</b> The parameter's settings override the corresponding SBC parameter of the IP Profile associated with the rule's IP Group.</p>
<p>'Allowed Coders Mode'</p> <p>allowed-coders-mode</p> <p>[Test_Call_AllowedCodersMode]</p>	<p>Defines the mode of the Allowed Coders feature for the Test Call.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) The mode is according to the 'Allowed Coders Mode' parameter of the IP Profile associated with the rule's IP Group (see the 'IP Group' parameter above).</li> <li>■ [0] <b>Restriction</b> = The device uses only allowed coders as configured in the 'Allowed Audio Coders Group' parameter (above) and removes all other coders from the SDP offer. If you have also configured additional coders in the 'Offered Audio Coders Group' parameter (above), then these coders are added to the SDP offer if they appear in the assigned Allowed Audio Coders Group.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Preference</b> = The device re-arranges the priority (order) of the coders in the incoming SDP offer according to their order of appearance in the Allowed Audio Coders Group. The coders in the original SDP offer are listed after the allowed coders.</li> <li>■ [2] <b>Restriction and Preference</b> = The device uses both the <b>Restriction</b> and <b>Preference</b> options.</li> </ul> <p><b>Note:</b> Except for <b>Not Configured</b>, the parameter's settings override the corresponding SBC parameter of the IP Profile associated with the rule's IP Group.</p>
'Media Security Mode' media-security-mode [Test_Call_MediaSecurityMode]	<p>Defines the handling of RTP and SRTP.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) Handling is according to the 'SBC Media Security Mode' parameter of the IP Profile associated with the rule's IP Group (see the 'IP Group' parameter above).</li> <li>■ [0] <b>As is</b> = No special handling for RTP\SRTP is done.</li> <li>■ [1] <b>SRTP</b> = Only SRTP media lines are negotiated and RTP media lines are removed from the incoming SDP offer-answer.</li> <li>■ [2] <b>RTP</b> = Only RTP media lines are negotiated and SRTP media lines are removed from the incoming SDP offer-answer.</li> <li>■ [3] <b>Both</b> = Each SDP offer-answer is extended (if not already) to two media lines - one for RTP and one for SRTP.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable SRTP, configure the [EnableMediaSecurity] parameter to [1].</li> <li>■ Except for <b>Not Configured</b>, the parameter's settings override the corresponding SBC parameter of the IP Profile that is associated with the rule's IP Group.</li> </ul>
'Play DTMF Method' play-dtmf-method	<p>Defines the method used by the device for sending DTMF digits that are played to the called party when the call is answered.</p>

Parameter	Description
[Test_Call_PlayDTMFMethod]	<ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = The mode is according to the 'Alternative DTMF Method' and 'RFC 2833 Mode' parameters of the IP Profile associated with the rule's IP Group (see the 'IP Group' parameter above).</li> <li>■ [0] <b>RFC 2833</b> = (Default) The device sends the DTMF digits using the RFC 2833 method (out-of-band).</li> <li>■ [1] <b>In Band</b> = The device sends the DTMF digits in-band (in the RTP stream).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the 'Play' parameter to <b>DTMF</b>.</li> <li>■ Playing DTMF digits requires DSP resources when the DTMF method is <b>In Band</b>.</li> <li>■ If the Test Call sends the SDP offer, the recommended DTMF configuration of the associated IP Profile is as follows: <ul style="list-style-type: none"> <li>✓ For RFC 2833: 'RFC 2833 Mode' = <b>Extend</b>; 'Alternative DTMF Method' = <b>As Is</b></li> <li>✓ For In Band: 'RFC 2833 Mode' = <b>Disallow</b>; 'Alternative DTMF Method' = <b>As Is</b></li> </ul> </li> <li>■ If the Test Call receives the SDP offer, the recommended configuration is as follows (i.e., incoming SDP offer determines the method): 'RFC 2833 Mode' = <b>As Is</b>; 'Alternative DTMF Method' = <b>As Is</b></li> </ul>
Authentication <b>Note:</b> These parameters are applicable only if the 'Call Party' parameter (below) is configured to <b>Caller</b> .	
'Auto Register' auto-register [Test_Call_AutoRegister]	<p>Enables automatic registration of the endpoint. The endpoint can register to the device itself or to the 'Destination Address' or 'IP Group' parameter settings (see above).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul>

Parameter	Description
'Username' user-name [Test_Call_UserName]	Defines the authentication username.  The valid value is a string of up to 60 characters. By default, no value is defined.
'Password' password [Test_Call_Password]	Defines the authentication password.  By default, no password is defined.  <b>Note:</b> The parameter cannot be configured with wide characters.
Test Setting	
'Call Party' call-party [Test_Call_CallParty]	Defines if the test endpoint is the initiator (caller) or receiving side (called) of the test call.  ■ [0] <b>Caller</b> = (Default) The device's test endpoint is the calling party (i.e., applicable only to outgoing test calls).  ■ [1] <b>Called</b> = The device's test endpoint is the called (callee) party (i.e., applicable only to incoming test calls).
'Maximum Channels for Session' max-channels [Test_Call_MaxChannels]	Defines the maximum number of concurrent channels for the test session. For example, if you have configured an endpoint "101" and you configure the parameter to "3", the device automatically creates three simulated endpoints - "101", "102" and "103" (i.e., consecutive endpoint URIs are assigned).  The default is 1.
'Call Duration' call-duration [Test_Call_CallDuration]	Defines the call duration (in seconds).  The valid value is -1 to 100000. The default is 20. A value of 0 means infinite. A value of -1 means that the parameter value is automatically calculated according to the values of the 'Calls per Second' and 'Maximum Channels for Session' parameters.  <b>Note:</b> The parameter is applicable only if you configure 'Call Party' to <b>Caller</b> .
'Calls per Second' calls-per-second [Test_Call_CallsPerSecond]	Defines the number of calls per second.  <b>Note:</b> The parameter is applicable only if you configure 'Call Party' to <b>Caller</b> .
'Test Mode'	Defines the test session mode.

Parameter	Description
test-mode [Test_Call_TestMode]	<ul style="list-style-type: none"> <li>■ [0] <b>Once</b> = (Default) The test runs until the lowest value between the following is reached: <ul style="list-style-type: none"> <li>✓ Maximum channels is reached for the test session, configured by 'Maximum Channels for Session'.</li> <li>✓ Call duration ('Call Duration') multiplied by calls per second ('Calls per Second').</li> <li>✓ Test duration expires, configured by 'Test Duration'.</li> </ul> </li> <li>■ [1] <b>Continuous</b> = The test runs until the configured test duration is reached. If it reaches the maximum channels configured for the test session (in the 'Maximum Channels for Session'), it waits until the configured call duration of a currently established tested call expires before making the next test call. In this way, the test session stays within the configured maximum channels.</li> </ul> <p><b>Note:</b> The parameter is applicable only if you configure 'Call Party' to <b>Caller</b>.</p>
'Test Duration' test-duration [Test_Call_TestDuration]	<p>Defines the test duration (in minutes).</p> <p>The valid value is 0 to 100000. The default is 0 (i.e., unlimited).</p> <p><b>Note:</b> The parameter is applicable only if you configure 'Call Party' to <b>Caller</b>.</p>
'Play' play [Test_Call_Play]	<p>Enables the playing of a tone to the answered side of the call.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = No tone is played.</li> <li>■ [1] <b>DTMF</b> = (Default) Plays (loop) a user-defined DTMF string, which is configured in <a href="#">Configuring DTMF Tones for Test Calls</a> on page 1688.</li> <li>■ [2] <b>PRT</b> = Plays (loop) a pre-recorded tone (audio file) from the PRT file that is installed on the device. You can either specify the tone (by index) to play from the PRT file in the 'Play Tone Index' parameter (below), or implement a basic NetAnn feature whereby the tone from the PRT file (and other characteristics) are specified by NetAnn parameters</li> </ul>

Parameter	Description
	<p>in the Request-URI of the incoming SIP INVITE message. When using NetAnn, instead of connecting the call (i.e., 200 OK), the device replies with a SIP 183 containing SDP.</p> <p>The NetAnn parameters include the following:</p> <ul style="list-style-type: none"> <li>• <b>early=yes:</b> Indicates that NetAnn is used for playing the tone.</li> <li>• <b>play=&lt;Prompt/Tone Index in PRT file&gt;:</b> Defines the tone to play from the PRT file.</li> <li>• <b>repeat=&lt;Times&gt;:</b> Defines how many times the tone is played (loops) before the device disconnects the call.</li> <li>• <b>delay=&lt;Delay Time&gt;:</b> Defines the delay time (in msec) between each played (loop) tone. If the parameter is not present, the default is 2,000 ms (2 seconds).</li> </ul> <p>The following shows an example of a Request-URI with NetAnn parameters that instruct the device to play three times (loops) the tone that is defined at Index 15 in the PRT file:</p> <pre>INVITE sip:200@1.1.1.1;early=yes;play=15;repeat=3</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure the DTMF signaling type (RFC 2833 or in-band), using the 'Play DTMF Method' parameter (above).</li> <li>■ Playing a tone from the PRT file requires DSP resources if the coder with which the tone was created is different to the coder used for the Test Call.</li> <li>■ You can also use NetAnn parameters to play a specific recorded tone to the caller (source) when the destination fails for a regular IP-to-IP SBC call. To configure this: <ul style="list-style-type: none"> <li>✓ Configure a Message Manipulation rule that</li> </ul> </li> </ul>

Parameter	Description
	<p>adds the NetAnn parameters, based on the tone that you want played, to the INVITE message's Request-URI.</p> <ul style="list-style-type: none"> <li>✓ Configure a Number Manipulation rule that changes the destination number to the Test Call ID.</li> <li>✓ Configure an IP Group to represent the device itself (which will be the Test Call module) and assign it the Message Manipulation rule and the Number Manipulation rule.</li> <li>✓ Configure an alternative routing rule in the IP-to-IP Routing table that re-routes the call to the IP Group presenting the Test Call module.</li> </ul> <p>When the IP-to-IP call fails, the device uses the alternative routing rule to re-route the call to the Test Call module, which sends a SIP 183 response to the caller, playing the specified tone.</p>
'Play Tone Index' play-tone-index [Test_Call_PlayToneIndex]	<p>Defines the tone that you want played from the installed PRT file, to the called party when the call is answered.</p> <p>The valid value is the index number (1-80) of the tone in the PRT file. By default (-1), the device plays the tone defined at index 22 "acDialTone2".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the 'Play' parameter to <b>PRT</b>.</li> <li>■ To play user-defined tones, you need to record your tones and then install them on the device using a loadable Prerecorded Tones (PRT) file, which is created using AudioCodes DConvert utility. When you create the PRT file, each recorded tone file must be added to the PRT file with the tone type "acUserDefineTone&lt;Index&gt;". For more information, see <a href="#">Uploading a Prerecorded Tones File</a> on page 1357.</li> </ul>
'Schedule Interval' schedule-interval [Test_Call_ScheduleInterval]	<p>Defines the interval (in minutes) between automatic outgoing test calls.</p> <p>The valid value range is 0 to 100000. The default is 0</p>

Parameter	Description
	(i.e., scheduling is disabled). <b>Note:</b> The parameter is applicable only if you configure 'Call Party' to <b>Caller</b> .

## Using SIP INVITE to Specify Test Call Duration

For test call endpoints where the remote SIP UA is the initiator of the test call (i.e., 'Call Party' parameter configured to **Called**), the duration of the test call can be determined by the incoming SIP INVITE message, instead of when the caller ends the call (i.e., sends a SIP BYE message).

The duration in the SIP INVITE message is specified using the 'duration=' parameter of the Request-URI, for example:

```
INVITE sip:3000@10.8.51.29;user=phone;duration=10000 SIP/2.0
```

The duration is in milliseconds, but the device rounds it off to the nearest seconds.

This feature is in accordance with RFC 4240 (Basic Network Services with SIP).

This feature is also used by the device for reporting MOS to WebRTC clients, as described in [Reporting MOS Triggered by WebRTC Client](#) on page 1279.

## Starting and Stopping Test Calls

The following procedure describes how to start, stop, and restart test calls.

### ➤ To start, stop, and restart a test call:

1. In the Test Call Rules table, select the required test call entry.
2. From the **Action** drop-down list, choose the required command:
  - **Dial:** Starts the test call (applicable only if the test call party is the caller).
  - **Drop Call:** Stops the test call.
  - **Restart:** Ends all established calls and then starts the test call session again.

## Viewing Test Call Status

You can view the status of test call rules in the 'Test Status' field of the Test Call Rules table. The status can be one of the following:

**Table 69-2: Test Call Status Description**

Status	Description
"Idle"	Test call is not active.
"Scheduled"	Test call is planned to run (according to the 'Schedule Interval' parameter).
"Running"	Test call has been started (i.e., by clicking <b>Dial</b> from the 'Action' drop-down list).
"Receiving":	Test call has been automatically activated by calls received from the remote endpoint for the test call endpoint (when all these calls end, the status returns to "Idle").
"Terminating"	Test call is in the process of terminating currently established calls (when <b>Drop Call</b> is clicked from the 'Action' drop-down list to stop the test).
"Done"	Test call has successfully completed (or was prematurely stopped by clicking the <b>Drop Call</b> from the 'Action' drop-down list).

## Viewing Test Call Statistics

You can view statistical information on the test call.

- On the receiving side, when the first call is accepted in "Idle" state, statistics are reset.
- The device also generates CDRs for test calls if you have enabled CDR generation (see [Configuring CDR Filters and Report Level](#) on page 1514). To view CDRs of test calls, see [Viewing Gateway CDR History](#) on page 1493.

### ➤ To view statistics of a test call:

1. In the Test Call Rules table, select the required test call row.
2. Scroll down the page to the area below the table. Statistics of the selected test call are displayed under the **Statistics** group, as shown in the example below:

STATISTICS	
Active Calls	0
Call Attempts	1
Total Established Calls	1
Total Failed Attempts	0
Remote Disconnections Count	1
Average CPS	1.00
Elapsed Time [HH:MM:SS]	00:00:20
Test Status	Done
Detailed Status	Done - Established Calls: 1, ASR: 100%
MOS Status	Local:N/A, Remote:N/A
Delay Status	Local:6 msec (Green), Remote:N/A
Jitter Status	Local:75 msec (Red), Remote:0 msec (Green)
Packet Loss Status	Local:0% (Green), Remote:0% (Green)
Bandwidth Status	Rx:0 KBytes/s (Green), Tx:0 KBytes/s (Green)

The statistics fields are described in the following table:

**Table 69-3: Test Call Statistics Description**

Statistics Field	Description
<b>Active Calls</b>	Number of currently established test calls.
<b>Call Attempts</b>	Number of calls that were attempted.
<b>Total Established Calls</b>	Total number of calls that were successfully established.
<b>Total Failed Attempts</b>	Total number of call attempts that failed.
<b>Remote Disconnections Count</b>	Number of calls that were disconnected by the remote side.
<b>Average CPS</b>	Average calls per second.
<b>Elapsed Time</b>	Duration of the test call since it was started (or restarted).
<b>Test Status</b>	Status (brief description) as displayed in the 'Test Status' field (see <a href="#">Viewing Test Call Status</a> on page 1684).
<b>Detailed Status</b>	Displays a detailed description of the test call status: <ul style="list-style-type: none"> <li>■ "Idle": Test call is currently not active.</li> <li>■ "Scheduled - Established Calls: &lt;number of established calls&gt;, ASR:</li> </ul>

Statistics Field	Description
	<p>&lt;ASR&gt;%": Test call is planned to run (according to 'Schedule Interval' parameter settings) and also shows the following summary of completed test calls:</p> <ul style="list-style-type: none"> <li>✓ Total number of test calls that were established.</li> <li>✓ Number of successfully answered calls out of the total number of calls attempted (ASR).</li> </ul> <p>■ "Running (Calls: &lt;number of active calls&gt;, ASR: &lt;ASR&gt;%)": Test call has been started (i.e., the <b>Dial</b> command was clicked) and shows the following:</p> <ul style="list-style-type: none"> <li>✓ Number of currently active test calls.</li> <li>✓ Number of successfully answered calls out of the total number of calls attempted (Answer Success Ratio or ASR).</li> </ul> <p>■ "Receiving (&lt;number of active calls&gt;)": Test call has been automatically activated by calls received for this configured test call endpoint from the configured remote endpoint. When all these calls terminate, the status returns to "Idle".</p> <p>■ "Terminating (&lt;number of active calls&gt;)": The <b>Drop Call</b> command has been clicked to stop the test call and the test call is in the process of terminating the currently active test calls.</p> <p>■ "Done - Established Calls: &lt;number of established calls&gt;, ASR: &lt;ASR&gt;%": Test call has been successfully completed (or was prematurely stopped by clicking the <b>Drop Call</b> command) and shows the following:</p> <ul style="list-style-type: none"> <li>✓ Total number of test calls that were established.</li> <li>✓ Number of successfully answered calls out of the total number of calls attempted (ASR).</li> </ul>
<b>MOS Status</b>	MOS count and color threshold status of local and remote sides according to the assigned QoE Profile.
<b>Delay Status</b>	Packet delay count and color-threshold status of local and remote sides according to the assigned QoE Profile.
<b>Jitter Status</b>	Jitter count and color-threshold status of local and remote sides according to the assigned QoE Profile.
<b>Packet Loss Status</b>	Packet loss count and color-threshold status of local and remote sides according to the assigned QoE Profile.

Statistics Field	Description
<b>Bandwidth Status</b>	Tx/Rx bandwidth and color-threshold status according to the assigned Bandwidth Profile.

## Configuring DTMF Tones for Test Calls

By default, the device plays the DTMF signal tone "3212333" to remote tested endpoints for answered calls (incoming and outgoing). For basic test calls (as described in [Configuring Basic Incoming Test Calls](#) below), the device can play only the configured DTMF tones (or none, if not configured). For test call endpoints that are configured in the Test Call Rules table, you can configure the device to play either DTMF tones or a tone from an installed PRT file (Test Call Tone). For more information, see [Configuring Test Call Endpoints](#) on page 1672.

- You can configure the DTMF signaling type (e.g., out-of-band or in-band) using the 'DTMF Transport Type' [DTMFTransportType] parameter.
- To generate DTMF tones, the device's DSP resources are required.

### ➤ To configure played DTMF signal to answered test call:

1. Open the Test Call Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Test Call** folder > **Test Call Settings**).
2. In the 'Test Call DTMF String' field, enter the DTMF string (up to 15 digits):

Test Call DTMF String

3212333

3. Click **Apply**.

## Configuring Basic Incoming Test Calls

The Basic Test Call feature tests **incoming** calls from remote SIP (IP) endpoints to a single simulated test endpoint on the device. The only required configuration is to assign a prefix number (*Test Call ID*) to the simulated endpoint. The device identifies incoming calls whose SIP INVITE Request-URI user part (i.e., called number) matches this prefix number as basic test calls and sends it to the simulated endpoint (see note below).

The device **first** checks if the incoming call matches a rule in the Test Calls Rules table (see [Configuring Test Call Endpoints](#) on page 1672). A matching rule is one whose 'Endpoint URI' parameter value is **identical** to the user part of the incoming SIP INVITE Request-URI. Only if there is no matching rule does the device check if the prefix of the user part matches the 'Test Call ID' parameter value (see below) configured for this Basic Test Call feature.

For example, if you configure the prefix number (Test Call ID) of the test endpoint (see procedure below) to "101" and the incoming INVITE Request-URI user part is 101, 10123, or 10145, the device considers this call as a basic test call because the prefix of the user part matches the test endpoint's Test Call ID ("101"). The figure below displays a basic test call example:

- You can configure the device to play DTMF tones to the remote endpoint (see [Configuring DTMF Tones for Test Calls](#) on the previous page).
- The Basic Test Call feature uses the default IP Group (ID #0) and its associated IP Profile (if exists).
- Test calls are done on all SIP Interfaces.

#### ➤ To configure basic call testing:

1. Open the Test Call Settings page (**Troubleshoot** menu > **Troubleshoot** tab > **Test Call** folder > **Test Call Settings**).
2. In the 'Test Call ID' field, enter a prefix for the simulated endpoint:

GENERAL

Test Call ID

For a full description of the parameter, see [SIP Test Call Parameters](#) on page 1766.

3. Click **Apply**.

## Test Call Rules Configuration Examples

Below are test call configuration examples.

■ **Outgoing Test Call:** This example describes the configuration for testing outgoing calls:

- Test Call Rules table:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "201"
  - ◆ Route By: **IP Group**
  - ◆ IP Group: **MyTest**

- ◆ Call Party: **Caller**
- ◆ Test Mode: **Once**

■ **Incoming Test Call:** This example describes the configuration for testing incoming calls:

- Test Call Rules table:
  - ◆ Endpoint URI: "201"
  - ◆ Route By: **IP Group**
  - ◆ IP Group: **MyTest**
  - ◆ Call Party: **Called**
  - ◆ Test Mode: **Once**

■ **Single Test Call:** This example describes the configuration of a simple outgoing test call scenario that includes a single test call between a simulated test endpoint on the device and a remote endpoint.

- Test Call Rules table:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "201"
  - ◆ Route By: **Dest Address**
  - ◆ Destination Address: "10.30.40.01"
  - ◆ SIP Interface: SIPInterface\_0
  - ◆ Call Party: **Caller**
  - ◆ Test Mode: **Once**

Alternatively, if you want to route the test call using the Tel-to-IP Routing table for the Gateway application, configure the following:

- Test Call Rules table:
  - ◆ Endpoint URI: 101@10.0.0.1
  - ◆ Route By: Tel-to-IP
  - ◆ SIP Interface: SIPInterface\_0

- ◆ Called URI: 201@10.30.40.1
- ◆ Call Party: Caller
- Tel-to-IP Routing table:
  - ◆ Destination Phone Prefix: 201 (i.e., the Called URI user-part)
  - ◆ Source Phone Prefix: 101 (i.e., the Endpoint URI user-part)
  - ◆ Destination IP Address: 10.30.40.1

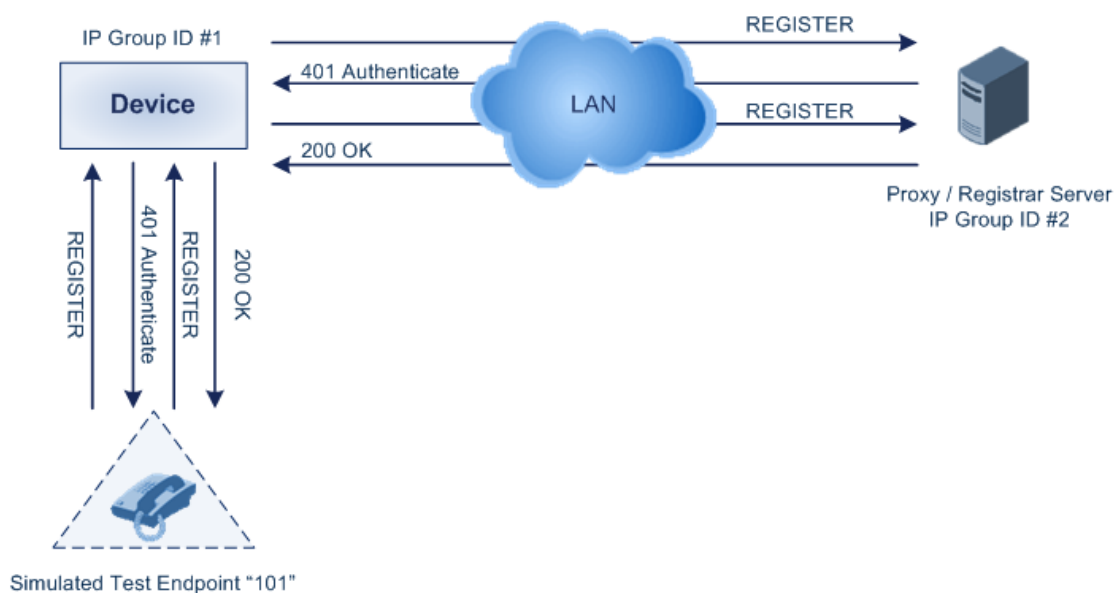

■ **Batch Test Calls:** This example describes the configuration of a batch test call setup for scheduled and continuous call testing of multiple endpoints. The test call is done between two AudioCodes devices - Device A and Device B - with simulated test endpoints. This eliminates the need for phone users, who would otherwise need to answer and end calls many times for batch testing. The calls are initiated from Device A, where Device B serves as the remote answering endpoint.

- Test Call Rules table at Device A:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "201"
  - ◆ Route By: **Dest Address**
  - ◆ Destination Address: "10.13.4.12"
  - ◆ SIP Interface: SIPInterface\_0
  - ◆ Call Party: **Caller**
  - ◆ Maximum Channels for Session: "3" (configures three endpoints - "101", "102" and "103")
  - ◆ Call Duration: "5" (seconds)
  - ◆ Calls per Sec: "1"
  - ◆ Test Mode: **Continuous**
  - ◆ Test Duration: "3" (minutes)
  - ◆ Schedule Interval: "180" (minutes)

- Test Call Rules table at Device B:
  - ◆ Endpoint URI: "201"
  - ◆ Maximum Channels for Session: "3" (configures three endpoints - "201", "202" and "203")

■ **Registration Test Call:** This example describes the configuration for testing the registration and authentication (i.e., username and password) process of a simulated test endpoint on the device with an external proxy/registrar server. This is useful, for example, for verifying that endpoints located in the LAN can register with an external proxy and subsequently, communicate with one another.

This example assumes that you have configured your device for communication between LAN phone users such as IP Groups to represent the device (10.13.4.12) and the proxy server, and IP-to-IP routing rules to route calls between these IP Groups.

- Test Call Rules table:
  - ◆ Endpoint URI: "101"
  - ◆ Called URI: "itsp"
  - ◆ Route By: **Dest Address**
  - ◆ Destination Address: "10.13.4.12" (this is the IP address of the device itself)
  - ◆ SIP Interface: SIPInterface\_0
  - ◆ Auto Register: **Enable**
  - ◆ User Name: "testuser"
  - ◆ Password: "12345"
  - ◆ Call Party: **Caller**

## 70 Pinging a Remote Host or IP Address

You can verify the network connectivity with a remote host or IP address by pinging the network entity.

- IPv4: The ping to an IPv4 address can be done from any of the device's VoIP interfaces that is configured with an IPv4 address. The ping is done using the following CLI command:

```
# ping <IPv4 ip address or hostname> source [voip] interface
```

For a complete description of the ping command, refer to the *CLI Reference Guide*.

## 71 Accessing Device's File System through SFTP for File Download

You can access certain files on the device's file system through Secure File Transfer Protocol (SFTP) and download (`get`) them to a folder on your local computer.

You can use any third-party SFTP clients such as WinSCP or FileZilla. SFTP uses the SSH protocol to authenticate and establish a secure connection. Therefore, before you can access the device's file system, your SFTP client needs to authenticate itself with the SFTP server (i.e., the device). The device performs standard user authentication, where you can set it up to check the user's credentials in the Local Users table (see [Configuring Local Management User Accounts](#) on page 55) or with a remote authentication server.

You can access the following folders under the root directory:

- **/configuration:** Contains the CLI Script file, Configuration Package file, ini file, License file. For more information on downloading the Configuration Package file, see [Downloading or Uploading Configuration Package File](#) on page 1389
- **/debug:** Contains the debug file and core dump file. For more information, see [Downloading the Debug \(and Core Dump\) File](#) on page 1657
- **/debug-capture:** Contains the stored network capture files (generated using the CLI command `debug capture`).
- **/mnt:** Contains the contents of a mounted USB drive when it's plugged into the device.

### ➤ To access device's file system through SFTP:

1. Enable SSH on the device (see [Configuring CLI over SSH using Public Key Authentication](#) on page 93).
2. Start your SFTP client and connect to the device.
3. Open the file system folder in which the required file is stored, and then view or download the file.

The following shows an example of the device's file system accessed through SFTP. Note that some folders may not be relevant to your device type.

- Access privileges to the device's file system through SFTP depends on user level:
  - ✓ **Security Administrator** users can access all folders.
  - ✓ **Administrator** users can access only folders containing the CDRs and SDRs (i.e., `/cdr`, `/cdr-gw`).
  - ✓ **Monitor** users can't access any folder.
- Only file viewing and downloading operations are supported through SFTP.
- The device may take a long time to prepare the debug file for SFTP transfer if it contains much information. Some SFTP clients (for example, WinSCP and FileZilla) have a short default connection timeout and if the file transfer is not started within this timeout, the transfer attempt is aborted. Therefore, it's recommended to configure a longer timeout for your SFTP client application.
- When the device is in HA mode, you can access from the active device the files stored on the redundant device's flash memory through SFTP. For more information, see [Accessing Files on Redundant Device from Active through SSH](#) on page 1326.
- If you're using the SFTP Cyberduck client and downloading a file from the `/configuration` or `/debug` folder, the client may display a "Transfer incomplete" error message, even though the download is successful. Therefore, please disregard this error message.

# Part XI

## Appendix

## 72 Patterns for Denoting Phone Numbers and SIP URIs

The table below lists the supported patterns (notations) that you can use in various configuration tables for matching rules, based on source and/or destination phone numbers and SIP URIs (user@host parts).

- When configuring phone numbers in the Web interface, enter them only as digits without any other characters. For example, if you wish to enter the phone number 555-1212, type it as 5551212 without the hyphen (-). If the hyphen is entered, the entry is invalid.
- For the Inbound Manipulations table (see [Configuring IP-to-IP Inbound Manipulations](#) on page 1231) and the Outbound Manipulations table (see [Configuring IP-to-IP Outbound Manipulations](#) on page 1236), the comma (,) can only be used as a separator in the pattern and not as a special comma character.

**Table 72-1: Supported Patterns for Phone Numbers and SIP URIs**

Pattern	Description
x (letter "x")	Wildcard that denotes any single digit or character.
# (pound symbol)	<ul style="list-style-type: none"> <li>■ When located at the end of a pattern, it denotes the end of a number. For example, <b>54324#</b> denotes a 5-digit number that starts with the digits 54324.</li> <li>■ When located anywhere in the pattern except at the end, it is part of the number (pound key). For example, <b>3#45</b> represents the prefix number 3#45.</li> <li>■ To denote the # key when it appears at the end of the number, enclose it in square brackets. For example, <b>134[#]</b> denotes any number that starts with 134#.</li> </ul>
* (asterisk symbol)	<ul style="list-style-type: none"> <li>■ When used on its own, it denotes any number or string.</li> <li>■ When used as part of a number, it denotes the asterisk (*) key. For example, <b>*345</b> denotes a number that starts with *345.</li> </ul>
\$ (dollar sign)	<p>For incoming IP calls: Denotes a Request-URI that doesn't have a user part.</p> <p>For incoming Tel calls: Denotes a Tel-to-IP call that doesn't have a called or calling number.</p> <p>This pattern is used for the following matching criteria:</p> <ul style="list-style-type: none"> <li>■ Source and Destination Phone</li> </ul>

Pattern	Description
	<ul style="list-style-type: none"> <li>■ Source and Destination Username</li> <li>■ Source and Destination Calling Name</li> </ul>
Range of Digits	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To denote a prefix that is a range, enclose it in square brackets, for example, <b>[4-8]</b> or <b>23xx[456]</b>.</li> <li>■ To denote a prefix that is not a range, do not enclose in brackets, for example, <b>12345#</b>.</li> <li>■ To denote a suffix, enclose it in parenthesis, for example, <b>(4)</b> and <b>(4-8)</b>.</li> <li>■ To denote a suffix that includes multiple ranges, enclose the range in square brackets, for example, <b>(23xx[4,5,6])</b>.</li> </ul> <p>Example of using both a prefix and a suffix in a pattern: Assume you want to match a rule whose destination phone prefix is 4 through 8, and suffix is 234, 235, or 236. The pattern for this would be: <b>[4-8](23[4,5,6])</b>.</p>
<b>[n-m]</b> or <b>(n-m)</b>	<p>Denotes a range of numbers.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ To denote prefix numbers from 5551200 to 5551300: <ul style="list-style-type: none"> <li>✓ <b>[5551200-5551300]#</b></li> </ul> </li> <li>■ To denote prefix numbers from 123100 to 123200: <ul style="list-style-type: none"> <li>✓ <b>123[100-200]#</b></li> </ul> </li> <li>■ To denote prefix and suffix numbers together: <ul style="list-style-type: none"> <li>✓ <b>03(100)</b>: for any number that starts with 03 and ends with 100.</li> <li>✓ <b>[100-199](100,101,105)</b>: for a number that starts with 100 to 199 and ends with 100, 101 or 105.</li> <li>✓ <b>03(abc)</b>: for any number that starts with 03 and ends with abc.</li> <li>✓ <b>03(5xx)</b>: for any number that starts with 03 and ends with 5xx.</li> <li>✓ <b>03(400,401,405)</b>: for any number that starts with 03 and ends with 400 or 401 or 405.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The value <i>n</i> must be less than the value <i>m</i>.</li> <li>■ Only numerical ranges are supported (not letters).</li> <li>■ For suffix ranges, the starting (<i>n</i>) and ending (<i>m</i>) numbers in the</li> </ul> </li></ul>

Pattern	Description
	range must include the same number of digits. For example, (23-34) is correct, but (3-12) is not.
<b>[n,m] or (n,m)</b>	<p>Denotes multiple numbers. The value can include digits or characters. Examples:</p> <ul style="list-style-type: none"> <li>■ To denote a one-digit number starting (prefix) with 2, 3, 4, 5, or 6: <b>[2,3,4,5,6]</b></li> <li>■ To denote a one-digit number ending (suffix) with 7, 8, or 9: <b>(7,8,9)</b></li> <li>■ Prefix with suffix: <b>[2,3,4,5,6](7,8,9)</b> - prefix is denoted in square brackets; suffix in parenthesis</li> </ul> <p>For <b>prefix only</b>, the patterns <i>d[n,m]e</i> and <i>d[n-m]e</i> can also be used:</p> <ul style="list-style-type: none"> <li>■ To denote a five-digit number that starts with 11, 22, or 33: <b>[11,22,33]xxx#</b></li> <li>■ To denote a six-digit number that starts with 111 or 222: <b>[111,222]xxx#</b></li> </ul>
<b>[n1-m1,n2-m2,a,b,c,n3-m3] or (n1-m1,n2-m2,a,b,c,n3-m3)</b>	<p>Denotes a mixed pattern of single numbers and multiple number ranges. For example, to denote numbers 123 through 130, 455, 766, and 780 through 790:</p> <ul style="list-style-type: none"> <li>■ Prefix: <b>[123-130,455,766,780-790]</b></li> <li>■ Suffix: <b>(123-130,455,766,780-790)</b></li> </ul> <p><b>Note:</b> The ranges and the single numbers in the mixed pattern must have the same number of digits. For example, each number range and single number in the examples above consists of three digits (e.g., 780).</p>
<b>Special ASCII Characters</b>	<p>The device doesn't support the use of ASCII characters in manipulation rules. Instead, you need to use the hexadecimal (HEX) format of the ASCII characters for phone numbers.</p> <p>The HEX value must be preceded by a backslash “\”. For example, you can configure a manipulation rule that changes the received number <b>+49 (7303) 165-xxxxx</b> to <b>+49 \287303\29 165-xxxxx</b>, where \28 is the ASCII HEX value for “(” and \29 is the ASCII HEX value for “)”. The manipulation rule in this example would denote the parenthesis in the destination number prefix using “x” wildcards (e.g., xx165xxxxx#); the prefix to add to the number would include the HEX values (e.g., +49 \287303\29 165-).</p> <p>Below is a list of common ASCII characters and their corresponding HEX values:</p>

Pattern	Description
	<ul style="list-style-type: none"><li>■ *:\2a</li><li>■ (\28</li><li>■ ):\29</li><li>■ \:\5c</li><li>■ /\2f</li></ul>

## 73 Configuration Parameters Reference

The device's VoIP functionality configuration parameters, default values, and their descriptions are documented in this section.

Parameters and values enclosed in square brackets [...] represent ini file parameters and their enumeration values.

### Management Parameters

This section describes the device's management-related parameters.

#### General Parameters

The general management parameters are described in the table below.

**Table 73-1: General Management Parameters**

Parameter	Description
'Web Server Name' <code>configure system &gt; web &gt; web-hostname</code> [WebHostname]	Defines a hostname (FQDN) for the device's Web interface. This can be used to access the Web interface instead of the device's IP address.  By default, no value is defined.  For more information, see <a href="#">Configuring a Hostname for Device's Web Interface</a> on page 87.  <b>Note:</b> If not configured, the device uses the [Hostname] parameter.
'Enforce Web Host Name' <code>configure system &gt; web &gt; enforce-web-host-name</code> [EnforceWebHostname]	Enables the enforcement of access to the device's Web interface through a hostname only, and blocks any attempt to access the Web interface through the device's IP address.  <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled. The Web interface can be accessed through a hostname or an IP address.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. Enforces access to the Web interface only through a hostname if you've configured a hostname. For more information, see <a href="#">Configuring a Hostname for Device's Web Interface</a> on page 87.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Due to a known issue, the following OVOC features <b>don't</b> function when the 'Enforce Web Host Name' parameter is enabled: <ul style="list-style-type: none"> <li>✓ OVOC Single Sign-On (SSO)</li> <li>✓ OVOC Performance Monitoring (PM)</li> <li>✓ OVOC Service Availability</li> </ul> </li> <li>■ If you need to use any of these OVOC features, make sure that the 'Enforce Web Host Name' parameter is disabled.</li> <li>■ To configure a hostname for the Web interface, see the 'Web Server Name' parameter.</li> <li>■ If you disable the parameter or you don't configure the 'Web Server Name' parameter, the Web interface can be accessed through an FQDN or IP address.</li> <li>■ If you're upgrading the device from version 7.4.500-2 (7.40A.500.775) or later to version 7.4.500-5 or later and have configured the 'Web Server Name' parameter and use the device's IP address to access the Web interface, access to the device through the IP address will be denied. If you want to retain such capability, disable the 'Enforce Web Host Name' parameter.</li> </ul>
<p>'Hostname'</p> <pre>configure system &gt; hostname</pre> <p>[Hostname]</p>	<p>Defines a hostname for the device, which is used for various functionality such as the CLI prompt name.</p> <p>The valid value is a string of up to 18 characters. By default, no value is defined.</p> <p>For more information, see <a href="#">Configuring a Hostname for the Device</a> on page 144.</p> <p><b>Note:</b> To configure a hostname for accessing the device's Web interface, use the [WebHostname] parameter.</p>
[WebLoginBlockAutoComplete]	Disables autocompletion when entering the

Parameter	Description
	<p>management login username in the 'Username' field of the device's Web interface. Disabling autocompletion may be useful for security purposes by hiding previously entered usernames and thereby, preventing unauthorized access to the device's management interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Autocompletion is enabled and the 'Username' field automatically offers previously logged in usernames.</li> <li>■ [1] <b>Enable</b> = Autocompletion is disabled.</li> </ul>
<p>'Enforce Username Complexity'</p> <pre>configure system &gt; users- settings &gt; enforce- username-complexity</pre> <p>[EnforceUsernameComplexity]</p>	<p>Enables the enforcement of username complexity.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information, see <a href="#">Configuring Login Username and Password Complexity</a> on page 65.</p>
<p>'Username Complexity Check By Regex'</p> <pre>configure system &gt; users- settings &gt; username- complexity-check-by-regex</pre> <p>[UsernameComplexityCheckByRegex]</p>	<p>Defines a username complexity policy by a regular expression (regex).</p> <p>By default, no regex is defined.</p> <p>For more information, see <a href="#">Configuring Login Username and Password Complexity</a> on page 65.</p>
<p>'Enforce Password Complexity'</p> <pre>configure system &gt; users- settings &gt; enforce- password-complexity</pre> <p>[EnforcePasswordComplexity]</p>	<p>Enables the enforcement of password complexity.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information, see <a href="#">Configuring Login Username and Password Complexity</a> on page 65.</p>
<p>'Password Complexity Check By Regex'</p>	<p>Defines a password complexity policy by a regular expression (regex).</p>

Parameter	Description
<pre>configure system &gt; users- settings &gt; password- complexity-check-by-regex</pre> [PasswordComplexityCheckByRegex]	<p>By default, no regex is defined.</p> <p>For more information, see <a href="#">Configuring Login Username and Password Complexity</a> on page 65.</p>
<pre>configure system &gt; web &gt; min-web-password-len</pre> [MinWebPasswordLen]	<p>Defines the minimum length (number of characters) of the management user's login password when password complexity is enabled.</p> <p>The valid value is a string of 8 to 20 characters. The default is 8.</p> <p><b>Note:</b> To enable password complexity, use the [EnforcePasswordComplexity] parameter.</p>
<pre>configure system &gt; web &gt; check-password-history</pre> [CheckPasswordHistory]	<p>Enables the device to enforce password history policy (reuse an old password), which prohibits a user from changing its password to any of the user's four previous passwords.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> The parameter is not applicable to the password for the CLI privileged mode (&gt; enable).</p>
<p>'Use OAuth for Web Login'</p> <pre>configure system &gt; mgmt- auth &gt; oauth-web-login</pre> [OAuthWebLogin]	<p>Enables user login authentication based on OAuth 2.0.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Disables OAuth-based login authentication.</li> <li>■ [1] <b>Enable with local login</b> = Enables both OAuth-based login authentication and local authentication (using the Local Users table as described in <a href="#">Configuring Local Management User Accounts</a> on page 55).</li> <li>■ [2] <b>Enable without local login</b> = Enables OAuth-based login authentication only (without local authentication).</li> </ul> <p>For more information, see <a href="#">Enabling OAuth-based User Login Authentication</a> on page 430.</p>
'Local Users Table can be Empty'	Enables (allows) the deletion of all users in the

Parameter	Description
<pre>configure system &gt; web &gt; local-users-table-can-be- empty</pre> <p>[AllowRemoveLocalUsersTable]</p>	<p>Local Users table (see <a href="#">Configuring Local Management User Accounts</a> on page 55). This is used when an external, third-party service (e.g., LDAP, RADIUS, or OAuth) is used to authenticate users.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information, see <a href="#">Deleting All Users in Local Users Table</a> on page 64.</p>
<p>'Lock'</p> <pre>admin state lock</pre> <p>[AdminState]</p>	<p>Locks the device, whereby existing calls are terminated (optionally, after a graceful period) and new calls are rejected.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Lock</b></li> <li>■ [2] <b>Unlock</b> (default)</li> </ul> <p>For more information, see <a href="#">Locking and Unlocking the Device</a> on page 1331.</p>
<p>'Graceful Option'</p> <pre>admin state lock graceful</pre> <p>[AdminStateLockControl]</p>	<p>Defines a graceful period (in seconds) before the device locks. During this period, the device doesn't accept any new calls, allowing only existing calls to continue until the timeout expires. If all existing calls end before the timeout expires, the device locks. If there are still existing calls when the timeout expires, the device terminates them and then locks.</p> <p>The valid value is 0 to 32,768 seconds. The default is 0, meaning no graceful lock (i.e., immediate lock). A value of -1 means that the device locks only after all the existing calls end (on their own accord).</p> <p>For more information, see <a href="#">Locking and Unlocking the Device</a> on page 1331.</p>
<p>'Disconnect Client Connections'</p> <pre>admin state lock no- graceful disconnect-client- connections</pre> <p>[AdminStateRestrictConnections]</p>	<p>Enables the device to close existing TLS/TCP client connections and reject incoming TLS/TCP client connections when the device is in locked state.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] Enable</li> </ul> <p>For more information, see <a href="#">Locking and Unlocking the Device</a> on page 1331.</p>
[CustomerSN]	<p>Defines a serial number (S/N) for the device.</p> <p><b>Note:</b> The device's original S/N is automatically added at the end of the configured S/N. For example, if the original S/N is 8906721 and the configured S/N is "abc123", the resultant S/N is "abc1238906721".</p>
[DisableDualImageFeature]	<p>Enables the device to fallback to the previously installed software version file (.cmp) if during a software upgrade the device restarts for whatever reason (e.g., a power off-on scenario), causing a software upgrade failure.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Enabled.</li> <li>■ [1] = Disabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to Mediant 800 Gateway &amp; E-SBC H/W Rev. C .</li> </ul>

## Web Parameters

The Web parameters are described in the table below.

**Table 73-2: Web Parameters**

Parameter	Description
'Password Change Interval' <code>configure system &gt;</code> <code>web &gt; web-password-</code> <code>change-interval</code> [WebPassChangeInterval]	<p>Defines the minimum duration (in minutes) between login password changes. For example, if you configure the parameter to 60, you can only change the password if at least 60 minutes has elapsed since the password was last changed.</p> <p>The valid value is 0 to 100,000. The default is 0, meaning that the password can be changed at any time.</p>
'Password Expired Alarm'	Defines the number of days before login password

Parameter	Description
<pre>configure system &gt; mgmt-auth &gt; password-expired- alarm</pre> <p>[RaiseAlarmXDaysBeforePwExpired]</p>	<p>expiration when the device sends the acExpiredPasswordAlarm SNMP alarm.</p> <p>The valid range is 0 to 120. The default is 14. A value of 0 disables this alarm from being sent.</p> <p>For more information, see <a href="#">Configuring Login Password Expiration Alarm</a> on page 70.</p>
<p>'User Inactivity Timer'</p> <pre>configure system &gt; web &gt; user- inactivity-timeout</pre> <p>[UserInactivityTimer]</p>	<p>Defines the duration (in days) for which a user has not logged in to the Web interface, after which the status of the user becomes inactive and can no longer access the Web interface. These users can only log in to the Web interface if their status is changed (to New or Valid) by a <b>Security Administrator</b> user.</p> <p>The valid value is 0 to 10000, where 0 means inactive. The default is 90.</p> <p><b>Note:</b> The parameter is applicable only when using the Local Users table.</p>
<p>'Session Timeout'</p> <pre>configure system &gt; web &gt; session- timeout</pre> <p>[WebSessionTimeout]</p>	<p>Defines the duration (in minutes) of inactivity of a logged-in user in the Web interface, after which the user is automatically logged off the Web session. In other words, the session expires when the user has not performed any operations (activities) in the Web interface for the configured duration.</p> <p>The valid value is 0, or 2 to 100000, where 0 means no timeout. The default is 15.</p> <p><b>Note:</b> You can also configure the feature per user in the Local Users table (see <a href="#">Configuring Local Management User Accounts</a> on page 55), which overrides this global setting.</p>
<p>'Deny Access On Fail Count'</p> <pre>configure system &gt; web &gt; deny-access- on-fail-count</pre> <p>[DenyAccessOnFailCount]</p>	<p>Defines the maximum number of failed login attempts, after which the requesting IP address (management station) for all users is blocked.</p> <p>The valid value range is 0 to 10. The value 0 means that the feature is disabled and no blocking is done. The default is 3.</p>
<p>'Deny Authentication Timer'</p> <pre>configure system &gt; web &gt; deny-auth- timer</pre>	<p>Defines the duration (in seconds) for which login to the Web interface is denied from a specific IP address (management station) for all users when the number of failed login attempts exceeds the maximum. This</p>

Parameter	Description
[DenyAuthenticationTimer]	<p>maximum is configured by the [DenyAccessOnFailCount] parameter. Only after this time expires can users attempt to log in from this same IP address.</p> <p>The valid value is 0 to 100000, where 0 means that login is not denied regardless of the number of failed login attempts. The default is 60.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the [BlockingDurationFactor] parameter is configured to a value greater than 1, the duration that the IP address is blocked is according to the [BlockingDurationFactor] parameter.</li> <li>■ To configure the duration for which the IP address is blocked, use the [DenyAuthenticationTimer] parameter.</li> <li>■ Up to 1,000 IP addresses (management stations) can be blocked concurrently.</li> </ul>
'Blocking Duration Factor' configure system > web > blocking- duration-factor [BlockingDurationFactor]	<p>Defines the number to multiple the previous blocking time for blocking the IP address (management station) or user upon the next failed login scenario.</p> <p>The valid value is 1 to 100. The default is 1, which means that the blocking time remains the same (not increased). For example, assume the following configuration:</p> <ul style="list-style-type: none"> <li>■ The 'Deny Access On Fail Count' parameter is configured to 3 (failed login attempts).</li> <li>■ The 'Block Duration' parameter in the Local Users table is configured to 10 (seconds) for user blocking, or the [DenyAuthenticationTimer] parameter is configured to 10 for IP address blocking.</li> <li>■ The [BlockingDurationFactor] parameter is configured to 2.</li> </ul> <p>After three failed login attempts, the device blocks the user for 10 seconds. If the user tries again to login but fails after three attempts, the device blocks the user for 20 seconds (i.e., 10 x 2). If the user tries again to login but fails after three attempts, the device blocks the user for 40 seconds (i.e., 20 x 2), and so on.</p>
'Valid time of Deny Access'	Defines the maximum time interval (in seconds) between

Parameter	Description
counting' configure system > web > deny-access- counting-valid-time [DenyAccessCountingValidTime]	<p>failed login attempts to be included in the count of failed login attempts for denying access to the user.</p> <p>The valid value is 30 to 10,000,000. The default is 60.</p> <p>For example, assume the following:</p> <ul style="list-style-type: none"> <li>■ The [DenyAccessOnFailCount] parameter is configured to 3 (failed login attempts).</li> <li>■ The [DenyAccessCountingValidTime] parameter is configured to 30 (seconds).</li> </ul> <p>If the user makes a failed login attempt, and then makes another failed login attempt 32 seconds later, and another failed login attempt 10 seconds later, the user is not blocked by the device. This is because the interval between the first and second attempt was greater than the 30 seconds configured for the [DenyAccessCountingValidTime] parameter. However, if the interval between all three failed login attempts is less than 30 seconds, the device blocks the user.</p>
'Display Last Login Information' configure system > web > display-last-login-info [DisplayLoginInformation]	<p>Enables the display of the user's login information upon each successful login attempt.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
'Invalid Login Report' configure system > web > invalid-login-report [InvalidLoginReport]	<p>Defines the information that is provided in the logged error message (Activity Log) when a user attempts to log in to the device with the wrong username or password (i.e., authentication failure).</p> <ul style="list-style-type: none"> <li>■ [0] <b>General Information</b> = (Default) The logged error message only indicates that incorrect credentials were entered, without specifying if it was the username or the password that was wrong.</li> <li>■ [1] <b>Detailed Information</b> = The logged error message indicates if it was the username or the password that was wrong.</li> </ul>
configure system > web > csrf-protection	<p>Enables cross-site request forgery (CSRF) protection of the device's embedded Web server.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable</li> </ul>

Parameter	Description
[CSRFProtection]	<ul style="list-style-type: none"> <li>■ [1] = (Default) Enable</li> </ul> <p>For more information, see <a href="#">Enabling CSRF Protection</a> on page 83.</p>
<pre>configure system &gt; web &gt; http-port</pre> [HTTPport]	<p>Defines the LAN HTTP port for Web management. To enable Web management from the LAN, configure the desired port.</p> <p>The default is 80.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[DisableWebConfig]	<p>Defines if the entire Web interface is read-only.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Enables modifications of parameters.</li> <li>■ [1] = Web interface is read-only.</li> </ul> <p>When in read-only mode, parameters can't be modified and the following pages can't be accessed: Web User Accounts, TLS Contexts, Time and Date, Maintenance Actions, Load Auxiliary Files, Software Upgrade Wizard, and Configuration File.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
[ResetWebPassword]	<p>Enables the device to restore the default management user accounts.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled - currently configured user accounts (usernames and passwords) are retained.</li> <li>■ [1] = Enabled - default user accounts (listed below) are restored and all other configured users (in the Local Users table) are deleted: <ul style="list-style-type: none"> <li>✓ Security Administrator user (username <b>Admin</b> and password <b>Admin</b>)</li> <li>✓ Monitor user (username <b>User</b> and password <b>User</b>)</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can also restore the default management user accounts (and delete all other configured users) through SNMP, by setting acSysGenericINLine to "ResetWebPassword = 1".</li> </ul>

Parameter	Description
	<p>■ You can change username and password through SNMP:</p> <p>✓ To change the current username, use the following syntax (but without angled brackets) in the acSysWEBAccessEntry table:</p> <pre>acSysWEBAccessUserName:&lt;current username&gt;/&lt;password&gt;/&lt;new username&gt;</pre> <p>✓ To change the current password, use the following syntax (but without angled brackets) in the acSysWEBAccessEntry table:</p> <pre>acSysWEBAccessUserCode:&lt;username&gt;/&lt;current password&gt;/&lt;new password&gt;</pre>
<p>'Check Weak Passwords'</p> <pre>configure system &gt; web &gt; check-weak-psw [WeakPasswordsCheck]</pre>	<p>Enables the weak password detection feature, which detects if a user in the Local Users table is configured with a weak password (listed in the Weak Passwords List table).</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>For more information, see <a href="#">Detection of Weak Login Passwords</a> on page 67.</p>
<pre>configure system &gt; welcome-msg [WelcomeMessage]</pre>	<p>Defines a welcome message displayed on the Web interface's Web Login page.</p> <p>The format of the ini file table parameter is:</p> <pre>[WelcomeMessage ] FORMAT Index = Text [\WelcomeMessage]</pre> <p>For example:</p> <pre>FORMAT Index = Text WelcomeMessage 1 = "*****" , WelcomeMessage 2 = "***** This is a</pre>

Parameter	Description
	<p>Welcome message ***" ;  WelcomeMessage 3 =  "*****" ;</p> <p>For more information, see <a href="#">Creating a Login Welcome Message</a> on page 51.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Each index row represents a line of text. Up to 20 lines (or rows) of text can be defined.</li> <li>■ The configured text message must be enclosed in double quotation marks (i.e., "...").</li> <li>■ If the parameter is not configured, no Welcome message is displayed.</li> </ul>
[UseProductName]	<p>Enables the option to customize the name of the device (product) that appears in the management interfaces.</p> <ul style="list-style-type: none"> <li>■ [0] = Disabled (default).</li> <li>■ [1] = Enables the display of a user-defined name, which is configured by the [UserProductName] parameter.</li> </ul> <p>For more information, see <a href="#">Customizing the Product Name</a> on page 48.</p>
[UserProductName]	<p>Defines a name for the device instead of the default name.</p> <p>The value can be a string of up to 29 characters.</p> <p>For more information, see <a href="#">Customizing the Product Name</a> on page 48.</p> <p><b>Note:</b> To enable customization of the device name, see the [UseProductName] parameter.</p>
<pre>configure system &gt; web &gt; web-logo- enable</pre> <p>[UseWebLogo]</p>	<p>Enables the Web interface to display user-defined text instead of an image (logo).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) The Web interface displays a logo image, which is configured by the [LogoFileName] parameter.</li> <li>■ [1] = The Web interface displays text (instead of an image), which is configured by the [WebLogoText] parameter (see note).</li> </ul>

Parameter	Description
	<p>For more information, see <a href="#">Corporate Logo</a> on page 44.</p> <p><b>Note:</b> If you want to display text instead of an image, configure [UseWebLogo] to 1 and make sure that [LogoFileName] is not configured to any value. If [LogoFileName] is configured, it overrides [UseWebLogo] and an image will always be displayed.</p>
<pre>configure system &gt; web &gt; web-logo-text [WebLogoText]</pre>	<p>Defines the text that is displayed instead of the logo in the Web interface.</p> <p>The valid value is a string of up to 15 characters.</p> <p>For more information, see <a href="#">Replacing Corporate Logo with Text</a> on page 46.</p> <p><b>Note:</b> The parameter is applicable only when the [UseWebLogo] parameter is configured to [1].</p>
[LogoFileName]	<p>Defines the name of the image file that you want loaded to the device. This image is displayed as the logo in the Web interface (instead of the AudioCodes logo).</p> <p>The file name can be up to 47 characters.</p> <p>For more information, see <a href="#">Replacing the Corporate Logo with an Image</a> on page 45.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ The image file type can be one of the following: GIF, PNG, JPG, or JPEG.</li> <li>■ The size of the image file can be up to 64 Kbytes.</li> </ul>
[ExternalDocumentsBaseURL]	<p>When the Web interface is set up for private labeling (e.g., non-default logo on toolbar), the parameter enables the Web interface's toolbar to display the  icon, which provides a drop-down list of documents that can be referenced.</p> <p>Add a forward slash ("/") at the end of the parameter's value:</p> <pre>ExternalDocumentsBaseURL = 'https://acredirect.azurewebsites.net/api/'</pre>

## Telnet and CLI Parameters

The Telnet parameters are described in the table below.

**Table 73-3: Telnet Parameters**

Parameter	Description
<b>'Enable Telnet Server'</b> <code>configure system &gt; cli- settings &gt; telnet</code> <b>[TelnetServerEnable]</b>	<p>Enables the device's embedded Telnet server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable Unsecured</b></li> <li>■ [2] <b>Enable Secured</b></li> </ul> <p><b>Note:</b> Only <b>Security Administrator</b> users can access the CLI's Privileged command mode.</p>
<b>'Idle Timeout'</b> <code>configure system &gt; cli- settings &gt; idle-timeout</code> <b>[TelnetServerIdleDisconnect]</b>	<p>Defines the duration of an idle CLI (Telnet or SSH) session after which the session is automatically disconnected.</p> <p>The valid range is any value. The default is 5. When configured to 0, idle sessions are not disconnected.</p> <p><b>Note:</b> If you change the parameter's value when there are current Telnet/SSH sessions, the parameter's previous setting is still applied to these current sessions and the parameter's new setting is applied only to new sessions.</p>
<b>'Maximum Telnet Sessions'</b> <code>configure system &gt; cli- settings &gt; telnet-max- sessions</code> <b>[TelnetMaxSessions]</b>	<p>Defines the maximum number of permitted, concurrent Telnet or SSH sessions.</p> <p>The valid range is 1 to 5 sessions. The default is 2.</p> <p><b>Note:</b> Before changing the value, make sure that not more than this number of sessions are currently active; otherwise, the new setting will not take effect.</p>
<code>configure system &gt; cli- settings &gt; privilege- password</code> <b>[CLIEnableModePassword]</b>	<p>Defines the password to access the Enable configuration mode in the CLI.</p> <p>The valid value is a string of up to 50 characters. The default is "Admin".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The password is case-sensitive.</li> <li>■ The parameter cannot be configured with wide characters.</li> </ul>
<b>'Default Terminal Window Height'</b> <code>configure system &gt; cli- settings &gt; default- window-height</code>	<p>Defines the number (height) of output lines displayed in the CLI terminal window. This applies to all new CLI sessions and is preserved after device restarts.</p>

Parameter	Description
[DefaultTerminalWindowHeight]	<p>The valid value range is -1 (default) and 0-65535:</p> <ul style="list-style-type: none"> <li>■ A value of -1 means that the parameter is disabled and the settings of the CLI command <b>window-height</b> is used.</li> <li>■ A value of 0 means that all the CLI output is displayed in the window.</li> <li>■ A value of 1 or greater displays that many output lines in the window and if there is more output, the "—MORE—" prompt is displayed. For example, if you configure the parameter to 4, up to four output lines are displayed in the window and if there is more output, the "—MORE—" prompt is displayed (at which you can press the spacebar to display the next four output lines).</li> </ul> <p><b>Note:</b> You can override this parameter for a specific CLI session and configure a different number of output lines, by using the <b>window-height</b> CLI command in the currently active CLI session.</p>
<pre>configure system &gt; mgmt- auth &gt; obscure-password- mode</pre> <p>[CliObscuredPassword]</p>	<p>Enables the device to enforce obscured (i.e., encrypted) passwords whenever you add a new management user or modify the password of an existing user, through CLI (<code>configure system &gt; user</code>).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled - passwords are configured in plain text.</li> <li>■ [1] = Enabled - passwords must be configured in encrypted format. To obtain an encrypted (obscured) password: <ul style="list-style-type: none"> <li>a. Enable the parameter.</li> <li>b. Configure the user's password in the Web interface's Local Users table (see <a href="#">Configuring Local Management User Accounts</a> on page 55).</li> <li>c. Save the device's CLI Script file to your local PC (see <a href="#">Downloading or Uploading CLI Script File</a> on page 1387).</li> <li>d. Open the file, and then copy the encrypted</li> </ul> </li> </ul>

Parameter	Description
	password to the CLI where you are configuring the user.

## SNMP Parameters

The SNMP parameters are described in the table below.

**Table 73-4: SNMP Parameters**

Parameter	Description
'Disable SNMP' configure system > snmp settings > disable [DisableSNMP]	Enables and disables device management through SNMP.  ■ [0] <b>No</b> = (Default) SNMP is enabled. ■ [1] <b>Yes</b> = SNMP is disabled.
'SNMP Port' configure system > snmp settings > port [SNMPPort]	Defines the device's local (LAN) UDP port used for SNMP Get/Set commands. The range is 100 to 3999. The default port is 161. For more information, see <a href="#">Configuring SNMP Get / Set Port</a> on page 108. <b>Note:</b> For the parameter to take effect, a device restart is required.
[ChassisPhysicalAlias]	Defines the 'alias' name object for the physical entity as specified by a network manager, and provides a non-volatile 'handle' for the physical entity. The valid range is a string of up to 255 characters.
[ChassisPhysicalAssetID]	Defines the user-assigned asset tracking identifier object for the device's chassis as specified by OVOC, and provides non-volatile storage of this information. The valid range is a string of up to 255 characters.
[ifAlias]	Defines the textual name of the interface. The value is equal to the ifAlias SNMP MIB object. The valid range is a string of up to 64 characters.

Parameter	Description
<pre>configure system &gt; snmp trap</pre> <pre>&gt; auto-send-keep-alive</pre> <p>[SendKeepAliveTrap]</p>	<p>Enables the device to send NAT keep-alive traps to the port of the SNMP network management station (e.g., AudioCodes OVOC). This is used for NAT traversal, and allows SNMP communication with OVOC management platform, located in the WAN, when the device is located behind NAT. It is needed to keep the NAT pinhole open for the SNMP messages sent from OVOC to the device. The device sends the trap periodically - every 9/10 of the time configured by the NATBindingDefaultTimeout parameter. The trap that is sent is acKeepAlive. For more information, refer to the <a href="#">SBC-Gateway Series SNMP Alarm Reference Guide</a>.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p>To configure the port number, use the KeepAliveTrapPort parameter.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[KeepAliveTrapPort]	<p>Defines the port of the SNMP network management station to which the device sends keep-alive traps.</p> <p>The valid range is 0 - 65534. The default is port 162.</p> <p>To enable NAT keep-alive traps, use the [SendKeepAliveTrap] parameter.</p>
<p>'Call Duration for Short Calls'</p> <pre>configure voip &gt; sbc</pre> <pre>settings &gt; short-call-</pre> <pre>seconds</pre> <p>[ShortCallSeconds]</p>	<p>Defines the maximum duration (in seconds) of an SBC call for it to be considered a short call and included in the performance monitoring count for short calls (shortCallsCounterTotal and shortCallsCounter). The duration must be less than or equal to the configured value for the call to be considered a short call.</p> <p>The valid value is 0 to 60. The default is 2. A value of 0 indicates calls of zero duration, which are calls that do not pass the device's Classification, Manipulation or Routing stages.</p>

Parameter	Description
	<p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Call Duration for Long Calls'</p> <pre>configure voip &gt; sbc settings &gt; long-call-minutes</pre> <p>[LongCallMinutes]</p>	<p>Defines the minimum duration (in minutes) of an SBC call for it to be considered a long call and included in the performance monitoring count for long calls (longCallsCounterTotal and longCallsCounter). The duration must be greater than or equal to the configured value for the call to be considered a long call.</p> <p>The valid value is 0 to 60. The default is 30. A value of 0 indicates calls of zero duration, which are calls that do not pass the device's Classification, Manipulation or Routing stages.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
[acUserInputAlarmDescription]	Defines the description of the input alarm.
[acUserInputAlarmSeverity]	Defines the severity of the input alarm.
<pre>configure system &gt; snmp settings &gt; alarm-history- table-max-size</pre> <p>[AlarmHistoryTableMaxSize]</p>	<p>Defines the maximum number of historical alarms that can be displayed in the Alarm History table. The parameter can be controlled by the Config Global Entry Limit MIB (located in the Notification Log MIB).</p> <p>The valid range is 50 to 1000. The default is 500.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure system &gt; snmp settings &gt; active-alarm- table-max-size</pre> <p>[ActiveAlarmTableMaxSize]</p>	<p>Defines the maximum number of active alarms that can be displayed in the Active Alarms table.</p> <p>When the table reaches this user-defined maximum capacity (i.e., full), the device sends the SNMP trap event, acActiveAlarmTableOverflow. If the table is full and a new alarm is raised by the device, the new alarm is not displayed in the table.</p> <p>The valid range is 50 to 300. The default is</p>

Parameter	Description
	<p>120.</p> <p>For more information on the Active Alarms table, see <a href="#">Viewing Active Alarms</a> on page 1454.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ To clear the acActiveAlarmTableOverflow trap, you must restart the device. The restart also deletes all the alarms in the Active Alarms table.</li> </ul>
<pre>configure system &gt; snmp alarm-settings &gt; alarms- persistent-history</pre> <p>[AlarmsPersistentHistory]</p>	<p>Enables the device to store the alarms of the Alarms History table on its flash memory. When enabled, the alarms are not deleted from table upon a device restart.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled</li> <li>■ [1] = Enabled</li> </ul> <p>For more information, see <a href="#">Storing Alarms History on Flash</a> on page 1457.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The device can't operate with OVOC when the parameter is enabled.</li> </ul>
<pre>configure system &gt; snmp alarm-settings &gt; persistent- history-save-interval</pre> <p>[SavePersistentHistoryInterval]</p>	<p>Defines how often (in minutes) the device saves the alarms of the Alarms History table to its flash memory.</p> <p>The valid value range is 1 to 50,000. The default is 1,440 (24 hours).</p> <p>For more information, see <a href="#">Storing Alarms History on Flash</a> on page 1457.</p>
<pre>no-alarm-for-disabled-port</pre> <p>[NoAlarmForDisabledPort]</p>	<p>Enables the device to not send the SNMP trap acBoardControllerFailureAlarm alarm. This alarm indicates a "disabled" telephony port, which is one that is not configured at all or that is configured but without a Trunk Group</p>

Parameter	Description
	<p>ID (i.e., Trunk Group ID is 0), in the Trunk Groups table.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled. The device sends the SNMP trap for non-configured ports.</li> <li>■ [1] = Enabled. The device doesn't send the SNMP trap for non-configured ports.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to all telephony (analog and digital) port types.</li> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>
<pre>configure voip &gt; gateway analog fxs-setting fxs- offhook-timeout-alarm [FXSOffhookTimeoutAlarm]</pre>	<p>Defines the duration (in seconds) of an FXS phone in off-hook state after which the device sends the SNMP alarm, <code>acAnalogLineLeftOffhookAlarm</code>. The device starts this timer once the reorder tone begins playing when the phone goes off-hook. The alarm is cleared when the phone's hook-flash button is pressed or the phone returns to on-hook state.</p> <p>The valid value is 0 to 180,000. The default is 0, meaning that this alarm is not sent when the phone goes off-hook.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The parameter's setting is applied only to phones that go off-hook after you have configured the parameter.</li> </ul>
[ContextEngineID]	<p>Defines the <code>contextEngineID</code> as mentioned in RFC 3411. An SNMP context is a collection of management information accessible by an SNMP entity. An item of management information may exist in more than one context and an SNMP entity potentially has access to many contexts. A context is identified by the <code>snmpEngineID</code> value of the</p>

Parameter	Description
	<p>entity hosting the management information (also called a contextEngineID) and a context name that identifies the specific context (also called a contextName).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When the device operates in HA mode, this parameter has the same value for both active and redundant devices (i.e., system identifier). If the devices return to Standalone mode (i.e., non-HA mode), you must configure the parameter to a 0 value on both devices. When the devices restart to Standalone mode, each device automatically sets this parameter to a unique value based on its serial number (S/N).</li> </ul>
<pre>configure system &gt; snmp settings &gt; engine-id</pre> <p>[SNMPEngineIDString]</p>	<p>Defines the SNMP engine ID for SNMPv2/SNMPv3 agents. This is used for authenticating a user attempting to access the SNMP agent on the device.</p> <p>The ID can be a string of up to 36 characters. The default is 00:00:00:00:00:00:00:00:00:00:00:00 (12 Hex octets characters). The provided key must be set with 12 Hex values delimited by a colon (":") in the format xx:xx:...:xx. For example, 00:11:22:33:44:55:66:77:88:99:aa:bb</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ Before setting the parameter, all SNMPv3 users must be deleted; otherwise, the parameter setting is ignored.</li> <li>■ If the supplied key doesn't pass validation of the 12 Hex values input or it is set with the default value, the engine ID is generated according to RFC 3411.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ When the device operates in HA mode, the parameter has the same value for both active and redundant devices (i.e., system identifier). If the two devices return to Standalone mode (i.e., non-HA mode), you must configure the parameter to a NULL value (i.e., no value) for both devices. When the devices restart to the Standalone mode, each device automatically sets the parameter to a unique value based on its' serial number (S/N).</li> </ul>
<b>'Activity Trap'</b> configure troubleshoot > activity-trap [EnableActivityTrap]	Enables the device to send an SNMP trap to notify of Web user activities in the Web interface. The activities to report are configured by the [ActivityListToLog] parameter (see <a href="#">Reporting Management User Activities</a> on page 1634). <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<b>'IPv4 Interface Name'</b> configure system > snmp settings > interface-name [SNMPInterface]	Assigns an IPv4 IP Interface (configured in the IP Interfaces table - see <a href="#">Configuring IP Network Interfaces</a> on page 159) to the SNMP application for SNMP over IPv4.  By default, the OAMP IP Interface is assigned to SNMP over IPv4.  For more information, see <a href="#">Configuring SNMP Interfaces</a> on page 114.
<b>'IPv6 Interface Name'</b> configure system > snmp settings > interface-ipv6-name [SNMPIPv6Interface]	Assigns an IPv6 IP Interface (configured in the IP Interfaces table - see <a href="#">Configuring IP Network Interfaces</a> on page 159) to the SNMP application for SNMP over IPv6.  For more information, see <a href="#">Configuring SNMP Interfaces</a> on page 114.
configure system > snmp settings > enable-authentication-trap	Disables the sending of the Authentication Failure SNMP trap (authenticationFailure, OID 1.3.6.1.6.3.1.1.5.5).

Parameter	Description
[EnableSnmpAuthenticationTrap]	<ul style="list-style-type: none"> <li>■ [0] = Disable - trap is not sent.</li> <li>■ [1] = (Default) Enable - trap is sent.</li> </ul>
'Trap Community String' configure system > snmp trap > community-string [SNMPTrapCommunityStringPassword]	Defines the community string for SNMP traps. For more information, see <a href="#">Configuring SNMP Community String for Traps</a> on page 113. <b>Note:</b> The parameter cannot be configured with wide characters.
configure troubleshoot > pool-thresholds settings > alarm-raise-threshold [PoolAlarmRaise]	Defines the threshold (in percentage) to raise the acResourcePoolAlarm SNMP alarm (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.162). The alarm is triggered (major severity level) when a specific resource pool utilization of the device reaches or exceeds this threshold. The default is 95.
configure troubleshoot > pool-thresholds settings > alarm-clear-threshold [PoolAlarmClear]	Defines the threshold (in percentage) to clear the acResourcePoolAlarm SNMP alarm (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.162). The alarm is triggered (major severity level) when a specific resource pool utilization of the device reaches or exceeds a specific threshold, configured by the [PoolAlarmRaise] parameter. The default is 90.

## WebSocket Tunneling with OVOC Parameters

The WebSocket tunneling with OVOC parameters are described in the table below. For more information on WebSocket tunneling between the device and OVOC, see [Configuring WebSocket Tunnel with OVOC](#) on page 123.

**Table 73-5: WebSocket Tunneling with OVOC Parameters**

Parameter	Description
'OVOC WebSocket Tunnel Server Address' configure network > ovoc-tunnel-settings > address [WSTunServer]	Defines the address of the WebSocket tunnel server (OVOC). The valid value is an IPv4 address (in dotted-decimal notation) or a hostname. By default, no value is defined. <b>Note:</b>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ If you configure the parameter to a hostname, the device uses the DNS server configured in <a href="#">Configuring a DNS Server for HTTP Services</a> on page 471 to resolve it into an IP address.</li> </ul>
<b>'Interface Name'</b> <code>configure network &gt; ovoc-tunnel-settings &gt; interface-name</code> [WSTunInterfaceName]	<p>Defines an IP Interface for communication with the WebSocket tunnel server.</p> <p>By default, no value is defined (i.e., device uses the default OAMP IP Interface).</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<b>'Path'</b> <code>configure network &gt; ovoc-tunnel-settings &gt; path</code> [WSTunServerPath]	<p>Defines the path of the WebSocket tunnel server.</p> <p>Configure the parameter to "tun" (without quotation marks) to match the default OVOC configuration.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<b>'Username'</b> <code>configure network &gt; ovoc-tunnel-settings &gt; username</code> [WSTunUsername]	<p>Defines the username for connecting the device to the WebSocket tunnel server (OVOC).</p> <p>The valid value is a string of up to 30 characters.</p> <p>Configure the parameter to "VPN" (without quotation marks) to match the default OVOC configuration.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The username must be the same as that configured on OVOC.</li> </ul>
<b>'Password'</b>	Defines the password for connecting the

Parameter	Description
<pre>configure network &gt; ovoc- tunnel-settings &gt; password [WSTunPassword]</pre>	<p>device to the WebSocket tunnel server (OVOC).</p> <p>The valid value is a string of up to 30 characters.</p> <p>Configure the parameter to "123456" (without quotation marks) to match the default OVOC configuration.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The password must be the same as that configured on OVOC.</li> </ul>
<p>'Secured (HTTPS)'</p> <pre>configure network &gt; ovoc- tunnel-settings &gt; secured [WSTunSecured]</pre>	<p>Enables secured (HTTPS) WebSocket tunneling connection.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>'Verify Server'</p> <pre>configure network &gt; ovoc- tunnel-settings &gt; verify-server [WSTunVerifyPeer]</pre>	<p>Enables the device to verify the TLS certificate that is presented by OVOC when establishing the WebSocket tunneling connection.</p> <p>You should upload the corresponding CA certificate to the device's Trusted Root store of the default TLS Context (Index #0).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled. No certificate verification is done.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. The device verifies that the TLS certificate presented by OVOC is signed by one of the known CAs.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the [WSTunSecured] parameter to [1].</li> </ul>

## Serial Parameters

The serial interface parameters are described in the table below.

**Table 73-6: Serial Parameters**

Parameter	Description
[DisableRS232]	<p>Enables or disables the device's RS-232 serial communication port.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Enables RS-232.</li> <li>■ [1] = Disables RS-232.</li> </ul> <p>The RS-232 serial port can be used to change the networking parameters and view error/notification messages. To establish serial communication with the device, see <a href="#">Establishing a CLI Session</a> on page 101.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[SerialBaudRate]	<p>Defines the serial communication baud rate.</p> <p>The valid values include the following: 1200, 2400, 9600, 14400, 19200, 38400, 57600, or 115200 (default).</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[SerialData]	<p>Defines the serial communication data bit.</p> <ul style="list-style-type: none"> <li>■ [7] = 7-bit</li> <li>■ [8] = (Default) 8-bit</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[SerialParity]	<p>Defines the serial communication polarity.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) None</li> <li>■ [1] = Odd</li> <li>■ [2] = Even</li> </ul>

Parameter	Description
	<b>Note:</b> For the parameter to take effect, a device restart is required.
[SerialStop]	<p>Defines the serial communication stop bit.</p> <ul style="list-style-type: none"> <li>■ [1] = (Default) 1-bit (default)</li> <li>■ [2] = 2-bit</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[SerialFlowControl]	<p>Defines the serial communication flow control.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) None</li> <li>■ [1] = Hardware</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure troubleshoot &gt; startup-n- recovery &gt; startup-dark- mode</pre> <p>[EnableDarkenMode]</p>	<p>Enables serial darkening, which hides the bootup log messages from being displayed in the CLI console during a device reset (boot up). However, if the device fails to load, serial darkening is disabled in the next bootup attempt.</p> <ul style="list-style-type: none"> <li>■ [0]</li> <li>■ [1] (Default)</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

## Auxiliary and Configuration File Name Parameters

The table below lists the parameters associated with the Auxiliary files. For more information on Auxiliary files, see [Uploading Auxiliary Files](#) on page 1347.

**Table 73-7: Auxiliary and Configuration File Parameters**

Parameter	Description
<b>General Parameters</b>	
[SetDefaultOnIniFileProcess]	<p>Determines if all the device's parameters are set to their defaults before processing the updated <i>ini</i> file.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable - parameters not included in the downloaded ini file are not returned to default settings (i.e., retain their current settings).</li> </ul>

Parameter	Description
	<p>■ [1] = Enable (default).</p> <p><b>Note:</b> The parameter is applicable only for automatic HTTP update or Web <i>ini</i> file upload (not applicable if the <i>ini</i> file is loaded using BootP).</p>
[SaveConfiguration]	<p>Determines if the device's configuration (parameters and files) is saved to flash (non-volatile memory).</p> <p>■ [0] = Configuration isn't saved to flash memory.</p> <p>■ [1] = (Default) Configuration is saved to flash memory.</p>
<b>Auxiliary Filename Parameters</b>	
'Call Progress Tones File' [CallProgressTonesFilename]	<p>Defines the name of the file containing the Call Progress Tones definitions.</p> <p>For the ini file, the name must be enclosed by a single quotation mark (e.g., 'cpt_us.dat').</p> <p>For more information on how to create and upload this file, refer to the document <a href="#">DConvert Utility User's Guide</a>.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
'Prerecorded Tones File' [PrerecordedTonesFileName]	<p>Defines the name of the file containing the Prerecorded Tones.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
'CAS File' [CASFileName_x]	<p>Defines the CAS file name (e.g., 'E_M_WinkTable.dat'), which defines the CAS protocol (where x denotes the CAS file ID 0 to 7). It is possible to define up to eight different CAS files by repeating the parameter. Each CAS file can be associated with one or more of the device's trunks, using the parameter CASTableIndex or it can be associated per B-channel using the parameter CASChannelIndex.</p> <p>For the ini file, the name must be enclosed by a single quotation mark (e.g., 'cas_us.dat').</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
'Dial Plan'	Defines the Dial Plan name (up to 11-character strings)

Parameter	Description
[CasTrunkDialPlanName_x]	<p>per trunk.</p> <p>For the ini file, the name must be enclosed by a single quotation mark (e.g., 'dial_plan_2.dat').</p> <p><b>Note:</b> The x in the ini file parameter name denotes the trunk number, where 0 is Trunk 1.</p>
'Dial Plan File' [DialPlanFileName]	<p>Defines the name of the Dial Plan file.</p> <p>For the ini file, the name must be enclosed by a single quotation mark (e.g., 'dial_plan.dat').</p> <p><b>Note:</b> This parameter is used only for backward compatibility. For loading (importing) Dial Plan files, use the Dial Plan table instead (see <a href="#">Importing Dial Plans</a> on page 838).</p>
[UserInfoFileName]	<p>Defines the name of the file containing the User Information data.</p> <p>For the ini file, the name must be enclosed by a single quotation mark (e.g., 'userinfo_us.dat').</p> <p><b>Note:</b> The parameter is only used for backward compatibility.</p>

## License Parameters

The license parameters are described in the table below.

**Table 73-8: License Parameters**

Parameter	Description
<p>'Floating License'</p> <pre>configure system &gt; floating-license &gt; floating-license</pre> <p>[EnableFloatingLicense]</p>	<p>Enables the device to operate with the Floating License.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information, see <a href="#">Floating License Model</a> on page 1374.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>'Allocation Profile'</p> <pre>configure system &gt; floating-license &gt; allocation-profile</pre>	<p>Defines an SBC capacity profile (<i>Allocation Profile</i>) for the Floating License feature.</p> <ul style="list-style-type: none"> <li>■ [0] <b>SIP Trunking</b> = (Default) Profile suited for SIP</li> </ul>

Parameter	Description
[AllocationProfile]	<p>Trunking applications.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Registered Users</b> = Profile suited for applications requiring registered users.</li> <li>■ [2] <b>Custom</b> = Customized Allocation Profile.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
('Allocation') 'Far End Users' configure system > floating-license > allocation- registered-users [AllocationRegisteredUsers]	<p>Defines the capacity of registered users for a customized Allocation Profile in the Floating License.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b>.</li> </ul>
('Allocation') 'SBC Media Sessions' configure system > floating-license > allocation-media- sessions [AllocationMediaSessions]	<p>Defines the capacity of SBC media sessions for a customized Allocation Profile in the Floating License.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b>.</li> </ul>
('Allocation') 'SBC Signaling Sessions' configure system > floating-license > allocation-signaling- sessions [AllocationSignalingSessions]	<p>Defines the capacity of SBC signaling sessions for a customized Allocation Profile in the Floating License.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b>.</li> </ul>
('Allocation') 'WebRTC Sessions' configure system > floating-license > allocation-webrtc- sessions [AllocationWebRTCSessions]	<p>Defines the capacity of WebRTC sessions for a customized Allocation Profile in the Floating License.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b>.</li> </ul>

Parameter	Description
('Allocation') 'SIPREC Streams' configure system > floating-license > allocation-siprec- sessions [AllocationSIPRecStreams]	Defines the capacity of SIPREC sessions for a customized Allocation Profile in the Floating License. <b>Note:</b> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b>.</li> </ul>
('Limit') 'Far End Users' configure system > floating-license > limit-registered- users [LimitRegisteredUsers]	Defines a limit for the registered users capacity for a customized Allocation Profile in the Floating License. The limit can be equal to or less than the allocated registered users capacity, configured by the [AllocationRegisteredUsers] parameter. <b>Note:</b> The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b> .
('Limit') 'SBC Media Sessions' configure system > floating-license > limit-media-sessions [LimitMediaSessions]	Defines a limit for the SBC media sessions capacity for a customized Allocation Profile in the Floating License. The limit can be equal to or less than the allocated SBC media sessions capacity, configured by the [AllocationMediaSessions] parameter. <b>Note:</b> The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b> .
('Limit') 'SBC Signaling Sessions' configure system > floating-license > limit-signaling- sessions [LimitSignalingSessions]	Defines a limit for the SBC SIP signaling sessions capacity for a customized Allocation Profile in the Floating License. The limit can be equal to or less than the allocated SBC SIP signaling sessions capacity, configured by the [AllocationSignalingSessions] parameter. <b>Note:</b> The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b> .
('Limit') 'Transcoding Sessions' configure system > floating-license > limit-transcoding- sessions [LimitTranscodingSessions]	Defines a limit for the transcoding sessions capacity for a customized Allocation Profile in the Floating License. The limit can be equal to or less than the allocated transcoding sessions capacity. <b>Note:</b> The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b> .
('Limit') 'WebRTC Sessions' configure system >	Defines a limit for the WebRTC sessions capacity for a customized Allocation Profile in the Floating License.

Parameter	Description
floating-license > limit-webrtc-sessions [LimitWebRTCSessions]	The limit can be equal to or less than the allocated WebRTC sessions capacity, configured by the [AllocationWebRTCSessions] parameter. <b>Note:</b> The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b> .
('Limit') 'SIPREC Streams' configure system > floating-license > limit-siprec-sessions [LimitSIPRecStreams]	Defines a limit for the SIPREC sessions capacity for a customized Allocation Profile in the Floating License. The limit can be equal to or less than the allocated SIPREC sessions capacity, configured by the [AllocationSIPRecStreams] parameter. <b>Note:</b> The parameter is applicable only when the 'Allocation Profile' is configured to <b>Custom</b> .

## Automatic Update Parameters

The automatic update parameters are described in the following table.

Auxiliary file upload through TFTP is not supported in HA mode.

**Table 73-9: Automatic Update of Software and Configuration Files Parameters**

Parameter	Description
<b>General Automatic Update Parameters</b>	
configure system > automatic-update > aupd-interface [AUPDInterface]	Assigns an IP Interface (in the IP Interfaces table - see <a href="#">Configuring IP Network Interfaces</a> on page 159) for the Auto-Update mechanism. By default, the device uses the IPv4 OAMP interface. For more information, see <a href="#">Assigning IP Interface for Auto-Update Mechanism</a> on page 1410.
configure system > automatic-update > update-firmware [AutoUpdateCmpFile]	Enables the Automatic Update mechanism for the cmp file. <ul style="list-style-type: none"><li>■ [0] = (Default) The Automatic Update mechanism doesn't apply to the cmp file.</li><li>■ [1] = The Automatic Update mechanism includes the cmp file.</li></ul> <b>Note:</b> For the parameter to take effect, a device restart is required.

Parameter	Description
<pre>configure system &gt; automatic-update &gt; update-frequency-sec</pre> <p>[AutoUpdateFrequencySeconds]</p>	<p>Defines the periodic interval (in seconds) between each automatic update. The count starts from a trigger for auto-update with the provisioning server. The valid value range is 0 to 604,800. The default is 0 (i.e., disabled).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ This feature can't work with the feature that specifies a specific time of day for automatic updates. Therefore, if you configure this parameter to any value other than 0, leave the [AutoUpdatePredefinedTime] parameter at its default value (i.e., undefined).</li> </ul>
<pre>configure system &gt; automatic-update &gt; predefined-time</pre> <p>[AutoUpdatePredefinedTime]</p>	<p>Defines the time of day at which the device performs automatic updates.</p> <p>The format syntax of the parameter is 'hh:mm', where <i>hh</i> denotes the hour and <i>mm</i> the minutes. The value must be enclosed by a single quotation mark (e.g., '20:18'). The default is undefined (i.e., disabled).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ By default, the actual update time is randomized by five minutes to reduce the load on the Web servers. To change this randomized time, use the [AutoUpdatePredefinedRandomTime] parameter.</li> <li>■ This feature can't work with the feature that specifies a periodic interval for automatic updates. Therefore, if you configure this parameter to any value other than default, leave the [AutoUpdateFrequencySeconds] parameter at its default value (i.e., disabled).</li> </ul>
<pre>configure system &gt; automatic-update &gt; predefined-random-time</pre> <p>[AutoUpdatePredefinedRandomTi]</p>	<p>Defines the maximum randomization interval (in seconds) for the daily scheduled automatic update (configured by the [AutoUpdatePredefinedTime] parameter). For example, if you configure the [AutoUpdatePredefinedTime] parameter to '13:00'</p>

Parameter	Description
me]	<p>(i.e., 1 pm) and [AutoUpdatePredefinedRandomTime] to '300' (i.e., 5 min.), the actual update can start anywhere between the time 13:00 and 13:05. The valid value range 60 to 86400. The default is 300.</p> <p><b>Note:</b> The parameter is applicable only to the [AutoUpdatePredefinedTime] parameter.</p>
<pre>configure system &gt; automatic-update &gt; max- transfer-time</pre> <p>[AupdMaxTransferTime]</p>	<p>Defines the file transfer timeout (minutes) for downloading a file from the provisioning server for automatic updates. If the download hasn't finished when this timeout expires, the device stops its attempt to download the file and continues to the next file in the Auto-Update file download queue. The valid value range is 1 to 5. The default is 5.</p>
<pre>configure system &gt; automatic-update &gt; aupd-graceful- shutdown</pre> <p>[AupdGracefulShutdown]</p>	<p>Enables the device to gracefully lock for the Automatic Update feature when updating the ini configuration file. When the file is downloaded from the provisioning server, the device gracefully locks. During this graceful period (configured by the [AdminStateLockControl] ini file parameter), no new calls are accepted. If all existing calls end before the timeout expires, the device locks and applies the settings of the file. If there are still existing calls when the timeout expires, the device terminates them and applies the settings of the file. For more information, see <a href="#">Applying Downloaded ini File after Graceful Timeout</a> on page 1409.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul>
<pre>configure system &gt; automatic-update &gt; http-user-agent</pre> <p>[AupdHttpUserAgent]</p>	<p>Defines the information that is included in the HTTP User-Agent header in HTTP Get requests sent by the device to the provisioning server for the Automatic Update mechanism.</p> <p>The valid value is a string of up to 511 characters. The information can include any user-defined string or the following case-sensitive, string variable tags (placeholders):</p> <ul style="list-style-type: none"> <li>■ &lt;NAME&gt;: Replaced with the product name</li> </ul>

Parameter	Description
	<p>(according to the License Key).</p> <ul style="list-style-type: none"> <li>■ &lt;MAC&gt;: Replaced with the device's MAC address.</li> <li>■ &lt;VER&gt;: Replaced with the currently installed software version.</li> <li>■ &lt;CONF&gt;: Replaced with the configuration version (configured by the [INIFileVersion] parameter or CLI command <code>configuration-version</code>).</li> </ul> <p>The device automatically populates these variables with actual values in the sent User-Agent header. If not configured (default), the device sends the following information in the User-Agent header:</p> <div style="background-color: #f0f0f0; padding: 10px; border-radius: 5px;"> <p>User-Agent: Mozilla/4.0 (compatible; AudioCodes; &lt;product name&gt;;&lt;software version&gt;;&lt;MAC address&gt;;&lt;configuration version&gt;)</p> </div> <p>For example, if you configure the parameter to <code>Aup-dHttpUserAgent = MyWorld-&lt;NAME&gt;;&lt;VER&gt;(&lt;MAC&gt;)</code>, the device sends the following User-Agent header:</p> <div style="background-color: #f0f0f0; padding: 10px; border-radius: 5px;"> <p>User-Agent: MyWorld-Mediant;7.40A.500.966;00:90:8f:5b:10:35;0</p> </div> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The variable tags are case-sensitive.</li> <li>■ If you configure the parameter with the &lt;CONF&gt; variable tag, you must restart the device with a save-to-flash for your settings to take effect.</li> <li>■ The tags can be defined in any order.</li> <li>■ The tags must be defined adjacent to one another (i.e., no spaces).</li> </ul>
<pre>configure system &gt; automatic-update &gt; auto-firmware [AutoCmpFileUrl]</pre>	<p>Defines the filename and path (URL) to the provisioning server from where the software file (.cmp) can be downloaded, based on timestamp for the Automatic Updated mechanism.</p> <p>The valid value is an IP address in dotted-decimal</p>

Parameter	Description
	notation or an FQDN.
<pre>configure system &gt; automatic-update &gt; aupd-verify-cert [AUPDVerifyCertificates]</pre>	<p>Enables the Automatic Update mechanism to verify the TLS certificate received from the provisioning server when the connection is HTTPS.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enables TLS certificate verification when the connection with the provisioning server is based on HTTPS. The device verifies the authentication of the certificate received from the provisioning server. The device authenticates the certificate against its trusted root certificate store (see <a href="#">TLS Certificates</a> on page 227) and if ok, allows communication with the provisioning server. If authentication fails, the device denies communication (i.e., handshake fails).</li> </ul>
<pre>configure system &gt; automatic-update &gt; credentials [AUPDUserPassword]</pre>	<p>Defines the username and password for digest (MD5 cryptographic hashing) and basic access authentication with the HTTP server on which the files to download are located for the Automatic Update feature.</p> <p>The valid value is a string of up to 128 characters. The syntax is 'username:password' (e.g., 'joe:1234'). By default, no value is defined.</p> <p><b>Note:</b> The device only uses the username and password configured by this parameter if no username and password has been configured for the parameter used to configure the URL of the server with the name of the file, for example, [CmpFileURL].</p>
<pre>configure system &gt; automatic-update &gt; crc- check regular [AUPDCheckIfIniChanged]</pre>	<p>Enables the device to perform cyclic redundancy checks (CRC) on downloaded configuration files during the Automatic Update process. The CRC checks whether the content (raw data) of the downloaded file is different to the content of the previously downloaded file from the previous Automatic Update process. The device compares the CRC check value (code) result with the check value of the previously downloaded file. If the check values are identical, it indicates that the file has no new configuration settings, and the device discards the</p>

Parameter	Description
	<p>file. If the check values are different, the device installs the downloaded file and applies the new configuration settings.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable - the device doesn't perform CRC and installs the downloaded file regardless.</li> <li>■ [1] = Enable CRC for the entire file, including line order (i.e., same text must be on the same lines). If there are differences between the files, the device installs the downloaded file. If there are no differences, the device discards the newly downloaded file.</li> <li>■ [2] = Enable CRC for individual lines only. Same as option [1], except that the CRC ignores the order of lines (i.e., same text can be on different lines).</li> </ul>
<pre>configure system &gt; automatic-update &gt; tftp-block-size [AUPDTftpBlockSize]</pre>	<p>Defines the size of the TFTP data blocks (packets) when downloading a file from a TFTP server for the Automatic Update mechanism. This is in accordance to RFC 2348. TFTP block size is the physical packet size (in bytes) that a network can transmit. When configured to a value higher than the default (512 bytes), but lower than the client network's Maximum Transmission Unit (MTU), the file download speed can be significantly increased.</p> <p>The valid value is 512 to 8192. The default is 512.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ A higher value doesn't necessarily mean better performance.</li> <li>■ The block size should be small enough to avoid IP fragmentation in the client network (i.e., below MTU).</li> <li>■ This feature is applicable only to TFTP servers that support this option.</li> </ul>
<p>'Default password for configuration package'</p> <pre>configure system &gt; automatic-update &gt; default-</pre>	<p>Defines the password to protect (encrypt) the Configuration Package file when it's uploaded to the device using the Automatic Update feature (see the <code>configuration-pkg</code> command below). If the file is not password-protected, ignore this command.</p>

Parameter	Description
configuration-package-password <password> [defaultConfigPackagePassword]	<b>Note:</b> This password is also used to protect (encrypt) the Configuration Package file when downloading it from the device through SFTP.
[ResetNow]	<p>Invokes an immediate device restart. This option can be used to activate offline (i.e., not on-the-fly) parameters that are loaded using the [IniFileUrl] parameter.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) The immediate restart mechanism is disabled.</li> <li>■ [1] = The device immediately restarts after an <i>ini</i> file with the parameter set to 1 is loaded.</li> </ul> <p><b>Note:</b> If you use the parameter in an ini file for periodic automatic provisioning with non-HTTP (e.g., TFTP) and without CRC, the device restarts upon every file download.</p>
<b>Software and Configuration File URL Path for Automatic Update Parameters</b>	
configure system > automatic-update > firmware [CmpFileURL]	<p>Defines the name of the <i>cmp</i> file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password (username:password) for access authentication with the server can also be configured.</p> <p>Example syntax:</p> <pre>'http://192.168.0.1/&lt;filename&gt;' 'https://&lt;username&gt;:&lt;password&gt;@&lt;IP address&gt;/&lt;file name&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When the parameter is configured, the device always uploads the <i>cmp</i> file after it restarts.</li> <li>■ The <i>cmp</i> file is validated before it's saved to flash. The checksum of the <i>cmp</i> file is also compared to the previously saved checksum to avoid unnecessary restarts.</li> <li>■ The maximum length of the URL address is 255 characters.</li> <li>■ When using the ini file, the value must be</li> </ul>

Parameter	Description
	enclosed by single quotation marks ('...').
<pre>configure system &gt; automatic-update &gt; ini- file [IniFileURL]</pre>	<p>Defines the name of the <i>ini</i> file (configuration) and the URL address (IP address or FQDN) of the server where the file is located. Parameters that are not included in the ini file are restored to default settings. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>Example syntax:</p> <pre>'http://192.168.0.1/&lt;filename&gt;' 'http://192.8.77.13/config_&lt;MAC&gt;.ini' 'https://&lt;username&gt;:&lt;password&gt;@&lt;IP address&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When using HTTP or HTTPS, the date and time of the <i>ini</i> file are validated. Only more recently dated <i>ini</i> files are loaded.</li> <li>■ The case-sensitive string "&lt;MAC&gt;" can be used in the URL path and filename, which is automatically replaced with the device's MAC address. This option allows the loading of specific configurations for specific devices. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ The maximum length of the URL address is 99 characters.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> <li>■ If you want the device to upload an ini file where parameters not included in the file remain at their current settings (i.e., incremental), then use the [IncrementalIniFileURL] parameter instead.</li> </ul>
<pre>configure system &gt; automatic-update</pre>	Defines the name of the incremental <i>ini</i> file

Parameter	Description
<pre>&gt; incremental-ini-file</pre> <p>[IncrementalIniFileURL]</p>	<p>(configuration) and the URL address (IP address or FQDN) of the server where the file is located. Parameters that are not included in the ini file remain at their current settings. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>Example syntax:</p> <pre>'http://192.168.0.1/&lt;filename&gt;' 'http://192.8.77.13/config_&lt;MAC&gt;.ini' 'https://&lt;username&gt;:&lt;password&gt;@&lt;IP address&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When using HTTP or HTTPS, the date and time of the <i>ini</i> file are validated. Only more recently dated <i>ini</i> files are loaded.</li> <li>■ The case-sensitive string "&lt;MAC&gt;" can be used in the URL path and filename, which is automatically replaced with the device's MAC address. This option allows the loading of specific configurations for specific devices. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ The maximum length of the URL address is 99 characters.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> <li>■ If you want the device to upload an ini file where parameters not included in the file are restored to default settings (i.e., not incremental), then use the [IniFileURL] parameter instead.</li> </ul>
<pre>configure system &gt; automatic-update &gt; cli- script &lt;URL&gt;</pre> <p>[CliScriptURL]</p>	<p>Defines the URL of the server where the CLI Script file containing the device's configuration is located. This file is used for automatic provisioning. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be</p>

Parameter	Description
	<p>configured.</p> <p><b>Note:</b> The case-sensitive string, "&lt;MAC&gt;" can be used in the URL path and filename, which is automatically replaced with the device's MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</p>
<pre>configure system &gt; automatic-update &gt; startup-script &lt;URL&gt; [CLIScriptUrl]</pre>	<p>Defines the URL address of the server where the CLI Startup Script file containing the device's configuration is located. This file is used for automatic provisioning. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> <li>■ The file is not supported when the device operates in HA mode.</li> </ul>
<pre>configure system &gt; automatic-update &gt; configuration-pkg [ConfPackageURL]</pre>	<p>Defines the name of the Configuration Package file (.7z) and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>For example:</p> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <pre>ConfPackageURL = 'http://www.corp.com/ConfBackupPkg5967 925.7z'</pre> </div> <p>For more information on the Configuration Package file, see <a href="#">Downloading or Uploading Configuration Package File</a> on page 1389.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the file is password-protected (encrypted), define the password using the [defaultConfigPackagePassword] parameter.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; prerecorded-tones [PrtFileURL]</pre>	<p>Defines the name of the Prerecorded Tones (PRT) file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>Example syntax:</p> <pre>'http://&lt;server_name&gt;/&lt;filename&gt;' 'https://&lt;server_name&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The maximum length of the URL address is 99 characters.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; call-progress-tones [CptFileURL]</pre>	<p>Defines the name of the Call Progress Tone (CPT) file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be</p>

Parameter	Description
	<p>configured.</p> <p>Example syntax:</p> <pre>'http://&lt;server_name&gt;/&lt;filename&gt;' 'https://&lt;server_name&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The maximum length of the URL address is 99 characters.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; voice-prompts [VpFileURL]</pre>	<p>Defines the name of the Voice Prompts file and the URL address (IP address or FQDN) of the server on which the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>Example syntax:</p> <pre>'http://&lt;server_name&gt;/&lt;filename&gt;' 'https://&lt;server_name&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The maximum length of the URL address is 99 characters.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>

Parameter	Description
<pre>configure system &gt; automatic-update &gt; cas- table</pre> <p>[CasFileURL]</p>	<p>Defines the name of the CAS file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>Example syntax:</p> <pre>'http://&lt;server_name&gt;/&lt;filename&gt;' 'https://&lt;server_name&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The maximum length of the URL address is 99 characters.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; dial-plan</pre> <p>[DialPlanCSVFileUrl]</p>	<p>Defines the name of the Dial Plan file (.csv) and the URL address of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;filename&gt;') for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; tls- root-cert</pre> <p>[TLSRootFileUrl]</p>	<p>Defines the name of the TLS trusted root certificate file and the URL address of the server where the file is located (e.g., tftp://172.17.116.216/Trust.pem). Optionally, the username and password</p>

Parameter	Description
	<p>('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter replaces all previous loaded trusted root certificate files with the new file.</li> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> </ul>
<pre>configure system &gt; automatic-update &gt; tls- root-cert-incr [TLsIncrRootFileUrl]</pre>	<p>Defines the name of the TLS trusted root certificate file and the URL address of the server where the file is located (e.g., tftp://172.17.116.216/Trust.pem). Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured. The parameter adds the file to any existing trusted root certificate file (i.e., incremental file upload).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...')</li> </ul>
<pre>configure system &gt; automatic-update &gt; tls- cert [TLSCertFileUrl]</pre>	<p>Defines the name of the TLS certificate file and the URL address of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;')</p>

Parameter	Description
	<p>for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; tls- private-key</pre> <p>[TLSPkeyFileUrl]</p>	<p>Defines the URL address of the server on which the TLS private key file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; gw- user-info</pre> <p>[GWUserInfoFileUrl]</p>	<p>Defines the name of the Gateway User Information file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured. For example:</p> <div style="background-color: #f0f0f0; padding: 10px; border-radius: 5px;"> <p>'https://www.company.com/GW-User_Info.csv'</p> </div> <p><b>Note:</b> You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which</p>

Parameter	Description
	the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.
<pre>configure system &gt; automatic-update &gt; sbc- user-info [SBCUserInfoFileUrl]</pre>	<p>Defines the name of the SBC User Information file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured. For example:</p> <pre>'https://www.company.com/SBC-User-Info.csv'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; user-info [UserInfoFileURL]</pre>	<p>Defines the name of the User Information file and the URL address (IP address or FQDN) of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;file name&gt;') for access authentication with the server can also be configured.</p> <p>The maximum length of the URL address is 99 characters.</p> <p>Example syntax:</p> <pre>'http://&lt;server_name&gt;/&lt;filename&gt;' 'https://&lt;server_name&gt;/&lt;filename&gt;'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is used for <b>backward compatibility only</b>. Use the [GWUserInfoFileUrl] or [SBCUserInfoFileUrl] parameter (above)</li> </ul>

Parameter	Description
	<p>instead.</p> <ul style="list-style-type: none"> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; feature-key [FeatureKeyURL]</pre>	<p>Defines the name of the License Key file and the URL address of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;filename&gt;') for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; template-url [TemplateUrl]</pre>	<p>Defines the URL address in the File Template for automatic updates, of the provisioning server where the files to download are located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;filename&gt;') for access authentication with the server can also be configured.</p> <p>For more information, see <a href="#">File Template for Automatic Provisioning</a> on page 1406.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<pre>configure system &gt; automatic-update &gt; template-files-list [AupdFilesList]</pre>	<p>Defines the list of file types in the File Template for automatic updates, to download from the provisioning server.</p> <p>For more information, see <a href="#">File Template for</a></p>

Parameter	Description
	<a href="#">Automatic Provisioning</a> on page 1406.
<pre>configure system &gt; automatic-update &gt; web- favicon</pre> <p>[WebFaviconFileUrl]</p>	<p>Defines the name of the favicon image file and the URL address of the server where the file is located. This is used for the Automatic Update feature. For more information, see <a href="#">Customizing the Browser Favicon</a> on page 50.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
<p>[SBCWizardUrl]</p> <pre>configure system &gt; automatic-update &gt; sbc- wizard</pre>	<p>Defines the name of the SBC Wizard configuration template file and the URL address of the server where the file is located. Optionally, the username and password ('https://username:password@10.1.1.1/&lt;filename&gt;') for access authentication with the server can also be configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
[MatrixCsvFileUrl]	<p>Defines a configuration table as a Comma-Separated Values (CSV) file and the URL address of the server where the file is located.</p> <p>The filename must include the name of the configuration table, for example:</p> <div> <p>MatrixCsvFileUrl =</p> <p>'http://www.corp.com/device_IPGroup.csv'</p> </div>

Parameter	Description
	<p>You can also include in the filename the string variable tag "MAC" (case-sensitive), which the device automatically replaces with its MAC address, for example:</p> <pre data-bbox="778 472 1377 622">MatrixCsvFileUrl = 'http://www.corp.com/device_&lt;MAC&gt;_ IPGroup.csv'</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to tables that support importing CSV files (e.g., Dial Plan table and SBC User Information table).</li> <li>■ The filename extension must be ".csv".</li> <li>■ You can use the placeholder string "&lt;MAC&gt;" (case-sensitive) in the URL path and filename, which the device replaces with its MAC address. For more information, see <a href="#">MAC Address Placeholder in URL and File Name</a> on page 1404.</li> <li>■ When using the ini file, the value must be enclosed by single quotation marks ('...').</li> </ul>
[AUPDResetURLOnWebConfig]	<p>Determines if the URLs configured for the [CmpFileURL] and [IniFileURL] parameters are deleted when you restart the device with a save to flash through the Web interface.</p> <ul style="list-style-type: none"> <li>■ [0] = The URLs remain defined for the parameters.</li> <li>■ [1] = (Default) The URLs are deleted (as the device assumes that you want to manually configure it instead of using the Automatic Update mechanism).</li> </ul> <p><b>Note:</b> If you have configured a URL for the [IniFileURL] parameter, the default value of the Web interface's 'Save to Flash' field changes to <b>No</b> instead of <b>Yes</b> (see <a href="#">Restarting the Device</a> on page 1329). This is to make sure that you don't unintentionally save configuration to flash when you restart the device through the Web interface.</p>

## Networking Parameters

This subsection describes the device's networking parameters.

### Ethernet Parameters

The Ethernet parameters are described in the table below.

**Table 73-10:Ethernet Parameters**

Parameter	Description
<pre>configure voip &gt; media settings &gt; arp-manager- timeout</pre> <p>[ArpManagerTimeout]</p>	<p>Defines the maximum duration or timeout (in seconds) that the device waits for an Address Resolution Protocol (ARP) reply. If no reply is received within this duration, the device terminates the call.</p> <p>The valid value is 1 to 20. The default is 3.</p> <p><b>Note:</b> The device first checks its internal ARP table for a MAC address that matches the destination IP address. It only sends an ARP request if no match is found.</p>

### Multiple VoIP Network Interfaces and VLAN Parameters

The IP network interfaces and VLAN parameters are described in the table below.

**Table 73-11:IP Network Interfaces and VLAN Parameters**

Parameter	Description
<b>VLAN Parameters</b>	
[EnableNTPasOAM]	<p>Defines the application type for Network Time Protocol (NTP) services.</p> <ul style="list-style-type: none"> <li>■ [1] = OAMP (default)</li> <li>■ [0] = Control</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

### ICMP Parameters

The ICMP parameters are described in the table below.

**Table 73-12:ICMP Parameters**

Parameter	Description
'Don't Send ICMP Unreachable Messages' configure network > network- settings > icmp-disable-unreachable [DisableICMPUnreachable]	Enables the device to generate and send ICMP messages, if required.  ■ [0] <b>No</b> = (Default) Device sends ICMP Unreachable messages.  ■ [1] <b>Yes</b> = Device doesn't send ICMP Unreachable messages.
'Send and Receive ICMP Redirect Messages' configure network > network- settings > icmp-disable-redirec [DisableICMPRedirects]	Enables sending and receiving ICMP Redirect messages.  ■ [0] <b>Yes</b> = (Default) Device sends and accepts ICMP Redirect messages.  ■ [1] <b>No</b> = Device rejects ICMP Redirect messages and also doesn't send them.

## Open Solution Network (OSN) Parameters

The OSN server parameters are described in the table below.

**Table 73-13:OSN Parameters**

Parameter	Description
'OSN Native VLAN ID' configure network > interface osn > native-vlan <id> [OSNAccessVlan]	Defines the OSN Native VLAN ID. The valid value is 0 to 4000. The default is 0. When configured to 0, the OSN uses the device's OAMP VLAN ID. When configured to any other value, it specifies a VLAN ID configured in the Ethernet Devices table and which is assigned to a Media and/or Control application in the IP Interfaces table.
'Block OSN Port' configure network > interface osn > shutdown [OSNBlockPort]	Enables or disables (blocks) the Ethernet port of the device's internal switch that interfaces with the OSN.  ■ [0] <b>No</b> = (Default) Enables the port.  ■ [1] <b>Yes</b> = Disables the port.
configure	Enables a single management platform when the device is

Parameter	Description
<pre>network &gt; network- settings &gt; osn-internal- vlan [OSNInternalVLAN]</pre>	<p>deployed as a Survivable Branch Appliance (SBA) in a Microsoft Skype for Business environment. It allows configuration and monitoring of the Gateway/SBC device through the SBA Management Interface.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p>For more information, refer to the SBA Installation and Maintenance Manual.</p>

## Quality of Service Parameters

The Quality of Service (QoS) parameters are described in the table below.

**Table 73-14:QoS Parameters**

Parameter	Description
<b>Layer-3 Class of Service (TOS/DiffServ) Parameters</b> CLI path: <code>configure network &gt; qos application-mapping</code>	
'Media Premium QoS' <pre>media-qos [PremiumServiceClassMediaDiffServ]</pre>	<p>Global parameter defining the DiffServ value for Premium Media CoS content.</p> <p>You can also configure this feature per specific calls, using IP Profiles ('RTP IP DiffServ' parameter) or Tel Profiles ('RTP IP DiffServ' parameter). For a detailed description of the parameter and To configure the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the device ignores this global parameter for calls associated with the profile.</p>
'Control Premium QoS' <pre>control-qos [PremiumServiceClassControlDiffServ]</pre>	<p>Global parameter defining the DiffServ value for Premium Control CoS content (Call Control applications).</p> <p>You can also configure the feature per specific calls, using IP Profiles ('Signaling DiffServ' parameter) or Tel Profiles ('Signaling DiffServ' parameter). For a detailed description of the parameter and To configure the feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on</p>

Parameter	Description
	<p>page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the device ignores this global parameter for calls associated with the profile.</p>
'Gold QoS' <code>gold-qos</code> <code>[GoldServiceClassDiffServ]</code>	<p>Defines the DiffServ value for the Gold CoS content (Streaming applications).</p> <p>The valid range is 0 to 63. The default is 26.</p>
'Bronze QoS' <code>bronze-qos</code> <code>[BronzeServiceClassDiffServ]</code>	<p>Defines the DiffServ value for the Bronze CoS content (OAMP applications).</p> <p>The valid range is 0 to 63. The default is 10.</p>

## NAT and STUN Parameters

The Network Address Translation (NAT) and Simple Traversal of UDP through NAT (STUN) parameters are described in the table below.

**Table 73-15:NAT and STUN Parameters**

Parameter	Description
<b>STUN Parameters</b>	
<code>[EnableStunForward]</code>	<p>Enables the device to forward incoming STUN packets (RFC 3849).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable. The device doesn't forward received STUN packets.</li> <li>■ [1] = Enable. The device forwards received STUN packets.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>NAT Parameters</b>	
'NAT Traversal' <code>configure voip &gt;</code> <code>media settings &gt;</code> <code>disable-NAT-traversal</code> <code>[NATMode]</code>	<p>Enables the NAT traversal feature for media when the device communicates with UAs located behind NAT.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Enable NAT Only if Necessary</b> = NAT traversal is performed only if the UA is located behind NAT:               <ul style="list-style-type: none"> <li>✓ UA behind NAT: The device sends the media packets to the IP address:port obtained from the</li> </ul> </li> </ul>

Parameter	Description
	<p>source address of the first media packet received from the UA.</p> <ul style="list-style-type: none"> <li>✓ UA not behind NAT: The device sends the packets to the IP address:port specified in the SDP 'c=' line (Connection) of the first received SIP message.</li> </ul> <p><b>Note:</b> If the SIP session is established (ACK) and the device (not the UA) sends the first packet, it sends it to the address obtained from the SIP message and only after the device receives the first packet from the UA does it determine whether the UA is behind NAT.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Disable NAT</b> = (Default) The device considers the UA as not located behind NAT and sends media packets to the UA using the IP address:port specified in the SDP 'c=' line (Connection) of the first received SIP message.</li> <li>■ [2] <b>Force NAT</b> = The device always considers the UA as behind NAT and sends the media packets to the IP address:port obtained from the source address of the first media packet received from the UA. The device only sends packets to the UA after it receives the first packet from the UA (to obtain the IP address).</li> <li>■ [3] <b>NAT by Signaling</b> = The device identifies whether or not the UA is located behind NAT based on SIP signaling. The device assumes that if signaling is behind NAT that the media is also behind NAT, and vice versa.</li> <li>✓ UA behind NAT: The device sends media according to option <b>Force NAT</b> (2). If the 'Media Latch Mode' parameter is configured to <b>Strict</b>, the 'Media Latch Mode' parameter automatically changes to <b>Dynamic</b>.</li> <li>✓ UA not behind NAT: The device sends media according to option <b>Disable NAT</b> (1).</li> </ul> <p><b>Note:</b> : This option is applicable only to SBC calls. If the parameter is configured to this option, Gateway calls use option <b>Enable NAT Only if Necessary</b> (0), by</p>

Parameter	Description
	<p>default.</p> <ul style="list-style-type: none"> <li>■ [4] <b>NAT by Signaling Restricted IP</b> = The device identifies whether or not the UA is located behind NAT based on SIP signaling. The device assumes that if signaling is behind NAT that the media is also behind NAT, and vice versa. <ul style="list-style-type: none"> <li>• UA behind NAT: The device sends media only when the source of the media packets is the signaling IP address (source of the INVITE). If the 'Media Latch Mode' parameter is configured to <b>Strict</b>, the 'Media Latch Mode' parameter automatically changes to <b>Dynamic</b>.</li> <li>• UA not behind NAT: The device sends media according to option <b>Disable NAT</b> (1).</li> </ul> </li> </ul> <p><b>Note:</b> This option is applicable only to SBC calls. For more information on NAT traversal, see <a href="#">First Incoming Packet Mechanism</a> on page 185.</p>
<p>'NAT IP Address'</p> <pre>configure voip &gt; sip- definition general- settings &gt; nat-ip- addr</pre> <p>[StaticNatIP]</p>	<p>Defines the global (public) IP address of the device to enable static NAT between the device and the Internet. For more information, see <a href="#">Configuring a Static NAT IP Address for All Interfaces</a> on page 181.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
[NATBindingDefaultTimeout]	<p>The device sends SNMP keep-alive traps periodically - every 9/10 of the time configured by the parameter (in seconds). Therefore, the parameter is applicable only if you configure the [SendKeepAliveTrap] parameter to [1].</p> <p>The parameter is used to allow SNMP communication with AudioCodes One Voice Operations Center (OVOC) management platform, located in the WAN, when the device is located behind NAT. It is needed to keep the NAT pinhole open for the SNMP messages sent from OVOC to the device.</p> <p>The valid range is 0 to 2,592,000. The default is 30.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

Parameter	Description
<p>'SIP NAT Detection'</p> <pre>configure voip &gt; sip- definition advanced- settings &gt; sip-nat- detect</pre> <p>[SIPNatDetection]</p>	<p>Enables the device's NAT Detection mechanism to detect if the incoming INVITE message is sent from an endpoint that's located behind NAT. If not enabled, the device processes incoming SIP messages as received from endpoints that are not located behind NAT and sends them according to the SIP standard.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul> <p>For more information on the NAT Detection feature, see <a href="#">Enabling SIP NAT Detection when UA Located behind NAT</a> on page 183.</p>
<p>'BFCP IP from Audio Media'</p> <pre>configure voip &gt; sbc settings &gt; bfcf-ip- from-audio</pre> <p>[BFCPNatFromAudio]</p>	<p>Enables the handling of calls with voice and Binary Floor Control Protocol (BFCP) media streams that are received from behind a NAT.</p> <p>You can also configure this functionality per specific calls, using IP Profiles. For a detailed description of the parameter and for configuring this functionality in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If this functionality is configured for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>

## DNS Parameters

The Domain name System (DNS) parameters are described in the table below.

**Table 73-16:DNS Parameters**

Parameter	Description
<p>'Default Primary DNS Server IP'</p> <pre>configure network &gt; dns settings &gt; dns- default-primary-server-ip</pre> <p>[DefaultPrimaryDnsServerIp]</p>	<p>Defines the address of the default primary IPv4 DNS server.</p> <p>The valid value is an IPv4 address in dotted-decimal notation. The default is 8.8.8.8.</p>

Parameter	Description
	For more information, see <a href="#">Configuring Default DNS Servers</a> on page 198.
'Default Secondary DNS Server IP' <code>configure network &gt; dns settings &gt; dns-default-secondary-server-ip</code> <code>[DefaultSecondaryDnsServerIp]</code>	Defines the address of the default secondary IPv4 DNS server.  The valid value is an IPv4 address in dotted-decimal notation. The default is 8.8.4.4.  For more information, see <a href="#">Configuring Default DNS Servers</a> on page 198.
'Default Primary DNS Server IPv6' <code>configure network &gt; dns settings &gt; dns-default-primary-server-ipv6</code> <code>[DefaultPrimaryDnsServerIpv6]</code>	Defines the address of the default primary IPv6 DNS server.  The valid value is an IPv6 address. The default is 2001:4860:4860::8888.  For more information, see <a href="#">Configuring Default DNS Servers</a> on page 198.
'Default Primary DNS Server IPv6' <code>configure network &gt; dns settings &gt; dns-default-secondary-server-ipv6</code> <code>[DefaultSecondaryDnsServerIpv6]</code>	Defines the address of the default secondary IPv6 DNS server.  The valid value is an IPv6 address. The default is 2001:4860:4860::8844.  For more information, see <a href="#">Configuring Default DNS Servers</a> on page 198.

## DHCP Parameters

The Dynamic Host Control Protocol (DHCP) parameters are described in the table below.

**Table 73-17:DHCP Parameters**

Parameter	Description
[DhcpOption160Support]	<p>Enables the use of DHCP Option 160.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p>For more information, see <a href="#">Provisioning the Device using DHCP Option 160</a> on page 1398.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[DHCP120OptionMode]	<p>Enables the acceptance of DHCP Option 120 in DHCP responses sent by a DHCP server.</p> <ul style="list-style-type: none"> <li>■ [0] = DHCP Option 120 is not supported and ignored if received in the DHCP response.</li> <li>■ [1] = (Default) DHCP Option 120 is supported and if received, the device adds the SIP server information to the Proxy Set.</li> </ul>
[DHCPSpeedFactor]	<p>Defines the device's DHCP renewal speed for a leased IP address from a DHCP server.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable</li> <li>■ [1] = (Default) Normal</li> <li>■ [2] to [10] = Fast</li> </ul> <p>When set to 0, the DHCP lease renewal is disabled. Otherwise, the renewal time is divided by this factor. Some DHCP-enabled routers perform better when set to 4.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

## Clock (Date and Time) Synchronization Parameters

The device's clock synchronization parameters are described in the table below.

**Table 73-18:Device Clock Synchronization Parameters**

Parameter	Description
<b>NTP</b>	
<p><b>Note:</b> For more information on Network Time Protocol (NTP), see <a href="#">Synchronizing Date and Time through SNTP</a> on page 138.</p>	

Parameter	Description
<p>'Enable NTP'</p> <pre>configure system &gt; ntp &gt; enable</pre> <p>[NTPEnable]</p>	<p>Enables the device (as an NTP client) to synchronize its local clock (date and time) with an NTP server.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = Disabled</li> <li>■ [1] Check box selected = (Default) Enabled</li> </ul>
<p>'NTP Interface'</p> <pre>configure system &gt; ntp &gt; ntp-network- interface</pre> <p>[NTPInterface]</p>	<p>Assigns an IP Interface from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for NTP communication.</p> <p>By default, the IPv4 OAMP interface is assigned.</p> <p><b>Note:</b> The IP address version (IPv4 or IPv6) of the assigned IP Interface and the NTP server's address (see 'Primary NTP Server Address' and 'Secondary NTP Server Address' parameters) must be the same.</p>
<p>'Primary NTP Server Address'</p> <pre>configure system &gt; ntp &gt; primary-server</pre> <p>[NTPServerIP]</p>	<p>Defines the address (IPv4 or IPv6, or FQDN) of the primary (main) NTP server. The benefit of using an FQDN is that multiple IP addresses can be resolved from the DNS server, providing NTP server redundancy.</p> <p>The default IP address is 0.0.0.0.</p> <p><b>Note:</b> The IP address version (IPv4 or IPv6) of the NTP server's address and the assigned IP Interface (see 'NTP Interface' parameter) must be the same.</p>
<p>'Secondary NTP Server Address'</p> <pre>configure system &gt; ntp &gt; secondary-server</pre> <p>[NTPSecondaryServerIP]</p>	<p>Defines the address (IPv4 or IPv6, or FQDN) of the secondary NTP server. This NTP is used for redundancy; if the primary NTP server fails, then this NTP server is used.</p> <p>The default IP address is 0.0.0.0.</p> <p><b>Note:</b> The IP address version (IPv4 or IPv6) of the NTP server's address and the assigned IP Interface (see 'NTP Interface' parameter) must be the same.</p>
<p>'NTP Update Interval'</p> <pre>configure system &gt; ntp &gt; update-interval</pre> <p>[NTPUpdateInterval]</p>	<p>Defines the time interval (in seconds) that the NTP client requests for a time update.</p> <p>The range is 0 to 214783647. The default interval is 86400 (i.e., 24 hours).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When configuring this parameter through CLI or ini file, the value must be a multiple of 60 (seconds). For example, to set an interval of 2 hours,</li> </ul>

Parameter	Description
	<p>configure the parameter to 7200 (i.e., 2 hours is 7200 seconds). If the value is not a multiple of 60, the device automatically rounds it to the nearest multiple of 60 and logs this adjustment in a syslog message. For example, if you enter 7195, the device rounds it to 7200.</p> <ul style="list-style-type: none"> <li>■ It's not recommended to configure the parameter to beyond one month (i.e., 2592000 seconds).</li> </ul>
'NTP Authentication Key Identifier' auth-key-id [NtpAuthKeyId]	<p>Defines the NTP authentication key identifier for authenticating NTP messages. The identifier must match the value configured on the NTP server. The NTP server may have several keys configured for different clients; this number identifies which key is used.</p> <p>The valid value is 1 to 65535. The default is 0 (i.e., no authentication is done).</p>
'NTP Authentication Secret Key' configure system > ntp > auth-key-md5 [ntpAuthMd5KeyPassword]	<p>Defines the secret authentication key shared between the device (client) and the NTP server for authenticating NTP messages.</p> <p>The valid value is a string of up to 32 characters. By default, no key is defined.</p> <p><b>Note:</b> The parameter cannot be configured with wide characters.</p>
<b>Regional Clock and Daylight Saving Time</b>	
'UTC Offset' configure system > clock > utc-offset [NTPServerUTCOffset]	<p>Defines the Universal Time Coordinate (UTC) offset (in seconds) from the local time.</p> <p>The valid range is -86400 (i.e., -24 hours) to 86400 seconds (i.e., +24 hours). The default is 0.</p> <p>For more information, see <a href="#">Configuring UTC Offset or Time Zone</a> on page 141.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The offset setting is applied only on the hour. For example, if you configure the parameter at 15:42, the device applies the setting only at 16:00.</li> <li>■ When configuring this parameter through CLI or ini file, the value must be a multiple of 60 (seconds). For example, to set an offset of 2 hours, configure</li> </ul>

Parameter	Description
	the parameter to 7200 (i.e., 2 hours is 7200 seconds). If the value is not a multiple of 60, the device automatically rounds it to the nearest multiple of 60 and logs this adjustment in a syslog message. For example, if you enter 7195, the device rounds it to 7200.
'Daylight Saving Time' configure system > clock > summer-time > summer-time [DayLightSavingTimeEnable]	Enables daylight saving time (DST). ■ [0] <b>Disable</b> (default) ■ [1] <b>Enable</b> For more information, see <a href="#">Configuring Daylight Saving Time</a> on page 142.
'Start Time / Day of Month Start' configure system > clock > summer-time > start [DayLightSavingTimeStart]	Defines the date and time when DST begins. This value can be configured using any of the following formats: ■ Day of year - <i>mm:dd:hh:mm</i> , where: ✓ <i>mm</i> denotes month ✓ <i>dd</i> denotes date of the month ✓ <i>hh</i> denotes hour ✓ <i>mm</i> denotes minutes For example, "05:01:08:00" denotes daylight saving starting from May 1 at 8 A.M. ■ Day of month - <i>mm:day/wk:hh:mm</i> , where: ✓ <i>mm</i> denotes month (e.g., 04) ✓ <i>day</i> denotes day of week (e.g., FRI) ✓ <i>wk</i> denotes week of the month (e.g., 03) ✓ <i>hh</i> denotes hour (e.g., 23) ✓ <i>mm</i> denotes minutes (e.g., 10) For example, "04:FRI/03:23:00" denotes Friday, the third week of April, at 11 P.M. The week field can be 1-5, where 5 denotes the last occurrence of the specified day in the specified month. For example, "04:FRI/05:23:00" denotes the last Friday of April, at 11 P.M. For more information, see <a href="#">Configuring Daylight Saving Time</a> on page 142.

Parameter	Description
'End Time / Day of Month End' configure system > clock > summer-time > end [DayLightSavingTimeEnd]	Defines the date and time when DST ends. For a description of the format of this value, see the [DayLightSavingTimeStart] parameter. For more information, see <a href="#">Configuring Daylight Saving Time</a> on page 142.
'Offset' configure system > clock > summer-time > offset [DayLightSavingTimeOffset]	Defines the DST offset (in minutes). The valid range is 0 to 120. The default is 60. For more information, see <a href="#">Configuring Daylight Saving Time</a> on page 142. <b>Note:</b> The offset setting is applied only on the hour. For example, if you configure the parameter at 15:42, the device applies the setting only at 16:00.
<b>Date Header Date and Time Synchronization</b>	
'Synchronize Time from SIP Date Header' configure system > clock > date-header-time-sync [DateHeaderTimeSync]	Enables the device to obtain its date and time for its internal clock from the SIP Date header in 200 OK messages received in response to sent REGISTER messages.  <div> <input type="checkbox"/> [0] Check box cleared = (Default) Disabled         <input type="checkbox"/> [1] Check box selected = Enabled       </div> For more information, see <a href="#">Synchronizing Date and Time through SIP</a> on page 140.
'Time Synchronization Interval' configure system > clock > date-header-time-sync-interval [DateHeaderTimeSyncInterval]	Defines the minimum time (in seconds) between synchronization updates using the SIP Date header method for clock synchronization. The valid value range is 60 to 86,400. The default is 900. For more information, see <a href="#">Synchronizing Date and Time through SIP</a> on page 140.

## Debugging and Diagnostics Parameters

This subsection describes the device's debugging and diagnostic parameters.

### General Parameters

The general debugging and diagnostic parameters are described in the table below.

**Table 73-19:General Debugging and Diagnostic Parameters**

Parameter	Description
[LifeLineType]	<p>Defines the condition (i.e., loss of power to the device) upon which the device activates the Lifeline feature for FXS interfaces. When the analog Lifeline is triggered, the device automatically connects a specific FXS port, which is connected to a "lifeline" POTS phone, to the PSTN (or PBX). Therefore, this allows the FXS endpoint user to continue making and receiving calls with the PSTN despite the loss of power.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Lifeline is activated upon the loss of power to the device, for example, due to a power outage or the unplugging of the device's power cable.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the FXS interfaces.</li> <li>■ The parameter has only one valid value.</li> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ If the device is in Lifeline mode and the condition that triggered it (e.g., a power outage) no longer exists (e.g., power returns), the device exits Lifeline mode and performs normal call routing.</li> <li>■ For information on Lifeline cabling, refer to the <i>Hardware Installation Manual</i>.</li> </ul>
'Delay After Reset [sec]' configure voip > sip- definition advanced- settings > delay- after-reset [GWAppDelayTime]	<p>Defines the time interval (in seconds) that the device's operation is delayed after a restart.</p> <p>The valid range is 0 to 45. The default is 7 seconds.</p> <p><b>Note:</b> This feature helps overcome connection problems caused by some LAN routers or IP configuration parameters' modifications by a DHCP server.</p>
configure system > hw > dual-powersupply- supported [DualPowerSupplySupported]	<p>Enables the device to send an SNMP alarm (acPowerSupplyAlarm) for one or both Power Supply modules if a module is removed from the chassis or not operating correctly (failure).</p> <ul style="list-style-type: none"> <li>■ [1] = (Default) Disable. The alarm is applicable only</li> </ul>

Parameter	Description
	<p>to the main Power Supply module (#1). The device sends the alarm if this module is removed from the chassis or fails. The alarm is not sent for the secondary Power Supply module (#2) even if it is removed or fails.</p> <ul style="list-style-type: none"> <li>■ [2] = Enable. The alarm is applicable to both Power Supply modules. If any of the modules are removed or fail, the device sends the alarm, indicating the affected module.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to the Mediant 800 Gateway &amp; E-SBC H/W Rev C.</li> <li>■ If configured to [2], make sure that the device is installed with two Power Supply modules. If only one module is installed, the device will send an alarm indicating a removed module.</li> <li>■ If you want to use only one Power Supply module for the device, make sure that the parameter is configured to [1]; otherwise, an alarm will be raised indicating a removed module.</li> </ul>
[EnableAutoRAITransmitBER]	<p>Enables the device to send a remote alarm indication (RAI) when the bit error rate (BER) is greater than 0.001.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul>
<p>'Ignore BRI LOS Alarm'</p> <pre>configure voip &gt; gateway digital settings &gt; ignore- bri-los-alarm</pre> <p>[IgnoreBRILOSAAlarm]</p>	<p>Enables the device to ignore LOS alarms received from the BRI user-side trunk and attempts to make a call (relevant for IP-to-Tel calls).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b> (default)</li> </ul> <p><b>Note:</b> The parameter is applicable only to BRI interfaces.</p>

## SIP Test Call Parameters

The SIP Signaling Test Call parameters are described in the table below.

**Table 73-20:SIP Test Call Parameters**

Parameter	Description
'Test Call DTMF String' configure troubleshoot > test-call settings > testcall-dtmf-string [TestCallDtmfString]	Defines the DTMF tone that is played for answered test calls (incoming and outgoing).  The DTMF string can be up to 15 strings. The default is "3212333". If no string is defined (empty), DTMF is not played.
'Test Call ID' configure troubleshoot > test-call settings > testcall-id [TestCallIID]	Defines the test call prefix number ( <i>ID</i> ) of the simulated phone on the device. Incoming calls received with this called prefix number are identified as test calls.  This can be any string of up to 15 characters. By default, no number is defined.  <b>Note:</b> The parameter is only for testing incoming calls destined to this prefix number.

## Syslog, CDR and Debug Parameters

The syslog, CDR and debug parameters are described in the table below.

**Table 73-21:Syslog, CDR and Debug Parameters**

Parameter	Description
<b>Syslog</b>	
'Enable Syslog' configure troubleshoot > syslog > syslog [EnableSyslog]	<p>Determines whether the device sends logs and error messages (e.g., CDRs) generated by the device to a syslog server.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you enable syslog, you also need to configure the syslog server's address (IP address or FQDN), using the [SyslogServerIP] parameter.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Syslog messages may increase the network traffic.</li> <li>■ To configure syslog SIP message logging levels, use the [GwDebugLevel] parameter.</li> <li>■ By default, logs are also sent to the RS-232 serial port. On how to establish serial communication with the device, refer to the <i>Installation Manual</i>.</li> </ul>
'Syslog Network Interface Name' <pre>configure troubleshoot &gt; syslog &gt; syslog-interface [SyslogInterface]</pre>	Assigns an IP Interface from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for communication with the primary syslog server. By default, the OAMP interface is used. <b>Note:</b> The IP address version (IPv4 or IPv6) of the IP Interface and the syslog server's address must be the same.
'Server IP Address' <pre>configure troubleshoot &gt; syslog &gt; syslog-ip [SyslogServerIP]</pre>	Defines the address (IP address or FQDN) of the computer on which the primary syslog server is running. The syslog server is an application designed to collect the logs and error messages generated by the device. The default IP address is 0.0.0.0. <b>Note:</b> <ul style="list-style-type: none"> <li>■ To configure secondary syslog servers, see <a href="#">Configuring Secondary Syslog Servers</a> on page 1624.</li> </ul>
'Server Port' <pre>configure troubleshoot &gt; syslog &gt; syslog-port [SyslogServerPort]</pre>	Defines the UDP port of the primary syslog server. The valid range is 0 to 65,535. The default port is 514. <b>Note:</b> To configure secondary syslog servers, see <a href="#">Configuring Secondary Syslog Servers</a> on page 1624.
'Syslog Protocol' <pre>configure troubleshoot &gt; syslog &gt; syslog-protocol</pre>	Defines the transport protocol for communicating with the primary syslog server.

Parameter	Description
<p>[SyslogProtocol]</p>	<ul style="list-style-type: none"> <li>■ [0] <b>UDP</b> (default)</li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>TLS</b>, you also need to select a TLS Context (certificate), as described in <a href="#">Configuring the Primary Syslog Server Address</a> on page 1622.</li> <li>■ To configure secondary syslog servers, see <a href="#">Configuring Secondary Syslog Servers</a> on page 1624.</li> </ul>
<p>'Syslog TLS Context'</p> <pre>configure troubleshoot &gt; syslog &gt; syslog-tls-context- name</pre> <p>[SyslogTLSContext]</p>	<p>Assigns a TLS Context when the TLS transport protocol is used for communication with the syslog server (primary and secondary servers). For configuring TLS Contexts, see <a href="#">Configuring TLS Certificate Contexts</a> on page 227.</p>
<p>'Log Severity Level'</p> <pre>log-level</pre> <p>[SyslogLogLevel]</p>	<p>Defines the minimum severity level of messages included in the syslog message that is generated by the device.</p> <p>The specified severity level and all higher severity levels are included in the syslog message. For example, if you configure the parameter to <b>Alert</b>, the syslog will include messages with Alert severity level and messages with Emergency severity level. The severity levels are listed below from highest to lowest severity.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Emergency</b></li> <li>■ [1] <b>Alert</b></li> <li>■ [2] <b>Critical</b></li> <li>■ [3] <b>Error</b></li> <li>■ [4] <b>Warning</b></li> <li>■ [5] <b>Notice</b> (default)</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [6] <b>Info [not recommended]</b></li> <li>■ [7] <b>Debug [not recommended]</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ It's recommended to leave the syslog severity level at its default setting (i.e., <b>Notice</b>) to prevent excessive utilization of the device's resources. Changing severity level is typically done only by AudioCodes Support for debugging.</li> <li>■ If you configure the parameter to <b>Info [not recommended]</b> or <b>Debug [not recommended]</b>, the parameter returns to default value (<b>Notice</b>) after a device restart or HA switchover.</li> </ul>
[EnableConsoleLog]	<p>Enables the device to send the syslog messages to the serial console (over the device's physical serial interface). This may be useful, for example, if you no longer have network access to the device and you would like to perform diagnostics.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ Even when enabled, the device continues sending the syslog messages to the configured remote syslog server.</li> </ul>
<b>HTTP Client Requests and Response</b>	
<pre>configure troubleshoot &gt; logging settings &gt; enable- http-client-dbg-msg</pre> <p>[EnableHttpClientDbgMsg]</p>	<p>Enables the device to log (syslog) HTTP requests and responses (like CURL's verbose data) received from HTTP clients.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> To log only specific HTTP clients</p>

Parameter	Description
	(based on URL filters), see the [HTTPLogFilter] parameter.
<pre>configure troubleshoot &gt; logging settings &gt; http-log- filter</pre> [HTTPLogFilter]	<p>Defines the HTTP clients whose requests and responses you want the device to log, based on the presence of specific strings within their URLs.</p> <p>The valid value is a string of up to 256 characters. You can configure the parameter with multiple strings, where each string is separated by a space (e.g., 'url1 url2 url3'). The value must be enclosed by single quotation marks (' '). The default is an empty string (' '), which means that the device logs requests and responses from all HTTP clients.</p> <p><b>Note:</b> To enable the logging of HTTP client requests and responses, see the [EnableHttpClientDbgMsg] parameter.</p>
<b>CDR</b>	
<p>'CDR Syslog Server IP Address'</p> <pre>configure troubleshoot &gt; cdr &gt; cdr-srvr-ip-adrr</pre> [CDRSyslogServerIP]	<p>Defines the address (IPv4 or IPv6, or FQDN) of the syslog server to where the device sends the CDRs.</p> <p>By default, no address is defined. If not configured, the device sends the CDRs (with the syslog messages) to the syslog server configured by the [SyslogServerIP] parameter. If you configure an address for the [CDRSyslogServerIP] parameter, the device sends the CDRs only to this CDR syslog server and not to the syslog server configured by the [SyslogServerIP] parameter.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The CDRs are sent to UDP port 514 (default syslog port).</li> <li>■ To enable the device to send CDRs, you also need to enable syslog (see <a href="#">Enabling Syslog</a> on page 1622).</li> </ul>

Parameter	Description
<p>'Call-End CDR SIP Reasons Filter'</p> <pre>configure troubleshoot &gt; cdr &gt; call-end-cdr-sip-reasons- filter</pre> <p>[CallEndCDRSIPReasonsFilter]</p>	<p>Defines SIP release cause codes that if received for the call, the device doesn't send Call-End CDRs for the call.</p> <p>The valid value is 300 through to 699. You can configure the parameter with multiple codes using a comma to separate them (e.g., 301,400,404). You can also use "xx" to denote a range (e.g., 3xx).</p>
<p>'Call-End CDR Zero Duration Filter'</p> <pre>configure troubleshoot &gt; cdr &gt; call-end-cdr-zero-duration- filter</pre> <p>[CallEndCDRZeroDurationFilter]</p>	<p>Enables the device to not send Call-End CDRs if the call's duration is zero (0).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<p>'CDR Report Level'</p> <pre>configure troubleshoot &gt; cdr &gt; cdr-report-level</pre> <p>[CDRReportLevel]</p>	<p>Enables media and signaling-related CDRs to be sent to a syslog server and defines the call stage at which they are sent.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) CDRs are not used.</li> <li>■ [1] <b>End Call</b> = CDR is sent to the syslog server at the end of each call.</li> <li>■ [2] <b>Start &amp; End Call</b> = CDR report is sent to syslog at the start and end of each call.</li> <li>■ [3] <b>Connect &amp; End Call</b> = CDR report is sent to syslog at connection and at the end of each call.</li> <li>■ [4] <b>Start &amp; End &amp; Connect Call</b> = CDR report is sent to syslog at the start, at connection, and at the end of each call.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the SBC application: The parameter enables only signaling-related CDRs. To enable media-related CDRs for SBC calls, use the [MediaCDRReportLevel] parameter.</li> <li>■ The CDR Syslog message complies with RFC 3164 and is identified by: Facility = 17 (local1) and Severity = 6</li> </ul>

Parameter	Description
	<p>(Informational).</p> <ul style="list-style-type: none"> <li>■ This mechanism is active only when syslog is enabled (i.e., the parameter [EnableSyslog] is set to [1]).</li> </ul>
<p>'Media CDR Report Level'</p> <pre>configure troubleshoot &gt; cdr &gt; media-cdr-rprt-level</pre> <p>[MediaCDRReportLevel]</p>	<p>Enables media-related CDRs of SBC calls to be sent to a syslog server and defines the call stage at which they are sent.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) No media-related CDR is sent.</li> <li>■ [1] <b>End Media</b> = Sends a CDR only at the end of the call.</li> <li>■ [2] <b>Start &amp; End Media</b> = Sends a CDR once the media starts. In some calls it may only be after the call is established, but in other calls the media may start at ringback tone. A CDR is also sent upon termination (end) of the media in the call.</li> <li>■ [3] <b>Update &amp; End Media</b> = Sends a CDR when an update occurs in the media of the call. For example, a call starts and a ringback tone occurs, a re-INVITE is sent for a fax call and as a result, a CDR with the MediaReportType field set to "Update" is sent, as the media was changed from voice to T.38. A CDR is also sent upon termination (end) of the media in the call.</li> <li>■ [4] <b>Start &amp; End &amp; Update Media</b> = Sends a CDR at the start of the media, upon an update in the media (if occurs), and at the end of the media.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ To enable CDR generation as well as enable signaling-related CDRs, use the CDRReportLevel parameter.</li> </ul>

Parameter	Description
<p>'REST CDR Report Level'</p> <pre>configure system &gt; cdr &gt; rest-cdr-report-level</pre> <p>[RestCdrReportLevel]</p>	<p>Enables signaling-related CDRs to be sent to a REST server and defines the call stage at which they are sent.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) CDRs are not sent.</li> <li>■ [1] <b>End Call</b> = CDRs are sent at the end (SIP BYE) of each call.</li> <li>■ [2] <b>Start &amp; End Call</b> = CDRs are sent at the start (SIP INVITE) and end of each call.</li> <li>■ [3] <b>Connect &amp; End Call</b> = CDRs are sent at call connection (200 OK) and end of each call.</li> <li>■ [4] <b>Start &amp; End &amp; Connect Call</b> = CDRs are sent at the start, connection, and end of each call.</li> <li>■ [5] <b>Connect Only</b> = CDRs are sent at call connection.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To specify the REST server, use the [RestCdrHttpServer] parameter.</li> <li>■ For the device to generate CDRs, you must enable syslog messaging (see the [EnableSyslog] parameter).</li> <li>■ CDRs are sent in JSON format.</li> </ul>
<p>'REST CDR HTTP Server Name'</p> <pre>configure system &gt; cdr &gt; rest-cdr-http-servers</pre> <p>[RestCdrHttpServer]</p>	<p>Defines the REST server (configured in the Remote Web Services table) to where the device sends CDRs through REST API.</p> <p>The valid value is a string (i.e., name of the REST server). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the ini file and CLI command, the parameter value is case sensitive.</li> <li>■ To enable CDR generation for the REST server, see the [RestCdrReportLevel] parameter.</li> <li>■ The REST server is configured in the</li> </ul>

Parameter	Description
	Remote Web Services table (see <a href="#">Configuring Remote Web Services</a> on page 438).
'Call Success SIP Reasons' <pre>configure troubleshoot &gt; cdr</pre> <pre>&gt; call-success-sip-reasons</pre> [CallSuccessSIPReasons]	<p>Defines the SIP response code that you want the device to consider as a call success, which is indicated by the optional 'Call Success' field in the sent CDR. This parameter overrides the device's default behavior of how it considers calls a success or failure based on SIP responses.</p> <p>The valid value is string of up to 128 characters to represent SIP response codes (e.g., 404). You can configure the parameter with multiple response codes, whereby each code is separated by a comma without spaces before or after (e.g., 404,408,406). You can also configure a range of responses using the "xx" wildcard (e.g., 4xx,502). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If an overlap of a SIP response occurs between the configured 'Call Success SIP Reasons' and 'Call Failure SIP Reasons' parameters, the device uses the parameter that is configured with the specific response code, instead of the parameter configured with the range ("xx"). For example, if you configure the 'Call Success SIP Reasons' parameter with "404,5xx" and the 'Call Failure SIP Reasons' parameter with "502", for 502 responses, the device uses the settings of the 'Call Failure SIP Reasons' parameter only. In other words, a call with SIP response code 502 is considered as a call failure.</li> <li>■ By default, the device considers these SIP response codes as a call success:               <ul style="list-style-type: none"> <li>✓ No answer (452 and 487)</li> <li>✓ Busy (486 and 600)</li> </ul> </li> </ul>

Parameter	Description
	<p>✓ Forwarded (300, 301, 302, 303, and 305)</p> <p>For all other SIP failure response codes, the device considers them as a call failure.</p>
<p>'Call Failure SIP Reasons'</p> <p><code>call-failure-sip-reasons</code></p> <p>[CallFailureSIPReasons]</p>	<p>Defines the SIP response codes that you want the device to consider as call failure, which is indicated by the optional 'Call Success' field in the sent CDR. This parameter overrides the device's default behavior of how it considers calls a success or failure based on SIP responses.</p> <p>The valid value is string of up to 128 characters to represent SIP response codes (e.g., 486). You can configure the parameter with multiple response codes, whereby each code is separated by a comma without spaces before or after (e.g., 486,408,406). You can also configure a range of responses using the "xx" wildcard (e.g., 4xx,502). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If an overlap of a SIP response occurs between the configured 'Call Success SIP Reasons' and 'Call Failure SIP Reasons' parameters, the device uses the parameter that is configured with the specific response code, instead of the parameter configured with the range ("xx"). For example, if you configure the 'Call Success SIP Reasons' parameter with "486,5xx" and the 'Call Failure SIP Reasons' parameter with "502", for 502 responses, the device uses the settings of the 'Call Failure SIP Reasons' parameter only. In other words, a call with SIP response code 502 is considered as a call failure.</li> <li>■ By default, the device considers these SIP response codes as a call success:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ No answer (452 and 487)</li> <li>✓ Busy (486 and 600)</li> <li>✓ Forwarded (300, 301, 302, 303, and 305)</li> </ul> <p>For all other SIP failure response codes, the device considers them as a call failure.</p>
'Call Success Internal Reasons' <code>call-success-internal-reasons</code> [CallSuccessInternalReasons]	<p>Defines the internal response codes (generated by the device) that you want the device to consider as call success, which is indicated by the optional 'Call Success' field in the sent CDR. This parameter overrides the device's default behavior of how it considers calls a success or failure based on internally responses.</p> <p>The valid value is string of up to 128 characters to represent internal response codes (e.g., 851). You can configure the parameter with multiple response codes, whereby each code is separated by a comma without spaces before or after (e.g., 851,320). You can also configure a range of responses using the "xx" wildcard (e.g., 8xx,320). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For a list of the internal response codes, see the 'Termination Reason' [410] CDR field in <a href="#">CDR Field Description</a> on page 1519.</li> <li>■ If an overlap of a SIP response occurs between the configured 'Call Success SIP Reasons' and 'Call Failure SIP Reasons' parameters, the device uses the parameter that is configured with the specific response code, instead of the parameter configured with the range ("xx"). For example, if you configure the 'Call Success SIP Reasons' parameter with "320,8xx" and the 'Call Failure SIP</li> </ul>

Parameter	Description
	Reasons' parameter with "851", for 851 responses, the device uses the settings of the 'Call Failure SIP Reasons' parameter only. In other words, a call with response code 851 is considered as a call failure.
'Call Failure Internal Reasons' call-failure-internal-reasons [CallFailureInternalReasons]	<p>Defines the internal response codes (generated by the device) that you want the device to consider as call failure, which is indicated by the optional 'Call Success' field in the sent CDR. This parameter overrides the device's default behavior of how it considers calls a success or failure based on internally responses.</p> <p>The valid value is string of up to 128 characters to represent internal response codes (e.g., 851). You can configure the parameter with multiple response codes, whereby each code is separated by a comma without spaces before or after (e.g., 851,320). You can also configure a range of responses using the "xx" wildcard (e.g., 8xx,320). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For a list of the internal response codes, see the 'Termination Reason' [410] CDR field in <a href="#">CDR Field Description</a> on page 1519.</li> <li>■ If an overlap of a SIP response occurs between the configured 'Call Success SIP Reasons' and 'Call Failure SIP Reasons' parameters, the device uses the parameter that is configured with the specific response code, instead of the parameter configured with the range ("xx"). For example, if you configure the 'Call Success SIP Reasons' parameter with "320,8xx" and the 'Call Failure SIP Reasons' parameter with "851", for 851 responses, the device uses the settings of the 'Call Failure SIP Reasons'</li> </ul>

Parameter	Description
	parameter only. In other words, a call with response code 851 is considered as a call failure.
'No User Response Before Connect' no-user-response-before-connect [NoUserResponseBeforeConnectSuccess]	<p>Defines if the device considers a call as a success or failure when the internal response (generated by the device) "GWAPP_NO_USER_RESPONDING" (18) is received before call connect (SIP 200 OK).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Call Failure</b></li> <li>■ [1] <b>Call Success</b> (default)</li> </ul>
'No User Response After Connect' no-user-response-after-connect [NoUserResponseAfterConnectSuccess]	<p>Defines if the device considers a call as a success or failure when the internal response (generated by the device) "GWAPP_NO_USER_RESPONDING" (18) is received after call connect (SIP 200 OK).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Call Failure</b> (default)</li> <li>■ [1] <b>Call Success</b></li> </ul>
'Call Transferred before Connect' call-transferred-before-connect [CallTransferredBeforeConnectSuccess]	<p>Defines if the device considers a call as a success or failure when the internal response (generated by the device) "RELEASE_BECAUSE_CALL_TRANSFERRED" (807) is generated before call connect (SIP 200 OK).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Call Failure</b> (default)</li> <li>■ [1] <b>Call Success</b></li> </ul>
'Call Transferred after Connect' call-transferred-after-connect [CallTransferredAfterConnectSuccess]	<p>Defines if the device considers a call as a success or failure when the internal response (generated by the device) "RELEASE_BECAUSE_CALL_TRANSFERRED" (807) is generated after call connect (SIP 200 OK).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Call Failure</b></li> <li>■ [1] <b>Call Success</b> (default)</li> </ul>
'VoIP Debug Level' configure troubleshoot >	Enables syslog debug reporting and logging level.

Parameter	Description
<pre>syslog &gt; debug-level</pre> <p>[GwDebugLevel]</p>	<ul style="list-style-type: none"> <li>■ [0] <b>No Debug</b> = (Default) Debug is disabled and syslog messages are not sent.</li> <li>■ [1] <b>Basic</b> = Sends debug logs of incoming and outgoing SIP messages.</li> <li>■ [5] <b>Detailed</b> = Sends debug logs of incoming and outgoing SIP message as well as many other logged processes.</li> </ul>
<pre>configure system &gt; cdr &gt; non-call-cdr-rprt</pre> <p>[EnableNonCallCdr]</p>	<p>Enables creation of CDR messages for non-call SIP dialogs (such as SUBSCRIBE, OPTIONS, and REGISTER).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Optimization'</p> <pre>configure troubleshoot &gt; syslog &gt; syslog-optimization</pre> <p>[SyslogOptimization]</p>	<p>Enables the device to accumulate and bundle multiple debug messages into a single UDP packet and then send it to a syslog server. The benefit of this feature is that it reduces the number of UDP syslog packets, thereby improving (optimizing) CPU utilization.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> The size of the bundled message is configured by the [MaxBundleSyslogLength] parameter.</p>
<pre>configure voip &gt; gateway digital settings &gt; mx-syslog-lgth</pre> <p>[MaxBundleSyslogLength]</p>	<p>Defines the maximum size (in bytes) threshold of logged syslog messages bundled into a single UDP packet, after which they are sent to a syslog server. The valid value range is 0 to 1220 (where 0 indicates that no bundling occurs). The default is 1220.</p> <p><b>Note:</b> The parameter is applicable only if the [GWDebugLevel] parameter is enabled.</p>

Parameter	Description
<p>'CPU Protection'</p> <pre>configure troubleshoot &gt; syslog &gt; syslog-cpu- protection</pre> <p>[SyslogCpuProtection]</p>	<p>Enables the protection of the device's CPU resources during debug reporting, ensuring voice traffic is unaffected. If CPU resources drop (i.e., high CPU usage) to a critical level (threshold), the device automatically lowers the debug level to free up CPU resources that were required for the previous debug-level functionality. When sufficient CPU resources become available again, the device increases the debug level. The threshold is configured by the 'Debug Level High Threshold' parameter (see below).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul>
<p>'Debug Level High Threshold'</p> <pre>configure troubleshoot &gt; syslog &gt; debug-level-high- threshold</pre> <p>[DebugLevelHighThreshold]</p>	<p>Defines the threshold (in percentage) for automatically switching to a different debug level, depending on CPU usage. The parameter is applicable only if the 'CPU Protection' parameter is enabled.</p> <p>The valid value is 0 to 100. The default is 90.</p> <p>The debug level is changed upon the following scenarios:</p> <ul style="list-style-type: none"> <li>■ CPU usage equals threshold: Debug level is reduced one level.</li> <li>■ CPU usage is at least 5% greater than threshold: Debug level is reduced another level.</li> <li>■ CPU usage is 5 to 19% less than threshold: Debug level is increased by one level.</li> <li>■ CPU usage is at least 20% less than threshold: Debug level is increased by another level.</li> </ul> <p>For example, assume that the threshold is set to 70% and the Debug Level to Detailed (5). When CPU usage reaches 70%, the debug level is reduced to Basic (1). When</p>

Parameter	Description
	<p>CPU usage increases by 5% or more than the threshold (i.e., greater than 75%), the debug level is disabled - No Debug (0). When the CPU usage decreases to 5% less than the threshold (e.g., 65%), the debug level is increased to Basic (1). When the CPU usage decreases to 20% less than the threshold (e.g., 50%), the debug level changes to Detailed (5).</p> <p><b>Note:</b> The device doesn't increase the debug level to a level that is higher than what you configured for the 'Debug Level' parameter.</p>
<pre>configure troubleshoot &gt; cdr &gt; time-zone-format</pre> <p>[TimeZoneFormat]</p>	<p>Defines the time zone that is displayed with the timestamp in CDRs. The timestamp appears in the CDR fields "Setup Time", "Connect Time", and "Release Time".</p> <p>The valid value is a string of up to six characters. The default is UTC. For example, if you configure the parameter TimeZoneFormat = GMT+11, the timestamp in CDRs are generated with the following time zone display:</p> <p>17:47:45.411 <b>GMT+11</b> Sun Jan 03 2018</p> <p><b>Note:</b> The time zone is only for display purposes; it doesn't configure the actual time zone.</p>
<pre>configure troubleshoot &gt; cdr &gt; call-duration-units</pre> <p>[CallDurationUnits]</p>	<p>Defines the unit of measurement for call duration ("Duration" field) in CDRs generated by the device.</p> <ul style="list-style-type: none"> <li>■ [0] Seconds (default)</li> <li>■ [1] Deciseconds</li> <li>■ [2] Centiseconds</li> <li>■ [3] Milliseconds</li> </ul> <p>The parameter applies to CDRs for syslog, RADIUS, local-device storage, and CDR history displayed in the Web interface.</p>

Parameter	Description
<p>'CDR Syslog Sequence Number'</p> <pre>configure system &gt; cdr &gt; cdr-seq-num</pre> <p>[CDRSyslogSeqNum]</p>	<p>Enables or disables the inclusion of the sequence number (S=) in CDR Syslog messages.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; send-acsessionid</pre> <p>[SendAcSessionIDHeader]</p>	<p>Enables the use of the Global Session ID in SIP messages (AC-Session-ID header), which is a unique identifier of the call session, even if it traverses multiple devices.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disables the feature. The device sends outgoing SIP messages without a Global Session ID (even if a Global Session ID was received in the incoming SIP message).</li> <li>■ [1] = Enables the feature. If the device receives an incoming SIP message containing a Global Session ID, it sends the same Global Session ID in the outgoing SIP message. If the incoming SIP message doesn't contain a Global Session ID or if a new session is initiated by the device, the device generates a new, unique Global Session ID and adds it to the outgoing SIP message.</li> </ul> <p>For more information, see <a href="#">Enabling Same Call Session ID over Multiple Devices</a> on page 1665.</p>
<p>'Activity Types to Report via Activity Log Messages'</p> <pre>configure troubleshoot &gt; activity-log</pre> <p>[ActivityListToLog]</p>	<p>Defines the operations (activities) performed in the Web interface that are reported to a syslog server.</p> <ul style="list-style-type: none"> <li>■ [PVC] <b>Parameters Value Change</b> = Changes made on-the-fly to parameters and tables, and Configuration file upload. Note that the ini file parameter, EnableParametersMonitoring can also be used to set this option.</li> <li>■ [AFL] <b>Auxiliary Files Loading</b> = Loading</li> </ul>

Parameter	Description
	<p>of Auxiliary files.</p> <ul style="list-style-type: none"> <li>■ [DR] <b>Device Restart</b> = Restarting the device from the Maintenance Actions page. <b>Note:</b> For this option to take effect, a device restart is required.</li> <li>■ [FB] <b>Flash Memory Burning</b> = Saving configuration with save to flash from the Maintenance Actions page.</li> <li>■ [SWU] <b>Device Software Upgrade</b> = Software updates (i.e., loading of cmp file) through the Software Upgrade Wizard.</li> <li>■ [NAA] <b>Non-Authorized Access</b> = Attempts to log in to the Web interface with a false or empty username or password.</li> <li>■ [SPC] <b>Sensitive Parameters Value Change</b> = Changes made to "sensitive" parameters: <ul style="list-style-type: none"> <li>✓ (1) IP Address</li> <li>✓ (2) Subnet Mask</li> <li>✓ (3) Default Gateway IP Address</li> <li>✓ (4) ActivityListToLog</li> </ul> </li> <li>■ [LL] <b>Login and Logout</b> = Web login and logout attempts.</li> <li>■ [CLI] <b>CLI Activity</b> = CLI commands entered by the user.</li> <li>■ [AE] <b>Action Executed</b> = Logs user actions that are not related to parameter changes. The actions can include, for example, file uploads, file downloads, file delete, lock-unlock maintenance actions, LDAP clear cache, register-unregister, and start-stop trunk. In the Web, these actions are typically done by clicking a button (e.g., the <b>LOCK</b> button).</li> </ul>

Parameter	Description
	<p>■ [INI] <b>Incremental INI</b> = Changes made to parameters due to the loading of an incremental ini file. If you choose this option, you can also define the maximum number of lines of parameters to log from the ini file, using the 'Incremental INI Activity Logs Max Number' parameter (see below).</p> <p><b>Note:</b> For the <i>ini</i> file parameter, enclose values in single quotation marks. To configure the ini file parameter with multiple values, use a comma-separated list, for example: ActivityListToLog = 'PVC', 'AFL', 'DR'.</p>
'Incremental INI Activity Logs Max Number' configure troubleshoot > max- ini-activity-logs [MaxINIActivityLog]	<p>Defines the maximum number of lines of parameters from the loaded incremental ini file to log for the Activity Types to Report feature. The parameter is applicable when you configure the [ActivityListToLog] parameter to also include the INI value. The valid value is 0 to 2,000. The default is 1,000.</p> <p><b>Note:</b> The maximum number of lines doesn't count empty lines or lines containing only comments.</p>
[EnableParametersMonitoring]	<p>Enables the monitoring, through syslog messages, of parameters that are modified on-the-fly.</p> <p>■ [0] = (Default) Disable</p> <p>■ [1] = Enable</p>
'ISDN Facility Trace' configure voip > gateway digital settings > isdn- facility-trace [FacilityTrace]	<p>Enables ISDN traces of Facility Information Elements (IE) for ISDN call diagnostics. This allows you to trace all the parameters contained in the Facility IE and view them in the syslog.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the feature to be functional, configure the [GWDebugLevel] parameter to at least level [1].</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'Destination IP Address'</p> <pre>configure troubleshoot &gt; logging settings &gt; dbg-rec- dest-ip</pre> <p>[DebugRecordingDestIP]</p>	<p>Defines the IP address (IPv4 or IPv6) of the server for capturing debug recording.</p>
<p>'Destination Port'</p> <pre>configure troubleshoot &gt; logging settings &gt; dbg-rec- dest-port</pre> <p>[DebugRecordingDestPort]</p>	<p>Defines the UDP port of the server for capturing debug recording.</p> <p>The default is 925.</p>
<p>'Debug Recording Timeout'</p> <pre>configure troubleshoot &gt; logging settings &gt; dbg-rec- timeout</pre> <p>[DebugRecordingTimeout]</p>	<p>Defines the maximum duration (in minutes) for the debug recording process. When this timer expires, the device automatically stops debug recording (unless you've explicitly stopped it before the timer expires, as described in <a href="#">Starting and Stopping Debug Recording</a> on page 1644). The valid value is 1 to 10,080 (7 days). The default is 60 (1 hour).</p> <p><b>Note:</b> If debug recording is currently running (i.e., started), the device resets the debug recording timer upon the following:</p> <ul style="list-style-type: none"> <li>■ A new rule is added to, or an existing rule is modified in the Logging Filters table.</li> <li>■ A device restart.</li> <li>■ An HA switchover.</li> </ul>
<p>'Start' Record/ 'Stop Record'</p> <pre>configure troubleshoot &gt; logging-settings &gt; dbg-rec-</pre>	<p>Starts or stops debug recording.</p> <p>For more information on starting and stopping debug recording, see <a href="#">Starting and</a></p>

Parameter	Description
status [DebugRecordingStatus]	<p><a href="#">Stopping Debug Recording</a> on page 1644.</p> <p><b>Note:</b> The CLI command also displays the current debug recording status (Started or Stopped), and resets the debug recording timer, configured by the [DebugRecordingTimeout] parameter.</p>
'Interface Name' configure troubleshoot > logging settings > dbg-rec- int-name [DebugRecordingIpInterfaceName]	<p>Defines the IP Interface through which the device sends captured traffic to the debug server.</p> <p>The valid value is the name of the IP Interface, as configured in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159). The default is the OAMP interface.</p>
'Enable Core Dump' enable-core-dump [EnableCoreDump]	<p>Enables the automatic generation of a Core Dump file upon a device crash.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>
'Core Dump Destination IP' core-dump-dest-ip [CoreDumpDestIP]	<p>Defines the IP address of the remote server where you want the device to send the Core Dump file.</p> <p>By default, no IP address is defined.</p>
'Call Flow Report Mode' call-flow-report [CallFlowReportMode]	<p>Enables the device to send SIP call messages to OVOC so that OVOC can display SIP call dialog sessions as SIP call flow diagrams.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>For more information, see <a href="#">Enabling SIP Call Flow Diagrams in OVOC</a> on page 1663.</p>
configure troubleshoot > syslog > system-log-size [SystemLogSize]	<p>Defines the maximum size (in kilobytes) of the system log file.</p> <p>The valid value range is 10 to 2000 KB. The default is 200 KB.</p> <p>To view the logged information in this file,</p>

Parameter	Description
	use the CLI command <code>show system log</code> .
[PLThresholdLevelsPerMille]	<p>Defines packet-loss percentage ranges that are used in sent syslog messages to report packet loss in incoming media streams (RTP) in 15-second intervals.</p> <p>The valid value range is 1 to 1,000. The default is 5, 10, 20, 50.</p> <p>The syntax for configuring the parameter is: <code>PLThresholdLevelsPerMille = Level1, Level2, Level3, Level4</code></p> <p>Where the levels represent the following ranges in the syslog:</p> <ul style="list-style-type: none"> <li>■ [No PL]</li> <li>■ [up to (Level1/10)% ]</li> <li>■ [(Level1/10)% - (Level2/10)%]</li> <li>■ [(Level2/10)% - (Level3/10)%]</li> <li>■ [(Level3/10)% - (Level4/10)%]</li> <li>■ [(Level4/10)% - 100%]</li> </ul> <p>For example (using default values):  <code>PLThresholdLevelsPerMille = 5, 10, 20, 50</code></p> <p>Therefore, the ranges are:</p> <ul style="list-style-type: none"> <li>■ [No PL]</li> <li>■ [up to 0.5% ]</li> <li>■ [0.5% - 1%]</li> <li>■ [1% - 2%]</li> <li>■ [2% - 5%]</li> <li>■ [5% - 100%]</li> </ul> <p>For more information, see <a href="#">Packet Loss Indication in Syslog</a> on page 1641.</p>
<b>CDR Local Storage</b>	
'File Size'	Defines the size (in kilobytes) of each locally

Parameter	Description
<pre>configure troubleshoot &gt; cdr &gt; file-size</pre> <p>[CDRLocalMaxFileSize]</p>	<p>stored CDR file. When the Current file reaches this size, the device creates a CDR file containing all the CDRs from the Current file.</p> <p>The valid value is 100 to 10,000. The default is 1024.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>CDR file creation works together with the 'Rotation Period' parameter, whereby the file is created as soon as one of the parameter's ('File Size' or 'Rotation Period') settings are fulfilled (whichever is met earlier). For example, if the 'File Size' parameter is 100 and 'Rotation Period' is 60, and the file size reaches 100 kbytes after only 30 minutes has passed, the device creates the CDR file.</li> <li>The parameter is applicable only to local storage of CDRs.</li> </ul>
<p>'Number of Files'</p> <pre>configure troubleshoot &gt; cdr &gt; files-num</pre> <p>[CDRLocalMaxNumOfFiles]</p>	<p>Defines the maximum number of locally stored CDR files. If the maximum number is reached and a new file is created, the oldest file is deleted to make space for the new file (i.e., FIFO).</p> <p>The valid value is 2 to 4096 . The default is 5.</p> <p><b>Note:</b> The parameter is applicable only to local storage of CDRs.</p>
<p>'Rotation Period'</p> <pre>configure troubleshoot &gt; cdr &gt; rotation-period</pre> <p>[CDRLocalInterval]</p>	<p>Defines how often (in minutes) the device creates a new CDR file for locally stored CDRs. For example, if configured to 60, every hour it creates a CDR file containing all the CDRs from the Current file.</p> <p>The valid value is 2 to 1440. The default is 60.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>CDR file creation works together with the 'File Size' parameter, whereby the</li> </ul>

Parameter	Description
	<p>file is created as soon as one of the parameter's ('File Size' or 'Rotation Period') settings are fulfilled (whichever is met earlier). For example, if the 'Rotation Period' parameter is 60 and 'File Size' is 100, and an hour has passed but the file size is only 50 kbytes, the device creates the CDR file.</p> <ul style="list-style-type: none"> <li>■ The CDR file is created even if there are no CDRs in the Current file.</li> <li>■ The parameter is applicable only to local storage of CDRs.</li> </ul>
<b>IP Trace Filters</b> (For more information, see <a href="#">Filtering IP Network Traces by Ethernet Port or VLAN</a> on page 1612.)	
<p>'Recording Mode'</p> <pre>configure troubleshoot &gt; logging settings &gt; dbg-rec- ip-trace-entity</pre> <p>[DebugRecordingIpTraceEntity]</p>	<p>Defines the filtering of IP traces for log filtering rules (in the Logging Filters table) whose 'Filter Type' parameter is configured to <b>IP Trace</b>.</p> <ul style="list-style-type: none"> <li>■ [0] <b>All Physical Ethernet Ports</b> = (Default) The log filter for the IP trace is applied on packets received and sent (tagged and untagged) on all the physical Ethernet ports.</li> <li>■ [1] <b>Physical Ethernet Port</b> = The log filter for the IP trace is applied on packets received and sent on an Ethernet port configured by the 'Physical Ethernet Port' parameter (below).</li> <li>■ [3] <b>VLAN ID</b> = The log filter for the IP trace is applied on packets received and sent on a VLAN ID (underlying Ethernet Device) configured by the 'VLAN ID' parameter (below).</li> </ul>
<p>'Physical Ethernet Port'</p> <pre>configure troubleshoot &gt; logging settings &gt; dbg-rec- ip-trace-phy-port</pre>	<p>Filters IP traces by a specific Ethernet port.</p>

Parameter	Description
[DebugRecordingIpTracePhysicalPort_ IpTracePhyPort]	
'VLAN ID' configure troubleshoot > logging settings > dbg-rec- ip-trace-vlan-id [DebugRecordingIpTraceVlanId_ IpTraceVlanId]	Filters IP traces by a specific VLAN ID.
<b>PII Masking (GDPR)</b>	
'Mask Digits' configure voip > sip- definition settings > pii- mask-digits [PIIMaskDigits]	<p>Enables the masking of DTMF and other digits detected by the device in the generated syslog messages and debug recording.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information, see <a href="#">Masking Digits in Syslog Messages</a> on page 211.</p>
'Mask PII in CDRs' configure voip > sip- definition settings > pii- mask-private-info-in-cdrs [PIIMaskPrivateInfoInCDRs]	<p>Enables the masking of personally identifiable information (PII) in CDRs generated by the device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = No masking is done.</li> <li>■ [1] <b>Mark PII in Web or CLI</b> = The device masks (by a single asterisk * symbol) private information (caller and callee) in the Web interface's SBC CDR History table (see <a href="#">Viewing CDR History of SBC and Test Calls</a> on page 1495) and Gateway CDR History table (see <a href="#">Viewing Gateway CDR History</a> on page 1493), and CLI (e.g., show voip calls). For example, the device masks the URI "name@domain.com" as "*".</li> <li>■ [2] <b>Mask PII in Detailed Records</b> = The device masks (by multiple asterisks *) private information in CDRs and SDRs.</li> </ul>

Parameter	Description
	<p>This applies to all destinations to where the device sends these records (i.e., syslog, REST, Local Storage, and RADIUS), except ARM and OVOC. This option also affects PII in the Web interface's SBC CDR History table Gateway CDR History table, and CLI (e.g., <code>show voip calls</code>). For URIs, only the user part is masked.</p> <p>For more information, see <a href="#">Masking PII in CDRs</a> on page 209.</p>
<p>'Number of Unmasked Characters in PII'</p> <pre>configure voip &gt; sip- definition settings &gt; pii- number-of-unmasked-chars</pre> <p>[PIINumberOfUnmaskedChars]</p>	<p>Defines the number of characters in the PII element to show when the 'Mask PII in CDRs' parameter is configured to <b>Mask PII in Detailed Records</b>. The rest of the characters are masked (each by an asterisk sign).</p> <p>The valid value is 0 to 255. The default is 0 (masks all characters).</p> <p>For more information, see <a href="#">Masking PII in CDRs</a> on page 209.</p>
<p>'Location in PII of Unmasked Characters'</p> <pre>configure voip &gt; sip- definition settings &gt; pii- unmasked-chars-location</pre> <p>[PIIUnmaskedCharsLocation]</p>	<p>Defines from where in the PII element to show the number of characters specified by the 'Number of Unmasked Characters in PII' parameters, when the Mask Private Information in CDRs' parameter is configured to <b>Mask PII in Detailed Records</b>.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Last Characters</b> = (Default) The device shows the number of characters specified by the 'Number of Unmasked Characters in PII' parameter, starting from the end of the PII element.</li> <li>■ [1] <b>First Characters</b> = The device shows the number of characters specified by the 'Number of Unmasked Characters in PII' parameter, starting from the beginning of the PII element.</li> </ul> <p>For more information, see <a href="#">Masking PII in CDRs</a> on page 209.</p>

Parameter	Description
'Mask PII in CDRs for OVOC' configure voip > sip- definition settings > pii- mask-private-info-for-ovoc [PIIMaskPrivateInfoForOVOC]	Enables the PII masking (with asterisks) of phone numbers, URI user parts, and display names in CDRs that the device sends to OVOC.  <input type="checkbox"/> [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  <input checked="" type="checkbox"/> [1] Check box selected <input checked="" type="checkbox"/> = Enabled.  For more information, see <a href="#">Masking PII in CDRs</a> on page 209.
'Mask URI Host Part in CDRs' configure voip > sip- definition settings > pii- mask-host [PIIMaskHost]	Enables the PII masking (with asterisks) of URI host parts (including IP addresses) in CDRs that the device sends to Web, CLI, syslog, REST, RADIUS, and Local Storage (depending on which targets are anonymized by the 'Mask PII in CDRs' parameter), or to OVOC if the 'Mask PII in CDRs for OVOC' parameter is enabled.  <input type="checkbox"/> [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  <input checked="" type="checkbox"/> [1] Check box selected <input checked="" type="checkbox"/> = Enabled.  For more information, see <a href="#">Masking PII in CDRs</a> on page 209.

## Heartbeat Packet Parameters

The Heartbeat packet parameters are described in the table below. The device sends a heartbeat packet to ensure that the far-end is passing traffic.

**Table 73-22:Heartbeat Packet Parameters**

Parameter	Description
[HeartBeatIntervalmsec]	Defines the delay (in msec) between consecutive heartbeat packets.  The parameter is used when the device operates in High-Availability (HA) mode. The active and redundant devices send heartbeat (keep-alive) messages to one another to check reachability. They send the keep-alive messages "in bulks" (from multiple local ports) every 100 msec to create multiple flows in the network equipment (e.g., switches or

Parameter	Description
	<p>SDN network). If there is no reply from the active device to the sent heartbeat packets within this timeout (HA timeout), the active device is considered unreachable, triggering an HA switchover to the redundant device.</p> <p>The parameter is measured in 10-msec units, meaning that whatever value you define for the parameter, the timeout is the value multiplied by 10. For example, if you configure the parameter to 100 (i.e., <math>100 \times 10 = 1,000</math> msec = 1 second), an HA switchover happens after a 1-second loss of keep-alive messages. You can increase it, for example, to 300 (i.e., <math>300 \times 10 = 3,000</math> msec = 3 seconds), which means that a switchover happens after a 3-second loss of keep-alive messages.</p> <p>The valid value range is 100 to 6,000 (i.e., 1 minute). The default is 100.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

## Resource Allocation Indication Parameters

The Resource Allocation Indication (RAI) parameters are described in the table below.

**Table 73-23:RAI Parameters**

Parameter	Description
[EnableRAI]	<p>Enables Resource Available Indication (RAI) alarm generation if the device's busy endpoints exceed a user-defined threshold, configured by the RAIHighThreshold parameter. When enabled and the threshold is crossed, the device sends the SNMP trap, acBoardCallResourcesAlarm.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>
[RAIHighThreshold]	<p>Defines the high threshold percentage of total calls that are active (busy endpoints). When the percentage of the device's busy endpoints exceeds this high threshold, the device sends the SNMP acBoardCallResourcesAlarm alarm trap with a 'major'</p>

Parameter	Description
	<p>alarm status.</p> <p>The range is 0 to 100. The default is 90.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The percentage of busy endpoints is calculated by dividing the number of busy endpoints by the total number of “enabled” endpoints (trunks are physically connected and synchronized without alarms and endpoints are defined in the Trunk Groups table).</li> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>
[RAILowThreshold]	<p>Defines the low threshold percentage of total calls that are active (busy endpoints).</p> <p>When the percentage of the device's busy endpoints falls below this low threshold, the device sends an SNMP acBoardCallResourcesAlarm alarm trap with a 'cleared' alarm status.</p> <p>The range is 0 to 100%. The default is 90%.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
[RAILoopTime]	<p>Defines the time interval (in seconds) that the device periodically checks call resource availability.</p> <p>The valid range is 1 to 200. The default is 10.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>

## PacketSmart Parameters

The PacketSmart parameters are described in the table below. For more information on PacketSmart, see [Configuring PacketSmart Agent for Network Monitoring](#) on page 1483.

**Table 73-24:PacketSmart Parameters**

Parameter	Description
<p>'PacketSmart Agent Mode'</p> <pre>configure system &gt; packetsmart enable</pre> <p>[PacketSmartAgentMode]</p>	<p>Enables the embedded PacketSmart agent.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (Default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

Parameter	Description
'PacketSmart Server IP Address' configure system > packetsmart server address [PacketSmartIpAddress]	Defines the IP address of the PacketSmart server with which the PacketSmart agent communicates. The default is 0.0.0.0.
'PacketSmart Server Port' configure system > packetsmart server port [PacketSmartIpAddressPort]	Defines the TCP port of the PacketSmart server to which the PacketSmart agent connects. The default is 80.
'Monitoring Interface' configure system > packetsmart monitor voip interface-if [PacketSmartMonitorInterface]	Assigns an IP network interface (configured in the IP Interfaces table) that handles the voice traffic. <b>Note:</b> For the parameter to take effect, a device restart is required.
'Network Interface' configure system > packetsmart network voip interface-if [PacketSmartNetworkInterface]	Assigns an IP network interface (configured in the IP Interfaces table) for communicating with the PacketSmart server. This is typically the OAMP interface. <b>Note:</b> For the parameter to take effect, a device restart is required.

## HA Parameters

The High Availability (HA) parameters are described in the table below.

When configuration is applied to the device whose MAC is the value of the HARemoteMAC parameter, all HA configuration is swapped between local and remote parameters, including the IP address of the Maintenance interface, which is swapped with the address configured for the HARemoteAddress parameter. For more information, see [Quick-and-Easy Initial HA Configuration](#) on page 1313.

**Table 73-25:HA Parameters**

Parameter	Description
[HAMaintenanceIFDiffServValue]	Defines the DiffServ value for HA Maintenance traffic flowing on the HA Maintenance interface. The valid value is 0 (lowest priority or best-effort service) to 63 (highest priority). The default is 46.

Parameter	Description
	<p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure network &gt; high-availability settings &gt; operational-state-delay</pre> <p>[HAOperationalStateDelayInSec]</p>	<p>Defines the duration (in seconds) to delay the transition from HA non-operational state, which occurs during HA synchronization between active and redundant devices, to HA operational state. This feature may be useful, for example, to delay HA switchover when using switches with spanning tree protocol (STP) that take a long time until their ports (to which the redundant device is connected) is ready. In such a scenario, if this feature were not enabled (i.e., 0), after synchronization there would be no connectivity between the redundant device's network interface and the switch.</p> <p>The valid value is 0 to 180. The default is 0.</p>
[HALocalMAC]	<p>Specifies the MAC address of one of the two devices in the HA system.</p> <p>For more information, see <a href="#">Quick-and-Easy Initial HA Configuration</a> on page 1313.</p> <p><b>Note:</b> When downloading an ini file from a device that is operating in HA mode, the parameter is the MAC address of the active device.</p>
[HARemoteMAC]	<p>Specifies the MAC address of one of the two devices in the HA system.</p> <p>For more information, see <a href="#">Quick-and-Easy Initial HA Configuration</a> on page 1313.</p> <p><b>Note:</b> When downloading an ini file from a device that is operating in HA mode, the parameter is the MAC address of the redundant device.</p>
<p>'HA Device Name'</p> <pre>configure network &gt; high-availability settings &gt; unit-id-name</pre> <p>[HAUnitIdName]</p>	<p>Defines a name for the active device, which is displayed on the Home page to indicate the active device.</p> <p>The valid value is a string of up to 128 characters. The default value is "Device 1".</p> <p><b>Note:</b> When the device sends alarms to OVOC, this name is displayed at the beginning of the</p>

Parameter	Description
	alarm description in OVOC, for example, "(SBCSITE01): Proxy lost. looking for another proxy". However, the name is not displayed for the alarms retrieved (from the device's Active Alarms table) when OVOC <b>initially</b> connects to the device.
'HA Remote Device Name' configure network > high-availability settings > redundant-unit-id-name [HARemoteUnitIdName]	<p>Defines a name for the redundant device, which is displayed on the Home page to indicate the redundant device.</p> <p>The valid value is a string of up to 128 characters. The default value is "Device 2".</p> <p><b>Note:</b> When the device sends alarms to OVOC, this name is displayed at the beginning of the alarm description in OVOC, for example, "(SBCSITE02): Proxy lost. looking for another proxy". However, the name is not displayed for the alarms retrieved (from the device's Active Alarms table) when OVOC <b>initially</b> connects to the device.</p>
'HA Remote Address' configure network > high-availability settings > remote-address [HARemoteAddress]	<p>Defines the Maintenance interface address of the redundant device in the HA system.</p> <p>By default, no value is defined.</p> <p><b>Note:</b>For the parameter to take effect, a device restart is required.</p>
'Preempt Mode' configure network > high-availability settings > revertive-mode [HARevertiveEnabled]	<p>Enables HA switchover based on HA priority.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. A switchover over to the redundant device is done only if a failure occurs in the currently active device.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. A switchover over to the redundant device is done if a failure occurs in the currently active device. However, a switchover to the device with the highest priority (configured by the HAPriority parameter) occurs whenever the device recovers from a failure. Therefore, whenever possible, the highest priority device is the active one.</li> </ul>

Parameter	Description
	For more information on the HA switchover mechanism, see <a href="#">Device Switchover upon Failure</a> on page 1303.
<b>'Preempt Priority'</b> <code>configure network &gt; high-availability settings &gt; priority</code> <b>[HAPriority]</b>	<p>Defines the priority of the active device used in the HA Preempt mechanism.</p> <p>The valid value is 1 (lowest priority) to 10 (highest priority). The default is 5.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you enable the 'Preempt Mode' parameter.</li> <li>■ You must configure each device in the HA system with different parameter values (priorities).</li> </ul>
<b>'HA Remote Preempt Priority'</b> <code>configure network &gt; high-availability &gt; redundant-priority</code> <b>[HARemotePriority]</b>	<p>Defines the priority of the redundant device used in the HA Preempt mechanism.</p> <p>The valid value is 1 (lowest priority) to 10 (highest priority). The default is 5.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you enable the 'Preempt Mode' parameter.</li> <li>■ You must configure each device in the HA system with different parameter values (priorities).</li> </ul>
<b>'HA Secured Connectivity Mode'</b> <code>configure network &gt; high-availability settings &gt; ha-secured-connectivity</code> <b>[HASecuredConnectivityMode]</b>	<p>Enables secure (TLS) communication (HA Maintenance interface) between the active and redundant devices in the HA system.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information, see <a href="#">Enabling Secured TLS Communication between Active and Redundant Devices</a> on page 1317.</p> <p><b>Note:</b>For the parameter to take effect, a device restart is required.</p>
<b>'HA File Transfer Port'</b> <code>configure network &gt; high-availability settings &gt;</code>	<p>Defines the device's port for unsecured file transfer between active and redundant devices in HA mode.</p>

Parameter	Description
<code>ha-file-transfer-port</code> [HaFileTransferPort]	<p>The default is 80.</p> <p>For more information, see <a href="#">Configuring Ports for File Transfer between Active and Redundant Devices</a> on page 1316.</p> <p><b>Note:</b>For the parameter to take effect, a device restart is required.</p>
<p>'HA Secured File Transfer Port'</p> <code>configure network &gt; high-availability settings &gt; ha-secure-file-transfer-port</code> [HaSecureFileTransferPort]	<p>Defines the device's port for secured (HTTPS) file transfer between active and redundant devices in HA mode.</p> <p>The default is 443.</p> <p>For more information, see <a href="#">Configuring Ports for File Transfer between Active and Redundant Devices</a> on page 1316.</p> <p><b>Note:</b>For the parameter to take effect, a device restart is required.</p>
<p>HA Network Monitor Parameters</p> <p>For more information, see <a href="#">Monitoring IP Entities and HA Switchover upon Ping Failure</a> on page 1317.</p>	
<p>'HA Network Monitor'</p> <code>configure network &gt; high-availability settings &gt; network-monitor-enabled</code> [HAPingEnabled]	<p>Enables the HA Network Monitor feature, which checks connectivity with network destinations, using pings. When a user-defined number of destinations fail the connectivity test (see 'Network Monitor Threshold' parameter), an HA switchover occurs.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>
<p>'Monitor Threshold'</p> <code>configure network &gt; high-availability settings &gt; network-monitor-threshold</code> [HaNetworkMonitorThreshold]	<p>Defines the minimum number of monitored rows (configured in the HA Network Monitor table) whose destinations are unreachable that are required to trigger an HA switchover.</p> <p>The valid value is 1 to 10. The default is 1.</p>

## Security Parameters

This subsection describes the device's security parameters.

## General Security Parameters

The general security parameters are described in the table below.

**Table 73-26:General Security Parameters**

Parameter	Description
<b>Media Latching</b>	
'Inbound Media Latch Mode' configure voip > media settings > inbound- media-latch-mode [InboundMediaLatchMode]	<p>Enables the Media Latching feature.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Strict</b> = The device is ready to receive (latch on to) media packets, but only if they are from a specific source IP address and UDP port, according to the remote IP address and UDP port in the negotiated SDP of the SIP message.</li> </ul> <p><b>Note:</b> If the SIP user agent is behind NAT and you have configured the [NATMode] parameter to [4] (<b>NAT By Signaling Restricted IP</b>), even if you have configured the 'Inbound Media Latch Mode' parameter to <b>Strict</b>, the device automatically changes it to <b>Dynamic</b>.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Dynamic</b> = (Default) Device latches on to the first stream. If it receives at least a minimum number of consecutive packets (configured by New&lt;media type&gt;StreamPackets) from a different source(s) and the device has not received packets from the current stream for a user-defined period (TimeoutToRelatch&lt;media type&gt;Msec), it latches on to the next packet received from any other stream. If other packets of a different media type are received from the new stream, based on IP address and SSRC for RTCP/RTP and based on IP address only for T.38, the packet is accepted immediately.</li> </ul> <p><b>Note:</b> If a packet from the original (first latched onto) IP address:port is received at any time, the device latches on to this stream.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Dynamic-Strict</b> = Device latches onto the first stream. If it receives at least a minimum number of consecutive packets (configured by New&lt;media type&gt;StreamPackets) all from the same source which is different to the first stream</li> </ul>

Parameter	Description
	<p>and the device has not received packets from the current stream for a user-defined period (TimeoutToRelatch&lt;media type&gt;Msec), it latches on to the next packet received from any other stream. If other packets of different media type are received from the new stream based on IP address and SSRC for RTCP and based on IP address only for T.38, the packet is accepted immediately.</p> <p><b>Note:</b> If a packet from the original (first latched onto) IP address:port is received at any time, the device latches on to this stream.</p> <p>■ [3] <b>Strict-On-First</b> = Typically used for NAT, where the correct IP address:port is initially unknown. The device latches on to the stream received in the first packet. The device doesn't change this stream unless a packet is later received from the original source.</p> <p><b>Note:</b> If you configure the parameter to <b>Strict</b>, the device can't perform NAT traversal. In this setup, configure the [NATMode] parameter to [1].</p>
'New RTP Stream Packets' [NewRtpStreamPackets]	<p>Defines the minimum number of continuous RTP packets received by the device's channel to allow latching onto the new incoming stream.</p> <p>The valid range is 0 to 20. The default is 3. If set to 0, the device is left exposed to attacks against multiple packet streams.</p>
'New RTCP Stream Packets' [NewRtcpStreamPackets]	<p>Defines the minimum number of continuous RTCP packets received by the device's channel to allow latching onto the new incoming stream.</p> <p>The valid range is 0 to 20. The default is 3. If set to 0, the device is left exposed to attacks against multiple packet streams.</p>
'New SRTP Stream Packets' [NewSRTPStreamPackets]	<p>Defines the minimum number of continuous SRTP packets received by the device's channel to allow latching onto the new incoming stream.</p> <p>The valid range is 0 to 20. The default is 3. If set to 0, the device is left exposed to attacks against multiple packet streams.</p>

Parameter	Description
'New SRTCP Stream Packets' [NewSRTCPStreamPackets]	Defines the minimum number of continuous SRTCP packets received by the device's channel to allow latching onto the new incoming stream.  The valid range is 0 to 20. The default is 3. If set to 0, the device is left exposed to attacks against multiple packet streams.
'Timeout To Relatch RTP' [TimeoutToRelatchRTPMsec]	Defines a period (msec) during which if no packets are received from the current RTP session, the channel can re-latch onto another stream.  The valid range is any value from 0. The default is 200.
'Timeout To Relatch SRTP' [TimeoutToRelatchSRTPMsec]	Defines a period (msec) during which if no packets are received from the current SRTP session, the channel can re-latch onto another stream.  The valid range is any value from 0. The default is 200.
'Timeout To Relatch Silence' [TimeoutToRelatchSilenceMsec]	Defines a period (msec) during which if no packets are received from the current RTP/SRTP session and the channel is in silence mode, the channel can re-latch onto another stream.  The valid range is any value from 0. The default is 200.
'Timeout To Relatch RTCP' [TimeoutToRelatchRTCPMsec]	Defines a period (msec) during which if no packets are received from the current RTCP session, the channel can re-latch onto another RTCP stream.  The valid range is any value from 0. The default is 10,000.
'Fax Relay Rx/Tx Timeout' [FaxRelayTimeoutSec]	Defines a period (sec) during which if no T.38 packets are received or sent from the current T.38 fax relay session, the channel can re-latch onto another stream.  The valid range is 0 to 255. The default is 10.

## HTTPS Parameters

The Secure Hypertext Transport Protocol (HTTPS) parameters are described in the table below.

Table 73-27:HTTPS Parameters

Parameter	Description
<p>'Secured Web Connection (HTTPS)'</p> <pre>configure system &gt; web &gt; secured-connection</pre> <p>[HTTPSOnly]</p>	<p>Defines the HTTP/S application protocol for accessing the device's management interface (Web interface or REST API).</p> <ul style="list-style-type: none"> <li>■ [0] <b>HTTP and HTTPS</b> = (Default) Access to the management interface is allowed from HTTP and HTTPS (secured) requests.</li> <li>■ [1] <b>HTTPS Only</b> = Access to the management interface is allowed only from HTTPS requests (and unencrypted HTTP packets are blocked).</li> <li>■ [2] <b>HTTPS Redirect</b> = Access to the management interface is allowed only from HTTPS redirect URLs. This is required when using OAuth login authentication with Azure AD, which redirects the user to a URI (device's address) upon successful authentication and authorization.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ If you configure the parameter to <b>HTTPS Redirect</b> and you're using Single-Sign On (SSO) to the device from OVOC, you must configure OVOC to connect to the device using HTTPS ('Communication Protocol' field set to <b>HTTPS</b>).</li> </ul>
<pre>configure system &gt; web &gt; https-port</pre> <p>[HTTPSPort]</p>	<p>Defines the local Secured HTTPS port of the device. The parameter allows secure remote device Web- or REST-based management from the LAN. To enable secure Web management from the LAN, configure the desired port.</p> <p>The valid range is 1 to 65535 (other restrictions may apply within this range). The default port is 443.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>'Require Client Certificates for HTTPS connection'</p> <pre>configure system &gt; web &gt; req-client-cert</pre> <p>[HTTPSRequireClientCertificate]</p>	<p>Enables the requirement of client certificates for HTTPS connection.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Client certificates are not required.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = Client certificates are required. The client certificate must be preloaded to the device and its matching private key must be installed on the managing PC. Time and date must be correctly set on the device for the client certificate to be verified.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ For a description on implementing client certificates, see <a href="#">TLS for Remote Device Management</a> on page 252.</li> </ul>

## SRTP Parameters

The Secure Real-Time Transport Protocol (SRTP) parameters are described in the table below.

**Table 73-28:SRTP Parameters**

Parameter	Description
<p>'Media Security'</p> <pre>configure voip &gt; media security &gt; media-security-enable</pre> <p>[EnableMediaSecurity]</p>	<p>Enables Secure Real-Time Transport Protocol (SRTP).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is not applicable to WebRTC.</li> </ul>
<p>'Media Security Behavior'</p> <pre>configure voip &gt; media security &gt; media-sec-bhviior</pre> <p>[MediaSecurityBehaviour]</p>	<p>Global parameter that defines the handling of SRTP, when the [EnableMediaSecurity] parameter is configured to 1. You can also configure this feature per specific calls, using IP Profiles ('Gateway Media Security Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see</p>

Parameter	Description
	<p><a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</li> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>
<p>'Master Key Identifier (MKI) Size'</p> <pre>configure voip &gt; media security &gt; srtp-tx-packet-mki-size</pre> <p>[SRTPTxPacketMKISize]</p>	<p>Global parameter that defines the size (in bytes) of the Master Key Identifier (MKI) in SRTP Tx packets. You can also configure this feature per specific calls, using IP Profiles ('MKI Size' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Symmetric MKI Negotiation'</p> <pre>configure voip &gt; media security &gt; symmetric-mki</pre> <p>[EnableSymmetricMKI]</p>	<p>Global parameter that enables symmetric MKI negotiation. You can also configure this feature per specific calls, using IP Profiles ('Symmetric MKI' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Offered SRTP Cipher Suites'</p> <pre>configure voip &gt; media security &gt; offer-srtp-cipher</pre>	<p>Defines the offered crypto suites (cipher encryption algorithms) for SRTP.</p>

Parameter	Description
[SRTPofferedSuites]	<ul style="list-style-type: none"> <li>■ [0] <b>All</b> = (Default) All available crypto suites.</li> <li>■ [1] <b>AES-CM-128-HMAC-SHA1-80</b> = device uses AES-CM encryption with a 128-bit key and HMAC-SHA1 message authentication with a 80-bit tag.</li> <li>■ [2] <b>AES-CM-128-HMAC-SHA1-32</b> = device uses AES-CM encryption with a 128-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> <li>■ [4] <b>ARIA-CM-128-HMAC-SHA1-80</b> = device uses ARIA encryption algorithm with a 128-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> <li>■ [8] <b>ARIA-CM-192-HMAC-SHA1-80</b> = device uses ARIA encryption algorithm with a 192-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> <li>■ [16] <b>AES-256-CM-HMAC-SHA1-32</b> = AES-CM encryption with a 256-bit key and HMAC-SHA1 message authentication with a 32-bit tag.</li> <li>■ [32] <b>AES-256-CM-HMAC-SHA1-80</b> = AES-CM encryption with a 256-bit key and HMAC-SHA1 message authentication with an 80-bit tag.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For enabling ARIA encryption, use the [AriaProtocolSupport] parameter.</li> <li>■ For the Gateway application, if you configure the parameter to <b>All</b>, the device sends only four crypto lines ('a=crypto') in the</li> </ul>

Parameter	Description
	<p>SDP Offer, which excludes the AES 256 crypto suites. Therefore, if you want to offer an AES 256 crypto suite, you need to configure the parameter to <b>AES-256-CM-HMAC-SHA1-32</b> or <b>AES-256-CM-HMAC-SHA1-80</b>.</p> <ul style="list-style-type: none"> <li>■ The parameter also affects the selection of the crypto in the device's answer. For example, if the device receives an offer with two crypto lines ('a=crypto:') containing HMAC_SHA1_80 and HMAC_SHA_32, it uses the HMAC_SHA_32 key in its SIP 200 OK response if the parameter is configured to <b>AES-CM-128-HMAC-SHA1-32</b>.</li> </ul>
<pre>configure voip &gt; sbc settings &gt; sbc-dtls-mtu</pre> <p>[SbcDtlsMtu]</p>	<p>Defines the maximum transmission unit (MTU) size for the DTLS handshake. The device doesn't attempt to send handshake packets that are larger than the configured value. Adjusting the MTU is useful when there are network constraints on the size of packets that can be sent.</p> <p>The valid value range is 228 to 1500. The default is 1400.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<pre>configure voip &gt; sbc settings &gt; dtls-time-between-transmissions</pre> <p>[DTLSTimeBetweenTransmissions]</p>	<p>Defines the minimum interval (in msec) that the device waits between transmission of DTLS packets in the same DTLS handshake. The configured value is applied in a "best-effort" manner (i.e., time between transmitted DTLS packets in the same handshake may differ due to constraints on the network layer and</p>

Parameter	Description
	<p>load on the device).</p> <p>The valid value is 0 (no forced delay between DTLS packet transmissions) to 100. The default is 5.</p>
<p>'ARIA Protocol Support'</p> <pre>configure voip &gt; media security &gt; ARIA-protocol-support</pre> <p>[AriaProtocolSupport]</p>	<p>Enables ARIA algorithm cipher encryption for SRTP. This is an alternative option to the existing support for the AES algorithm. ARIA is a symmetric key block cipher algorithm standard developed by the Korean National Security Research Institute.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To configure the ARIA bit-key encryption size (128 or 192 bit) with HMAC SHA-1 cryptographic hash function, use the SRTPofferedSuites parameter.</li> <li>■ The ARIA feature is available only if the device is installed with a License Key that includes this feature. For installing a License Key, see <a href="#">License Key</a> on page 1362.</li> </ul>
<p>'Authentication on Transmitted RTP Packets'</p> <pre>configure voip &gt; media security &gt; RTP-authentication-disable-tx</pre> <p>[RTPAuthenticationDisableTx]</p>	<p>Enables authentication on transmitted RTP packets in a secured RTP session.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Enable</b> (default)</li> <li>■ [1] <b>Disable</b></li> </ul>
<p>'Encryption on Transmitted RTP Packets'</p> <pre>configure voip &gt; media security &gt; RTP-encryption-disable-tx</pre> <p>[RTPEncryptionDisableTx]</p>	<p>Enables encryption on transmitted RTP packets in a secured RTP session.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Enable</b> (default)</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Disable</b></li> </ul>
<p>'Encryption on Transmitted RTCP Packets'</p> <pre>configure voip &gt; media security &gt; RTCP-encryption-disable-tx</pre> <p>[RTCPEncryptionDisableTx]</p>	<p>Enables encryption on transmitted RTCP packets (outgoing leg) in a secured RTP session (i.e., SRTP). The device generates the cryptos.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Enable</b> (default)</li> <li>■ [1] <b>Disable</b></li> </ul> <p><b>Note:</b> The parameter is applicable only if the IP Profile parameter 'Encryption on RTCP Packets' is configured to <b>As Is</b> for the outgoing leg.</p>
<p>'SRTP Tunneling Authentication for RTP'</p> <pre>configure voip &gt; media security &gt; srtp-tnl-vld-rtp-auth</pre> <p>[SRPTunnelingValidateRTPRxAuthentication]</p>	<p>Enables validation of SRTP tunneling authentication for RTP.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device doesn't perform any validation and forwards the packets as is.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device validates the packets (e.g., sequence number) and if successful, forwards the packets. If validation fails, it drops the packets.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to SRTP-to-SRTP calls and when both endpoints use the same authentication keys.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'SRTP Tunneling Authentication for RTCP'</p> <pre>configure voip &gt; media security &gt; srtp-tnl-vld-rtcp-auth</pre> <p>[SRPTunnelingValidateRTCPRxAuthentication]</p>	<p>Enables validation of RTP tunneling authentication for RTCP.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device doesn't perform any validation</li> </ul>

Parameter	Description
	<p>and forwards the packets as is.</p> <ul style="list-style-type: none"> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device validates the packets (e.g., sequence number) and if successful, forwards the packets. If validation fails, it drops the packets.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to SRTP-to-SRTP calls and when both endpoints use the same authentication keys.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; reset-srtp-upon-re-key</pre> <p>[ResetSRTPStateUponRekey]</p>	<p>Global parameter that enables synchronization of the SRTP state between the device and a server when a new SRTP key is generated upon a SIP session expire. You can also configure this feature per specific calls, using IP Profiles ('Reset SRTP Upon Re-key' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</li> <li>■ This parameter resets the SRTP stream on both legs. If you want the device to reset only the SRTP stream with the leg (call party) that changed the crypto key, enable this parameter and the [SrtpResetTxRxSeparately]</li> </ul>

Parameter	Description
	parameter (below).
<pre>configure voip &gt; media security &gt; srtp-reset-tx-rx-separately</pre> <p>[SrtpResetTxRxSeparately]</p>	<p>Enables the device to reset only the SRTP stream (roll-over counter / ROC index and other SRTP fields) with the call party that changed the SRTP key ('a=crypto' line in SDP body) during a call. It doesn't reset the SRTP stream with the other call party. The SRTP key is sometimes updated by the call party, using a SIP re-INVITE message (for example, due to a session refresh).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled</li> <li>■ [1] = Enabled</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For this functionality, you also need to enable the 'Reset SRTP Upon Re-key' (ResetSRTPStateUponRekey) parameter.</li> <li>■ If the [SrtpResetTxRxSeparately] parameter is disabled and the 'Reset SRTP Upon Re-key' parameter is enabled, the device resets the SRTP stream of both call parties if the key is changed.</li> </ul>

## TLS Parameters

The Transport Layer Security (TLS) parameters are described in the table below.

**Table 73-29:TLS Parameters**

Parameter	Description
<p>'TLS Client Re-Handshake Interval'</p> <pre>configure network &gt; security-settings &gt; tls- re-hndshk-int</pre> <p>[TLSReHandshakeInterval]</p>	<p>Defines the time interval (in minutes) between TLS Re-Handshakes initiated by the device.</p> <p>The interval range is 0 to 1,500 minutes. The default is 0 (i.e., no TLS Re-Handshake).</p>

Parameter	Description
<p>'TLS Mutual Authentication'</p> <pre>configure network &gt; security-settings &gt; sips- require-client- certificate</pre> <p>[SIPSRequireClientCertificate]</p>	<p>Defines the device's mode of operation regarding mutual authentication and certificate verification for TLS connections for SIP.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled: <ul style="list-style-type: none"> <li>✓ Device acts as a client: Verification of the server's certificate depends on the [VerifyServerCertificate] parameter.</li> <li>✓ Device acts as a server: The device doesn't request the client certificate.</li> </ul> </li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled: <ul style="list-style-type: none"> <li>✓ Device acts as a client: Verification of the server certificate is required to establish the TLS connection.</li> <li>✓ Device acts as a server: The device requires the receipt and verification of the client certificate to establish the TLS connection.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure this feature per SIP Interface (see <a href="#">Configuring SIP Interfaces</a> on page 570).</li> <li>■ You can change the SIPS certificate files using the [HTTPSCertFileName] and [HTTPSRootFileName] parameters.</li> </ul>
<p>'Peer Host Name Verification Mode'</p> <pre>configure network &gt; security-settings &gt; peer- hostname-verification- mode</pre> <p>[PeerHostNameVerificationMode]</p>	<p>Enables the device to verify the Subject Name of a TLS certificate received from SIP entities for authentication and establishing TLS connections.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Server Only</b> = The device verifies the certificate's Subject Name only when it acts as a client for the TLS connection.</li> <li>■ [2] <b>Server &amp; Client</b> = The device verifies the certificate's Subject Name when it acts as a server or client for the TLS connection.</li> </ul> <p>If the device receives a certificate from a SIP entity (IP Group) and the parameter is configured to <b>Server Only</b> or <b>Server &amp; Client</b>, it attempts to</p>

Parameter	Description
	<p>authenticate the certificate based on the certificate's address:</p> <ol style="list-style-type: none"> <li>1. If the connection was classified to a Proxy Set, the device compares the certificate's Subject Alternative Names (SANs) with the Proxy Set's addresses (IP address or FQDN). The device checks the FQDN itself and not the DNS-resolved IP addresses.</li> <li>2. If a SAN matches an address, the device considers the certificate as valid and establishes the TLS connection and allows the call.</li> <li>3. If there is no match and the SAN is marked as "critical", the device rejects the call. If there is no match and the SAN isn't marked as "critical", the device compares the Proxy Set's 'TLS Remote Subject Name' parameter value (or global [TLSRemoteSubjectName] parameter) with the certificate's Common Name (CN). If they match, the device establishes the TLS connection and allows the call; otherwise, the device rejects the call.</li> </ol> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure this functionality per Proxy Set (see <a href="#">Configuring Proxy Sets</a> on page 632). If configured for a Proxy Set, the Proxy Set's settings override this global parameter's settings.</li> <li>■ If you configure the parameter to <b>Server &amp; Client</b>, enable the global 'TLS Mutual Authentication' parameter [SIPSRequireClientCertificate].</li> <li>■ For FQDN, the certificate may use wildcards (*) to replace parts of the domain name.</li> </ul>
<p>'TLS Remote Subject Name'</p> <pre>configure network &gt; security-settings &gt; tls- rmt-subs-name</pre> <p>[TLSRemoteSubjectName]</p>	<p>Defines the Subject Name of the TLS certificate received from the remote side when establishing TLS connections.</p> <p>When the device receives the certificate from the remote side, it validates the certificate by comparing the certificate's Subject Alternative</p>

Parameter	Description
	<p>Names (SANs) with the Proxy Set's addresses (IP address and FQDN). If a SAN matches an address, the device considers the certificate as valid and establishes the TLS connection.</p> <p>If there is no match and the SAN is marked as "critical", the device doesn't establish a TLS connection and rejects the call. If there is no match and the SAN isn't marked as "critical", the device compares the parameter's value with the certificate's Common Name (CN). If they match, the device establishes a TLS connection; otherwise, the device doesn't establish a TLS connection and rejects the call.</p> <p>The valid range is a string of up to 49 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You can configure this functionality per Proxy Set (see <a href="#">Configuring Proxy Sets</a> on page 632). If configured for a Proxy Set, the Proxy Set's settings override this global parameter's settings.</li> <li>If the CN uses a domain name, the certificate can also use wildcards ('*') to replace parts of the domain name.</li> <li>The parameter is applicable only if you configure the global parameter [PeerHostNameVerificationMode] or Proxy Set parameter 'Peer Host Name Verification Mode' to <b>Server Only</b> or <b>Server &amp; Client</b>.</li> </ul>
<p>'TLS Client Verify Server Certificate'</p> <pre>configure network &gt; security-settings &gt; tls- vrfy-srvr-cert</pre> <p>[VerifyServerCertificate]</p>	<p>Enables the device, when acting as a client for TLS connections, to verify the Server certificate. The certificate is verified with the Root CA information.</p> <ul style="list-style-type: none"> <li>[0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>[1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> If Subject Name verification is needed, configure the [PeerHostNameVerificationMode] parameter as well.</p>
<p>'TLS Expiry Check Start'</p> <pre>configure network &gt;</pre>	<p>Defines when the device sends an SNMP alarm (acCertificateExpiryAlarm) to notify that the</p>

Parameter	Description
<pre>security-settings &gt; tls- expiry-check-start</pre> [TLSExpiryCheckStart]	<p>installed TLS server certificate (of TLS Contexts) is about to expire. This is defined by the number of days before the certificate's expiration date. For example, if configured to 5, the alarm is sent 5 days before the expiration date. For more information on the alarm, refer to the <a href="#">SBC-Gateway Series SNMP Alarm Reference Guide</a>.</p> <p>The valid value is 0 to 3650. The default is 60.</p>
<p>'TLS Expiry Check Period'</p> <pre>configure network &gt; security-settings &gt; tls- expiry-check-period</pre> [TLSExpiryCheckPeriod]	<p>Defines the periodical interval (in days) for checking the TLS server certificate expiry date (of TLS Contexts).</p> <p>The valid value is 1 to 3650. The default is 7.</p>

## SSH Parameters

Secure Shell (SSH) parameters are described in the table below.

**Table 73-30:SSH Parameters**

Parameter	Description
<p>'Enable SSH Server'</p> <pre>configure system &gt; cli-settings &gt; ssh</pre> [SSHServerEnable]	<p>Enables the device's embedded SSH server.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul>
<p>'Redundant Device Server Port'</p> <pre>configure system &gt; cli-settings &gt; ssh- red-device-port</pre> [SSHRedundantProxyPort]	<p>Defines the proxy SSH port number on the active device for accessing the redundant device's embedded SSH server from the active device for downloading files from the redundant device.</p> <p>The valid value is any valid port number. The default port is 0 (i.e., disabled).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only when the device is in HA mode.</li> <li>■ The port number must be different to the regular SSH port number, which is configured by the [SSHServerPort] parameter.</li> </ul>
<p>'Public Key'</p>	<p>Enables RSA or ECDSA public keys for SSH.</p>

Parameter	Description
<pre>configure system &gt; cli-settings &gt; ssh- require-public-key</pre> [SSHRequirePublicKey]	<ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. RSA or ECDSA public keys are optional if a public key is configured.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. RSA or ECDSA public keys are mandatory.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Public keys are configured per management user in the Local Users table (see <a href="#">Configuring Local Management User Accounts</a> on page 55).</li> <li>■ To define the key size, use the [TLSPkeySize] parameter.</li> </ul>
<p>'Max Payload Size'</p> <pre>ssh-max-payload-size</pre> [SSHMaxPayloadSize]	<p>Defines the maximum uncompressed payload size (in bytes) for SSH packets.</p> <p>The valid value is 550 to 32768. The default is 32768.</p>
<p>'Max Binary Packet Size'</p> <pre>configure system &gt; cli-settings &gt; ssh- max-binary-packet-size</pre> [SSHMaxBinaryPacketSize]	<p>Defines the maximum packet size (in bytes) for SSH packets.</p> <p>The valid value is 582 to 35000. The default is 35000.</p>
<p>'Maximum SSH Sessions'</p> <pre>configure system &gt; cli-settings &gt; ssh- max-sessions</pre> [SSHMaxSessions]	<p>Defines the maximum number of simultaneous SSH sessions.</p> <p>The valid range is 1 to 5. The default 5.</p>
<p>'Enable Last Login Message'</p> <pre>configure system &gt; cli-settings &gt; ssh- last-login-message</pre> [SSHEnableLastLoginMessage]	<p>Enables message display in SSH sessions of the time and date of the last SSH login. The message displays the number of unsuccessful login attempts since the last successful login.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul> <p><b>Note:</b> The last SSH login information is cleared when the device restarts.</p>
<p>'Max Login Attempts'</p> <pre>configure system &gt;</pre>	<p>Defines the maximum SSH login attempts allowed for entering an incorrect password by an administrator</p>

Parameter	Description
<pre>cli-settings &gt; ssh- max-login-attempts</pre> <p>[SSHMaxLoginAttempts]</p>	<p>before the SSH session is rejected.</p> <p>The valid range is 1 to 5. The default is 3.</p> <p><b>Note:</b> The new setting takes effect only for new subsequent SSH connections.</p>
<p>'Kex Algorithms String'</p> <pre>configure system &gt; cli-settings &gt; ssh- kex-algorithms-string</pre> <p>[SSHKexAlgorithmsString]</p>	<p>Defines the SSH Key Exchange Algorithms.</p> <p>The valid values include:</p> <ul style="list-style-type: none"> <li>■ diffie-hellman-group-exchange-sha256</li> <li>■ diffie-hellman-group14-sha1</li> <li>■ diffie-hellman-group1-sha1</li> <li>■ diffie-hellman-group14-sha256</li> <li>■ diffie-hellman-group16-sha512</li> <li>■ ecdh-sha2-nistp256</li> <li>■ ecdh-sha2-nistp384</li> <li>■ ecdh-sha2-nistp521</li> <li>■ curve25519-sha256</li> </ul> <p>You can configure the parameter with multiple values, using the colon (:) as a separator. For example, diffie-hellman-group1-sha1:diffie-hellman-group-exchange-sha256.</p> <p>The default is curve25519-sha256:ecdh-sha2-nistp256:ecdh-sha2-nistp384:ecdh-sha2-nistp521:diffie-hellman-group-exchange-sha256:diffie-hellman-group16-sha512:diffie-hellman-group14-sha256:diffie-hellman-group14-sha1.</p>
<p>'Ciphers String'</p> <pre>configure system &gt; cli-settings &gt; ssh- ciphers-string</pre> <p>[SSHCiphersString]</p>	<p>Defines the SSH cipher string.</p> <p>The valid values include:</p> <ul style="list-style-type: none"> <li>■ aes128-ctr</li> <li>■ aes128-cbc</li> <li>■ aes256-ctr</li> <li>■ aes256-cbc</li> </ul> <p>You can configure the parameter with multiple values, using the colon (:) as a separator. For example, aes128-ctr:aes128-cbc.</p> <p>The default is aes128-ctr:aes128-cbc.</p>

Parameter	Description
<b>'MACs String'</b> <code>configure system &gt;</code> <code>cli-settings &gt; ssh-</code> <code>macs-string</code> <b>[SSHMACsString]</b>	<p>Defines the SSH MAC algorithms.</p> <p>The valid values include:</p> <ul style="list-style-type: none"> <li>■ hmac-sha1</li> <li>■ hmac-sha2-256</li> </ul> <p>You can configure the parameter with both values using the colon (:) as a separator, for example, hmac-sha1:hmac-sha2-256.</p> <p>The default is hmac-sha1:hmac-sha2-256.</p>

## IDS Parameters

The Intrusion Detection System (IDS) parameters are described in the table below.

**Table 73-31:IDS Parameters**

Parameter	Description
<b>'Intrusion Detection System (IDS)'</b> <code>configure voip &gt; ids</code> <code>global-parameters &gt;</code> <code>enable-ids</code> <b>[EnableIDS]</b>	<p>Enables the IDS feature.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<b>'Alarm Clear Period'</b> <code>configure voip &gt; ids</code> <code>global-parameters &gt;</code> <code>alarm-clear-period</code> <b>[IDSAlarmClearPeriod]</b>	<p>Defines the interval (in seconds) after which an IDS alarm is cleared from the Active Alarms table if no thresholds are crossed during this time. However, this "quiet" period must be at least twice the Threshold Window value. For example, if IDSAlarmClearPeriod is set to 20 sec and the Threshold Window is set to 15 sec, the IDSAlarmClearPeriod parameter is ignored and the alarm is cleared only after 30 seconds (2 x 15 sec).</p> <p>The valid value is 0 to 86400. The default is 300.</p>
<b>'Excluded Response Codes'</b> <code>configure voip &gt; ids</code> <code>global-parameters &gt;</code> <code>excluded-responses</code> <b>[IDSExcludedResponseCodes]</b>	<p>Defines the SIP response codes that are excluded from the IDS count for SIP dialog establishment failures.</p> <p>The valid value is 400 through to 699. The maximum length is 100 characters. You can configure the parameter with multiple codes, where each code is separated by a comma (without spaces). The default is 408,422,423,480,481,486,487,500,501,502,503,504,505,600.</p>

Parameter	Description
	<p>For more information, see <a href="#">Configuring SIP Response Codes to Exclude from IDS</a> on page 275.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter applies only to rejected responses received from the remote network; not rejected responses generated by the device (except for 404).</li> <li>■ The response codes 401 and 407 are considered authentication failures and therefore, are not applicable to this parameter.</li> </ul>

## OCSP Parameters

The Online Certificate Status Protocol (OCSP) parameters are described in the table below.

**Table 73-32:OCSP Parameters**

Parameter	Description
<p>'Enable OCSP Server'</p> <pre>configure network &gt; ocsp &gt; enable</pre> <p>[OCSPEnable]</p>	<p>Enables or disables certificate checking using OCSP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For a description of OCSP, see <a href="#">Configuring Certificate Revocation Checking (OCSP)</a>.</p>
<p>'Primary Server IP'</p> <pre>configure network &gt; ocsp &gt; server-ip</pre> <p>[OCSPServerIP]</p>	<p>Defines the IP address of the OCSP server.</p> <p>The default IP address is 0.0.0.0.</p>
<p>'Secondary Server IP'</p> <pre>configure network &gt; ocsp &gt; secondary-server-ip</pre> <p>[OCSPSecondaryServerIP]</p>	<p>Defines the IP address (in dotted-decimal notation) of the secondary OCSP server (optional).</p> <p>The default IP address is 0.0.0.0.</p>
<p>'Server Port'</p> <pre>configure network &gt; ocsp &gt; server-port</pre> <p>[OCSPServerPort]</p>	<p>Defines the OCSP server's TCP port number.</p> <p>The default port number is 2560.</p>

Parameter	Description
'Default Response When Server Unreachable' configure network > ocsp > default-response [OCSPDefaultResponse]	Determines whether the device allows or rejects peer certificates when the OCSP server cannot be contacted.  ■ [0] <b>Reject</b> (default)  ■ [1] <b>Allow</b>

## Proxy, Registration and Authentication Parameters

The proxy server, registration and authentication SIP parameters are described in the table below.

**Table 73-33:Proxy, Registration and Authentication SIP Parameters**

Parameter	Description
'Use Default Proxy' configure voip > sip-definition proxy-and-registration > enable-proxy [IsProxyUsed]	Enables the use of Proxy Set ID 0 (for backward compatibility).  ■ [0] <b>No</b> = (Default) Proxy Set 0 is not used. ■ [1] <b>Yes</b> = Proxy Set ID 0 is used.  <b>Note:</b>  ■ The parameter must be used only for backward compatibility. If not required for backward compatibility, make sure that the parameter is disabled and use the Proxy Sets table for configuring all your Proxy Sets (except for Proxy Set #0).  ■ If you are not using a proxy server, you must configure routing rules to route the call.  ■ The parameter is applicable only to the Gateway application.
'Proxy Name' configure voip > sip-definition proxy-and-registration > proxy-name [ProxyName]	Defines the Home Proxy domain name. If specified, this name is used as the Request-URI in REGISTER, INVITE and other SIP messages, and as the host part of the To header in INVITE messages. If not specified, the Proxy IP address is used instead. The valid value is a string of up to 49 characters.  <b>Note:</b> The parameter functions together with the [UseProxyIPasHost] parameter.

Parameter	Description
<p>'Use Proxy IP as Host'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; use-proxy- ip-as-host</pre> <p>[UseProxyIPasHost]</p>	<p>Enables the use of the proxy server's IP address (in dotted-decimal notation) as the host name in SIP From and To headers in REGISTER requests.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>If the parameter is disabled and the device registers to an IP Group (i.e., proxy server), it uses the string configured by the ProxyName parameter as the host name in the REGISTER's Request-URI and uses the string configured by the IP Groups table parameter, SIPGroupName as the host name in the To and From headers. If the IP Group is configured with a Proxy Set that has multiple IP addresses, all the REGISTER messages sent to these proxies are sent with the same host name.</p> <p><b>Note:</b> If the parameter is disabled and the [ProxyName] parameter is not configured, the proxy's IP address is used as the host name in the REGISTER Request-URI.</p>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; use-rand- user</pre> <p>[UseRandomUser]</p>	<p>Enables the device to assign a random string value for the user part of the SIP Contact header in the REGISTER message (generated by the device) for new user Account registrations with the device.</p> <p>The string includes letters and may include numbers, but it always begins with a letter. The string is unique to each Account. An example of a randomly assigned user part is shown (in bold) below:</p> <p>Contact:</p> <pre>&lt;sip:HRaNEmZnfX6xZl4 @pc33.atlanta.com&gt;</pre> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable.</li> <li>■ [1] = Enable. The device generates <b>one</b> unique string for the user part per Account. Each Account registers with its unique user part string. All INVITE messages for this new Account are sent with this unique user part. This same unique user part string is also used for registration refreshes and for un-registering</li> </ul>

Parameter	Description
	<p>the Account.</p> <ul style="list-style-type: none"> <li>■ [2] = Enable per registration. The device generates a new string for the user part for <b>each</b> REGISTER message sent for the Account, including initial registration as well as registration refreshes.</li> </ul> <p>The device stops using the random user part in the following scenarios:</p> <ul style="list-style-type: none"> <li>■ The user sends an unregister request.</li> <li>■ The device sends a REGISTER request for the user, but doesn't receive a SIP 200 OK in response.</li> <li>■ The parameter is disabled. When enabled again, new random user parts are assigned to the Accounts.</li> </ul> <p>To configure Accounts, see <a href="#">Configuring Registration Accounts</a> on page 777.</p>
<p>'Redundancy Mode'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; redundancy-mode [ProxyRedundancyMode]</pre>	<p>Determines whether the device switches back to the primary Proxy after using a redundant Proxy.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Parking</b> = (Default) The device continues working with a redundant (now active) Proxy until the next failure, after which it works with the next redundant Proxy.</li> <li>■ [1] <b>Homing</b> = The device always tries to work with the primary Proxy server (i.e., switches back to the primary Proxy whenever it's available).</li> </ul> <p><b>Note:</b> To use this Proxy Redundancy mechanism, you need to enable the keep-alive with Proxy option, by setting the parameter EnableProxyKeepAlive to 1 or 2.</p>
<p>'Proxy IP List Refresh Time'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; proxy-ip- lst-rfrsh-time [ProxyIPListRefreshTime]</pre>	<p>Defines the interval (in seconds) at which the device performs DNS resolution for Proxy Sets that are configured with an FQDN (host name) to translate (resolve) it into IP addresses. The device maintains a cache of DNS resolutions, and will use cached responses as long as the TTL has not</p>

Parameter	Description
	<p>expired. If the TTL is expired, a new DNS request is sent to the DNS server.</p> <p>For example, if configured to 60, the device queries the DNS server every 60 seconds. If successful, the device refreshes the Proxy Set's list of DNS-resolved IP addresses.</p> <p>The valid value is 0, or 5 to 2,000,000. The default is 60. The value 0 disables periodic DNS queries and DNS resolution is done only once - upon device restart, device power up, or new and modified configuration.</p> <p>The device caches the DNS-resolved IP addresses of the last successful DNS query of a Proxy Set, which is used if the DNS server goes offline. This functionality occurs regardless of the setting of the [DNSCache] parameter.</p>
<pre>configure network &gt; network-settings &gt; dns- cache [DNSCache]</pre>	<p>Enables the device to cache (store) DNS-resolved IP addresses of the last successful DNS query of entities (e.g., for Remote Web Services, Access List, and LDAP servers) that are configured with an FQDN. The device clears every entry in the cache 30 minutes after their DNS time-to-live (TTL) value expires.</p> <p>When enabled and the DNS server doesn't respond (for whatever reason) to the device's DNS query request, instead of taking the entity offline, the device reuses the cached DNS-resolved addresses, thereby maintaining call service. In such a scenario, the device continues to query the DNS server every 10 seconds. However, if the DNS server is still not responding after the device has cleared the cached DNS-resolved IP addresses, the device considers the entity as offline.</p> <p>■ [0] <b>Disable</b></p> <p>■ [1] <b>Enable</b> (default)</p>
<p>'Enable Fallback to Routing Table'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; fallback- to-routing</pre>	<p>Enables the device to fallback to the Tel-to-IP Routing table for call routing when proxy servers are unavailable. When this occurs, the device continues scanning for an online proxy. If the device detects an online proxy, it stops using the</p>

Parameter	Description
[IsFallbackUsed]	<p>Tel-to-IP Routing table and switches back to proxy routing.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> To enable the redundant Proxy mechanism, configure the [EnableProxyKeepAlive] parameter to 1 or 2.</p>
<p>'Prefer Routing Table'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; prefer- routing-table</pre> <p>[PreferRouteTable]</p>	<p>Enables the device to route calls according to the Tel-to-IP Routing table instead of Proxy server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Only a Proxy server is used to route calls.</li> <li>■ [1] <b>Yes</b> = The device checks the routing rules in the Tel-to-IP Routing table for a match with the Tel-to-IP call. Only if a match is not found is a Proxy used.</li> </ul>
<p>'Always Use Proxy'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; always- use-proxy</pre> <p>[AlwaysSendToProxy]</p>	<p>Enables the device to send SIP requests and responses through a SIP proxy server. Otherwise, it uses the standard SIP routing rules.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> The parameter is applicable only if a Proxy server is used (i.e., [IsProxyUsed] parameter is configured to 1).</p>
<p>'SIP Re-routing Mode'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; sip- rerouting-mode</pre> <p>[SIPReroutingMode]</p>	<p>Defines the routing mode after call redirection (i.e., a 3xx SIP response is received) or call transfer (i.e., a SIP REFER request is received).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Standard Mode</b> = (Default) INVITE messages that are generated as a result of Transfer or Redirect are sent directly to the URI, according to the Refer-To header in the REFER message, or Contact header in the 3xx response.</li> <li>■ [1] <b>Send to Proxy</b> = Sends a new INVITE to the Proxy. If the INVITE sent to the Proxy fails, the device re-routes the call according to <b>Standard Mode</b>.</li> </ul> <p><b>Note:</b> This option is applicable only if a Proxy</p>

Parameter	Description
	<p>server is used and the [AlwaysSendtoProxy] parameter is configured to 0.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Use Routing Table</b> = The device uses the Routing table to locate the destination and then sends a new INVITE to this destination. If the INVITE fails, the device re-routes the call according to <b>Standard Mode</b>. If DNS resolution fails, the device attempts to route the call to the Proxy. If routing to the Proxy also fails, the Redirect/Transfer request is rejected.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ If the parameter is configured to <b>Use Routing Table</b>, you can use the [XferPrefix] parameter to configure different routing rules for redirect calls.</li> <li>■ The parameter is disregarded if the [AlwaysSendToProxy] parameter is configured to 1.</li> </ul>
<p>'DNS Query Type'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; dns-query [DNSQueryType]</pre>	<p>Enables the use of DNS Naming Authority Pointer (NAPTR) and Service Record (SRV) queries to resolve Proxy and Registrar servers and to resolve all domain names that appear in the SIP Contact and Record-Route headers.</p> <ul style="list-style-type: none"> <li>■ [0] <b>A-Record</b> = (Default) No NAPTR or SRV queries are performed.</li> <li>■ [1] <b>SRV</b> = If the Proxy/Registrar IP address parameter, Contact/Record-Route headers, or IP address configured in the routing tables contain a domain name, an SRV query is performed. The device uses the first host name received from the SRV query. The device then performs a DNS A-record query for the host name to locate an IP address.</li> <li>■ [2] <b>NAPTR</b> = An NAPTR query is performed. If it is successful, an SRV query is sent according to the information received in the NAPTR</li> </ul>

Parameter	Description
	<p>response. If the NAPTR query fails, an SRV query is performed according to the configured transport type.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the Proxy/Registrar IP address parameter, the domain name in the Contact/Record-Route headers, or the IP address configured in the routing tables contain a domain name with a port definition, the device performs a regular DNS A-record query.</li> <li>■ If a specific Transport Type is configured, a NAPTR query is not performed.</li> <li>■ To enable NAPTR/SRV queries for Proxy servers only, use the global parameter ProxyDNSQueryType, or use the Proxy Sets table.</li> </ul>
<p>'Proxy DNS Query Type'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; proxy-dns- query</pre> <p>[ProxyDNSQueryType]</p>	<p>Global parameter that defines the DNS query record type for resolving the Proxy server's configured domain name (FQDN) into an IP address.</p> <ul style="list-style-type: none"> <li>■ [0] <b>A-Record</b>= (Default) A-record DNS query.</li> <li>■ [1] <b>SRV</b> = If the Proxy IP address parameter contains a domain name without port definition (e.g., ProxyIP = domain.com), an SRV query is performed. The SRV query returns up to four Proxy host names and their weights. The device then performs DNS A-record queries for each Proxy host name (according to the received weights) to locate up to four Proxy IP addresses. Thus, if the first SRV query returns two domain names and the A-record queries return two IP addresses each, no additional searches are performed.</li> <li>■ [2] <b>NAPTR</b> = NAPTR query is done. If successful, an SRV query is sent according to the information received in the NAPTR response. If the NAPTR query fails, an SRV query is done according to the configured transport type. If the Proxy IP address parameter contains a</li> </ul>

Parameter	Description
	<p>domain name with port definition (e.g., ProxyIP = domain.com:5080), the device performs a regular DNS A-record query. If a specific Transport Type is defined, a NAPTR query is not performed.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature can be configured per Proxy Set in the Proxy Sets table (see <a href="#">Configuring Proxy Sets</a> on page 632).</li> <li>■ When enabled, NAPTR/SRV queries are used to discover Proxy servers even if the parameter DNSQueryType is disabled.</li> </ul>
<p>'Use Gateway Name for OPTIONS'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; use-gw- name-for-opt</pre> <p>[UseGatewayNameForOptions]</p>	<p>Defines if the device's IP address, proxy's IP address, or device's name is used as the host part for the Request-URI in keep-alive SIP OPTIONS messages sent to the proxy (if enabled). The device uses the OPTIONS messages as a keep-alive with its primary and redundant SIP proxy servers. Proxy keep-alive by SIP OPTIONS is enabled per Proxy Set, by configuring the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS</b> (see <a href="#">Configuring Proxy Sets</a> on page 632).</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device's IP address is used in the keep-alive OPTIONS messages.</li> <li>■ [1] <b>Yes</b> = The device's name, configured by the [SIPGatewayName] parameter, is used in the keep-alive OPTIONS messages.</li> <li>■ [2] <b>Server</b> = The proxy's IP address is used in the SIP From and To headers in the keep-alive OPTIONS messages.</li> </ul>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; failed- options-retry-time</pre> <p>[FailedOptionsRetryTime]</p>	<p>Defines how long the device waits (in seconds) before re-sending a SIP OPTIONS keep-alive message to the proxy after the device considers the proxy as offline. It considers the proxy as offline after all the device's retransmissions (configured by the Proxy Set parameter 'Failure Detection Retransmissions') have failed.</p> <p>The valid value range is 1 to 3600. The default is 1.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you enable proxy keep-alive by SIP OPTIONS messages (i.e., 'Proxy Keep-Alive' parameter configured to <b>Using OPTIONS</b> in the Proxy Sets table).</li> <li>■ A failed SIP response is either no response, or a response that is specified by the Proxy Sets table parameter 'Keep-Alive Failure Responses'.</li> </ul>
<pre>configure voip &gt; sbc settings &gt; abort-retries- on-icmp-error</pre> <p>[AbortRetriesOnICMPError]</p>	<p>When using UDP as the transport protocol, the device retries failed transmissions to a proxy server according to the Proxy Set parameter 'Failure Detection Retransmissions'. However, when the failed attempt receives an ICMP error (which indicates Host Unreachable or Network Unreachable) as opposed to a timeout, it may be desirable to abandon additional retries in favor of trying the next IP address (proxy server) in the Proxy Set. This is often desirable when Proxy Hot Swap is enabled.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable. The device retries the same proxy according to the Proxy Set parameter 'Failure Detection Retransmissions' (regardless of error response type).</li> <li>■ [1] = (Default) Enable. Upon the receipt of an ICMP error response, the device doesn't try the proxy again (i.e., ignores the Proxy Set parameter 'Failure Detection Retransmissions'), but instead tries the next proxy in the Proxy Set.</li> </ul>
<p>'User Name'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; user-name- 4-auth</pre> <p>[UserName]</p>	<p>Defines the username for registration and Basic/Digest authentication with a Proxy/Registrar server.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only if single device registration is used (i.e., 'Registration Mode' parameter is configured to <b>Per Gateway</b> [AuthenticationMode]).</li> <li>■ Analog interfaces: Instead of configuring the parameter, the Authentication table can be used (see <a href="#">Configuring Authentication</a> on page 1093).</li> </ul>
<b>'Password'</b> <code>configure voip &gt; sip-definition proxy-and-registration &gt; auth-password</code> [AuthPassword]	<p>Defines the password for Basic/Digest authentication with a Proxy/Registrar server. A single password is used for all device ports. The default is 'Default_Passwd'.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Analog interfaces: Instead of configuring the parameter, the Authentication table can be used (see <a href="#">Configuring Authentication</a> on page 1093).</li> <li>■ The parameter cannot be configured with wide characters.</li> </ul>
<b>'Cnonce'</b> <code>configure voip &gt; sip-definition proxy-and-registration &gt; cnonce-4-auth</code> [Cnonce]	<p>Defines the Cnonce string used by the SIP server and client to provide mutual authentication. The value is free format, i.e., 'Cnonce = 0a4f113b'. The default is 'Default_Cnonce'.</p>
<b>'Challenge Caching Mode'</b> <code>configure voip &gt; sip-definition proxy-and-registration &gt; challenge-caching</code> [SIPChallengeCachingMode]	<p>Enables local caching of SIP message authorization challenges from Proxy servers.</p> <p>The device sends the first request to the Proxy without authorization. The Proxy sends a 401/407 response with a challenge for credentials. The device saves (caches) the response for further uses. The device sends a new request with the appropriate credentials. Subsequent requests to the Proxy are automatically sent with credentials (calculated from the saved challenge). If the Proxy doesn't accept the new request and sends another challenge, the old challenge is replaced with the new one. One of the benefits of the feature is that</p>

Parameter	Description
	<p>it may reduce the number of SIP messages transmitted through the network.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) Challenges are not cached. Every new request is sent without preliminary authorization. If the request is challenged, a new request with authorization data is sent.</li> <li>■ [1] <b>INVITE Only</b> = Challenges issued for INVITE requests are cached. This prevents a mixture of REGISTER and INVITE authorizations.</li> <li>■ [2] <b>Full</b> = Caches all challenges from the proxies.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Challenge caching is used with all proxies and not only with the active one.</li> <li>■ For the Gateway application: The challenge can be cached per endpoint or per Account.</li> <li>■ For the SBC application: The challenge can be cached per Account or per user whose credentials are configured in the SBC User Information table.</li> </ul>
<b>Registrar Parameters</b>	
<p>'Enable Registration'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; enable- registration</pre> <p>[IsRegisterNeeded]</p>	<p>Enables the device to register with a Proxy/Registrar server. Registration occurs when the device is powered up and periodically, configured by the [RegistrationTime] parameter.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The device sends a REGISTER request for each channel or for the entire device (according to the 'Registration Mode' parameter).</li> </ul>
<p>'Registrar Name'</p> <pre>configure voip &gt; sip-</pre>	<p>Defines the Registrar domain name. If specified, the name is used as the Request-URI in REGISTER</p>

Parameter	Description
<pre>definition proxy-and- registration &gt; registrar- name</pre> <p>[RegistrarName]</p>	<p>messages. If it isn't specified (default), the Registrar IP address, or Proxy name or IP address is used instead.</p> <p>The valid range is up to 100 characters.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Registrar IP Address'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; ip-addr- rgstrr</pre> <p>[RegistrarIP]</p>	<p>Defines the IP address (or FQDN) and port number (optional) of the Registrar server. The IP address is in dotted-decimal notation, e.g., 201.10.8.1:&lt;5080&gt;.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ If not specified, the REGISTER request is sent to the primary Proxy server.</li> <li>■ When a port number is specified, DNS NAPTR/SRV queries aren't performed, even if the parameter DNSQueryType is set to 1 or 2.</li> <li>■ If the parameter RegistrarIP is set to an FQDN and is resolved to multiple addresses, the device also provides real-time switching (hotswap mode) between different Registrar IP addresses (the parameter IsProxyHotSwap is set to 1). If the first Registrar doesn't respond to the REGISTER message, the same REGISTER message is sent immediately to the next Proxy. To allow this mechanism, the parameter EnableProxyKeepAlive must be set to 0.</li> <li>■ When a specific transport type is defined using the parameter RegistrarTransportType, a DNS NAPTR query is not performed even if the parameter DNSQueryType is set to 2.</li> </ul>
<p>'Registrar Transport Type'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; registrar- transport</pre> <p>[RegistrarTransportType]</p>	<p>Determines the transport layer used for outgoing SIP dialogs initiated by the device to the Registrar.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> (default)</li> <li>■ [0] <b>UDP</b></li> <li>■ [1] <b>TCP</b></li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] TLS</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ When set to 'Not Configured', the value of the parameter SIPTransportType is used.</li> </ul>
<p>'Registration Time'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; registration-time</pre> <p>[RegistrationTime]</p>	<p>Defines the time interval (in seconds) for registering to a Proxy server. The value is used in the SIP Expires header. The parameter also defines the time interval between Keep-Alive messages when the parameter EnableProxyKeepAlive is set to 2 (REGISTER).</p> <p>Typically, the device registers every 3,600 sec (i.e., one hour). The device resumes registration according to the parameter RegistrationTimeDivider.</p> <p>The valid range is 10 to 2,000,000. The default is 180.</p>
<p>'Re-registration Timing [%]'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; re- registration-timing</pre> <p>[RegistrationTimeDivider]</p>	<p>Defines the re-registration timing (in percentage). The timing is a percentage of the re-register timing set by the Registrar server.</p> <p>The valid range is 50 to 100. The default is 50.</p> <p>For example: If the parameter is set to 70% and the Registration Expires time is 3600, the device re-sends its registration request after 3600 x 70% (i.e., 2520 sec).</p> <p><b>Note:</b> The parameter may be overridden if the parameter RegistrationTimeThreshold is greater than 0.</p>
<p>'Registration Retry Time'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; registration-retry-time</pre> <p>[RegistrationRetryTime]</p>	<p>Defines the time interval (in seconds) after which a registration request is re-sent if registration fails with a 4xx response or if there is no response from the Proxy/Registrar server.</p> <p>The default is 30 seconds. The range is 10 to 3600.</p> <p><b>Note:</b> Registration retry time can also be configured with the MaxRegistrationBackoffTime parameter.</p>

Parameter	Description
<p>'Max Registration Backoff Time'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; max- registration-backoff-time [MaxRegistrationBackoffTime]</pre>	<p>Defines a dynamic time-to-wait interval before the device attempts to register the SIP entity again after a registration failure. The parameter is applicable only to registrations initiated by the device on behalf of SIP entities (for example, User Info, Accounts, Endpoints or the device itself) with a SIP proxy server (registrar).</p> <p>The valid value is 0 to 3000000 (i.e., 3 million seconds). The default is 0 (i.e., disabled).</p> <p>In contrast to the <code>RegistrationRetryTime</code> parameter, which defines a fixed time to wait between registration attempts due to registration failure, this parameter configures the device to increase the time-to-wait interval for each subsequent registration attempt (per RFC 5626, Section 4.5) for a specific registration flow. In other words, the interval changes between registration attempts.</p> <p>The parameter operates together with the <code>RegistrationRetryTime</code> parameter. When the <code>MaxRegistrationBackoffTime</code> parameter is configured, the wait-time before another registration attempt increases after each failed registration (until it reaches the maximum value specified by the parameter).</p> <p>The device uses the following algorithm to calculate the incremental augmented wait-time between each registration attempt:</p> $\text{Wait Time} = \min (\text{max-time}, (\text{base-time} * (2 ^ \text{consecutive-failures})))$ <p>Where:</p> <ul style="list-style-type: none"> <li>■ <i>max-time</i> is the value configured by <code>MaxRegistrationBackoffTime</code></li> <li>■ <i>base-time</i> is the value configured by <code>RegistrationRetryTime</code></li> </ul> <p>For example, if <i>max-time</i> is 1800 seconds and <i>base-time</i> is 30 seconds, and there were three consecutive registration failures, then the upper-bound wait time is the minimum of (1800, 30*</p>

Parameter	Description
	<p>(<math>2^3</math>)), which is (1800, 240) and thus, the minimum of the two values is 240 (seconds). The actual time the device waits before retrying registration is computed by a uniform random time between 50% and 100% of the upper-bound wait time (e.g., for an upper-bound wait-time of 240, the actual wait-time is between 120 and 240 seconds). As can be seen from the algorithm, the upper-bound wait time can never exceed the value of the MaxRegistrationBackoffTime parameter.</p>
<p>'Registration Time Threshold'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; registration-time-thres</pre> <p>[RegistrationTimeThreshold]</p>	<p>Defines a threshold (in seconds) for re-registration timing. If the parameter is greater than 0, but lower than the computed re-registration timing (according to the parameter RegistrationTimeDivider), the re-registration timing is set to the following: timing set by the Registration server in the SIP Expires header minus the value of the parameter RegistrationTimeThreshold.</p> <p>The valid range is 0 to 2,000,000. The default is 0.</p>
<p>'Re-register On INVITE Failure'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; reg-on- invite-fail</pre> <p>[RegisterOnInviteFailure]</p>	<p>Enables an immediate re-registration if the device doesn't receive a response for its sent SIP INVITE request.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device immediately expires its re-registration timer and commences re-registration to the same Proxy upon any of the following scenarios: <ul style="list-style-type: none"> <li>✓ The response to an INVITE request is 407 (Proxy Authentication Required) without an authentication header included.</li> <li>✓ The remote SIP UA abandons a call before the device has received any provisional response (indicative of an outbound proxy server failure).</li> <li>✓ The remote SIP UA abandons a call and the only provisional response the device has received for the call is 100 Trying (indicative of a home proxy server failure,</li> </ul> </li> </ul>

Parameter	Description
	<p>i.e., the failure of a proxy in the route after the outbound proxy).</p> <ul style="list-style-type: none"> <li>✓ The device terminates a call due to the expiration of RFC 3261 Timer B or due to the receipt of a 408 (Request Timeout) response and the device has not received any provisional response for the call (indicative of an outbound proxy server failure).</li> <li>✓ The device terminates a call due to the receipt of a 408 (Request Timeout) response and the only provisional response the device has received for the call is the 100 Trying provisional response (indicative of a home proxy server failure).</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'ReRegister On Connection Failure'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; reg-on- conn-failure</pre> <p>[ReRegisterOnConnectionFailure]</p>	<p>Enables the device to perform a SIP re-registration upon a TCP/TLS connection failure.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<p>'Gateway Registration Name'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; gw- registration-name</pre> <p>[GWRegistrationName]</p>	<p>Defines the user part in the From and To headers in SIP REGISTER messages. If no value is specified (default) for the parameter, the [UserName] parameter is used instead.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The parameter is applicable only for single registration per device (i.e., 'Registration Mode' parameter is configured to <b>Per Gateway</b> [AuthenticationMode]). When the device registers each channel separately (i.e., 'Registration Mode' parameter configured to <b>Per Endpoint</b>), the username is set to the channel's phone number.</li> </ul>

Parameter	Description
<p>'Registration Mode'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; authentication-mode [AuthenticationMode]</pre>	<p>Defines the device's registration and authentication method.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Per Endpoint</b> = The device registers and authenticates each endpoint (B-channel, FXS, and FXO) separately with the endpoint's authentication username and password.</li> <li>■ [1] <b>Per Gateway</b> = (Default) Single registration and authentication is done for the entire device. This is typically used for FXO interfaces and digital interfaces.</li> <li>■ [3] <b>Per FXS</b> = The device registers and authenticates only endpoints that are FXS endpoints.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to endpoints that are either not associated with any row configured in the Trunk Group Settings table, or are associated with a row and the row's 'Registration Mode' parameter is not configured (see <a href="#">Configuring Trunk Group Settings</a> on page 937).</li> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>
<p>'Set Out-Of-Service On Registration Failure'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; set-oos- on-reg-failure [OOSOnRegistrationFail]</pre>	<p>Enables the device to set the endpoint, trunk, or entire device (i.e., all endpoints) to out-of-service if registration fails.</p> <p>If registration is per endpoint (i.e., 'Registration Mode' parameter is configured to <b>Per Endpoint</b>) or per Account (see <a href="#">Configuring Trunk Group Settings</a> on page 937) and a specific endpoint / Account registration fails (SIP 4xx or no response), the device sets that endpoint to out-of-service until a success response is received in a subsequent registration request. If registration is per the entire device (i.e., 'Registration Mode' parameter is configured to <b>Per Gateway</b>) and registration fails, the device sets all endpoints to out-of-service. If all the Accounts of a specific Trunk Group fail registration and if the Trunk Group comprises a</p>

Parameter	Description
	<p>complete trunk, the device sets the entire trunk to out-of-service.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The out-of-service method is configured using the [FXSOOSBehavior] parameter.</li> </ul>
<p>'Register By Served Trunk Group Status'</p> <pre>configure voip &gt; gateway advanced &gt; register-by- served-tg-status</pre> <p>[RegisterByTrunkGroupStatus]</p>	<p>Defines if the device sends a registration request (SIP REGISTER) to a Serving IP Group (SIP registrar), based on the Trunk Group's status (in-service or out-of-service).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Register Only if In-Service</b> = (Default) The device sends a registration request only if the Trunk Group's status is in-service.</li> <li>■ [1] <b>Register Always</b> = The device sends a registration request regardless of the Trunk Group's status (in-service or out-of-service). For example, even if the Trunk Group is configured, but its E1/T1 PSTN cable has yet to be connected to the device (i.e., out-of-service), the device still sends a registration request.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application (ISDN PRI and CAS).</li> <li>■ The parameter is applicable only if the Trunk Group's 'Registration Mode' parameter in the Trunk Group Settings table is configured to <b>Per Account</b> (see <a href="#">Configuring Trunk Group Settings</a> on page 937).</li> </ul>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; expl-un- reg</pre> <p>[UnregistrationMode]</p>	<p>Enables the device to perform explicit unregisters.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = The device sends an asterisk ("*") value in the SIP Contact header, instructing the</li> </ul>

Parameter	Description
	<p>Registrar server to remove all previous registration bindings. The device removes SIP User Agent (UA) registration bindings in a Registrar, according to RFC 3261. Registrations are soft state and expire unless refreshed, but they can also be explicitly removed. A client can attempt to influence the expiration interval selected by the Registrar. A UA requests the immediate removal of a binding by specifying an expiration interval of "0" for that contact address in a REGISTER request. UA's should support this mechanism so that bindings can be removed before their expiration interval has passed. Use of the "*" Contact header field value allows a registering UA to remove all bindings associated with an address-of-record (AOR) without knowing their precise values.</p> <p><b>Note:</b> The REGISTER-specific Contact header field value of "*" applies to all registrations, but it can only be used if the Expires header field is present with a value of "0".</p>
<p>'Add Empty Authorization Header'</p> <pre>configure voip &gt; sip- definition settings &gt; add-empty-author-hdr [EmptyAuthorizationHeader]</pre>	<p>Enables the inclusion of the SIP Authorization header in initial registration (REGISTER) requests sent by the device.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>The Authorization header carries the credentials of a user agent (UA) in a request to a server. The sent REGISTER message populates the Authorization header with the following parameters:</p> <ul style="list-style-type: none"> <li>■ username - set to the value of the private user identity</li> <li>■ realm - set to the domain name of the home network</li> <li>■ uri - set to the SIP URI of the domain name of the home network</li> <li>■ nonce - set to an empty value</li> <li>■ response - set to an empty value</li> </ul>

Parameter	Description
	<p>For example:</p> <p>Authorization: Digest username=alice_private@home1.net, realm="home1.net", nonce="", response="e56131d19580cd833064787ecc"</p> <p><b>Note:</b> This registration header is according to the IMS 3GPP TS24.229 and PKT-SP-24.220 specifications.</p>
<p>'Add initial Route Header'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; add-init- rte-hdr</pre> <p>[InitialRouteHeader]</p>	<p>Enables the inclusion of the SIP Route header in initial registration or re-registration (REGISTER) requests sent by the device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>When the device sends a REGISTER message, the Route header includes either the Proxy's FQDN, or IP address and port according to the configured Proxy Set, for example:</p> <p>Route:  &lt;sip:10.10.10.10;lr;transport=udp&gt;  or  Route: &lt;sip: pcscf-  gm.ims.rr.com;lr;transport=udp&gt;</p>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; ping-pong- keep-alive</pre> <p>[UsePingPongKeepAlive]</p>	<p>Enables the use of the carriage-return and line-feed sequences (CRLF) Keep-Alive mechanism, according to RFC 5626 "Managing Client-Initiated Connections in the Session Initiation Protocol (SIP)" for reliable, connection-orientated transport types such as TCP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>The SIP user agent/client (i.e., device) uses a simple periodic message as a keep-alive mechanism to keep their flow to the proxy or registrar alive (used for example, to keep NAT bindings open). For connection-oriented transports such as TCP/TLS this is based on CRLF. This mechanism uses a client-to-server "ping" keep-alive and a corresponding server-to-client "pong"</p>

Parameter	Description
	<p>message. This ping-pong sequence allows the client, and optionally the server, to tell if its flow is still active and useful for SIP traffic. If the client doesn't receive a pong in response to its ping, it declares the flow "dead" and opens a new flow in its place. In the CRLF Keep-Alive mechanism the client periodically (defined by the PingPongKeepAliveTime parameter) sends a double-CRLF (the "ping") then waits to receive a single CRLF (the "pong"). If the client doesn't receive a "pong" within an appropriate amount of time, it considers the flow failed.</p> <p><b>Note:</b> The device sends a CRLF message to the Proxy Set only if the Proxy Keep-Alive feature (EnableProxyKeepAlive parameter) is enabled and its transport type is set to TCP or TLS. The device first sends a SIP OPTION message to establish the TCP/TLS connection and if it receives any SIP response, it continues sending the CRLF keep-alive sequences.</p>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; ping-pong- keep-alive-time</pre> <p>[PingPongKeepAliveTime]</p>	<p>Defines the periodic interval (in seconds) after which a "ping" (double-CRLF) keep-alive is sent to a proxy/registrar, using the CRLF Keep-Alive mechanism.</p> <p>The default range is 5 to 2,000,000. The default is 120.</p> <p>The device uses the range of 80-100% of this user-defined value as the actual interval. For example, if the parameter value is set to 200 sec, the interval used is any random time between 160 to 200 seconds. This prevents an "avalanche" of keep-alive by multiple SIP UAs to a specific server.</p>
<p>'Max Generated Register Rate'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; max-gen- reg-rate</pre> <p>[MaxGeneratedRegistersRate]</p>	<p>Defines the maximum number of user register requests (REGISTER messages) that the device sends (to a proxy or registrar server) at a user-defined rate configured by the [GeneratedRegistersInterval] parameter. The parameter is useful in that it may be used to prevent an overload on the device's CPU caused by sending many registration requests at a given time. The valid value is 30 to 300 register requests per</p>

Parameter	Description
	<p>second. The default is 150.</p> <p>For configuration examples, see the description of the [GeneratedRegistersInterval] parameter.</p>
<p>'Generated Register Interval'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; gen-reg- int</pre> <p>[GeneratedRegistersInterval]</p>	<p>Defines the rate (in seconds) at which the device sends user register requests (REGISTER messages). The parameter is based on the maximum number of REGISTER messages that can be sent at this rate, configured by the [MaxGeneratedRegistersRate] parameter.</p> <p>The valid value is 1 to 5. The default is 1.</p> <p>Configuration examples:</p> <ul style="list-style-type: none"> <li>■ If you configure the [MaxGeneratedRegistersRate] parameter to 100 and [GeneratedRegistersInterval] to 5, the device sends a maximum of 20 REGISTER messages per second (i.e., 100 messages divided by 5 sec; 100 per 5 seconds).</li> <li>■ If you configure the [MaxGeneratedRegistersRate] parameter to 100 and [GeneratedRegistersInterval] to 1, the device sends a maximum of a 100 REGISTER messages per second.</li> </ul>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; reg-sync- mode</pre> <p>[RegistrationSyncMode]</p>	<p>Enables the synchronization of the registration process. This prevents the device from sending multiple SIP REGISTER requests for multiple Accounts and users in the SBC User Information table registering to the same proxy server (serving IP Group) that is currently offline.</p> <p>These are Accounts that are configured in the Accounts table (see <a href="#">Configuring Registration Accounts</a> on page 777) and users that are configured in the SBC User Information table (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803).</p> <p>If an Account or user receives a response timeout (see note below) or a response failure (e.g., SIP 403) for a sent SIP REGISTER request, the device stops sending SIP REGISTER messages for all the other Accounts and users that are associated with</p>

Parameter	Description
	<p>the same proxy server (<i>serving IP Group</i>). The Account or user that first detected the no response (or failure) from the proxy is considered the <i>lead</i> Account or user. The device continues sending REGISTER requests to the proxy only for this lead Account or user.</p> <p>When the lead Account or user receives a successful response from the proxy, the device resumes the registration process for all the other Accounts and users that are associated with this same proxy.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> You can configure the response timeout using the [SipT1Rtx], [SipT2Rtx], or [SIPMaxRtx] parameters.</p>
<pre>configure voip &gt; sip- definition settings &gt; account-invite-failure- trigger-codes</pre> <p>[AccountInviteFailureTriggerCodes]</p>	<p>Defines SIP response codes that if received for a failed INVITE message sent for an Account, triggers the device to re-register the Account. The parameter is applicable only if the Account's 'Re-Register on Invite Failure' parameter in the Accounts table is configured to <b>Enable</b> (see <a href="#">Configuring Registration Accounts</a> on page 777).</p> <p>The valid value is a SIP response code. Multiple response codes can be configured, where each value is separated by a comma. The default is "403,408,480" (without quotation marks).</p> <p><b>Note:</b> SIP response code 408 also refers to an INVITE timeout (i.e., no reply from server). Therefore, if re-registration is needed for such a scenario, make sure that you configure the parameter with "408" as well.</p>
<pre>configure voip &gt; sip- definition settings &gt; ignore-auth-stale</pre> <p>[IgnoreAuthorizationStale]</p>	<p>Enables the device to retry registering even if the last SIP 401\407 response included "stale=false".</p> <p>When the device initiates a REGISTER request with an Authorization header (according to the relevant configured credentials), and it receives a SIP 401\407 response with the stale parameter set to "false", by default the device doesn't try to send</p>

Parameter	Description
	<p>another REGISTER message. When the parameter is enabled, the device retries registering even if the last 401\407 response had "stale=false".</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) If the device receives a SIP 401\407 response with "stale=true" or no stale parameter at all, it sends another REGISTER message. If "stale=false", the device doesn't send another REGISTER message.</li> <li>■ [1] = If the device receives a SIP 401\407 response with "stale=false", it sends another REGISTER message.</li> </ul> <p><b>Note:</b> This parameter is applicable only to REGISTER requests which the device initiates (e.g., for an Account or for Gateway endpoints); it's not for REGISTER requests that the device forwards from the user to the registrar server.</p>
<pre>configure voip &gt; sip- definition proxy-and- registration &gt; account- registrar-avoidance-time</pre> <p>[AccountRegistrarAvoidanceTime]</p>	<p>Defines a graceful time (in seconds) which is intended to prevent the device from sending REGISTER requests to a registrar server where the device previously registered, if the device also registered successfully to another server since the last successful registration to the registrar server. This can occur if the registrar server has been offline for a brief time. For more information, see the 'Registrar Search Mode' parameter in <a href="#">Configuring Registration Accounts</a> on page 777.</p> <p>The valid value is 0 to 15.2 million. The default is 0.</p>
<pre>configure voip &gt; sip- definition settings &gt; authenticated-message- handling</pre> <p>[AuthenticatedMessageHandling]</p>	<p>Defines if a Message Manipulation Set is run again on incoming authenticated SIP messages received after the device sends a SIP 401 response for challenging initial incoming SIP REGISTER requests. Typically, this is not required and the rules of a Message Manipulation Set that are configured to run on incoming REGISTER requests are applied only when the initial unauthenticated REGISTER request is received. However, if the Message Manipulation Set includes a Message Manipulation rule that specifies that manipulation must be done on the SIP Authorization header (i.e., 'Condition'</p>

Parameter	Description
	<p>parameter value is "Header.Authorization !exists"), which is present only in authenticated messages, then configure the parameter to [1].</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable - The Message Manipulation Set is not run again on authenticated messages and only applied to initial unauthenticated messages. The device uses this manipulated initial REGISTER request for further processing (e.g., classification or routing).</li> <li>■ [1] = The Message Manipulation Set is run again on authenticated messages (if it includes a rule whose condition is the Authorization header). The device uses this manipulated authenticated REGISTER request for further processing (e.g., classification or routing).</li> </ul>

## Network Application Parameters

The SIP network application parameters are described in the table below.

**Table 73-34:SIP Network Application Parameters**

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; tcp-keepalive-time</pre> <p>[TCPKeepAliveTime]</p>	<p>Defines the interval (in sec) between the last data packet sent and the first keep-alive probe to send. The valid value is 10 to 65,000. The default is 60.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Simple ACKs such as keepalives are not considered data packets.</li> <li>■ TCP keepalive is enabled per SIP Interface in the SIP Interfaces table.</li> </ul>

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; tcp-keepalive-interval</pre> <p>[TCPKeepAliveInterval]</p>	<p>Defines the interval (in sec) between consecutive keep-alive probes, regardless of what the connection has exchanged in the meantime.</p> <p>The valid value is 10 to 65,000. The default is 10.</p> <p><b>Note:</b> TCP keepalive is enabled per SIP Interface in the SIP Interfaces table.</p>
<pre>configure voip &gt; sip-definition settings &gt; tcp-keepalive-retry</pre> <p>[TCPKeepAliveRetry]</p>	<p>Defines the number of unacknowledged keep-alive probes to send before considering the connection down.</p> <p>The valid value is 1 to 100. The default is 5.</p> <p><b>Note:</b> TCP keepalive is enabled per SIP Interface in the SIP Interfaces table.</p>

## General SIP Parameters

The general SIP parameters are described in the table below.

**Table 73-35:General SIP Parameters**

Parameter	Description
<p>'Classify By Proxy Set Mode'</p> <pre>configure voip &gt; sip-definition settings &gt; classify-by-proxy-set-mode</pre> <p>[ClassifyByProxySetMode]</p>	<p>Defines which IP address to use for classifying the incoming SIP dialog message to a Server-type IP Group, based on Proxy Set.</p> <ul style="list-style-type: none"> <li>■ [0] <b>IP address</b> = (Default) The device checks if the source IP address (ISO Layer 3) of the incoming SIP dialog matches an IP address in the Proxy Set that is associated with the IP Group. If a match is found in the Proxy Set, the call is classified to the IP Group.</li> <li>■ [1] <b>Contact Header</b> = The device checks if the IP address in the SIP Contact header of the incoming SIP dialog matches an IP address in the Proxy Set that is associated with the IP Group. This is only applicable if the header contains a SIP</li> </ul>

Parameter	Description
	<p>URI that has an IP address (not hostname) in the host part. If a match is found in the Proxy Set, the call is classified to the IP Group. This option is useful, for example, when the source IP address is an internal address.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Both</b> = The device first checks if the source IP address (ISO Layer 3) of the incoming SIP dialog matches an IP address in the Proxy Set that is associated with the IP Group. Only if there is no match, does the device check if the IP address in the SIP Contact header of the incoming SIP dialog matches an IP address in the Proxy Set.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable classification by Proxy Set, configure the IP Group table's 'Classify By Proxy Set' parameter to <b>Enable</b> (see <a href="#">Configuring IP Groups</a> on page 591).</li> <li>■ Classification using the SIP Contact header is supported only when the header's SIP URI has an IP address (not a DNS hostname).</li> <li>■ For IDS, only the source IP address is used (see <a href="#">Configuring IDS Policies</a> on page 264).</li> <li>■ For TLS Contexts, only the source IP address is used. (If a Proxy Set is not found, the TLS Context configured for the SIP Interface is used.)</li> <li>■ This parameter is applicable only to the SBC application.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; max- sdp-sess-ver-id [MaxSDPSessionVersionId]</pre>	<p>Defines the maximum number of characters allowed in the SDP body's "o=" (originator and session identifier) field for the session ID and session version values.</p> <p>Below is an example of an "o=" line with session ID and session version values (in bold):</p> <pre>o=jdoe <b>2890844526 2890842807</b> IN IP4 10.47.16.5</pre> <p>The valid value range is 1,000 to 214,748,3647 (default).</p>
<pre>configure voip &gt; sip-definition settings &gt; unreg-on-startup [UnregisterOnStartup]</pre>	<p>Enables the device to unregister all user Accounts that were registered with the device, upon a device restart. During device start-up, each Account sends a REGISTER message (containing "Contact: *") to unregister all contact URIs belonging to its Address-of-Record (AOR), and then a second after they are unregistered, the device re-registers the Account.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p>To configure Accounts, see <a href="#">Configuring Registration Accounts</a> on page 777.</p>
<p>'Send Reject (503) upon Overload'</p> <pre>configure voip &gt; sip-definition settings &gt; reject-on-ovrld [SendRejectOnOverload]</pre>	<p>Disables the sending of SIP 503 (Service Unavailable) responses upon receipt of new SIP dialog-initiating requests when the device's CPU is overloaded and thus, unable to accept and process new SIP messages.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled. SIP 503 response isn't sent upon CPU overload.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. SIP 503 response is sent upon CPU overload.</li> </ul> <p><b>Note:</b> Even if the parameter is disabled (i.e., 503 is not sent), the device still discards the new SIP dialog-initiating requests when the CPU is overloaded.</p>
<p>'SIP 408 Response upon non-INVITE'</p> <pre>configure voip &gt; sip-definition settings &gt; enbl- non-inv-408 [EnableNonInvite408Reply]</pre>	<p>Enables the device to send SIP 408 responses (Request Timeout) upon receipt of non-INVITE transactions, if necessary. Disabling this response complies with RFC 4320/4321. By default, and in certain circumstances such as a timeout expiry, the device sends a SIP 408 Request Timeout in response to non-INVITE requests (e.g., REGISTER).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul>
<p>'Remote Management by SIP NOTIFY'</p> <pre>configure voip &gt; sip-definition settings &gt; sip- remote-reset [EnableSIPRemoteReset]</pre>	<p>Enables a specific device action upon the receipt of a SIP NOTIFY request, where the action depends on the value in the Event header.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>The action depends on the Event header value:</p> <ul style="list-style-type: none"> <li>■ "Event: check-sync;reboot=false": Triggers the regular Automatic Update feature (if Automatic Update has been enabled on the device).</li> <li>■ "Event: check-sync;reboot=true": Triggers a device restart.</li> <li>■ "Event: soft-sync": Triggers the device to disconnect all current calls.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If the 'reboot=' parameter is not specified in the Event header, it defaults to 'true' (i.e., triggers a device restart).</li> </ul> <p><b>Note:</b> The Event header value is proprietary to AudioCodes.</p>
'Max SIP Message Length' [MaxSIPMessageLength]	<p>Defines the maximum size (in Kbytes) for each SIP message that can be sent over the network. The device rejects messages exceeding this user-defined size.</p> <p>The valid value range is 1 to 100. The default is 100.</p>
[SIPForceRport]	<p>Determines whether the device sends SIP responses to the UDP port from where SIP requests are received even if the 'rport' parameter is not present in the SIP Via header.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled. The device sends the SIP response to the UDP port defined in the Via header. If the Via header contains the 'rport' parameter, the response is sent to the UDP port from where the SIP request is received.</li> <li>■ [1] = Enabled. SIP responses are sent to the UDP port from where SIP requests are received even if the 'rport' parameter is not present in the Via header.</li> </ul>
'Reject Cancel after Connect' configure voip > sip-definition settings > rej- cancel-after- conn [RejectCancelAfterConnect]	<p>Enables the device to accept or reject SIP CANCEL requests received after the receipt of a 200 OK in response to an INVITE (i.e., call established). According to the SIP standard, a CANCEL can be sent only during the INVITE transaction (before 200 OK), and once a 200 OK response is received the call can be rejected only by a BYE request.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. Accepts a CANCEL request received during the INVITE transaction by sending a 200 OK response and terminates the call session.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Rejects a CANCEL request received during the INVITE transaction by sending a SIP 481 (Call/Transaction Does Not Exist) response and maintains the call session.</li> </ul>
configure voip > sip-definition settings > call- info-list [CallInfoListMode]	<p>Defines how the device handles SIP Call-Info headers with multiple values in outgoing SIP messages.</p> <ul style="list-style-type: none"> <li>■ [0] = The device sends the outgoing SIP message with a Call-Info header for each value.</li> <li>■ [1] = The device sends the outgoing SIP message with a <b>single</b> Call-Info header that contains all the values (comma-</li> </ul>

Parameter	Description
	separated list) per RFC 3261.
<pre>configure voip &gt; sip-definition settings &gt; verify-rcvd- requi [VerifyRecievedReques tUri]</pre>	<p>Enables the device to reject SIP requests (e.g., ACK, BYE, or re-INVITE) whose user part in the Request-URI is different from the user part in the Contact header of the last sent SIP request.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable. Even if the user part is different, the device accepts the SIP request.</li> <li>■ [1] = Enable. If the user part in the Contact header of the previous SIP request is different to the user part in the Request-URI for in-dialog requests, the device rejects the SIP request. A BYE request is responded with a SIP 481, a re-INVITE request is responded with a SIP 404, and an ACK request is ignored.</li> <li>■ [2] = If the user part in the Contact header of the previous SIP request is different to the user part in the Request-URI for dialog-initiating INVITE requests, the device rejects the SIP request.</li> <li>■ Verify dialog-initiating INVITE for all required conditions (Via, Source IP and user in Request-URI)</li> <li>■ [3] = Verify dialog-initiating INVITE and in-dialog requests.</li> </ul> <p>The [VerifyRecievedRequestUri] parameter functions together with the [RegistrarProxySetID] parameter, as follows:</p> <ul style="list-style-type: none"> <li>■ <b>Handling Dialog-Initiating INVITES:</b> If the [VerifyRecievedRequestUri] parameter is configured to [2] or [3] and the [RegistrarProxySetID] parameter is configured to some Proxy Set, the device accepts dialog-initiating INVITE requests received from the registrar at which the Accounts (configured in the Accounts table) are registered. For dialog-initiating INVITE requests received from the registrar on a specific SIP Interface, the following rules apply (listed according to priority): <ul style="list-style-type: none"> <li>✓ The top-most Via header must contain a host-resolved IP address of the registrar; otherwise, the device drops the INVITE request.</li> <li>✓ The source IP address must be the same as the IP address of the registrar; otherwise, the device rejects the requests and sends a SIP 403 (Forbidden) response to the registrar.</li> </ul> </li> </ul>

Parameter	Description
	<p>✓ The user part, specified in the Request-URI header, must be identical to the Contact user part configured for the associated Account, and the Account must be registered. Otherwise, the device rejects the request with a SIP 404 (Not Found) response. If the [RegistrarProxySetID] parameter is not configured or no Accounts are configured, the device accepts the dialog-initiating INVITE request.</p> <p><b>Note:</b> This handling is applicable only to the SBC application.</p> <p>■ <b>Handling In-dialog Requests:</b> If the [VerifyRecievedRequestUri] parameter is configured to [1] or [3], for all incoming in-dialog requests (including ACK and CANCEL), the device checks if the Request-URI user part matches the remote Contact user part (i.e., the Contact user configured for the Account). If there is no match, the device rejects the request and sends a SIP 481 response for requests such as BYE and CANCEL, or a SIP 404 for other requests, and for ACK it doesn't send any response.</p> <p><b>Note:</b> This handling is applicable to the Gateway and SBC applications.</p>
[RegistrarProxySetID]	<p>Defines a Proxy Set for the registrar. The parameter functions together with the [VerifyRecievedRequestUri] parameter. For more information, see the description of the [VerifyRecievedRequestUri] parameter.</p> <p>The default value is -1 (not defined).</p> <p><b>Note:</b> This setting assumes that the SIP Interface has only one registrar.</p>
'Max Number of Active Calls' <pre>configure voip &gt; sip-definition settings &gt; max- nb-of--act-calls</pre> [MaxActiveCalls]	<p>Defines the maximum number of simultaneous active calls supported by the device. If the maximum number of calls is reached, new calls are not established.</p> <p>The valid range is 1 to the maximum number of supported channels. The default value is the maximum available channels (i.e., no restriction on the maximum number of calls).</p>
'QoS Statistics in Release Msg' <pre>configure voip &gt;</pre>	<p>Enables the device to include call Quality of Service (QoS) statistics in SIP BYE messages and SIP 200 OK responses to BYE messages, using the proprietary SIP header X-RTP-Stat.</p>

Parameter	Description
sip-definition settings > qos- statistics-in- release-msg [QoSStatistics]	<ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>The X-RTP-Stat header contains the following statistics:</p> <ul style="list-style-type: none"> <li>■ Number of received and sent voice packets</li> <li>■ Number of received and sent voice octets</li> <li>■ Received packet loss, jitter (in ms), and latency (in ms)</li> </ul> <p>The X-RTP-Stat header contains the following fields:</p> <ul style="list-style-type: none"> <li>■ PS=&lt;voice packets sent&gt;</li> <li>■ OS=&lt;voice octets sent&gt;</li> <li>■ PR=&lt;voice packets received&gt;</li> <li>■ OR=&lt;voice octets received&gt;</li> <li>■ PL=&lt;receive packet loss&gt;</li> <li>■ JI=&lt;jitter in ms&gt;</li> <li>■ LA=&lt;latency in ms&gt;</li> </ul> <p>Below is an example of the X-RTP-Stat header in a SIP BYE message:</p> <pre> BYE sip:302@10.33.4.125 SIP/2.0 Via: SIP/2.0/UDP 10.33.4.126;branch=z9hG4bKac2127550866 Max-Forwards: 70 From: &lt;sip:401@10.33.4.126;user=phone&gt;;tag=1c2113553324 To: &lt;sip:302@company.com&gt;;tag=1c991751121 Call-ID: 991750671245200001912@10.33.4.125 CSeq: 1 BYE <b>X-RTP-Stat:</b> <b>PS=207;OS=49680;;PR=314;OR=50240;PL=0;JI=600;LA=40;</b> Supported: em,timer,replaces,path,resource- priority Allow: REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTI FY,PRACK,REFER,INFO,SUBSCRIBE,UPDATE User-Agent: Sip-Gateway-/7.60A.100.022           </pre>

Parameter	Description
	Reason: Q.850 ;cause=16 ;text="local" Content-Length: 0 <b>Note:</b> The parameter is applicable only to the Gateway application.
'PRACK Mode' prack-mode [PrackMode]	Determines the PRACK (Provisional Acknowledgment) mechanism mode for SIP 1xx reliable responses. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Supported</b> (default)</li> <li>■ [2] <b>Required</b></li> </ul> <b>Note:</b> <ul style="list-style-type: none"> <li>■ The Supported and Required headers contain the '100rel' tag.</li> <li>■ The device sends PRACK messages if 180/183 responses are received with '100rel' in the Supported or Required headers.</li> <li>■ The parameter is applicable only to the Gateway application.</li> </ul>
'Enable Early Media' early-media [EnableEarlyMedia]	Global parameter enabling the Early Media feature for sending media (e.g., ringing) before the call is established. You can also configure this feature per specific calls, using IP Profiles ('Early Media' parameter) or Tel Profiles ('Enable Early Media' parameter). For a detailed description of the parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755. <b>Note:</b> If the feature is configured for a specific profile, the settings of the global parameter is ignored for calls associated with the profile.
'Early 183' early-183 [EnableEarly183]	Global parameter that enables the device to send SIP 183 responses with SDP to the IP upon receipt of INVITE messages. You can also configure this feature per specific calls, using IP Profiles ('Early 183' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674. <b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.

Parameter	Description
[IgnoreAlertAfterEarlyMedia]	<p>Defines the device's interworking of Alerting messages for IP-to-Tel calls (ISDN). It determines whether the device sends a 180 Ringing response to the caller after the device sends a 183 Session Progress response to the caller. The 180 Ringing response indicates that the INVITE has been received by the ISDN side and that alerting is taking place (i.e., ISDN Progress message), indicating to the IP PBX to play a ringback tone. The 183 Session Progress response allows an early media session to be established prior to the call being answered, for example, to hear a ring tone, busy tone or recorded announcement.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable. If the device sends a 183 response with SDP (due to a received ISDN Progress or Proceeding with PI messages, i.e., a ring tone, busy tone or recorded announcement played to the ISDN side) and an Alerting message is then received from the ISDN side (with or without Progress Indicator), the device also sends a 180 Ringing response to the caller. Therefore, in this case, early media is played to the ISDN side and then the ringback tone is played by the IP PBX.</li> <li>■ [1] = Enable. If the device sends a 183 response with SDP (due to a received ISDN Progress or Proceeding with PI messages) and an Alerting message is then received from the ISDN side (with or without Progress Indicator), the device doesn't send a 180 Ringing response to the caller and the voice channel remains open. Therefore, in this case, early media is played to the ISDN side and a ringback tone is not played by the IP PBX.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ The parameter is applicable only if the [EnableEarlyMedia] parameter is set to 1 (i.e., enabled).</li> </ul>
<p>'183 Message Behavior'</p> <pre>configure voip &gt; sip-definition settings &gt; 183- msg-behavior [SIP183Behaviour]</pre>	<p>Digital: Defines the ISDN message that is sent when the 183 Session Progress message is received for IP-to-Tel calls.</p> <p>Analog: Defines the response of the device upon receipt of a SIP 183 response.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Progress</b> = (Default) <ul style="list-style-type: none"> <li>✓ Digital: The device sends a Progress message.</li> <li>✓ Analog: A 183 response (without SDP) doesn't cause the</li> </ul> </li> </ul>

Parameter	Description
	<p>device to play a ringback tone.</p> <ul style="list-style-type: none"> <li>■ [1] Alert = <ul style="list-style-type: none"> <li>✓ Digital: The device sends an Alerting message (upon receipt of a 183 response) instead of an ISDN Progress message.</li> <li>✓ Analog: 183 response is handled by the device as if a 180 Ringing response is received, and the device plays a ringback tone.</li> </ul> </li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
[ReleaseIP2ISDNCallOnProgressWithCause]	<p>Typically, if an Q.931 Progress message with a Cause is received from the PSTN for an outgoing IP-to-ISDN call and the [EnableEarlyMedia] parameter is set to 1 (i.e., the Early Media feature is enabled), the device interworks the Progress to 183 + SDP to enable the originating party to hear the PSTN announcement about the call failure. Conversely, if EnableEarlyMedia is set to 0, the device disconnects the call by sending a SIP 4xx response to the originating party. However, if the [ReleaseIP2ISDNCallOnProgressWithCause] parameter is set to 1, then the device sends a SIP 4xx response even if the [EnableEarlyMedia] parameter is set to 1.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) If a Progress with Cause message is received from the PSTN for an outgoing IP-to-ISDN call, the device doesn't disconnect the call by sending a SIP 4xx response to the originating party.</li> <li>■ [1] = The device sends a SIP 4xx response when the [EnableEarlyMedia] parameter is set to 0.</li> <li>■ [2] = The device always sends a SIP 4xx response, even if the [EnableEarlyMedia] parameter is set to 1.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
'Session-Expires Time' configure voip > sip-definition settings > session-expires- time [SIPSessionExpires]	<p>Defines the numerical value sent in the Session-Expires header in the first SIP INVITE request or response (if the call is answered).</p> <p>The valid range is 1 to 86,400 sec. The default is 0 (i.e., the Session-Expires header is disabled).</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>

Parameter	Description
<p>'Minimum Session-Expires'</p> <pre>configure voip &gt; sip-definition settings &gt; min-session-expires</pre> <p>[MinSE]</p>	<p>Defines the time (in seconds) in the SIP Min-SE header. The header defines the minimum time that the user agent refreshes the session.</p> <p>The valid range is 10 to 100,000. The default is 90.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Session Expires Disconnect Time'</p> <pre>configure voip &gt; sip-definition settings &gt; sess-exp-disc-time</pre> <p>[SessionExpiresDisconnectTime]</p>	<p>Defines a session expiry timeout.</p> <p>The new session expiry timeout is calculated by subtracting the configured value from the original timeout as specified in the Session-Expires header. However, the new timeout must be greater than or equal to one-third (1/3) of the Session-Expires value. If the refresher doesn't send a refresh request within the new timeout, the device disconnects the session (i.e., sends a SIP BYE).</p> <p>For example, if you configure the parameter to 32 seconds and the Session-Expires value is 180 seconds, the session timeout occurs 148 seconds (i.e., 180 minus 32) after the last session refresh. If the Session-Expires header value is 90 seconds, the timeout occurs 60 seconds after the last refresh. This is because 90 minus 32 is 58 seconds, which is less than one third of the Session-Expires value (i.e., 60/3 is 30, and 90 minus 30 is 60).</p> <p>The valid range is 0 to 32 (in seconds). The default is 32.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Session Expires Method'</p> <pre>configure voip &gt; sip-definition settings &gt; session-exp-method</pre> <p>[SessionExpiresMethod]</p>	<p>Defines the SIP method used for session-timer updates.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Re-INVITE</b> = (Default) Uses re-INVITE messages for session-timer updates.</li> <li>■ [1] <b>UPDATE</b> = Uses UPDATE messages.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The device can receive session-timer refreshes using both methods.</li> <li>■ The UPDATE message used for session-timer is excluded from the SDP body.</li> </ul>
[RemoveToTagInFailure]	Determines whether the device removes the 'to' header tag

Parameter	Description
Response]	<p>from final SIP failure responses to INVITE transactions.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Do not remove tag.</li> <li>■ [1] = Remove tag.</li> </ul>
[EnableRTCPAttribute]	<p>Enables the use of the 'rtcp' attribute in the outgoing SDP.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
[OPTIONSUserPart]	<p>Defines the user part value of the Request-URI for outgoing SIP OPTIONS requests. If no value is configured, the endpoint number (analog) or configuration parameter 'Username' value (digital) is used.</p> <p>A special value is 'empty', indicating that no user part in the Request-URI (host part only) is used.</p> <p>The valid range is a 30-character string. By default, this value is not defined.</p>
<p>'Trunk Status Reporting Mode'</p> <pre>configure voip &gt; gateway digital settings &gt; trunk-status- reporting</pre> <p>[TrunkStatusReporting Mode]</p>	<p>Enables the device to not respond to received SIP OPTIONS messages from, and/or not to send keep-alive messages to, a proxy server associated with Trunk Group ID 1 if all its member trunks are down.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Device responds to SIP OPTIONS messages from, and sends keep-alive messages to, a proxy server associated with Trunk Group ID 1 if all its member trunks are down.</li> <li>■ [1] <b>Don't reply OPTIONS</b> = The device doesn't respond to SIP OPTIONS received from the proxy associated with Trunk Group 1 when all its trunks are down.</li> <li>■ [2] <b>Don't send Keep-Alive</b> = The device doesn't send keep-alive messages to the proxy associated with Trunk Group 1 when all its trunks are down.</li> <li>■ [3] <b>Don't Reply and Send</b> = Both options [1] and [2] are applied.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ When the parameter is set to not respond to SIP OPTIONS</li> </ul>

Parameter	Description
	<p>received from the proxy, it is applicable only if the OPTIONS message doesn't include a user part in the Request-URI.</p> <ul style="list-style-type: none"> <li>The proxy server is determined by the Proxy Set that is associated with the Serving IP Group of the Trunk Group in the Trunk Group Settings table.</li> </ul>
'TDM Over IP Minimum Calls For Trunk Activation' [TDMOverIPMinCallsForTrunkActivation]	<p>Defines the minimal number of SIP dialogs that must be established when using TDM Tunneling, for the specific trunk to be considered active.</p> <p>When using TDM Tunneling, if calls from this defined number of B-channels pertaining to a specific Trunk fail (i.e., SIP dialogs are not correctly set up), an AIS alarm is sent on this trunk toward the PSTN and all current calls are dropped. The originator gateway continues the INVITE attempts. When this number of calls succeed (i.e., SIP dialogs are correctly set up), the AIS alarm is cleared.</p> <p>The valid range is 0 to 31. The default is 0 (i.e., don't send AIS alarms).</p> <p><b>Note:</b> TDM Tunneling is applicable only to E1/T1 interfaces.</p>
[TDMoIPInitiateInviteTime]	<p>Defines the time (in msec) between the first INVITE issued within the same trunk when implementing the TDM tunneling application.</p> <p>The valid value range is 500to 1,000. The default is 500.</p> <p><b>Note:</b> TDM Tunneling is applicable only to E1/T1 interfaces.</p>
[TDMoIPInviteRetryTime]	<p>Defines the time (in msec) between call release and a new INVITE when implementing the TDM tunneling application.</p> <p>The valid value range is 10,000to 20,000. The default is 10,000.</p> <p><b>Note:</b> TDM Tunneling is applicable only to E1/T1 interfaces.</p>
'Fax Signaling Method' fax-sig-method [IsFaxUsed]	<p>Global parameter defining the SIP signaling method for establishing and transmitting a fax session when the device detects a fax.</p> <p>You can also configure this feature per specific calls, using IP Profiles ('Fax Signaling Method' parameter) and Tel Profiles ('Fax Signaling Method' parameter). For a detailed description of the parameter, see <a href="#">Configuring IP Profiles</a> on page 674 and <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile or Tel Profile, the device ignores this global parameter for calls associated with the IP Profile or Tel Profile.</p>

Parameter	Description
<code>fax-vbd-behvr</code> [FaxVBDBehavior]	<p>Determines the device's fax transport behavior when G.711 VBD coder is negotiated at call start.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) If the device is configured with a VBD coder (see the [CodersGroup] parameter) and is negotiated OK at call start, then both fax and modem signals are sent over RTP using the bypass payload type (and no mid-call VBD or T.38 Re-INVITES occur).</li> <li>■ [1] = If the [IsFaxUsed] parameter is set to 1, the channel opens with the [FaxTransportMode] parameter set to 1 (relay). This is required to detect mid-call fax tones and to send T.38 Re-INVITE messages upon fax detection. If the remote party supports T.38, the fax is relayed over T.38.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If VBD coder negotiation fails at call start and if the [IsFaxUsed] parameter is set to 1 (or 3), then the channel opens with the [FaxTransportMode] parameter set to 1 (relay) to allow future detection of fax tones and sending of T.38 Re-INVITES. In such a scenario, the [FaxVBDBehavior] parameter has no effect.</li> <li>■ This feature can be used only if the remote party supports T.38 fax relay; otherwise, the fax fails.</li> </ul>
[NoAudioPayloadType]	<p>Defines the payload type of the outgoing SDP offer.</p> <p>The valid value range is 96 to 127 (dynamic payload type). The default is 0 (i.e. NoAudio is not supported). For example, if set to 120, the following is added to the INVITE SDP:</p> <pre>a=rtpmap:120 NoAudio/8000\r\n</pre> <p><b>Note:</b> For incoming SDP offers, NoAudio is always supported.</p>
'SIP Transport Type' <code>configure voip &gt;</code> <code>sip-definition</code> <code>settings &gt; app-</code> <code>sip-transport-</code> <code>type</code> [SIPTransportType]	<p>Determines the default transport layer for outgoing SIP calls initiated by the device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>UDP</b> (default)</li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS (SIPS)</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ It's recommended to use TLS for communication with a SIP Proxy and not for direct device-to-device communication.</li> <li>■ For received calls (i.e., incoming), the device accepts all</li> </ul>

Parameter	Description
	these protocols.
'Display Default SIP Port' <pre>configure voip &gt; sip-definition settings &gt; display-default- sip-port</pre> [DisplayDefaultSIPPort]	<p>Enables the device to add the default SIP port 5060 (UDP/TCP) or 5061 (TLS) to outgoing messages that are received without a port. This condition also applies to manipulated messages where the resulting message has no port number. The device adds the default port number to the following SIP headers: Request-Uri, To, From, P-Asserted-Identity, P-Preferred-Identity, and P-Called-Party-ID. If the message is received with a port number other than the default, for example, 5070, the port number is not changed.</p> <p>An example of a SIP From header with the default port is shown below:</p> <p>From:            &lt;sip:+4000@10.8.4.105:<b>5060</b>            ;user=phone&gt;;tag=f25419a96a;epid=009FAB8F3E</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>
'SIPS' <pre>configure voip &gt; sip-definition settings &gt; enable-sips</pre> [EnableSIPS]	<p>Enables secured SIP (SIPS URI) connections over multiple hops.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>When the [SIPTransportType] parameter is set to 2 (i.e., TLS) and the parameter [EnableSIPS] is disabled, TLS is used for the next network hop only. When the [SIPTransportType] parameter is set to 2 or 1 (i.e., TCP or TLS) and [EnableSIPS] is enabled, TLS is used through the entire connection (over multiple hops).</p> <p><b>Note:</b> If the parameter is enabled and the [SIPTransportType] parameter is set to 0 (i.e., UDP), the connection fails.</p>
'TCP/TLS Connection Reuse' <pre>tcp-conn-reuse</pre> [EnableTCPConnection Reuse]	<p>Enables the device to use the same established TCP or TLS connection with the SIP user agent (UA) for subsequent SIP requests sent to the UA. For all new out-of-dialog requests (e.g., INVITE or REGISTER) the device uses this same secured connection. A benefit of this feature is that it may improve performance, by eliminating the need for performing additional TCP/TLS handshakes with the UA, allowing sessions to be established rapidly. If disabled, the device uses a new TCP or TLS connection with the UA for all subsequent SIP requests.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For SIP responses, the device always uses the same TCP/TLS connection, regardless of the parameter's settings.</li> </ul>
'Fake TCP Alias' configure voip > sip-definition settings > fake- tcp-alias [FakeTCPAlias]	<p>Enables the device to use the same TCP/TLS connection for sessions with the same SIP UA even if the 'alias' parameter is not present in the SIP Via header of the SIP dialog-initiating INVITE request.</p> <p>If disabled, the device uses the same TCP/TLS connection <b>only</b> if the 'alias' parameter is present (per RFC 5923).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> To enable TCP/TLS connection reuse, see the <a href="#">[EnableTCPConnectionReuse]</a> parameter.</p>
'Reliable Connection Persistent Mode' configure voip > sip-definition settings > reliable-conn- persistent [ReliableConnectionPer sistentMode]	<p>Enables all reusable TCP/TLS (reliable) connections to be persistent (i.e., not released).</p> <p>When sending a SIP message, the device's reliable connection reuse policy determines if current connections to the specific destination are reused.</p> <p>Persistent connections ensure less network traffic due to fewer setting up and tearing down of reliable connections and reduced latency on subsequent requests because there is no need for initial TCP handshakes. Persistent connections may reduce the number of costly TLS handshakes to establish security associations, in addition to the initial TCP connection setup.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device releases all reliable connections that aren't being used. However, if the destination is a Proxy server (configured in the Proxy Sets table), the reliable connection is always persistent, regardless of the parameter's settings.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device makes reusable reliable connections to all destinations persistent and doesn't release them (see note below). A persistent connection stays open even when it's no longer in use (i.e., not used by any SIP dialog or transaction, and isn't associated with a registered user).</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device releases unnecessary persistent TLS connections to prevent them from accumulating and reaching the device's maximum number of supported TLS connections (refer to the document <a href="#">Release Notes</a>). If the number of incoming TLS connections exceeds 80% of the maximum, the device closes incoming TLS connections that aren't in use (i.e., no active SIP dialogs and not associated with a registered user) and that are kept open only because they are persistent.</li> <li>■ Similar to the above note, the device releases reliable (TCP/TLS) connections that aren't in use and are kept open only because they are persistent, when reaching 80% of the maximum number of supported reliable connections.</li> <li>■ The device sends the SNMP alarm <code>acTLSSocketsLimitAlarm</code> when the number of incoming TLS connections exceeds 95% of the maximum TLS connections supported by the device.</li> <li>■ Connection reuse depends on the <code>[EnableTCPConnectionReuse]</code> parameter; for incoming connections, reuse also depends on SIP message characteristics (presence of Via header's 'alias' parameter in initial request).</li> </ul>
<p>'TCP Timeout'</p> <pre>configure voip &gt; sip-definition settings &gt; tcp- timeout</pre> <p><code>[SIPTCPTimeout]</code></p>	<p>Defines the Timer B (INVITE transaction timeout timer) and Timer F (non-INVITE transaction timeout timer), as defined in RFC 3261, when the SIP transport type is TCP.</p> <p>The valid range is 0 to 60 sec. The default is 0, which means that the parameter's value is set to 64 multiplied by the value of the <code>[SipT1Rtx]</code> parameter. For example, if you configure <code>[SipT1Rtx]</code> to 500 msec (0.5 sec) and leave the <code>[SIPTCPTimeout]</code> parameter at its default value (0), the actual value of <code>[SIPTCPTimeout]</code> is 32 sec (64 x 0.5 sec).</p>
<p><code>[ReliableConnectionFailureRetries]</code></p>	<p>Defines the number of retry attempts that the device makes when attempting to reconnect to a server (Proxy Set) after a TCP/TLS connection failure.</p> <p>The valid range is 1 to 20. The default port is 5.</p>
<p>'SIP Destination Port'</p> <pre>configure voip &gt; sip-definition</pre>	<p>Defines the SIP destination port for sending initial SIP requests.</p> <p>The valid range is 1 to 65534. The default port is 5060.</p> <p><b>Note:</b> SIP responses are sent to the port specified in the Via</p>

Parameter	Description
<code>settings &gt; sip-dst-port</code> [SIPDestinationPort]	header.
'Use user=phone in SIP URL' <code>configure voip &gt; sip-definition settings &gt; user-phone-in-url</code> [IsUserPhone]	Defines if the 'user=phone' string is added to the SIP URI and SIP To header. <ul style="list-style-type: none"> <li>■ [0] No</li> <li>■ [1] Yes (default)</li> </ul> <b>Note:</b> The parameter is applicable only to the Gateway application.
'Use user=phone in From Header' <code>configure voip &gt; sip-definition settings &gt; user-phone-in-from</code> [IsUserPhoneInFrom]	Defines if the 'user=phone' string is added to the From and Contact SIP headers. <ul style="list-style-type: none"> <li>■ [0] No (default)</li> <li>■ [1] Yes</li> </ul> <b>Note:</b> The parameter is applicable only to the Gateway application.
'Use Tel URI for Asserted Identity' <code>configure voip &gt; sip-definition settings &gt; uri-for-assert-id</code> [UseTelURIForAssertedID]	Defines the format of the URI in the SIP P-Asserted-Identity and P-Preferred-Identity headers. <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The format is 'sip:'.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The format is 'tel:'.</li> </ul>
<code>configure voip &gt; sip-definition settings &gt; p-preferred-id-list</code> [PPreferredIdListMode]	Defines the number of P-Preferred-Identity SIP headers included in the outgoing SIP message when the header contains multiple values. <ul style="list-style-type: none"> <li>■ [0] = (Default) The device includes multiple P-Preferred-Identity SIP headers in the outgoing message, for example: <ul style="list-style-type: none"> <li>✓ Incoming message containing a P-Preferred-Identity header with multiple values:</li> </ul> <div style="border: 1px solid #ccc; padding: 10px; margin: 10px 0; background-color: #f9f9f9;"> P-Preferred-Identity:  &lt;sip:someone@test.org&gt;,&lt;tel:+123456789&gt; </div> <li>✓ Outgoing message sent with multiple P-Preferred-</li> </li></ul>

Parameter	Description
	<p>Identity headers, each with a value:</p> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> P-Preferred-Identity:  &lt;sip:someone@test.org&gt;  P-Preferred-Identity: &lt;tel:+123456789&gt; </div> <ul style="list-style-type: none"> <li>■ [1] = The device includes only one P-Preferred-Identity header in the outgoing message, for example:</li> <li>✓ Incoming message containing multiple P-Preferred-Identity headers:</li> </ul> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> P-Preferred-Identity:  &lt;sip:someone@test.org&gt;  P-Preferred-Identity: &lt;tel:+123456789&gt; </div> <ul style="list-style-type: none"> <li>✓ Outgoing message sent with a single P-Preferred-Identity header containing the multiple values:</li> </ul> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> P-Preferred-Identity:  &lt;sip:someone@test.org&gt;, &lt;tel:+123456789&gt; </div> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If more than two P-Preferred-Identity headers are received in the incoming message, the device keeps the first two headers (if configured to 0) or the first header (if configured to 1), and removes the others in the outgoing message.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Tel to IP No Answer Timeout'</p> <pre>configure voip &gt; gateway advanced &gt; tel2ip-no-ans- timeout [IPAlertTimeout]</pre>	<p>Defines the time (in seconds) that the device waits for a 200 OK response from the called party (IP side) after sending an INVITE message, for Tel-to-IP calls. If the timer expires, the call is released.</p> <p>The valid range is 0 to 3600. The default is 180.</p>
<p>'Remote Party ID'</p> <pre>configure voip &gt; sip-definition settings &gt; remote-party-id</pre>	<p>Enables the device to include the SIP Remote-Party-Identity header in SIP INVITE messages for both called and calling numbers in Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> </ul>

Parameter	Description											
[EnableRPIheader]	<ul style="list-style-type: none"> <li>[1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>											
'History-Info Header' <pre>configure voip &gt; sip-definition settings &gt; hist- info-hdr</pre> [EnableHistoryInfo]	<p>Enables the use of the SIP History-Info header.</p> <ul style="list-style-type: none"> <li>[0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>[1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>User Agent Client (UAC) Behavior:</p> <ul style="list-style-type: none"> <li>Initial request: The History-Info header is equal to the Request-URI. If a PSTN Redirect number is received, it is added as an additional History-Info header with an appropriate reason.</li> <li>Upon receiving the final failure response, the device copies the History-Info as is, adds the reason of the failure response to the last entry, and concatenates a new destination to it (if an additional request is sent). The order of the reasons is as follows:               <ol style="list-style-type: none"> <li>Q.850 Reason</li> <li>SIP Reason</li> <li>SIP Response code</li> </ol> </li> <li>Upon receiving the final response (success or failure), the device searches for a Redirect reason in the History-Info (i.e., 3xx/4xx SIP reason). If found, it is passed to ISDN according to the following table:</li> </ul> <table border="1"> <thead> <tr> <th>SIP Reason Code</th><th>ISDN Redirecting Reason</th></tr> </thead> <tbody> <tr> <td>302 - Moved Temporarily</td><td>Call Forward Universal (CFU)</td></tr> <tr> <td>408 - Request Timeout</td><td>Call Forward No Answer (CFNA)</td></tr> <tr> <td>480 - Temporarily Unavailable</td><td rowspan="4">Call Forward Busy (CFB)</td></tr> <tr> <td>487 - Request Terminated</td></tr> <tr> <td>486 - Busy Here</td></tr> <tr> <td>600 - Busy Everywhere</td></tr> </tbody> </table> <ul style="list-style-type: none"> <li>If history reason is a Q.850 reason, it is translated to the SIP</li> </ul>	SIP Reason Code	ISDN Redirecting Reason	302 - Moved Temporarily	Call Forward Universal (CFU)	408 - Request Timeout	Call Forward No Answer (CFNA)	480 - Temporarily Unavailable	Call Forward Busy (CFB)	487 - Request Terminated	486 - Busy Here	600 - Busy Everywhere
SIP Reason Code	ISDN Redirecting Reason											
302 - Moved Temporarily	Call Forward Universal (CFU)											
408 - Request Timeout	Call Forward No Answer (CFNA)											
480 - Temporarily Unavailable	Call Forward Busy (CFB)											
487 - Request Terminated												
486 - Busy Here												
600 - Busy Everywhere												

Parameter	Description
	<p>reason (according to the SIP-ISDN tables) and then to ISDN Redirect reason according to the table above.</p> <p>User Agent Server (UAS) Behavior:</p> <ul style="list-style-type: none"> <li>■ The History-Info header is sent only in the final response.</li> <li>■ Upon receiving a request with History-Info, the UAS checks the policy in the request. If a 'session', 'header', or 'history' policy tag is found, the (final) response is sent without History-Info; otherwise, it is copied from the request.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Use SIP tgrp Information'</p> <pre>configure voip &gt; sip-definition settings &gt; use- tgrp-inf [UseSIPtgrp]</pre>	<p>Enables the device to add the SIP 'tgrp' parameter to outgoing SIP message requests. This parameter specifies the Trunk Group to which the call belongs (according to RFC 4904). For example, the INVITE message below indicates that the call belongs to Trunk Group ID 1:</p> <pre>INVITE sip:++16305550100;tgrp=1;trunk- context=example.com@10.1.0.3;user=phone SIP/2.0</pre> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device doesn't use (and add) the 'tgrp' parameter.</li> <li>■ [1] <b>Send Only</b> = The device adds the Trunk Group number or name (configured in the Trunk Group Settings table) as the 'tgrp' parameter value in the Contact header of outgoing INVITE messages. If a Trunk Group number or name is not associated with the call, the device doesn't add the 'tgrp' parameter. If a 'tgrp' value is present in incoming messages, the device ignores it.</li> <li>■ [2] <b>Send &amp; Receive</b> = The functionality of outgoing SIP messages is identical to the functionality described for option <b>Send Only</b>. In addition, for incoming SIP INVITEs (IP-to-Tel), if the Request-URI includes the 'tgrp' parameter, the device routes the call according to that value (if possible). In the outgoing SIP INVITE (Tel-to-IP call), the device adds "tgrp=&lt;source trunk group ID&gt;;trunk-context=&lt;gateway IP address&gt;" to the Contact header. The &lt;source trunk group ID&gt; is the Trunk Group ID where incoming calls from Tel is received. For IP-to-Tel calls, the SIP 200 OK device's response contains "tgrp=&lt;destination trunk group ID&gt;;trunk-context=&lt;gateway IP address&gt;". The &lt;destination trunk group ID&gt; is the Trunk Group ID used for outgoing Tel calls.</li> </ul>

Parameter	Description
	<p>You can configure the &lt;gateway IP address&gt; in “trunk-context”, using the [SIPGatewayName] parameter.</p> <p>■ [3] <b>Hotline</b> = Interworks the hotline "Off Hook Indicator" parameter between SIP and ISDN. This option is applicable only to digital interfaces.</p> <p>✓ IP-to-ISDN calls:</p> <ul style="list-style-type: none"> <li>• The device interworks the SIP 'tgrp=hotline' parameter (received in INVITE) to ISDN Setup with the Off Hook Indicator IE of “Voice”, and “Speech” Bearer Capability IE. Note that the Off Hook Indicator IE is described in UCR 2008 specifications.</li> <li>• The device interworks the SIP 'tgrp=hotline-ccdata' parameter (received in INVITE) to ISDN Setup with an Off Hook Indicator IE of “Data”, and with “Unrestricted 64k” Bearer Capability IE. The following is an example of an INVITE with 'tgrp=hotline-ccdata':</li> </ul> <pre>INVITE sip:1234567;tgrp=hotline-ccdata;trunk-context=dsn.mil@example.com</pre> <p>✓ ISDN-to-IP calls:</p> <ul style="list-style-type: none"> <li>• The device interworks ISDN Setup with an Off Hook Indicator of “Voice” to SIP INVITE with 'tgrp=hotline;trunk-context=dsn.mil' in the Contact header.</li> <li>• The device interworks ISDN Setup with an Off Hook indicator of “Data” to SIP INVITE with 'tgrp=hotline-ccdata;trunk-context=dsn.mil' in the Contact header.</li> <li>• If ISDN Setup doesn't contain an Off Hook Indicator IE and the Bearer Capability IE contains “Unrestricted 64k”, the outgoing INVITE includes 'tgrp=ccdata;trunk-context=dsn.mil'. If the Bearer Capability IE contains “Speech”, the INVITE in this case doesn't contain 'tgrp' and 'trunk-context' parameters.</li> </ul> <p>■ [4] <b>Hotline Extended</b> = Interworks the ISDN Setup message's hotline "OffHook Indicator" Information Element (IE) to SIP INVITE's Request-URI and Contact headers. (Note: For IP-to-</p>

Parameter	Description
	<p>ISDN calls, the device handles the call as described in option <b>Hotline</b>.) This option is applicable only to digital interfaces.</p> <ul style="list-style-type: none"> <li>✓ The device interworks ISDN Setup with an Off Hook Indicator of “Voice” to SIP INVITE Request-URI and Contact header with 'tgrp=hotline;trunk-context=dsn.mil'.</li> <li>✓ The device interworks ISDN Setup with an Off Hook indicator of “Data” to SIP INVITE Request-URI and Contact header with 'tgrp=hotline-ccdata;trunk-context=dsn.mil'.</li> <li>✓ If ISDN Setup doesn't contain an Off Hook Indicator IE and the Bearer Capability IE contains “Unrestricted 64k”, the outgoing INVITE Request-URI and Contact header includes 'tgrp=ccdata;trunk-context=dsn.mil'. If the Bearer Capability IE contains “Speech”, the INVITE in this case doesn't contain tgrp and trunk-context parameters.</li> </ul> <ul style="list-style-type: none"> <li>■ [5] <b>Send Only Including Register</b> = The device adds the 'tgrp', 'trunk-context', and 'user=phone' parameters to the Contact header of outgoing SIP INVITE and REGISTER requests.</li> <li>■ [6] <b>Send &amp; Receive Including Register</b> = The device adds the 'tgrp', 'trunk-context', and 'user=phone' parameters to the Contact header of outgoing SIP INVITE and REGISTER requests. In addition, the device uses these parameters if they are present in the Request-URI of incoming INVITE requests.</li> </ul> <p><b>Note:</b> IP-to-Tel configuration (see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960) overrides the 'tgrp' parameter in incoming INVITE messages.</p>
<pre>configure voip &gt; gateway routing settings &gt; tgrp- routing-prec [TGRPrountingPreceden ce]</pre>	<p>Defines the precedence method for IP-to-Tel call routing - according to the IP-to-Tel Routing table or the SIP 'tgrp' parameter.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) IP-to-Tel routing is determined by the IP-to-Tel Routing table (see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960). If a matching routing rule is not found, the device uses the Trunk Group parameters for routing the call.</li> <li>■ [1] = The device first places precedence on the 'tgrp'</li> </ul>

Parameter	Description
	<p>parameter for IP-to-Tel routing. If the received Request-URI in the INVITE message doesn't contain the 'tgrp' parameter, or if the Trunk Group number is not defined, the device uses the IP-to-Tel Routing table to route the call.</p> <p>The following example shows an INVITE Request-URI with the 'tgrp' parameter, indicating that the IP call should be routed to Trunk Group 7:</p> <pre>INVITE sip:200;tgrp=7;trunk-context=example.com@10.33.2.68;user=phone SIP/2.0</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable routing based on the SIP 'tgrp' parameter, see the [UseSIPtgrp] parameter.</li> <li>■ Instead of the 'tgrp' parameter for IP-to-Tel routing, you can use the SIP 'dtg' parameter (see the [UseBroadsoftDTG] parameter).</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; use- dtg [UseBroadsoftDTG]</pre>	<p>Defines if the device uses the SIP 'dtg' parameter for routing IP-to-Tel calls to a specific Trunk Group.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p>When enabled, if the Request-URI in the received SIP INVITE includes the 'dtg' parameter, the device routes the call to the Trunk Group according to its value. The parameter is used instead of the 'tgrp' and 'trunk-context' parameters. The 'dtg' parameter appears in the INVITE Request-URI (and in the To header). For example, the following received SIP message routes the call to Trunk Group ID 56:</p> <pre>INVITE sip:123456@192.168.1.2;dtg=56;user=phone SIP/2.0</pre> <p><b>Note:</b> If the Trunk Group is not found based on the 'dtg' parameter, the device uses the IP-to-Tel Routing table to route the call to the appropriate Trunk Group.</p>
<pre>'GRUU' configure voip &gt; sbc settings &gt; gruu [EnableGRUU]</pre>	<p>Enables the use of the Globally Routable User Agent URIs (GRUU) mechanism (according to RFC 5627). This is used for obtaining a GRUU from a registrar and for communicating a GRUU to a peer within a dialog.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>A GRUU is a SIP URI that routes to an instance-specific UA and can be reachable from anywhere. There are a number of contexts in which it is desirable to have an identifier that addresses a single UA (using GRUU) rather than the group of UA's indicated by an Address of Record (AOR). For example, in call transfer where user A is talking to user B, and user A wants to transfer the call to user C. User A sends a REFER to user C:</p> <pre>REFER sip:C@domain.com SIP/2.0 From: sip:A@domain.com;tag=99asd To: sip:C@domain.com Refer-To: (URI that identifies B's UA)</pre> <p>The Refer-To header needs to contain a URI that user C can use to place a call to user B. This call needs to route to the specific UA instance that user B is using to talk to user A. User B should provide user A with a URI that has to be usable by anyone. It needs to be a GRUU.</p> <ul style="list-style-type: none"> <li>■ Obtaining a GRUU: The mechanism for obtaining a GRUU is through registrations. A UA can obtain a GRUU by generating a REGISTER request containing a Supported header field with the value "gruu". The UA includes a "+sip.instance" Contact header parameter of each contact for which the GRUU is desired. This Contact parameter contains a globally unique ID that identifies the UA instance. The global unique ID is created from one of the following: <ul style="list-style-type: none"> <li>✓ If the REGISTER is per the device's client (endpoint), it is the MAC address concatenated with the phone number of the client.</li> <li>✓ If the REGISTER is per device, it is the MAC address only.</li> <li>✓ When using TP, "User Info" can be used for registering per endpoint. Thus, each endpoint can get a unique id – its phone number. The globally unique ID in TP is the MAC address concatenated with the phone number of the endpoint.</li> </ul> </li> </ul> <p>If the remote server doesn't support GRUU, it ignores the parameters of the GRUU. Otherwise, if the remote side also supports GRUU, the REGISTER responses contain the "gruu" parameter in each Contact header. The parameter contains a</p>

Parameter	Description
	<p>SIP or SIPS URI that represents a GRUU corresponding to the UA instance that registered the contact. The server provides the same GRUU for the same AOR and instance-id when sending REGISTER again after registration expiration. RFC 5627 specifies that the remote target is a GRUU target if its' Contact URL has the "gr" parameter with or without a value.</p> <ul style="list-style-type: none"> <li>■ Using GRUU: The UA can place the GRUU in any header field that can contain a URI. It must use the GRUU in the following messages: INVITE request, its 2xx response, SUBSCRIBE request, its 2xx response, NOTIFY request, REFER request and its 2xx response.</li> </ul>
[IsCiscoSCEMode]	<p>Determines whether a Cisco gateway exists at the remote side.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) No Cisco gateway exists at the remote side.</li> <li>■ [1] = A Cisco gateway exists at the remote side.</li> </ul> <p>When a Cisco gateway exists at the remote side, the device must set the value of the 'annexb' parameter of the fmtp attribute in the SDP to 'no'. This logic is used if the coder is enabled for Silenced Suppression. In this case, Silence Suppression is used on the channel but not declared in the SDP.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The [IsCiscoSCEMode] parameter is applicable only when the selected coder is G.729.</li> </ul>
'User-Agent Information' configure voip > sip-definition settings > user- agent-info [UserAgentDisplayInfo]	<p>Defines the string that is used in the SIP User-Agent and Server response headers. When configured, the string &lt;UserAgentDisplayInfo value&gt;/software version' is used, for example:</p> <p>User-Agent: myproduct/7.60A.100.022</p> <p>If not configured, the default string, "&lt;product-name&gt;/&lt;software version&gt;" is used, for example:</p> <p>User-Agent: AudioCodes-Sip-Gateway/&lt;swver&gt;</p> <p>The maximum string length is 50 characters.</p> <p><b>Note:</b> The software version number and preceding forward slash (/) cannot be modified. Therefore, it is recommended not to include a forward slash in the parameter's value (to avoid two forward slashes in the SIP header, which may cause problems).</p>
'SDP Session Owner'	Defines the value of the Owner line ('o' field) in outgoing SDP

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; sdp- session-owner</pre> <p>[SIPSDPSessionOwner]</p>	<p>messages.</p> <p>The valid range is a string of up to 39 characters. The default is "AudioCodesGW".</p> <p>For example:</p> <pre>o=AudioCodesGW 1145023829 1145023705 IN IP4 10.33.4.126</pre> <p><b>Note:</b> The parameter is applicable only to the SBC application when the device creates a new SIP message (and SDP) such as when the device plays a ringback tone. The parameter is not applicable to SIP messages that the device receives from one end and sends to another (i.e., doesn't modify the SDP's 'o' field).</p>
<pre>configure voip &gt; sip-definition settings &gt; sdp- ver-nego</pre> <p>[EnableSDPVersionNegotiation]</p>	<p>Enables the device to ignore new SDP re-offers (from the media negotiation perspective) in certain scenarios (such as session expires). According to RFC 3264, once an SDP session is established, a new SDP offer is considered a new offer only when the SDP origin value is incremented. In scenarios such as session expires, SDP negotiation is irrelevant and thus, the origin field is not changed.</p> <p>Even though some SIP devices don't follow this behavior and don't increment the origin value even in scenarios where they want to re-negotiate, the device can assume that the remote party operates according to RFC 3264, and in cases where the origin field is not incremented, the device doesn't re-negotiate SDP capabilities.</p> <ul style="list-style-type: none"> <li>■ [0] Disable = (Default) The device negotiates any new SDP re-offer, regardless of the origin field.</li> <li>■ [1] Enable = The device negotiates only an SDP re-offer with an incremented origin field.</li> </ul>
<pre>configure voip &gt; gateway advanced &gt; use- conn-sdp-ses-or- media</pre> <p>[GwSDPConnectionMode]</p>	<p>Defines how the device displays the Connection ("c=") line in the SDP Offer/Answer model.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) The Connection ("c=") line is displayed as follows: <ul style="list-style-type: none"> <li>✓ Offer: In the session description only.</li> <li>✓ Answer: In the session description and in each media ("m=") description.</li> </ul> </li> <li>■ [1] = For Offer and Answer, the Connection ("c=") line is displayed only in the session description; not in any media</li> </ul>

Parameter	Description
	<p>("m=") descriptions.</p> <ul style="list-style-type: none"> <li>■ [2] = The Connection ("c=") line is displayed only in media ("m=") descriptions.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Subject'</p> <pre>configure voip &gt; sip-definition settings &gt; usr- def-subject [SIPSubject]</pre>	<p>Defines the Subject header value in outgoing INVITE messages. If not specified, the Subject header isn't included (default). The maximum length is up to 50 characters.</p>
<pre>configure voip &gt; sip-definition settings &gt; coder-priority- nego [CoderPriorityNegotiation]</pre>	<p>Defines the priority for coder negotiation in the incoming SDP offer, between the device's or remote UA's coder list.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Coder negotiation is given higher priority to the remote UA's list of supported coders.</li> <li>■ [1] = Coder negotiation is given higher priority to the device's (local) supported coders list.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Send All Coders on Retrieve'</p> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; send- all-cdrs-on-rtrv [SendAllCodersOnRetrieve]</pre>	<p>Enables coder re-negotiation in the sent re-INVITE for retrieving an on-hold call.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Sends only the initially chosen coder when the call was first established and then put on-hold.</li> <li>■ [1] <b>Enable</b> = Includes all supported coders in the SDP of the re-INVITE sent to the call made un-hold (retrieved). The used coder is therefore, re-negotiated.</li> </ul> <p>The parameter is useful in the following call scenario example:</p> <ol style="list-style-type: none"> <li>1. Party A calls party B and coder G.711 is chosen.</li> <li>2. Party B is put on-hold while Party A blind transfers Party B to Party C.</li> <li>3. Party C answers and Party B is made un-hold. However, as Party C supports only G.729 coder, re-negotiation of the supported coder is required.</li> </ol> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>

Parameter	Description
<p>'Multiple Packetization Time Format'</p> <pre>configure voip &gt; sip-definition settings &gt; mult- ptime-format</pre> <p>[MultiPtimeFormat]</p>	<p>Determines whether the 'mptime' attribute is included in the outgoing SDP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) Disabled.</li> <li>■ [1] <b>PacketCable</b> = Includes the 'mptime' attribute in the outgoing SDP - PacketCable-defined format.</li> </ul> <p>The mptime' attribute enables the device to define a separate packetization period for each negotiated coder in the SDP. The 'mptime' attribute is only included if the parameter is enabled even if the remote side includes it in the SDP offer. Upon receipt, each coder receives its 'ptime' value in the following precedence: from 'mptime' attribute, from 'ptime' attribute, and then from default value.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<pre>configure voip &gt; sip-definition settings &gt; enable-ptime</pre> <p>[EnablePtime]</p>	<p>Defines if the 'ptime' attribute is included in the SDP.</p> <ul style="list-style-type: none"> <li>■ [0] = Remove the 'ptime' attribute from SDP.</li> <li>■ [1] = (Default) Include the 'ptime' attribute in SDP.</li> </ul>
<p>'3xx Behavior'</p> <pre>3xx-behavior</pre> <p>[3xxBehavior]</p>	<p>Determines the device's behavior regarding call identifiers when a 3xx response is received for an outgoing INVITE request. The device can use the same call identifiers (Call-ID, To, and From tags) or change them in the new initiated INVITE.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Forward</b> = (Default) Use different call identifiers for a redirected INVITE message.</li> <li>■ [1] <b>Redirect</b> = Use the same call identifiers in the new INVITE as the original call.</li> </ul>
<p>'P-Charging Vector'</p> <pre>p-charging- vector</pre> <p>[EnablePChargingVector]</p>	<p>Enables the device to include the SIP P-Charging-Vector header in outgoing INVITE messages.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<pre>configure voip &gt; sip-definition settings</pre>	<p>Defines the device's behavior when it receives a SIP 503 (Service Unavailable) containing a Retry-After header, in response to a SIP message (e.g., REGISTER) sent to a proxy</p>

Parameter	Description
<pre>&gt; retry-after-mode</pre> <p>[RetryAfterMode]</p>	<p>server.</p> <p>In certain scenarios (depending on the value of this parameter), the device considers the proxy as offline (down) for the number of seconds specified in the Retry-After header. During this timeout, the device doesn't send any SIP messages to the proxy. This condition is indicated in the syslog message as "server is now Unavailable - setting Retry-After timer to x secs".</p> <ul style="list-style-type: none"> <li>■ [1] = (Default) Handle Locally. The device considers the proxy as offline regardless of the type of SIP message sent to the proxy for which the 503 response was received.</li> <li>■ [0] = Transparent. The behavior depends on the type of SIP message sent to the proxy for which the 503 response was received: <ul style="list-style-type: none"> <li>✓ SIP OPTIONS message: The device considers the proxy as offline.</li> <li>✓ SIP REGISTER message generated (created) by the device: The device doesn't send REGISTER messages to the proxy for this <b>specific</b> registration process (i.e., Accounts table or SBC User Information table) during the timeout specified in the Retry-After header of the 503 response. However, the device considers the proxy as online and therefore, it continues sending traffic of other entities to the proxy.</li> <li>✓ All other SIP dialogs (e.g., INVITE): The device ignores the Retry-After header and forwards the 503 response transparently to the other user agent.</li> </ul> </li> </ul>
<p>'Retry-After Time'</p> <pre>configure voip &gt; sip-definition settings &gt; retry-afr-time</pre> <p>[RetryAfterTime]</p>	<p>Defines the time (in seconds) used in the Retry-After header when a 503 (Service Unavailable) response is generated by the device.</p> <p>The time range is 0 to 3,600. The default is 0.</p>
<p>'Fake Retry After'</p> <pre>fake-retry-after</pre> <p>[FakeRetryAfter]</p>	<p>Defines if the device, upon receiving a SIP 503 response without a Retry-After header, behaves as if the 503 response included a Retry-After header and with the period (in seconds) specified by the parameter.</p> <ul style="list-style-type: none"> <li>■ [0] Disable (default)</li> <li>■ Any positive value (in seconds) for defining the period</li> </ul>

Parameter	Description
	<p>When enabled, this feature allows the device to operate with Proxy servers that do not include the Retry-After SIP header in SIP 503 (Service Unavailable) responses to indicate an unavailable service.</p> <p>The Retry-After header is used with the 503 (Service Unavailable) response to indicate how long the service is expected to be unavailable to the requesting SIP client. The device maintains a list of available proxies, by using the Keep-Alive mechanism. The device checks the availability of proxies by sending SIP OPTIONS every keep-alive timeout to all proxies. If the device receives a SIP 503 response to an INVITE, it also marks that the proxy is out of service for the defined "Retry-After" period.</p>
'P-Associated-URI Header' p-associated-uri-hdr [EnablePAssociatedURI Header]	<p>Defines the device usage of the SIP P-Associated-URI header. This header can be received in 200 OK responses to REGISTER requests. When enabled, the first URI in the P-Associated-URI header is used in subsequent requests as the From/P-Asserted-Identity headers value.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p><b>Note:</b> P-Associated-URIs in registration responses is handled only if the device is registered per endpoint (using the User Information file).</p>
configure voip > gateway digital settings > format-dst- phone-number [FormatDestPhoneNu mber]	<p>Defines if the destination phone number that the device sends to the Tel side (for IP-to-Tel calls), includes the user-part parameters (e.g., 'password' and 'phone-context') of the destination URI received in the incoming SIP INVITE message.</p> <p>■ [0] = (Transparent) The device includes the user-part parameters (if exist) in the destination phone number sent to the Tel side.</p> <p>■ [1] = (Default) The device excludes the user-part parameters and letters (if exist) from the destination phone number sent to the Tel side.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
'Source Number Preference'	<p>Defines the SIP header from which the source (calling) number is obtained in incoming INVITE messages.</p>

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; src- nb-preference</pre> <p>[SourceNumberPreference]</p>	<ul style="list-style-type: none"> <li>■ If not configured or if any string other than "From" or "Pai2" is configured, the calling number is obtained from a specific header using the following logic: <ul style="list-style-type: none"> <li>a. P-Preferred-Identity header.</li> <li>b. If the above header is not present, then the first P-Asserted-Identity header is used.</li> <li>c. If the above header is not present, then the Remote-Party-ID header is used.</li> <li>d. If the above header is not present, then the From header is used.</li> </ul> </li> <li>■ "From" = The calling number is obtained from the From header.</li> <li>■ "Pai2" = The calling number is obtained using the following logic: <ul style="list-style-type: none"> <li>e. If a P-Preferred-Identity header is present, the number is obtained from it.</li> <li>f. If no P-Preferred-Identity header is present and two P-Asserted-Identity headers are present, the number is obtained from the second P-Asserted-Identity header.</li> <li>g. If only one P-Asserted-Identity header is present, the calling number is obtained from it.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The "From" and "Pai2" values are not case-sensitive.</li> <li>■ Once a URL is selected, all the calling party parameters are set from this header. If P-Asserted-Identity is selected and the Privacy header has the value 'id', the calling number is assumed restricted.</li> </ul>
<p>'Enforce Media Order'</p> <pre>configure voip &gt; gateway advanced &gt; enforce-media- order</pre> <p>[EnforceMediaOrder]</p>	<p>Enables the device to include all previously negotiated media lines ('m=') within the current session in the SDP offer-answer exchange (RFC 3264).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For example, assume a call (audio) has been established between two endpoints and one endpoint wants to subsequently send an image in the same call session. If the</p>

Parameter	Description
	<p>parameter is enabled, the endpoint includes the previously negotiated media type (i.e., audio) with the new negotiated media type (i.e., image) in its SDP offer:</p> <pre>v=0 o=bob 2890844730 2890844731 IN IP4 host.example.com s= c=IN IP4 host.example.com t=0 0 <b>m=audio</b> 0 RTP/AVP 0 m=image 12345 udpt1 t38</pre> <p>In this example, if the parameter is disabled, the only 'm=' line included in the SDP is the newly negotiated media (i.e., image).</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<pre>configure voip &gt; sip-definition settings &gt; sec- call-src</pre> <p>[SecondCallingNumber Source]</p>	<p>Defines if the device sends a second source (calling) number, obtained from the incoming SIP INVITE message, to the Tel side.</p> <p>The valid value is "P-Asserted" (without quotation marks). By default, no value is defined.</p> <p>If the parameter is not configured to any value (i.e., default) or configured to any value other than "P-Asserted", the device doesn't send a second source number. If the parameter is configured to "P-Asserted" and the incoming INVITE message contains a P-Asserted-Identity header(s), the device sends a second source number that is obtained from the first listed P-Asserted-Identity header in the message. If the message doesn't include a P-Asserted-Identity header, the device sends a second source number that it obtains from the first source number (i.e., same number).</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Source Header For Called Number'</p> <pre>configure voip &gt; sip-definition settings &gt; src- hdr-4-called-nb</pre> <p>[SelectSourceHeaderFo rCalledNumber]</p>	<p>Defines the SIP header from which the called (destination) number is obtained for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>use RequestURI header</b> = (Default) Obtains the destination number from the user part of the Request-URI.</li> <li>■ [1] <b>use To header</b> = Obtains the destination number from the user part of the To header.</li> <li>■ [2] <b>use P-Called-Party-ID header</b> = Obtains the destination</li> </ul>

Parameter	Description
	<p>number from the P-Called-Party-ID header.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Reason Header'</p> <pre>configure voip &gt; sip-definition settings &gt; reason-header</pre> <p>[EnableReasonHeader]</p>	<p>Enables the device to include the SIP Reason header in the outgoing SIP response when a SIP request message fails.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<p>'Gateway Name'</p> <pre>configure voip &gt; sip-definition settings &gt; gw- name</pre> <p>[SIPGatewayName]</p>	<p>Defines a name for the device (e.g., device123.com), which is used as the host part for the SIP URI in the From header for outgoing messages. If not configured, the device's IP address is used instead (default).</p> <p>The valid value is a string of up to 100 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Ensure that the parameter value is the one with which the proxy has been configured with to identify the device.</li> <li>■ If you enable keep-alive by SIP OPTIONS messages with the proxy (see the Proxy Set parameter 'Proxy Keep-Alive'), you can configure, using the [UseGatewayNameForOptions] parameter, if the device's IP address, the proxy's IP address, or the device's name (configured by the [SIPGatewayName] parameter) is used in the keep-alive SIP OPTIONS messages (host part of the Request-URI).</li> <li>■ The parameter can also be configured for an IP Group (in the IP Groups table).</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; zero- sdp-behavior</pre> <p>[ZeroSDPHandling]</p>	<p>Defines if the device's response to an incoming SDP that includes an IP address of 0.0.0.0 in the SDP's Connection Information field (i.e., "c=IN IP4 0.0.0.0").</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Sets the IP address of the outgoing SDP's c= field to 0.0.0.0.</li> <li>■ [1] = Sets the IP address of the outgoing SDP c= field to the IP address of the device. If the incoming SDP doesn't contain the "a=inactive" line, the returned SDP contains the "a=recvonly" line.</li> </ul>

Parameter	Description
'Delayed Offer' configure voip > sip-definition settings > delayed-offer [EnableDelayedOffer]	<p>Defines if the device sends the initial INVITE message with or without an SDP. Sending the first INVITE without SDP is typically done by clients for obtaining the far-end's full list of capabilities before sending their own offer. (An alternative method for obtaining the list of supported capabilities is by using SIP OPTIONS, which is not supported by every SIP agent.)</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device sends the initial INVITE message with an SDP.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device sends the initial INVITE message without an SDP.</li> </ul>
configure voip > sip-definition settings > digest-auth-uri- mode [SIPDigestAuthorization URIMode]	<p>Defines if the device includes or excludes URI parameters for the Digest URI in the SIP Proxy-Authorization or Authorization headers of the request that the device sends in reply to a received SIP 401 (Unauthorized) or 407 (Proxy Authentication Required) response.</p> <p>Below shows an example of a request with an Authorization header containing a Digest URI (shown in bold):</p> <pre>Authorization: Digest username="alice at AudioCodes.com", realm="AudioCodes .com", nonce="", response="", uri="sip: <b>AudioCodes.com</b>"</pre> <ul style="list-style-type: none"> <li>■ [0] = (Default) The device sends the request without a Digest URI.</li> <li>■ [1] = The device sends the request with a Digest URI, which is set to the same value as the URI in the original Request-URI.</li> </ul>
configure voip > sip-definition settings > crypto-life- time-in-sdp [DisableCryptoLifeTime InSDP]	<p>Enables the device to send "a=crypto" lines without the lifetime parameter in the SDP. For example, if the SDP contains "a=crypto:12 AES_CM_128_HMAC_SHA1_80 inline:hhQe10yZRcRcpIFPkH5xYY9R1de37ogh9G1MpvNp 2^31", it removes the lifetime parameter "2^31".</p> <ul style="list-style-type: none"> <li>■ [0] Disable (default)</li> <li>■ [1] Enable</li> </ul>
'AES-256 Encryption Key' configure voip > sip-definition	<p>Defines the AES-256 encryption key for encrypting (and decrypting) the SIP header value.</p> <p>The valid value is a string of 32 characters. By default, no value is defined.</p>

Parameter	Description
<pre>settings &gt; encrypt-key- aes256</pre> <p>[EncryptKeyAES256]</p>	<p>For more information, see <a href="#">Configuring SIP Header Value Encryption</a> on page 276.</p>
<pre>'Contact Restriction' contact- restriction</pre> <p>[EnableContactRestriction]</p>	<p>Enables the device to set the SIP Contact header in outgoing INVITE requests to 'anonymous' for restricted calls.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; anonymous-mode</pre> <p>[AnonymousMode]</p>	<p>Defines if the device's IP address is used as the URI host part instead of "anonymous.invalid" in the INVITE's From header for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) If the device receives a call from the Tel with blocked caller ID, it sends an INVITE with From: "anonymous"&lt;anonymous@anonymous.invalid&gt;</li> <li>■ [1] = The device's IP address is used as the URI host part instead of "anonymous.invalid".</li> </ul> <p>The parameter may be useful, for example, for service providers who identify their SIP Trunking customers by their source phone number or IP address, reflected in the From header of the SIP INVITE. Therefore, even customers blocking their Caller ID can be identified by the service provider. Typically, if the device receives a call with blocked Caller ID from the PSTN side (e.g., Trunk connected to a PBX), it sends an INVITE to the IP with a From header as follows: "From: "anonymous"&lt;anonymous@anonymous.invalid&gt;". This is in accordance with RFC 3325. However, when the parameter is set to 1, the device replaces the "anonymous.invalid" with its IP address.</p>
<pre>configure voip &gt; sip-definition settings &gt; p- assrtd-usr-name</pre> <p>[PAssertedUserName]</p>	<p>Defines a 'representative number' (up to 50 characters) that is used as the user part of the Request-URI in the P-Asserted-Identity header of an outgoing INVITE for Tel-to-IP calls.</p> <p>The default is null.</p>
<pre>configure voip &gt; sip-definition settings &gt; use- aor-in-refer-to- header</pre>	<p>Defines the source for the SIP URI set in the Refer-To header of outgoing REFER messages.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Use SIP URI from Contact header of the initial call.</li> </ul>

Parameter	Description
[UseAORInReferToHeader]	<ul style="list-style-type: none"> <li>■ [1] = Use SIP URI from To/From header of the initial call.</li> </ul>
'User-Information Usage' <pre>configure voip &gt; sip-definition settings &gt; user-inf-usage</pre> [EnableUserInfoUsage]	<p>Enables the User Information table and functionality. For more information on User Information, see <a href="#">Configuring User Information</a> on page 795.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; sip-definition settings &gt; handle-reason-header</pre> [HandleReasonHeader]	<p>Defines if the device uses the value of the incoming SIP Reason header for Release Reason mapping.</p> <ul style="list-style-type: none"> <li>■ [0] = Disregard Reason header in incoming SIP messages.</li> <li>■ [1] = (Default) Use the Reason header value for Release Reason mapping.</li> </ul>
[EnableSilenceSuppInSDP]	<p>Determines the device's behavior upon receipt of SIP Re-INVITE messages that include the SDP's 'silencesupp:off' attribute.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disregard the 'silecesupp' attribute.</li> <li>■ [1] = Handle incoming Re-INVITE messages that include the 'silencesupp:off' attribute in the SDP as a request to switch to the Voice-Band-Data (VBD) mode. In addition, the device includes the attribute 'a=silencesupp:off' in its SDP offer.</li> </ul> <p><b>Note:</b> The parameter is applicable only if the G.711 coder is used.</p>
'Enables Rport option in VIA header' <pre>configure voip &gt; sip-definition settings &gt; rport-support</pre> [EnableRport]	<p>Enables the use of the 'rport' parameter in the SIP Via header.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>The device adds an 'rport' parameter to the Via header of each outgoing SIP message. The first Proxy that receives this message sets the 'rport' value of the response to the actual port from where the request was received. This method is used, for example, to enable the device to identify its port mapping outside a NAT.</p> <ul style="list-style-type: none"> <li>■ If the Via header doesn't include the 'rport' parameter, the destination port of the response is obtained from the host</li> </ul>

Parameter	Description
	<p>part of the Via header.</p> <ul style="list-style-type: none"> <li>■ If the Via header includes the 'rport' parameter without a port value, the destination port of the response is the source port of the incoming request.</li> <li>■ If the Via header includes 'rport' with a port value (e.g., rport=1001), the destination port of the response is the port indicated in the 'rport' parameter.</li> </ul>
<p>'X-Channel Header'</p> <pre>configure voip &gt; sip-definition settings &gt; x- channel-header [XChannelHeader]</pre>	<p>Enables the device to add the SIP X-Channel header to outgoing SIP messages. The header provides information on the physical analog channel or Trunk/B-channel on which the call is received or sent.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The X-Channel header is not added.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The X-Channel header is generated by the device and sent in SIP INVITE requests and 180, 183, and 200 OK responses. The header includes the analog channel or Trunk/B-channel and the device's IP address, using the following syntax: <p>x-channel: ds/ds1-&lt;digital Trunk number&gt;/&lt;analog channel or Trunk/B-channel&gt;;IP=&lt;device's IP address&gt;</p> <p>For example, the below shows a call on Trunk 1, channel 4 of the device with IP address 192.168.13.1:</p> <p>x-channel: ds/ds1-1/4;IP=192.168.13.1</p> </li></ul>
<p>'Progress Indicator to IP'</p> <pre>configure voip &gt; sip-definition settings &gt; prog- ind-2ip [ProgressIndicator2IP]</pre>	<p>Global parameter defining the progress indicator (PI) sent to the IP.</p> <p>You can also configure the feature per specific calls, using IP Profiles ('Progress Indicator to IP' parameter) or Tel Profiles ('Progress Indicator to IP' parameter). For a detailed description of the parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If you configure this feature for a specific profile, the device ignores this global parameter for calls associated with the profile.</p>
<p>'Enable Rekey After 181'</p> <pre>configure voip &gt;</pre>	<p>Enables the device to send a SIP re-INVITE request with a new (different) SRTP key (in the SDP) if a SIP 181 response is received ("call is being forwarded"). The device sends the re-INVITE</p>

Parameter	Description
gateway digital settings > rekey-after-181 [EnableRekeyAfter181]	<p>immediately after receiving the 200 OK (when the call is answered).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> The parameter is applicable only if SRTP is used.</p>
configure voip > sip-definition settings > number-of-active-dialogs [NumberOfActiveDialogs]	<p>Defines the maximum number of concurrent, outgoing SIP REGISTER dialogs. The parameter is used to control the registration rate.</p> <p>The valid range is 1 to 20. The default is 20.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Once a 200 OK is received in response to a REGISTER message, the REGISTER message is not considered in this maximum count limit.</li> <li>■ The parameter applies only to outgoing REGISTER messages (i.e., incoming is unlimited).</li> </ul>
'Network Node ID' configure voip > sip-definition settings > net-node-id [NetworkNodeid]	<p>Defines the Network Node Identifier of the device for Avaya UCID.</p> <p>The valid value range is 1 to 0x7FFF. The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To use this feature, you must set the parameter to any value other than 0.</li> <li>■ To enable the generation by the device of the Avaya UCID value and adding it to the outgoing INVITE sent to the IP Group (Avaya entity), use the IP Groups table's parameter 'UUI Format'.</li> </ul>
'Default Release Cause' configure voip > sip-definition settings > dflt-release-cse [DefaultReleaseCause]	<p>Defines the default Release Cause (sent to IP) for IP-to-Tel calls when the device initiates a call release and an explicit matching cause for this release is not found.</p> <p>The default release cause is NO_ROUTE_TO_DESTINATION (3). Other common values include NO_CIRCUIT_AVAILABLE (34), DESTINATION_OUT_OF_ORDER (27), etc.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The default release cause is described in the Q.931 notation and is translated to corresponding SIP 40x or 50x values (e.g., 3 to SIP 404, and 34 to SIP 503).</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Analog: For more information on mapping PSTN release causes to SIP responses, see <a href="#">Mapping PSTN Release Cause to SIP Response for Analog Interfaces</a> on page 1022.</li> <li>■ Digital: When the Trunk is disconnected or is not synchronized, the internal cause is 27. This cause is mapped, by default, to SIP 502.</li> <li>■ For mapping SIP-to-Q.931 and Q.931-to-SIP release causes, see <a href="#">Configuring Release Cause Mapping</a> on page 1009.</li> <li>■ For a list of SIP responses-Q.931 release cause mapping, see <a href="#">Alternative Routing to Trunk upon Q.931 Call Release Cause Code</a> on page 977.</li> </ul>
'Enable Microsoft Extension' <pre>configure voip &gt; sip-definition settings &gt; microsoft-ext [EnableMicrosoftExt]</pre>	<p>Enables the modification of the called and calling number for numbers received with Microsoft's proprietary "ext=xxx" parameter in the SIP INVITE URI user part. Microsoft Office Communications Server sometimes uses this proprietary parameter to indicate the extension number of the called or calling party.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For example, if a calling party makes a call to telephone number 622125519100 Ext. 104, the device receives the SIP INVITE (from Microsoft's application) with the URI user part as INVITE sip:622125519100;ext=104@10.1.1.10 (or INVITE tel:622125519100;ext=104). If the parameter [EnableMicrosoftExt] is enabled, the device modifies the called number by adding an "e" as the prefix, removing the "ext=" parameter, and adding the extension number as the suffix (e.g., e622125519100104). Once modified, the device can then manipulate the number further, using the Number Manipulation tables to leave only the last 3 digits (for example) for sending to a PBX.</p>
<pre>configure voip &gt; sip-definition settings &gt; sip- uri-for- diversion-header [UseSIPURIForDiversio nHeader]</pre>	<p>Defines the URI format in the SIP Diversion header.</p> <ul style="list-style-type: none"> <li>■ [0] = 'tel:' (default)</li> <li>■ [1] = 'sip:'</li> </ul>

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; 100- to-18x-timeout</pre> <p>[TimeoutBetween100And18x]</p>	<p>Defines the timeout (in msec) between receiving a 100 Trying response and a subsequent 18x response. If a 18x response is not received within this timeout period, the call is disconnected. The valid range is 0 to 180,000 (i.e., 3 minutes). The default is 32000 (i.e., 32 sec).</p>
<pre>configure voip &gt; sip-definition settings &gt; immediate-trying</pre> <p>[EnableImmediateTrying]</p>	<p>Determines if and when the device sends a 100 Trying in response to an incoming INVITE request.</p> <ul style="list-style-type: none"> <li>■ [0] = 100 Trying response is sent upon receipt of a Proceeding message from the PSTN.</li> <li>■ [1] = (Default) 100 Trying response is sent immediately upon receipt of INVITE request.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; trans-coder- present</pre> <p>[TransparentCoderPresentation]</p>	<p>Determines the format of the Transparent coder representation in the SDP.</p> <ul style="list-style-type: none"> <li>■ [0] = clearmode (default)</li> <li>■ [1] = X-CCD</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; ignore-remote- sdp-mki</pre> <p>[IgnoreRemoteSDPMKI]</p>	<p>Determines whether the device ignores the Master Key Identifier (MKI) if present in the SDP received from the remote side.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul>
<p>'Comfort Noise Generation Negotiation'</p> <pre>configure voip &gt; media rtp-rtcp &gt; com-noise-gen- nego</pre> <p>[ComfortNoiseNegotiation]</p>	<p>Enables negotiation and the use of Comfort Noise (CN) for Gateway calls.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information, see <a href="#">Enabling Comfort Noise Generation</a> on page 298.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<pre>configure voip &gt; sip-definition settings &gt; sdp-</pre>	<p>Defines the echo canceller format in the outgoing SDP. The 'ecan' attribute is used in the SDP to indicate the use of echo cancellation.</p>

Parameter	Description
<code>ecan-frmt</code> [SDPEcanFormat]	<ul style="list-style-type: none"> <li>■ [0] = (Default) The 'ecan' attribute appears on the 'a=gpmid' line.</li> <li>■ [1] = The 'ecan' attribute appears as a separate attribute.</li> <li>■ [2] = The 'ecan' attribute is not included in the SDP.</li> <li>■ [3] = The 'ecan' attribute and the 'vbd' parameter are not included in the SDP.</li> </ul> <p><b>Note:</b> The parameter is applicable only when the [IsFaxUsed] parameter is set to 2, and for re-INVITE messages generated by the device as result of modem or fax tone detection.</p>
'First Call Ringback Tone ID' <code>configure voip &gt;</code> <code>sip-definition</code> <code>settings &gt; 1st-</code> <code>call-rbt-id</code> [FirstCallRBTId]	<p>Defines the index of the first ringback tone in the CPT file. This option enables an Application server to request the device to play a distinctive ringback tone to the calling party according to the destination of the call. The tone is played according to the Alert-Info header received in the 180 Ringing SIP response (the value of the Alert-Info header is added to the value of the parameter).</p> <p>The valid range is -1 to 1,000. The default is -1 (i.e., play standard ringback tone).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ It is assumed that all ringback tones are defined in sequence in the CPT file.</li> <li>■ In case of an MLPP call, the device uses the value of the parameter plus 1 as the index of the ringback tone in the CPT file (e.g., if this value is set to 1, then the index is 2, i.e., 1 + 1).</li> </ul>
'Reanswer Time' <code>configure voip &gt;</code> <code>sip-definition</code> <code>settings &gt;</code> <code>reanswer-time</code> [RegretTime]	<p>Analog: Defines the time interval from when the user hangs up the phone until the call is disconnected (FXS). This allows the user to hang up and then pick up the phone (before this timeout) to continue the call conversation. Thus, it's also referred to as regret time.</p> <p>Digital: Defines the time period the device waits for an MFC R2 Resume (Reanswer) signal once a Suspend (Clear back) signal is received from the PBX. If this timer expires, the call is released.</p> <p>The valid range is 0 to 255 (in seconds). The default is 0.</p> <p><b>Note:</b> For digital interfaces, the parameter is applicable only to the MFC-R2 CAS Brazil variant.</p>
<code>configure voip &gt;</code>	For FXS interfaces: Enables the device to send a SIP INFO

Parameter	Description
<pre>gateway advanced &gt; reans-info- enbl</pre> <p>[EnableReansweringINFO]</p>	<p>message with the On-Hook/Off-Hook parameter when the FXS phone goes on-hook during an ongoing call and then off-hook again, within the user-defined regret timeout (configured by the [RegretTime] parameter). Therefore, the device notifies the far-end that the call has been re-answered.</p> <p>Digital: The parameter is used for private wire services (see <a href="#">Configuring Private Wire Interworking</a> on page 919).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p>For FXS interfaces: The parameter is typically implemented for incoming IP-to-Tel collect calls to the FXS port. If the FXS user doesn't wish to accept the collect call, the user disconnects the call by on-hooking the phone. The device notifies the softswitch (or Application server) of the unanswered collect call (on-hook) by sending a SIP INFO message. As a result, the softswitch disconnects the call (sends a BYE message to the device). If the call is a regular incoming call and the FXS user on-hooks the phone without intending to disconnect the call, the softswitch doesn't disconnect the call (during the regret time).</p> <p>The INFO message format is as follows:</p> <pre>INFO sip:12345@10.50.228.164:5082 SIP/2.0 Via: SIP/2.0/UDP 127.0.0.1;branch=z9hG4bK_ 05_905924040-90579 From: &lt;sip:+551137077803@ims.acme.com.br:5080;use r=phone&gt;;tag=008277765 To: &lt;sip:notavailable@unknown.invalid&gt;;tag=svw- 0-1229428367 Call-ID: ConorCCR-0-LU- 1229417827103300@dtas-stdn.fs5000group0- 000.1 CSeq: 1 INFO Contact: sip:10.20.7.70:5060 Content-Type: application/On-Hook (application/Off-Hook) Content-Length: 0</pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the [RegretTime] parameter is configured.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For digital interfaces, the parameter is applicable only to E1/T1 CAS.</li> <li>■ For analog interfaces, the parameter is applicable only to FXS interfaces.</li> </ul>
'Presence Publish IP Group ID' presence-publish-ip-group-name [PresencePublishIPGroupName]	<p>Assigns the IP Group configured for Microsoft Teams providing user presence service. the device sends SIP PUBLISH messages to this IP Group to notify changes in presence status of Teams users when making and receiving calls using third-party endpoint devices.</p> <p>For more information on integration with Microsoft presence, see <a href="#">Microsoft Skype for Business Presence of Third-Party Endpoints</a> on page 514.</p>
'Microsoft Presence Status' [EnableMSPresence]	<p>Enables the device to notify (using SIP PUBLISH messages) Microsoft Teams (presence server) of changes in presence status of Teams users when making and receiving calls using third-party endpoint devices.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information on integration with Microsoft presence, see <a href="#">Microsoft Skype for Business Presence of Third-Party Endpoints</a> on page 514.</p>
'PSTN Alert Timeout' configure voip > sip-definition settings > pstn-alert-timeout [PSTNAlertTimeout]	<p>Digital: Defines the Alert Timeout (in seconds) for calls sent to the PSTN. This timer is used between the time a Setup message is sent to the Tel side (IP-to-Tel call establishment) and a Connect message is received. If an Alerting message is received, the timer is restarted. If the timer expires before the call is answered, the device disconnects the call and sends a SIP 408 request timeout response to the SIP party that initiated the call.</p> <p>Analog: Defines the Alert Timeout (in seconds) for calls to the Tel side. This timer is used between the time a ring is generated (FXS) or a line is seized (FXO), until the call is connected. For example: If the FXS device receives an INVITE, it generates a ring to the phone and sends a SIP 180 Ringing response to the IP. If the phone is not answered within the time interval set by the parameter, the device cancels the call by sending a SIP 408 response.</p> <p>The valid value range is 1 to 600 (in seconds). The default is 180.</p>

Parameter	Description
	<p><b>Note:</b> For digital interfaces: If per trunk configuration, using the [TrunkPSTNAlertTimeout] parameter, is set to other than default, the [PSTNAlertTimeout] parameter value is overridden.</p>
<p>'RTP Only Mode'</p> <pre>configure voip &gt; sip-definition settings &gt; rtp- only-mode</pre> <p>[RTPOnlyMode]</p>	<p>Enables the device to send and receive RTP packets to and from remote endpoints without the need to establish a SIP session. The remote IP address is determined according to the Tel-to-IP Routing table (Prefix parameter). The port is the same port as the local RTP port (configured by the [BaseUDPPort] parameter and the channel on which the call is received).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Transmit &amp; Receive</b> = Send and receive RTP packets.</li> <li>■ [2] <b>Transmit Only</b>= Send RTP packets only.</li> <li>■ [3] <b>Receive Only</b>= Receive RTP packets only.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ Digital interfaces: To activate the RTP Only feature without using ISDN / CAS signaling, you must do the following: <ul style="list-style-type: none"> <li>✓ Configure E1/T1 Transparent protocol type (set the [ProtoType] parameter to 5 or 6).</li> <li>✓ Enable the TDM-over-IP feature (set the [EnableTDMoverIP] parameter to 1).</li> </ul> </li> <li>■ To configure the RTP Only mode per trunk, use the [RTPOnlyModeForTrunk_x] parameter.</li> <li>■ If per trunk configuration (using the [RTPOnlyModeForTrunk_ID] parameter) is set to a value other than the default, the [RTPOnlyMode] parameter value is ignored.</li> </ul>
[RTPOnlyModeForTrunk_x]	<p>Enables the RTP Only feature per trunk. The x in the parameter name denotes the trunk number, where 0 is Trunk 1. For a description of the parameter, see the [RTPOnlyMode] parameter.</p> <p><b>Note:</b> For using the global parameter (i.e., setting the RTP Only feature for all trunks), set the parameter to -1 (default).</p>
'Media IP Version'	Global parameter that defines the preferred RTP media IP

Parameter	Description
<b>Preference'</b> <code>configure voip &gt; media settings &gt; media-ip-ver- pref</code> <b>[MediaIPVersionPreference]</b>	addressing version (IPv4 or IPv6) for outgoing SIP calls. You can also configure this feature per specific calls, using IP Profiles ('Media IP Version Preference' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.
<b>'SIT Q850 Cause'</b> <code>configure voip &gt; sip-definition settings &gt; sit- q850-cause</code> <b>[SITQ850Cause]</b>	Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when a Special Information Tone (SIT) is detected on an IP-to-Tel call.  The valid range is 0 to 127. The default is 34.  <b>Note:</b> For mapping specific SIT tones, use the following parameters: [SITQ850CauseForNC], [SITQ850CauseForIC], [SITQ850CauseForVC], and [SITQ850CauseForRO].
<b>'SIT Q850 Cause For NC'</b> <code>configure voip &gt; sip-definition settings &gt; release-cause- for-sit-nc</code> <b>[SITQ850CauseForNC]</b>	Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-NC (No Circuit Found Special Information Tone) is detected from the Tel side for IP-to-Tel calls.  The valid range is 0 to 127. The default is 34.  <b>Note:</b> When not configured (i.e., default), the [SITQ850Cause] parameter is used.
<b>'SIT Q850 Cause For IC'</b> <code>configure voip &gt; sip-definition settings &gt; q850- cause-for-sit-ic</code> <b>[SITQ850CauseForIC]</b>	Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-IC (Operator Intercept Special Information Tone) is detected from the Tel for IP-to-Tel calls.  The valid range is 0 to 127. The default is -1 (not configured).  <b>Note:</b> When not configured (i.e., default), the [SITQ850Cause] parameter is used.
<b>'SIT Q850 Cause For VC'</b> <code>configure voip &gt; sip-definition settings &gt; q850- cause-for-sit-vc</code> <b>[SITQ850CauseForVC]</b>	Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-VC (Vacant Circuit - non-registered number Special Information Tone) is detected from the Tel for IP-to-Tel calls.  The valid range is 0 to 127. The default is -1 (not configured).  <b>Note:</b> When not configured (i.e., default), the [SITQ850Cause] parameter is used.
<b>'SIT Q850 Cause For RO'</b>	Defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when SIT-RO (Reorder

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; q850- cause-for-sit-ro</pre> <p>[SITQ850CauseForRO]</p>	<p>- System Busy Special Information Tone) is detected from the Tel for IP-to-Tel calls.</p> <p>The valid range is 0 to 127. The default is -1 (not configured).</p> <p><b>Note:</b> When not configured (i.e., default), the [SITQ850Cause] parameter is used.</p>
<pre>configure voip &gt; message settings &gt; inbound-map- set</pre> <p>[GWInboundManipulationSet]</p>	<p>Gateway application only: Assigns a Manipulation Set ID for manipulating all inbound INVITE messages.</p> <p>Gateway and SBC applications: Assigns a Manipulation Set ID for manipulating incoming responses of requests that the device initiates.</p> <p>The Manipulation Set is defined using the [MessageManipulations] parameter. By default, no manipulation is done (i.e. Manipulation Set ID is set to -1).</p> <p>For more information, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p>
<pre>configure voip &gt; message settings &gt; outbound-map- set</pre> <p>[GWOOutboundManipulationSet]</p>	<p>Gateway application only: Assigns a Manipulation Set ID for manipulating all outbound INVITE messages.</p> <p>Gateway and SBC applications: Assigns a Manipulation Set ID for manipulating outgoing requests that the device initiates.</p> <p>The Manipulation Set is defined using the [MessageManipulations] parameter. By default, no manipulation is done (i.e. Manipulation Set ID is set to -1).</p> <p>For more information, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p>
<p>'WebSocket Keep-Alive Period'</p> <pre>configure voip &gt; sip-definition settings &gt; websocket- keepalive</pre> <p>[WebSocketProtocolKeepAlivePeriod]</p>	<p>Defines how often (in seconds) the device sends ping messages (keep alive) to check whether the WebSocket session with the Web client is still connected.</p> <p>The valid value is 5 to 2000000. The default is 0 (i.e., ping messages are not sent).</p> <p>For more information on WebSocket, see <a href="#">SIP over WebSocket</a> on page 1272.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device always replies to WebSocket ping control messages with pong messages.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Registered User MOS'	Defines the length of each interval (in hours) in the observation

Parameter	Description
<p>Observation Window'</p> <pre>configure voip &gt; qoe reg-user- voice-quality &gt; mos-observ-win</pre> <p>[RegUserMosObservationWindow]</p>	<p>window (12 intervals) for calculating average MOS of calls belonging to users registered with the device.</p> <p>The valid value is 1 or 2. The default is 1.</p> <p>As the device measures MOS in 12 intervals, if configured to 1, then MOS is measured over a 12 hour period; if configured to 2, then MOS is calculated over a 24 hour period. It measures the average and minimum MOS per interval. Intervals without calls are not used in the calculation.</p> <p>For more information on this feature, see <a href="#">Configuring Voice Quality for Registered Users</a> on page 544.</p> <p><b>Note:</b> This parameter is applicable only to the SBC application.</p>
<p>'MOS Stored Timeout For No Calls'</p> <pre>configure voip &gt; qoe reg-user- voice-quality &gt; mos-stored- timeout-for-no- calls</pre> <p>[MosStoredTimeoutForNoCalls]</p>	<p>Defines the duration (in minutes) of no calls after which the MOS measurement is reset (0 and gray color). In addition, if an alternative IP Profile is configured for the Quality of Service rule and is currently being used, the device changes back to the original IP Profile.</p> <p>The valid value range is 1 to 1,440. The default is 60.</p> <p>For more information on this feature, see <a href="#">Configuring Voice Quality for Registered Users</a> on page 544.</p> <p><b>Note:</b> This parameter is applicable only to the SBC application.</p>
<pre>configure voip &gt; sip-definition settings &gt; message-policy- reject-response- type</pre> <p>[MessagePolicyRejectResponseType]</p>	<p>Defines the SIP response code that the device sends when it rejects an incoming SIP message due to a matched Message Policy in the Message Policies table, whose 'Send Reject' parameter is configured to <b>Policy Reject</b>.</p> <p>The default is 400 "Bad Request".</p> <p>To configure Message Policies, see <a href="#">Configuring SIP Message Policy Rules</a> on page 867.</p>
<p>[ENUMAllowNonDigits]</p>	<p>Defines if non-digits can be included in ENUM queries sent by the device to an ENUM server for retrieving a SIP URI address for an E.164 telephone number (destination).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable – non-digits are not accepted in ENUM queries. For example: 9.2.0.0.3.0.9.3.0.3.0.2.5.3.4.4.2.5.7.7.8.My_Domain</li> <li>■ [1] = Enable – non-digits are accepted in ENUM queries (request). For example: 0.0.0.0.0.2.3.3.3.2.2.*.9.9.j.a.k.s.*.j.k.a.n.d.b.j.s.+My_</li> </ul>

Parameter	Description
	<p>Domain</p> <p>For the Gateway application: ENUM queries can be used for Tel-to-IP Routing (see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946). For the SBC application: ENUM queries can be used for IP-to-IP routing with Call Setup Rules (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186 and <a href="#">Configuring Call Setup Rules</a> on page 809).</p>
<p>'Regions Connectivity Dial Plan'</p> <pre>configure voip &gt; sbc settings &gt; regions- connectivity- dial-plan</pre> <p>[RegionsConnectivityDialPlan]</p>	<p>Defines the Dial Plan that the device must search in the Dial Plans table to check if the source and destination Teams sites share a common group number. If they do, the call is a direct media call.</p> <p>For more information, see <a href="#">Using Dial Plans for Microsoft Local Media Optimization</a> on page 852</p> <p><b>Note:</b> The ini file parameter is a table, using the following syntax:</p> <pre>[ RegionsConnectivityDialPlan ] FORMAT Index = RCDialPlan; RegionsConnectivityDialPlan 0 = "NameofDialPlan"; [ \RegionsConnectivityDialPlan ]</pre> <p><b>Note:</b> The feature is applicable only to Teams-to-PSTN calls.</p>
<pre>configure voip &gt; sip-definition settings &gt; preserve- multipart- content-type</pre> <p>[PreserveMultipartContentType]</p>	<p>Defines the device's handling of the SIP Content-Type header's value when the device sends a SIP message that has multiple bodies.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled. The device sets the type parameter in the Content-Type header to "multipart/mixed" and adds a unique value to the 'boundary' parameter of the Content-Type header.</li> <li>■ [1] = Enabled. The device doesn't change the type or boundary parameter of the Content-Type header. For example, if the incoming message contains 'Content-Type: multipart/relative;boundary=&lt;someUniqueValue&gt;', then this is how the Content-Type will be in the outgoing message.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>Out-of-Service (Busy Out) Parameters</b>	
<p>'Enable Busy Out'</p> <pre>configure voip &gt;</pre>	<p>Enables the Busy Out feature.</p>

Parameter	Description
sip-definition settings > busy- out [EnableBusyOut]	<ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>When enabled and certain scenarios exist, the device does the following:</p> <ul style="list-style-type: none"> <li>■ Analog: The FXS port behaves according to the settings of the [FXSOOSBehavior] parameter such as plays a reorder tone when the phone is off-hooked, or changes the line polarity.</li> <li>■ Digital: All trunks are automatically taken out-of-service by taking down the D-Channel, or for T1 PRI trunks, by sending a Service Out message supporting these messages (NI-2, 4/5-ESS, DMS-100, and Meridian).</li> </ul> <p>The above behavior is done upon one of the following scenarios:</p> <ul style="list-style-type: none"> <li>■ The device is physically disconnected from the network (i.e., Ethernet cable is disconnected).</li> <li>■ The device can't communicate with the Proxy Sets (according to the Proxy Keep-Alive mechanism) associated with the destination IP Groups of matching routing rules in the Tel-to-IP Routing table and no other alternative route exists to send the call.</li> <li>■ The IP Connectivity mechanism is enabled (by the [AltRoutingTel2IPEnable] parameter) and there is no connectivity to any destination IP address of matching routing rules in the Tel-to-IP Routing table.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you enable the [AltRoutingTel2IPEnable] parameter, the Busy Out feature doesn't function with the Proxy Set keep-alive mechanism. To use the Busy Out feature with the Proxy Set keep-alive mechanism (for IP Groups), disable the [AltRoutingTel2IPEnable] parameter.</li> <li>■ Analog: The [FXSOOSBehavior] parameter defines the behavior of the FXS endpoints when a Busy Out or Graceful Lock occurs.</li> <li>■ Analog: FXO endpoints during Busy Out and Lock are inactive.</li> <li>■ Digital: The Busy Out behavior depends on the PSTN</li> </ul>

Parameter	Description
	<p>protocol type.</p> <ul style="list-style-type: none"> <li>■ Digital: The Busy Out condition is also applied per Trunk Group. This occurs if there is no connectivity to the Serving IP Group of a specific Trunk Group configured in the Trunk Group Settings table. In such a scenario, all the physical trunks of the Trunk Group are set to the Busy Out condition. Each trunk uses the out-of-service method according to the ISDN / CAS variant.</li> <li>■ Digital: To configure the method for taking trunks/channels out-of-service, see the [DigitalOOSBehaviorForTrunk_x] parameter for per trunk or the [DigitalOOSBehavior] parameter for all trunks.</li> </ul>
<p>'Graceful Busy Out Timeout'</p> <pre>configure voip &gt; sip-definition settings &gt; graceful-bsy- out-t-out</pre> <p>[GracefulBusyOutTime out]</p>	<p>Defines the timeout interval (in seconds) for out-of-service graceful shutdown mode for busy trunks (per trunk) if communication fails with a Proxy server (or Proxy Set). In such a scenario, the device rejects new calls from the PSTN (i.e., Serving Trunk Group), but maintains currently active calls for this user-defined timeout. Once this timeout elapses and there are still active calls, the device terminates the calls and takes the trunk out-of-service (sending the PSTN busy-out signal). Trunks without any active calls are immediately taken out-of-service regardless of the timeout.</p> <p>The parameter is applicable to the locking of Trunk Groups feature (see <a href="#">Locking and Unlocking Trunk Groups</a> on page 1335) and the Busy Out feature (see the [EnableBusyOut] parameter), where trunks/channels are taken out-of-service.</p> <p>The range is 0 to 86,400. The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ To configure the method for taking trunks/channels out-of-service, see the [DigitalOOSBehaviorForTrunk_x] parameter for per trunk or the [DigitalOOSBehavior] parameter for all trunks.</li> </ul>
<p>'Out-Of-Service Behavior'</p> <pre>configure voip &gt; sip-definition settings &gt; oos- behavior</pre>	<p>Defines the behavior of FXS endpoints when a Busy Out condition exists.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = Silence is heard when the FXS endpoint goes off-hook.</li> <li>■ [1] <b>Reorder Tone</b> = (Default) The device plays a reorder tone</li> </ul>

Parameter	Description
[FXSOOSBehavior]	<p>to the connected phone / PBX.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Polarity Reversal</b> = The device reverses the polarity of the endpoint making it unusable (relevant, for example, for PBX DID lines).</li> <li>■ [3] <b>Reorder Tone + Polarity Reversal</b> = Same as options [1] and [2].</li> <li>■ [4] <b>Current Disconnect</b> = The device disconnects the current to the FXS endpoint.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ A device restart is required for the parameter to take effect when it is set to [2], [3], or [4].</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; isdn- busy-out-based- on-table</pre> <p>[ISDNBusyOutBasedOn Table]</p>	<p>Defines which configuration table (Trunk Group Settings table or Tel-to-IP Routing table) the device uses to determine busy out for a Trunk Group.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Busy Out is determined by the Trunk Group Settings table (see <a href="#">Configuring Trunk Group Settings</a> on page 937). Busy Out of a Trunk Group occurs if its associated Serving IP Group in the table is down.</li> <li>■ [1] = Busy Out is determined by the Tel-to-IP Routing table (see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946). Busy Out of a Trunk Group occurs only when all its associated destination IP Groups in the table are down. Busy Out is cleared when at least one IP Group is up.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital (ISDN) interfaces.</li> <li>■ For this Busy Out feature, you need to enable proxy keep-alive for the Proxy Set associated with the IP Group.</li> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
<b>Retransmission Parameters</b>	
<p>'SIP T1 Retransmission Timer'</p> <pre>configure voip &gt; sip-definition</pre>	<p>Defines the time interval (in msec) between the first transmission of a SIP message and the first retransmission of the same message.</p> <p>The default is 500.</p>

Parameter	Description
<pre>settings &gt; t1- re-tx-time</pre> <p>[SipT1Rtx]</p>	<p><b>Note:</b> The time interval between subsequent retransmissions of the same SIP message starts with SipT1Rtx. For INVITE requests, it is multiplied by two for each new retransmitted message. For all other SIP messages, it is multiplied by two until SipT2Rtx. For example, assuming SipT1Rtx = 500 and SipT2Rtx = 4000:</p> <ul style="list-style-type: none"> <li>■ The first retransmission is sent after 500 msec.</li> <li>■ The second retransmission is sent after 1000 (2*500) msec.</li> <li>■ The third retransmission is sent after 2000 (2*1000) msec.</li> <li>■ The fourth retransmission and subsequent retransmissions until [SIPMaxRtx] are sent after 4000 (2*2000) msec.</li> </ul>
<p>'SIP T2 Retransmission Timer'</p> <pre>configure voip &gt; sip-definition settings &gt; t2- re-tx-time</pre> <p>[SipT2Rtx]</p>	<p>Defines the maximum interval (in msec) between retransmissions of SIP messages (except for INVITE requests). The default is 4000.</p> <p><b>Note:</b> The time interval between subsequent retransmissions of the same SIP message starts with SipT1Rtx and is multiplied by two until SipT2Rtx.</p>
<p>'SIP Maximum RTX'</p> <pre>configure voip &gt; sip-definition settings &gt; sip- max-rtx</pre> <p>[SIPMaxRtx]</p>	<p>Defines the maximum number of UDP transmissions of SIP messages (first transmission plus retransmissions). The range is 1 to 30. The default is 7.</p>
<p>'Number of RTX Before Hot-Swap'</p> <pre>configure voip &gt; sip-definition proxy-and- registration &gt; nb-of-rtx-b4- hot-swap</pre> <p>[HotSwapRtx]</p>	<p>Defines the number of retransmitted INVITE/REGISTER messages before the call is routed (hot swap) to another Proxy/Registrar. The valid range is 1 to 30. The default is 3.</p> <p>For example, if configured to 3 and no response is received from an IP destination, the device attempts another three times to send the call to the IP destination. If still unsuccessful, it attempts to redirect the call to another IP destination.</p> <p><b>Note:</b> The parameter is also used for alternative routing (see <a href="#">Alternative Tel-to-IP Routing Based on IP Connectivity</a> on page 970).</p>
<pre>configure voip &gt; sip-definition settings &gt;</pre>	<p>Defines the interworking between the SIP INVITE's User-to-User header and the ISDN User-to-User (UU) IE data.</p>

Parameter	Description
usr2usr-hdr-frmt  [UserToUserHeaderFormat]	<ul style="list-style-type: none"> <li>■ [0] = (Default) SIP header format: X-UserToUser.</li> <li>■ [1] = SIP header format: User-to-User with Protocol Discriminator (pd) attribute (according to IETF Internet-Draft draft-johnston-sipping-cc-uu-04). For example:  User-to- User=3030373435313734313635353b313233343b3834;pd=4</li> <li>■ [2] = SIP header format: User-to-User with encoding=hex at the end and pd embedded as the first byte (according to IETF Internet-Draft draft-johnston-sipping-cc-uu-03). For example:  User-to- User=043030373435313734313635353b313233343b3834; encoding=hex  where "04" at the beginning of this message is the pd.</li> <li>■ [3] = Interworks the SIP User-to-User header containing text format to ISDN UUIE in hexadecimal format, and vice versa. For example:  SIP Header in text format: User-to-User=01800213027b712a;NULL;4582166;  Translated to hexadecimal in the ISDN UUIE: 303138303032313330323762373132613b4e554c4c3b343538323136363b  The Protocol Discriminator (pd) used in UUIE is "04" (IUA characters).</li> </ul> <p><b>Note:</b> The parameter is applicable for Tel-to-IP and IP-to-Tel calls.</p>

## Channel Parameters

This section describes the device's channel parameters.

## Voice Parameters

The voice parameters are described in the table below.

**Table 73-36:Voice Parameters**

Parameter	Description
<p>'Input Gain'</p> <pre>configure voip &gt; media voice &gt; input-gain</pre> <p>[InputGain]</p>	<p>Global parameter defining the pulse-code modulation (PCM) input (received) gain control level (in decibels).</p> <p>You can also configure the feature per specific calls, using IP Profiles ('Input Gain' parameter) or Tel Profiles ('Input Gain' parameter). For a detailed description of the parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the settings of the global parameter is ignored for calls associated with the profile.</p>
<p>'Voice Volume'</p> <pre>configure voip &gt; media voice &gt; voice-volume</pre> <p>[VoiceVolume]</p>	<p>Global parameter defining the voice gain control (in decibels). This defines the level of the transmitted signal (for the Gateway application, in IP-to-Tel calls).</p> <p>You can also configure the feature per specific calls, using IP Profiles ('Voice Volume' parameter) or Tel Profiles ('Voice Volume' parameter). For a detailed description of the parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the settings of the global parameter is ignored for calls associated with the profile.</p>
<pre>configure voip &gt; media voice codecs &gt; G726-voice-payload- format</pre> <p>[VoicePayloadFormat]</p>	<p>Determines the bit ordering of the G.726 voice payload format.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Little Endian</li> <li>■ [1] = Big Endian</li> </ul> <p><b>Note:</b> To ensure high voice quality when using G.726, both communicating ends should use the same endianness format. Therefore, when the device communicates</p>

Parameter	Description
	with a third-party entity that uses the G.726 voice coder and voice quality is poor, change the settings of the parameter (between Big Endian and Little Endian).
<b>'Echo Canceller'</b> <code>configure voip &gt; media voice</code> <code>&gt; echo-canceller-enable</code> <b>[EnableEchoCanceller]</b>	<p>Global parameter enabling echo cancellation (i.e., echo from voice calls is removed). You can also configure this feature per specific calls, using IP Profiles ('Echo Canceller' parameter) or Tel Profiles ('Echo Canceller' parameter). For a detailed description of the parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the device ignores this global parameter for calls associated with the profile.</p>
<b>'Network Echo Suppressor Enable'</b> <code>configure voip/media</code> <code>voice/acoustic-echo-</code> <code>suppressor-enable</code> <b>[AcousticEchoSuppressorSupport]</b>	<p>Enables the network Acoustic Echo Suppressor feature for SBC calls. This feature removes echoes and sends only the near-end's desired speech signal to the network (i.e., to the far-end party).</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>
<b>'Echo Canceller Type'</b> <code>configure voip/media</code> <code>voice/echo-canceller-type</code> <b>[EchoCancellerType]</b>	<p>Defines the echo canceller type.</p> <p>■ [0] <b>Line echo canceller</b> = (Default) Echo canceller for Tel side.</p> <p>■ [1] <b>Acoustic Echo suppressor - network</b> = Echo canceller for IP side.</p>
<b>'Attenuation Intensity'</b> <code>configure voip/media</code> <code>voice/acoustic-echo-</code> <code>suppressor-attenuation-</code> <code>intensity</code> <b>[AcousticEchoSuppAttenuationIntensity]</b>	<p>Defines the acoustic echo suppressor signals identified as echo attenuation intensity. The valid range is 0 to 3. The default is 0.</p>

Parameter	Description
<b>'Max ERL Threshold - DB'</b> <code>configure voip/media</code> <code>voice/acoustic-echo-</code> <code>suppressor-max-ERL</code> <b>[AcousticEchoSuppMaxERLThreshold]</b>	Defines the acoustic echo suppressor maximum ratio between signal level and returned echo from the phone (in decibels). The valid range is 0 to 60. The default is 10.
<b>'Min Reference Delay x10 msec'</b> <code>configure voip/media</code> <code>voice/acoustic-echo-</code> <code>suppressor-min-reference-</code> <code>delay</code> <b>[AcousticEchoSuppMinRefDelayx10ms]</b>	Defines the acoustic echo suppressor minimum reference delay (in 10-ms units). The valid range is 0 to 40. The default is 0.
<b>'Max Reference Delay x10 msec'</b> <code>configure voip/media</code> <code>voice/acoustic-echo-</code> <code>suppressor-max-reference-</code> <code>delay</code> <b>[AcousticEchoSuppMaxRefDelayx10ms]</b>	Defines the acoustic echo suppressor maximum reference delay (in 10-ms units). The valid range is 0 to 40. The default is 40 (i.e., 40 x 10 = 400 ms).
<code>configure voip &gt; media voice</code> <code>&gt; echo-canceller-hybrid-loss</code> <b>[ECHybridLoss]</b>	Defines the four-wire to two-wire worst-case Hybrid loss, the ratio between the signal level sent to the hybrid and the echo level returning from the hybrid. <ul style="list-style-type: none"> <li>■ [0] = (Default) 6 dB</li> <li>■ [1] = N/A</li> <li>■ [2] = 0 dB</li> <li>■ [3] = 3 dB</li> </ul>
<code>configure voip &gt; media voice</code> <code>&gt; echo-canceller-NLP-mode</code> <b>[ECNLPMode]</b>	Global parameter enabling Non-Linear Processing (NLP) mode for echo cancellation. You can also configure the feature per specific calls, using Tel Profiles ('EC NLP Mode' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.  <b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.

Parameter	Description
<pre>configure voip &gt; media voice &gt; echo-canceller-aggressive- NLP</pre> <p>[EchoCancellerAggressiveNLP]</p>	<p>Enables the Aggressive NLP at the first 0.5 second of the call.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable</li> <li>■ [1] = (Default) Enable. The echo is removed only in the first half of a second of the incoming IP signal.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; media RTP- RTCP &gt; number-of-SID- coefficients</pre> <p>[RTPSIDCoeffNum]</p>	<p>Defines the number of spectral coefficients added to an SID packet being sent according to RFC 3389.</p> <p>The valid values are [0] (default), [4], [6], [8] and [10].</p>

## Coder Parameters

The coder parameters are described in the table below.

**Table 73-37:Coder Parameters**

Parameter	Description
<p>'SILK Tx Inband FEC'</p> <pre>configure voip &gt; media settings &gt; silk-tx- inband-fec</pre> <p>[SilkTxInbandFEC]</p>	<p>Enables forward error correction (FEC) for the SILK coder.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul>
<p>'SILK Max Average Bit Rate'</p> <pre>configure voip &gt; media settings &gt; silk-max- average-bitrate</pre> <p>[SilkMaxAverageBitRate]</p>	<p>Defines the maximum average bit rate for the SILK coder.</p> <p>The valid value range is 6,000 to 50,000. The default is 50,000.</p> <p>The SILK coder is Skype's default audio codec used for Skype-to-Skype calls.</p>
<p>'Opus Max Average Bitrate'</p> <pre>configure voip &gt; sip- definition settings &gt; opus-max-avg-bitrate</pre> <p>[OpusMaxAverageBitRate]</p>	<p>Defines the maximum average bit rate (in bps) for the Opus coder.</p> <p>The valid value range is 6000 to 50,000. The default is 50,000.</p>

Parameter	Description
<pre>configure voip &gt; media settings &gt; vbr-coder- header-format</pre> [VBRCoderHeaderFormat]	<p>Defines the format of the RTP header for VBR coders.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Payload only (no header, TOC, or m-factor) - similar to RFC 3558 Header Free format.</li> <li>■ [1] = Supports RFC 2658 - 1 byte for interleaving header (always 0), TOC, no m-factor.</li> <li>■ [2] = Payload including TOC only, allow m-factor.</li> <li>■ [3] = RFC 3558 Interleave/Bundled format.</li> </ul>
<pre>configure voip &gt; media settings &gt; vbr-coder- hangover</pre> [VBRCoderHangover]	<p>Defines the required number of silence frames at the beginning of each silence period when using the VBR coder silence suppression.</p> <p>The range is 0 to 255. The default is 1.</p>
'AMR Payload Format' [AmrOctetAlignedEnable]	<p>Defines the AMR payload format type.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Bandwidth Efficient</b></li> <li>■ [1] <b>Octet Aligned</b> (default)</li> </ul> <p><b>Note:</b> The AMR payload type can also be configured per Coder Group (see <a href="#">Configuring Coders Groups</a> on page 661). The Coder Group configuration overrides the parameter.</p>
<pre>configure voip &gt; media settings &gt; amr-header- format</pre> [AMRCoderHeaderFormat]	<p>Defines the payload format of the AMR header.</p> <ul style="list-style-type: none"> <li>■ [0] = Non-standard multiple frames packing in a single RTP frame. Each frame has a CMR and TOC header.</li> <li>■ [1] = AMR frame according to RFC 3267 bundling.</li> <li>■ [2] = AMR frame according to RFC 3267 interleaving.</li> <li>■ [3] = AMR is passed using the AMR IF2 format.</li> </ul> <p><b>Note:</b> Bandwidth Efficient mode is not supported; the mode is always Octet-aligned.</p>
'Fax/Modem Bypass Packing Factor' <pre>configure voip &gt; media fax-modem &gt; packing- factor</pre> [FaxModemBypassM]	<p>Defines the number (20 msec) of coder payloads used to generate a fax/modem bypass packet.</p> <p>The valid range is 1, 2, or 3 coder payloads. The default is 1 coder payload.</p>

Parameter	Description
'Transparent on Data Call' [TransparentCoderOnDataCall]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Only use coders from the coder list.</li> <li>■ [1] <b>Enable</b> = Use Transparent coder for data calls (according to RFC 4040).</li> </ul> <p>The Transparent coder can be used on data calls. When the device receives a Setup message from the ISDN with 'TransferCapabilities = data', it can initiate a call using the coder 'Transparent' (even if the coder is not included in the coder list).</p> <p>The initiated INVITE includes the following SDP attribute:</p> <pre>a=rtpmap:97 CLEARMODE/8000</pre> <p>The default payload type is set according to the [CodersGroup] parameter. If the Transparent coder is not defined, the default is set to 56. The payload type is negotiated with the remote side, i.e., the selected payload type is according to the remote side selection. The receiving device must include the 'Transparent' coder in its coder list.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
configure voip > sip-definition settings > transparent-payload-type [TransparentPayloadType]	<p>Defines the payload type of the Transparent coder for outgoing data calls (ISDN-to-IP).</p> <p>When the device receives a Setup message from the ISDN with 'TransferCapabilities = data', it can initiate a call using the coder 'Transparent' (even if the coder is not included in the coder list).</p> <p>The initiated INVITE includes the following SDP attribute:</p> <pre>a=rtpmap:97 CLEARMODE/8000</pre> <p>The valid value range is 1 to 127. The default value is 56.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>

## DTMF Parameters

The dual-tone multi-frequency (DTMF) parameters are described in the table below.

**Table 73-38:DTMF Parameters**

Parameter	Description
<p>'DTMF Transport Type'</p> <pre>configure voip &gt; media voice &gt; DTMF-transport- type</pre> <p>[DTMFTransportType]</p>	<p>Defines the DTMF transport type.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Mute DTMF</b> = DTMF digits are removed from the voice stream and are not relayed to remote side.</li> <li>■ [2] <b>Transparent DTMF</b> = DTMF digits remain in the voice stream.</li> <li>■ [3] <b>RFC 2833 Relay DTMF</b> = (Default) DTMF digits are removed from the voice stream and are relayed to the remote side according to RFC 2833.</li> <li>■ [7] <b>RFC 2833 Relay Decoder Mute</b> = DTMF digits are sent according to RFC 2833 and muted when received.</li> </ul> <p><b>Note:</b> The parameter is automatically updated if the parameters [FirstTxDTMFOption] or [RxDTMFOption] are configured.</p>
<p>'DTMF Volume' (-31 to 0 dB)</p> <pre>configure voip &gt; media voice &gt; DTMF-volume</pre> <p>[DTMFVolume]</p>	<p>Global parameter defining the DTMF gain control value (in decibels). For analog interfaces, this is the gain control to the Tel side.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('DTMF Volume' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
<p>DTMF Generation Twist</p> <pre>configure voip &gt; media voice &gt; DTMF-generation- twist</pre> <p>[DTMFGenerationTwist]</p>	<p>Defines the range (in decibels) between the high and low frequency components in the DTMF signal. Positive decibel values cause the higher frequency component to be stronger than the lower one. Negative values cause the opposite effect. For any parameter value, both components change so that their average is constant.</p> <p>The valid range is -10 to 10 dB. The default is 0 dB.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>inter-digit- interval</p> <p>[DTMFInterDigitInterval]</p>	<p>Defines the time (in msec) between generated DTMF digits (to the Tel side for the Gateway application) if FirstTxDTMFOption = 1, 2 or 3.</p>

Parameter	Description
	The valid range is 0 to 32767. The default is 100.
[DTMFDigitLength]	Defines the time (in msec) for generating DTMF tones (to the Tel side for the Gateway application) if FirstTxDTMFOption = 1, 2 or 3. It also configures the duration that is sent in INFO (Cisco) messages. The valid range is 0 to 32767. The default is 100.
configure voip > media voice > digit-hangover- time-rx [RxDTMFHangOverTime]	Defines the Voice Silence time (in msec) after playing DTMF or MF digits (to the Tel side for the Gateway application) that arrive as Relay (from the IP side for the Gateway application). Valid range is 0 to 2,000 msec. The default is 1,000 msec.
configure voip > media voice > digit-hangover- time-tx [TxDTMFHangOverTime]	Defines the Voice Silence time (in msec) after detecting the end of DTMF or MF digits (on the Tel side for the Gateway application) when the DTMF Transport Type is either Relay or Mute. Valid range is 0 to 2,000 msec. The default is 1,000 msec.
'NTE Max Duration' configure voip > media voice > telephony-events- max-duration [NTEMaxDuration]	Defines the maximum time for sending Named Telephony Events / NTEs -- RFC 4733/2833 DTMF relay -- (to the IP side for the Gateway application), regardless of the DTMF signal duration on the other side (TDM for the Gateway application). The range is -1 to 200,000,000 msec. The default is -1 (i.e., NTE stops only upon detection of an End event).

## RTP, RTCP and T.38 Parameters

The RTP, RTCP and T.38 parameters are described in the table below.

**Table 73-39:RTP/RTCP and T.38 Parameters**

Parameter	Description
'Dynamic Jitter Buffer Minimum Delay' configure voip > media rtp-rtcp > jitter-buffer- minimum-delay [DJBufMinDelay]	Global parameter defining the minimum delay (in msec) of the device's dynamic Jitter Buffer. You can also configure the feature per specific calls, using IP Profiles ('Dynamic Jitter Buffer Minimum Delay' parameter) or Tel Profiles ('Dynamic Jitter Buffer Minimum Delay' parameter). For a detailed description of the

Parameter	Description
	<p>parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the settings of the global parameter is ignored for calls associated with the profile.</p>
<p>'Dynamic Jitter Buffer Optimization Factor'</p> <pre>configure voip &gt; media   rtp-rtcp &gt; jitter-buffer-     optimization-factor</pre> <p>[DJBufOptFactor]</p>	<p>Global parameter defining the Dynamic Jitter Buffer frame error/delay optimization factor.</p> <p>You can also configure the feature per specific calls, using IP Profiles ('Dynamic Jitter Buffer Optimization Factor' parameter) or Tel Profiles ('Dynamic Jitter Buffer Optimization Factor' parameter). For a detailed description of the parameter and for configuring the feature, see <a href="#">Configuring IP Profiles</a> on page 674 or <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific profile, the settings of the global parameter is ignored for calls associated with the profile.</p>
<p>'Analog Signal Transport Type'</p> <p>[AnalogSignalTransportType]</p>	<p>Defines the analog signal transport type.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Ignore Analog Signals</b> = (Default) Ignore.</li> <li>■ [1] <b>RFC 2833 Analog Signal Relay</b> = Transfer hookflash using RFC 2833.</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXS and FXO interfaces.</p>
<p>'RTP Redundancy Depth'</p> <pre>configure voip &gt; media   rtp-rtcp &gt; RTP-redundancy-     depth</pre> <p>[RTPRedundancyDepth]</p>	<p>Global parameter that enables the device to generate RFC 2198 redundant packets. You can also configure this feature per specific calls, using IP Profiles ('RTP Redundancy Depth' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Enable RTP Redundancy Negotiation'</p> <pre>configure voip &gt; sip-</pre>	<p>Enables the device to include the RTP redundancy dynamic payload type in the SDP (according to RFC 2198).</p>

Parameter	Description
<pre>definition settings &gt; rtp- rdcy-nego-enbl</pre> <p>[EnableRTPRedundancyNegotiation]</p>	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = The device includes in the SDP message the RTP payload type "red" and the payload type configured by the [RFC2198PayloadType] parameter.</li> </ul> <pre>a=rtpmap:&lt;PT&gt; red/8000</pre> <p>Where &lt;PT&gt; is the payload type as defined by the [RFC2198PayloadType] parameter. The device sends the SIP INVITE message with "a=rtpmap:&lt;PT&gt; red/8000" and responds with a 18x/200 OK containing "a=rtpmap:&lt;PT&gt; red/8000" in the SDP.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ For this feature to work, configure the [RTPRedundancyDepth] parameter to 1 (i.e., enabled).</li> <li>■ Currently, negotiation of the "red" payload type is not supported and therefore, should be configured to the same PT value for both parties.</li> </ul>
<p>'RFC 2198 Payload Type'</p> <pre>configure voip &gt; media rtp-rtcp &gt; RTP-redundancy- payload-type</pre> <p>[RFC2198PayloadType]</p>	<p>Defines the RTP redundancy packet payload type (according to RFC 2198).</p> <p>The valid value is 96 to 127. The default is 104.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the [RTPRedundancyDepth] parameter to 1.</li> <li>■ The device ignores this parameter for Rx payload types and uses the payload type determined during SDP negotiation. For using this configured payload type, see the <a href="#">[BackwardPTBehavior]</a> on page 1928 parameter.</li> </ul>
<p>'Packing Factor'</p> <p>[RTPPackagingFactor]</p>	<p>N/A (controlled internally by the device according to the selected coder).</p>

Parameter	Description
'RFC 2833 TX Payload Type' configure voip > media rtp-rtcp > telephony- events-payload-type-tx [RFC2833TxPayloadType]	<p>Defines the Tx RFC 2833 DTMF relay dynamic payload type for outbound calls.</p> <p>The valid range is 96 to 127. The default is 96.</p> <p><b>Note:</b> When RFC 2833 payload type negotiation is used (i.e., the parameter FirstTxDTMFOption is set to 4), this payload type is used for the received DTMF packets. If negotiation isn't used, this payload type is used for receive and for transmit.</p>
'RFC 2833 RX Payload Type' configure voip > media rtp-rtcp > telephony- events-payload-type-rx [RFC2833RxPayloadType]	<p>Defines the Rx RFC 2833 DTMF relay dynamic payload type for inbound calls.</p> <p>The valid range is 96 to 127. The default is 96.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device ignores this parameter for Rx payload types and uses the payload type determined during SDP negotiation. For using this configured payload type, see the <a href="#">[BackwardPTBehavior]</a> on page 1928] parameter.</li> <li>■ When RFC 2833 payload type negotiation is used (i.e., the parameter [FirstTxDTMFOption] is set to 4), this payload type is used for the received DTMF packets. If negotiation isn't used, this payload type is used for receive and transmit.</li> </ul>
[EnableDetectRemoteMACChange]	<p>Determines whether the device changes the RTP packets according to the MAC address of received RTP packets and according to Gratuitous Address Resolution Protocol (GARP) messages.</p> <ul style="list-style-type: none"> <li>■ [0] = Nothing is changed.</li> <li>■ [1] = If the device receives RTP packets with a different source MAC address (than the MAC address of the transmitted RTP packets), then it sends RTP packets to this MAC address and removes this IP entry from the device's ARP cache table.</li> <li>■ [2] = (Default) The device uses the received</li> </ul>

Parameter	Description
	<p>GARP packets to change the MAC address of the transmitted RTP packets.</p> <ul style="list-style-type: none"> <li>■ [3] = Options 1 and 2 are used.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ If the device is located in a network subnet which is connected to other gateways using a router that uses Virtual Router Redundancy Protocol (VRRP) for redundancy, then set the parameter to 0 or 2.</li> </ul>
'Forward Invalid RTP Packets' [RTPFWInvalidPacketHandling]	<p>Defines the device's handling of invalid RTP and RTCP packets.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Forward Packets</b> = Forwards the invalid packets as is.</li> <li>■ [1] <b>Forward Packets and Issue Warnings</b> = (Default) Forwards the invalid packets and issues warnings (sent to the syslog) to notify of the invalid packets.</li> <li>■ [2] <b>Drop Packets and Issue Warnings</b> = Drops the invalid packets and issues warnings to notify of the invalid packets.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the IP Profile parameter 'Mediation Mode' is configured to <b>RTP Forwarding</b>.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Forward Unknown RTP Payload Types' [RtpFWNonConfiguredPTHandling]	<p>Defines the device's handling of RTP packets that are received with non-configured (unknown) payload types.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Handle as Invalid Packet</b> = (Default) Handles the packet as an invalid packet, according to the RTPFWInvalidPacketHandling parameter.</li> <li>■ [1] <b>Handle as Valid Packet</b> = Handles the</li> </ul>

Parameter	Description
	<p>packet as a valid packet.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the IP Profile parameter 'Mediation Mode' is configured to <b>RTP Forwarding</b>.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'RTP Base UDP Port'</p> <pre>configure voip &gt; media rtp-rtcp &gt; base-udp-port [BaseUDPport]</pre>	<p>Global parameter that defines the lower boundary of the UDP port used for RTP, RTCP (RTP port + 1) and T.38 (RTP port + 2). For more information on configuring the UDP port range, see <a href="#">Configuring RTP Base UDP Port</a> on page 301.</p> <p>The range of possible UDP ports is 6,000 to 65,535. The default base UDP port is 6000.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; media rtp-rtcp &gt; udp-port- spacing [UdpPortSpacing]</pre>	<p>Defines the port spacing ("jumps") of local UDP ports allocated by the device to media channels (legs) within the configured port range.</p> <ul style="list-style-type: none"> <li>■ [2] = The device allocates ports in "jumps" of 2 ports.</li> </ul> <p><b>Note:</b> For UDP port spacing of 2, you must configure the device to use the same port for RTP and T.38, by configuring the [T38UseRTPPort] ini file parameter to 1.</p> <ul style="list-style-type: none"> <li>■ [4] = The device allocates ports in "jumps" of 4 ports.</li> <li>■ [5] = The device allocates ports in "jumps" of 5 ports.</li> <li>■ [10] = (Default) The device allocates ports in "jumps" of 10 ports.</li> </ul> <p>For more information on configuring the UDP port range, port allocation and spacing, see <a href="#">Configuring RTP Base UDP Port</a> on page 301.</p> <p><b>Note:</b> A device restart is required for the parameter to take effect.</p>

Parameter	Description
<pre>configure voip &gt; gateway digital settings &gt; rtcp- act-mode</pre> <p>[RTCPActivationMode]</p>	<p>Disables RTCP traffic when there is no RTP traffic. This feature is useful, for example, to stop RTCP traffic that is typically sent when calls are put on hold (by an INVITE with 'a=inactive' in the SDP).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Active Always - RTCP is active even during inactive RTP periods, i.e., when the media is in 'recvonly' or 'inactive' mode.</li> <li>■ [1] = Inactive only If RTP inactive - No RTCP is sent when RTP is inactive.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'T.38 Fax Session'</p> <pre>configure voip &gt; sip- definition settings &gt; t38- sess-imm-strt</pre> <p>[T38FaxSessionImmediateStart]</p>	<p>Enables fax transmission of T.38 "no-signal" packets to the terminating fax machine.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Immediate Start on Fax</b> = Device activates T.38 fax relay upon receipt of a re-INVITE with T.38 only in the SDP.</li> <li>■ [2] <b>Immediate Start on Fax &amp; Voice</b> = Device activates T.38 fax relay upon receipt of a re-INVITE with T.38 and audio media in the SDP.</li> </ul> <p>The parameter is used for transmission from fax machines connected to the device and located inside a NAT. Generally, the firewall blocks T.38 (and other) packets received from the WAN, unless the device behind NAT sends at least one IP packet from the LAN to the WAN through the firewall. If the firewall blocks T.38 packets sent from the termination IP fax, the fax fails.</p> <p>To overcome this, the device sends No-Op ("no-signal") packets to open a pinhole in the NAT for the answering fax machine. The originating fax doesn't wait for an answer, but immediately starts sending T.38 packets to the terminating fax machine.</p> <p><b>Note:</b> To enable No-Op packet transmission, use the [NoOpEnable] and [NoOpInterval] parameters.</p>
<pre>configure voip &gt; sip-</pre>	<p>Defines the port (with relation to RTP port) for</p>

Parameter	Description
<pre>definition settings &gt; t38- use-rtp-port</pre> <p>[T38UseRTPPort]</p>	<p>sending and receiving T.38 packets.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Use the RTP port +2 to send/receive T.38 packets.</li> <li>■ [1] = Use the same port as the RTP port to send/receive T.38 packets.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When the device is configured to use V.152 to negotiate audio and T.38 coders, the UDP port published in SDP for RTP and for T38 must be different. Therefore, set the T38UseRTPPort parameter to 0.</li> </ul>
<p>'T38 Fax Max Buffer'</p> <pre>configure voip &gt; sip- definition settings &gt; t38- fax-mx-buff</pre> <p>[T38FaxMaxBufferSize]</p>	<p>Defines the maximum size (in bytes) of the device's T.38 buffer. This value is included in the outgoing SDP when T.38 is used for fax relay over IP.</p> <p>The valid range is 500 to 3000. The default is 3,000.</p>
<b>QoE Parameters</b>	
[QoEMediaStatisticTimer]	<p>Defines the interval (in msec) for QoE collection and report generation.</p> <p>The valid value range is 0 to 65,535. The default is 30,000 (i.e., 30 seconds).</p> <p>For more information, see <a href="#">Configuring Interval for QoE Report Collection and Generation</a> on page 528.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
<b>No-Op Packets Parameters</b>	
<pre>no-operation-enable</pre> <p>[NoOpEnable]</p>	<p>Enables the device to send RTP or T.38 No-Op packets during RTP or T.38 silence periods. This mechanism ensures that the NAT binding remains open.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> You can also enable the feature per IP Profile (for SBC calls only), using the 'Generate No-Op Packets' IP Profile parameter.</p>
[NoOpInterval]	<p>Defines the interval (msec) between each RTP or T.38 No-Op packet sent by the device during the silence period (i.e., no RTP/T.38 traffic).</p> <p>The valid range is 20 to 600,000. The default is 1,000.</p> <p><b>Note:</b> To enable No-Op packet transmission, use the [NoOpEnable] parameter.</p>
no-operation-interval [RTPNoOpPayloadType]	<p>Defines the payload type of No-Op packets.</p> <p>The valid range is 96 to 127. For the range of Dynamic RTP Payload Type for all types of non hard-coded RTP Payload types, refer to RFC 3551. The default is 120.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the IP Profile parameter 'Generate No-Op Packets' is enabled, or the <a href="#">[[BackwardPTBehavior]</a> on page 1928] parameter is enabled.</li> <li>■ When configuring the parameter, make sure that its settings don't cause collisions with other payload types.</li> <li>■ The device ignores this parameter for Rx payload types and uses it only for Tx payload types.</li> </ul>
<b>RTP Control Protocol Extended Reports (RTCP XR) Parameters</b> For more information on RTCP XR, see <a href="#">Configuring RTCP XR</a> on page 1506.	
'Enable RTCP XR' configure voip > media rtp-rtcp > voice-quality- monitoring-enable [VQMonEnable]	<p>Enables voice quality monitoring and RTCP XR, according to RFC 3611.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable Fully</b> = Calculates voice quality metrics, uses them for QoE calculations, reports them to OVOC (if configured), and</li> </ul>

Parameter	Description
	<p>sends them to remote side using RTCP XR.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Enable Calculation Only</b> = Calculates voice quality metrics, uses them for QoE calculations, reports them to OVOC (if configured), but doesn't send them to remote side using RTCP XR.</li> </ul>
'Minimum Gap Size' [VQMonGMin]	<p>Defines the voice quality monitoring - minimum gap size (number of frames).</p> <p>The default is 16.</p>
'Burst Threshold' [VQMonBurstHR]	<p>Defines the voice quality monitoring - excessive burst alert threshold.</p> <p>The default is -1 (i.e., no alerts are issued).</p>
'Delay Threshold' [VQMonDelayTHR]	<p>Defines the voice quality monitoring - excessive delay alert threshold.</p> <p>The default is -1 (i.e., no alerts are issued).</p>
'R-Value Delay Threshold' [VQMonEOCRValTHR]	<p>Defines the voice quality monitoring - end of call low quality alert threshold.</p> <p>The default is -1 (i.e., no alerts are issued).</p>
'Tx RTCP Packets Interval' configure voip > media rtp-rtcp > rtcp-interval [RTCPInterval]	<p>Defines the time interval (in msec) between adjacent RTCP XR reports. This interval starts from call establishment. Thus, the device can send RTCP XR reports during the call, in addition to at the end of the call. If the duration of the call is shorter than this interval, RTCP XR is sent only at the end of the call.</p> <p>The valid value range is 0 to 65,535. The default is 5,000.</p>
'Disable RTCP XR Interval Randomization' configure voip > media rtp-rtcp > disable-RTCP-randomization [DisableRTCPRandomize]	<p>Determines if RTCP report intervals are randomized or each report interval is according to the [RTCPInterval] parameter.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. RTCP report intervals are randomized</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Each report interval is according to the [RTCPInterval] parameter.</li> </ul>

Parameter	Description
<p>'Gateway RTCP XR Report Mode'</p> <pre>configure voip &gt; sip- definition settings &gt; rtcp-xr-rep-mode</pre> <p>[RTCPXRReportMode]</p>	<p>Enables the device to send RTCP XR in SIP PUBLISH messages and defines the interval at which they are sent.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) RTCP XR is not sent.</li> <li>■ [1] <b>End Call</b> = RTCP XR is sent at the end of the call.</li> <li>■ [2] <b>End Call &amp; Periodic</b> = RTCP XR is sent at the end of the call and periodically according to the RTCPInterval parameter.</li> <li>■ [3] <b>End Call &amp; End Segment</b> = RTCP XR is sent at the end of the call and at the end of each media segment of the call. A media segment is a change in media, for example, when the coder is changed or when the caller toggles between two called parties (using call hold/retrieve). The RTCP XR sent at the end of a media segment contains information only of that segment. If the segment doesn't contain RTP/RTCP content, the RTCP XR is not sent. For call hold, the device sends an RTCP XR each time the call is placed on hold and each time it is retrieved. In addition, the Start timestamp in the RTCP XR indicates the start of the media segment; the End timestamp indicates the time of the last sent periodic RTCP XR (typically, up to 5 seconds before reported segment ends).</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Publication IP Group ID'</p> <pre>publication-ip-group-id</pre> <p>[PublicationIPGroupID]</p>	<p>Defines the IP Group to where the device sends RTCP XR reports.</p> <p>By default, no value is defined.</p>
<p>'SBC RTCP XR Report Mode'</p> <pre>configure voip &gt; sip- definition settings &gt; sbc- rtcpxr-report-mode</pre> <p>[SBCRtcpXrReportMode]</p>	<p>Enables the sending of RTCP XR reports of QoE metrics at the end of each call session (i.e., after a SIP BYE). The RTCP XR is sent in the SIP PUBLISH message.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>End of Call</b></li> </ul>

Parameter	Description
	<b>Note:</b> The parameter is applicable only to the SBC application.

## Gateway Application Parameters

this section describes the parameters of the Gateway application.

### Fax and Modem Parameters

The fax and modem parameters are described in the table below.

**Table 73-40:Fax and Modem Parameters**

Parameter	Description
'Fax Transport Mode' configure voip > media fax-modem > fax-transport-mode [FaxTransportMode]	Determines the fax transport mode used by the device. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = transparent mode</li> <li>■ [1] <b>T.38 Relay</b> (default)</li> <li>■ [2] <b>Bypass</b></li> <li>■ [3] <b>Events Only</b></li> </ul> <b>Note:</b> The parameter is overridden by the parameter [IsFaxUsed]. If the parameter [IsFaxUsed] is set to 1 (T.38 Relay) or 3 (Fax Fallback), then [FaxTransportMode] is always set to 1 (T.38 relay).
V34-fax-transport-type [V34FaxTransportType]	Determines the V.34 fax transport method (whether V34 fax falls back to T.30 or pass over Bypass). <ul style="list-style-type: none"> <li>■ [0] = Transparent</li> <li>■ [1] = (Default) Relay</li> <li>■ [2] = Bypass</li> <li>■ [3] = Transparent with Events</li> </ul> <b>Note:</b> To configure [V34FaxTransportType] to [1] (i.e., fax relay), you also need to configure [FaxTransportMode] to [1] (fax relay).

Parameter	Description
'V.21 Modem Transport Type' configure voip > media fax-modem > V21-modem-transport-type [V21ModemTransportType]	Determines the V.21 modem transport type. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Transparent.</li> <li>■ [2] <b>Enable Bypass</b></li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul> <p><b>Note:</b> You can also configure this feature per specific calls, using IP Profiles ('Vxx Modem Transport Type' parameter). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
'V.22 Modem Transport Type' configure voip > media fax-modem > V22-modem-transport-type [V22ModemTransportType]	Determines the V.22 modem transport type. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Transparent.</li> <li>■ [2] <b>Enable Bypass</b> (default)</li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul> <p><b>Note:</b> You can also configure this feature per specific calls, using IP Profiles ('Vxx Modem Transport Type' parameter). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
'V.23 Modem Transport Type' configure voip > media fax-modem > V23-modem-transport-type [V23ModemTransportType]	Determines the V.23 modem transport type. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Transparent.</li> <li>■ [2] <b>Enable Bypass</b> (default)</li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul> <p><b>Note:</b> You can also configure this feature per specific calls, using IP Profiles ('Vxx Modem Transport Type' parameter). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
'V.32 Modem Transport Type' configure voip > media fax-modem	Determines the V.32 modem transport type.

Parameter	Description
<code>&gt; V32-modem-transport-type</code> [V32ModemTransportType]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Transparent.</li> <li>■ [2] <b>Enable Bypass</b> (default)</li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter applies only to V.32 and V.32bis modems.</li> <li>■ You can also configure this feature per specific calls, using IP Profiles ('Vxx Modem Transport Type' parameter). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</li> </ul>
' <b>V.34 Modem Transport Type</b> ' <code>configure voip &gt; media fax-modem</code> <code>&gt; V34-modem-transport-type</code> [V34ModemTransportType]	<p>Determines the V.90/V.34 modem transport type.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Transparent.</li> <li>■ [2] <b>Enable Bypass</b> (default)</li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul> <p><b>Note:</b> You can also configure this feature per specific calls, using IP Profiles ('Vxx Modem Transport Type' parameter). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
<code>bell-modem-transport-type</code> [BellModemTransportType]	<p>Determines the Bell modem transport method.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Transparent.</li> <li>■ [2] <b>Enable Bypass</b></li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul>
' <b>Fax CNG Mode</b> ' <code>configure voip &gt; media fax-modem</code> <code>&gt; fax_cng_mode</code> [FaxCNGMode]	<p>Determines the device's handling of fax relay upon detection of a fax CNG tone or a V.34/Super G3 V8-CM (Call Menu) signal from originating faxes.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Doesn't send T.38 Re-INVITE</b> =</li> </ul>

Parameter	Description
	<p>(Default) SIP re-INVITE is not sent.</p> <ul style="list-style-type: none"> <li>■ <b>[1] Sends on CNG tone</b> = Sends a SIP re-INVITE with T.38 parameters in SDP to the terminating fax upon detection of a fax CNG tone, if the CNGDetectorMode parameter is set to 1.</li> <li>■ <b>[2] Sends on CNG or v8-cn</b> = Sends a SIP re-INVITE with T.38 parameters in SDP to the terminating fax upon detection of a fax CNG tone (if the CNGDetectorMode parameter is set to 1) or upon detection of a V8-CM signal.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is set to [2] and the CNGDetectorMode parameter is set to [0], the device sends a re-INVITE only if it detects a V8-CM signal from the originating fax.</li> <li>■ This feature is applicable only if the IsFaxUsed parameter is set to [1] or [3].</li> <li>■ The device also sends T.38 re-INVITE if the CNGDetectorMode parameter is set to [2], regardless of the FaxCNGMode parameter settings.</li> </ul>
<p>'CNG Detector Mode'</p> <pre>configure voip &gt; media fax-modem &gt; coder [CNGDetectorMode]</pre>	<p>Global parameter that enables the detection of the fax calling tone (CNG) and defines the detection method. You can also configure this feature per specific calls, using IP Profiles ('CNG Detector Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this</p>

Parameter	Description
	global parameter for calls associated with the IP Profile.
'Fax Detect Timeout Since Connect' <code>fax-detect-timeout-since-connect</code> <code>[FaxDetectTimeoutSinceConnect]</code>	<p>Defines a timeout (in msec) for detecting fax from the Tel side during an established voice call. The interval starts from when the voice call is established. If the device detects a fax tone within the interval, it ends the voice session and sends a T.38 or VBD re-INVITE message to the IP side and processes the fax. If the interval expires without any received fax event, the device ignores all subsequent fax events during the voice session.</p> <p>The valid value is 0 to 120000. The default is 0. If set to 0, the device can detect fax during the entire voice call.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
'SIP T.38 Version' <code>configure voip &gt; sip-definition</code> <code>settings &gt; sip-t38-ver</code> <code>[SIPT38Version]</code>	<p>Defines the T.38 fax relay version.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) No T.38</li> <li>■ [0] <b>Version 0</b></li> <li>■ [3] <b>Version 3</b> = T.38 Version 3 (V.34 over T.38)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Interworking of T.38 Version 3 is supported only for Gateway calls. For SBC calls, the device forwards T.38 Version 3 transparently (as is) to the other leg (i.e., no transcoding).</li> <li>■ For a description on V.34 over T.38 fax relay, see <a href="#">V.34 Fax Support</a> on page 291.</li> </ul>
<code>configure voip &gt; media fax-modem</code> <code>&gt; rx-t38-over-rtp-payload-type</code>	Defines the received T.38 over RTP payload type.

Parameter	Description
[RxT38OverRTPPayloadType]	<p>The valid range is 96 to 127. The default is 106.</p> <p><b>Note:</b> The device ignores this parameter for Rx payload types and uses the payload type determined during SDP negotiation. For using this configured payload type, see the <a href="#">[BackwardPTBehavior]</a> parameter.</p>
'Fax Relay Enhanced Redundancy Depth' configure voip > media fax-modem > enhanced-redundancy-depth [FaxRelayEnhancedRedundancyDepth]	<p>Defines the number of times that control packets are retransmitted when using the T.38 standard.</p> <p>The valid range is 0 to 4. The default is 2.</p>
'Fax Relay Redundancy Depth' configure voip > media fax-modem > redundancy-depth [FaxRelayRedundancyDepth]	<p>Defines the number of times that each fax relay payload is retransmitted to the network.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = (Default) No redundancy</li> <li>■ [1] <b>1</b> = One-packet redundancy</li> <li>■ [2] <b>2</b> = Two-packet redundancy</li> </ul> <p><b>Note:</b> The parameter is applicable only to non-V.21 packets.</p>
'Fax Relay Max Rate' (bps) configure voip > media fax-modem > max-rate [FaxRelayMaxRate]	<p>Defines the maximum rate (in bps) at which fax relay messages are transmitted (outgoing calls).</p> <ul style="list-style-type: none"> <li>■ [0] <b>2400</b> = 2.4 kbps</li> <li>■ [1] <b>4800</b> = 4.8 kbps</li> <li>■ [2] <b>7200</b> = 7.2 kbps</li> <li>■ [3] <b>9600</b> = 9.6 kbps</li> <li>■ [4] <b>12000</b> = 12.0 kbps</li> <li>■ [5] <b>14400</b> = 14.4 kbps (default)</li> <li>■ [6] <b>16800bps</b> = 16.8 kbps</li> <li>■ [7] <b>19200bps</b> = 19.2 kbps</li> <li>■ [8] <b>21600bps</b> = 21.6 kbps</li> <li>■ [9] <b>24000bps</b> = 24 kbps</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [10] <b>26400bps</b> = 26.4 kbps</li> <li>■ [11] <b>28800bps</b> = 28.8 kbps</li> <li>■ [12] <b>31200bps</b> = 31.2 kbps</li> <li>■ [13] <b>33600bps</b> = 33.6 kbps</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The rate is negotiated between both sides (i.e., the device adapts to the capabilities of the remote side). Negotiation of the T.38 maximum supported fax data rate is provided in SIP's SDP [T38MaxBitRate] parameter. The negotiated [T38MaxBitRate] is the minimum rate supported between the local and remote endpoints.</li> <li>■ Fax relay rates greater than 14.4 kbps are applicable only to V.34 / T.38 fax relay. For non-T.38 V.34 supporting devices, configuration greater than 14.4 kbps is truncated to 14.4 kbps.</li> </ul>
'Fax Relay ECM Enable' configure voip > media fax-modem > ecm-mode [FaxRelayECMEnable]	Enables Error Correction Mode (ECM) mode during fax relay. <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul>
'Fax/Modem Bypass Coder Type' [FaxModemBypassCoderType]	Determines the coder used by the device when performing fax/modem bypass. Typically, high-bit-rate coders such as G.711 should be used. <ul style="list-style-type: none"> <li>■ [0] <b>G.711Alaw</b> = (Default) G.711 A-law 64</li> <li>■ [1] <b>G.711Mulaw</b> = G.711 Mu-law</li> </ul>
configure voip > media fax-modem > fax-modem-telephony-events-mode	Determines whether the device sends RFC 2833 ANS/ANSam events upon detection of fax and/or modem Answer

Parameter	Description
[FaxModemNTEMode]	<p>tones (i.e., CED tone).</p> <ul style="list-style-type: none"> <li>■ [0] = Disabled (default)</li> <li>■ [1] = Enabled</li> </ul> <p><b>Note:</b> The parameter is applicable only when the fax or modem transport type is set to bypass or Transparent-with-Events.</p>
<p>'Fax Bypass Payload Type'</p> <pre>configure voip &gt; media rtp-rtcp &gt; fax-bypass-payload-type</pre> <p>[FaxBypassPayloadType]</p>	<p>Defines the fax bypass RTP dynamic payload type.</p> <p>The valid range is 0 to 127. The default is 102.</p> <p><b>Note:</b> The device ignores this parameter for Rx payload types and uses the payload type determined during SDP negotiation. For using this configured payload type, see the <a href="#">[BackwardPTBehavior]</a> parameter.</p>
<p>'Modem Bypass Payload Type'</p> <pre>configure voip &gt; media rtp-rtcp &gt; modem-bypass-payload-type</pre> <p>[ModemBypassPayloadType]</p>	<p>Defines the modem bypass dynamic payload type.</p> <p>The range is 0 to 127. The default is 103.</p> <p><b>Note:</b> The device ignores this parameter for Rx payload types and uses the payload type determined during SDP negotiation. For using this configured payload type, see the <a href="#">[BackwardPTBehavior]</a> parameter.</p>
<p>'Enable RFC 3389 CN Payload Type'</p> <pre>configure voip &gt; media rtp-rtcp &gt; enable-standard-sid-payload-type</pre> <p>[EnableStandardSIDPayloadType]</p>	<p>Enables sending and receiving of Silence Indicator (SID) packets according to RFC 3389.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<p>volume</p> <p>[FaxModemRelayVolume]</p>	<p>Defines the fax gain control.</p> <p>The range is -18 to -3, corresponding to -18 dBm to -3 dBm in 1-dB steps. The default is -6 dBm fax gain control.</p>

Parameter	Description
'Fax Bypass Output Gain' configure voip > media fax-modem > fax-bypass-output-gain [FaxBypassOutputGain]	Defines the fax bypass output gain control.  The range is -31 to +31 dB, in 1-dB steps. The default is 0 (i.e., no gain).
'Modem Bypass Output Gain' configure voip > media fax-modem > modem-bypass-output-gain [ModemBypassOutputGain]	Defines the modem bypass output gain control.  The range is -31 dB to +31 dB, in 1-dB steps. The default is 0 (i.e., no gain).
modem-bypass-output-gain [FaxModemBypassBasicRTPPacketInterval]	Defines the basic frame size used during fax/modem bypass sessions.  <ul style="list-style-type: none"> <li>■ [0] = (Default) Determined internally</li> <li>■ [1] = 5 msec (not recommended)</li> <li>■ [2] = 10 msec</li> <li>■ [3] = 20 msec</li> </ul> <p><b>Note:</b> When set to 5 msec (1), the maximum number of simultaneous channels supported is 120.</p>
jitter-buffer-minimum-delay [FaxModemBypassJBufMinDelay]	Defines the Jitter Buffer delay (in milliseconds) during fax and modem bypass session.  The range is 0 to 150 msec. The default is 40.
enable-fax-modem-inband-network-detection [EnableFaxModemInbandNetworkDetection]	Enables in-band network detection related to fax/modem.  <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable.</li> <li>■ [1] = Enable. When the parameter is enabled on Bypass and transparent with events mode (VxxTransportType is set to 2 or 3), a detection of an Answer Tone from the network triggers a switch to bypass mode in addition to the local Fax/Modem tone detections. However, only a high bit-rate coder voice session effectively detects the</li> </ul>

Parameter	Description
	Answer Tone sent by a remote endpoint. This can be useful when, for example, the payload of voice and bypass is the same, allowing the originator to switch to bypass mode as well.
NSE-mode [NSEMode]	Global parameter that enables Cisco's compatible fax and modem bypass mode, Named Signaling Event (NSE) packets. You can also configure this feature per specific calls, using IP Profiles ('NSE Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.  <b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.
NSE-payload-type [NSEPayloadType]	Defines the NSE payload type for Cisco Bypass compatible mode.  The valid range is 96-127. The default is 105.  <b>Note:</b> <ul style="list-style-type: none"> <li>■ Cisco gateways usually use NSE payload type of 100.</li> <li>■ The device ignores this parameter for Rx payload types and uses the payload type determined during SDP negotiation. For using this configured payload type, see the <a href="#">[BackwardPTBehavior]</a> parameter.</li> </ul>
'T.38 Max Datagram Size' configure voip > sip-definition settings > t38-mx-datagram-sz [T38MaxDatagramSize]	Defines the maximum size of a T.38 datagram that the device can receive. This value is included in the outgoing SDP when T.38 is used.  The valid range is 120 to 600. The default is 560 .

Parameter	Description
<p>'Detect Fax on Answer Tone'</p> <p><code>det-fax-on-ans-tone</code></p> <p>[DetFaxOnAnswerTone]</p>	<p>Determines when the device initiates a T.38 session for fax transmission.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Initiate T.38 on Preamble</b> = (Default) The device to which the called fax is connected initiates a T.38 session on receiving HDLC (analog) . Preamble signal from the fax.</li> <li>■ [1] <b>Initiate T.38 on CED</b> = The device to which the called fax is connected initiates a T.38 session on receiving a CED answer tone from the fax. This option can only be used to relay fax signals, as the device sends T.38 Re-INVITE on detection of any fax/modem Answer tone (2100 Hz, amplitude modulated 2100 Hz, or 2100 Hz with phase reversals). The modem signal fails when using T.38 for fax relay.</li> </ul> <p><b>Note:</b> The parameters is applicable only if the [IsFaxUsed] parameter is set to 1 (T.38 Relay) or 3 (Fax Fallback).</p>
<p>'CED Transfer Mode'</p> <p><code>configure voip &gt; media fax-modem</code>  <code>&gt; ced-transfer-mode</code></p> <p>[CEDTransferMode]</p>	<p>Defines the method for sending fax/modem CED (answering) tones.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Fax Relay or VBD</b> = (Default) The device transfers the CED tone in Relay mode and starts the fax session immediately.</li> <li>■ [1] <b>Voice Mode or VBD</b> = The device transfers the CED tone in either Voice or Bypass mode and starts the fax session on V21 preamble.</li> <li>■ [2] <b>RFC 4733 Blocking RTP VBD</b> = The device transfers the CED tone in RFC 2833.</li> <li>■ [3] <b>RFC 4733 Along with RTP VBD</b> = The device transfers the CED tone in RFC 2833 and bypass, in parallel.</li> </ul>

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; backward-pt-behavior</pre> [BackwardPTBehavior]	<p>Enables backward compatibility for the following parameters that configure Rx payload types for media features (e.g., RFC 2833 DTMF, RTP redundancy, and fax bypass): [FaxBypassPayloadType], [ModemBypassPayloadType], [Rxt38OverRTPPayloadType], [V1501SSEPayloadTypeRx], [V1501SPRTPayloadTypeRx], [NSEPayloadType], [RFC2833RxPayloadType], and [RFC2198PayloadType].</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disables backward compatibility. The device only supports media features that are negotiated in SDP (and ignores the configured payload types).</li> <li>■ [1] = Enables backward compatibility. The device supports media features by using the configured payload types.</li> </ul>

## DTMF and Hook-Flash Parameters

The DTMF and hook-flash parameters are described in the table below.

**Table 73-41:DTMF and Hook-Flash Parameters**

Parameter	Description
<b>Hook-Flash Parameters</b>	
<pre>'Hook-Flash Code'</pre> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; hook- flash-code</pre> [HookFlashCode]	<p>Analog interfaces: Defines the digit pattern that when received from the Tel side, indicates a Hook Flash event.</p> <p>Digital interfaces: Defines the digit pattern used by the PBX to indicate a Hook Flash event. When this pattern is detected from the Tel side, the device responds as if a Hook Flash event has occurred and sends a SIP INFO message if the HookFlashOption parameter is set to 1, 5, 6, or 7 (indicating a Hook Flash). If configured and a Hook Flash indication is</p>

Parameter	Description
	<p>received from the IP side, the device generates this pattern to the Tel side.</p> <p>The valid range is a 25-character string. The default is a null string.</p> <p><b>Note:</b> The parameter can also be configured in a Tel Profile.</p>
<p>'Hook-Flash Option'</p> <pre>configure voip &gt; gateway dtmf-supp-service dtmf-and- dialing &gt; hook-flash-option</pre> <p>[HookFlashOption]</p>	<p>Defines the hook-flash transport type (i.e., method by which hook-flash is sent and received).</p> <p>Digital interfaces: The feature is applicable only if the HookFlashCode parameter is configured.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = (Default) Hook-Flash indication is not sent.</li> <li>■ [1] <b>INFO</b> = Sends proprietary INFO message (Broadsoft) with Hook-Flash indication.</li> </ul> <p>Digital interfaces: The device sends the INFO message as follows:</p> <pre>Content-Type: application/broadsoft; version=1.0 Content-Length: 17 event flashhook</pre> <ul style="list-style-type: none"> <li>■ [4] <b>RFC 2833</b> = This option is currently not supported for digital interfaces.</li> <li>■ [5] <b>INFO (Lucent)</b> = Sends proprietary SIP INFO message with Hook-Flash indication.</li> </ul> <p>The device sends the INFO message as follows:</p> <pre>Content-Type: application/hook- flash Content-Length: 11 signal=hf</pre> <ul style="list-style-type: none"> <li>■ [6] <b>INFO (NetCentrex)</b> = Sends proprietary SIP INFO message with Hook-Flash indication. The device sends the INFO message as follows:</li> </ul> <pre>Content-Type: application/dtmf-</pre>

Parameter	Description
	<p>relay</p> <p>Signal=16</p> <p>Where 16 is the DTMF code for hook flash.</p> <ul style="list-style-type: none"> <li>■ <b>[7] INFO (HUAWEI)</b> = Sends a SIP INFO message with Hook-Flash indication. The device sends the INFO message as follows: <p>Content-Length: 17</p> <p>Content-Type: application/sscc</p> <p>event=flashhook</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Digital interfaces: The device can interwork DTMF HookFlashCode to SIP INFO messages with Hook Flash indication.</li> <li>■ FXO interfaces support only the receipt of RFC 2833 Hook-Flash signals and INFO [1] type.</li> <li>■ FXS interfaces send Hook-Flash signals only if the EnableHold parameter is set to 0.</li> </ul> </li></ul>
<pre>configure voip &gt; gw dtmf- and-suppl &gt; gw digitalgw digital-gw-parameters &gt; flash-from-media-ip</pre> <p>[HookFlashFromMediaIP]</p>	<p>Defines the device's handling of hook-flash telephony events that are received in the media (RTP) from the IP side (typically, RFC 2833) and then sent to the PSTN CAS side.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) The device ignores incoming hook-flash events from the media IP.</li> <li>■ [1] = The device generates a wink to the CAS side when it receives a hook-flash event from the media IP.</li> </ul> <p><b>Note:</b> The parameter is applicable only to E1/T1 CAS.</p>
<p>'Min. Flash-Hook Detection Period'</p> <pre>configure voip &gt; interface fxs-fxo &gt; min-flash-hook- time</pre> <p>[MinFlashHookTime]</p>	<p>Defines the minimum time (in msec) for detection of a hook-flash event. Detection is guaranteed for hook-flash periods of at least 60 msec (when setting the minimum time to 25). Hook-flash signals that last a shorter period of time are ignored.</p> <p>The valid range is 25 to 300. The default is 300.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ It's recommended to reduce the detection time by 50 msec from the desired value. For example, if you want to set the value to 200 msec, then enter 150 msec (i.e., 200 minus 50).</li> </ul>
<p>'Max. Flash-Hook Detection Period'</p> <pre>configure voip &gt; interface fxs-fxo &gt; flash-hook-period</pre> <p>[FlashHookPeriod]</p>	<p>Global parameter defining the hook-flash period (in msec) for Tel and IP sides.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('Flash Hook Period' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS and FXO interfaces.</li> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
<b>DTMF Parameters</b>	
<pre>notify-on-sig-end</pre> <p>[MGCPDTMFDetectionPoint]</p>	<p>Determines when the detection of DTMF events is notified.</p> <ul style="list-style-type: none"> <li>■ [0] = DTMF event is reported at the end of a detected DTMF digit.</li> <li>■ [1] = (Default) DTMF event is reported at the start of a detected DTMF digit.</li> </ul>
<p>'Declare RFC 2833 in SDP'</p> <pre>configure voip &gt; gateway dtmf-supp-service dtmf-and- dialing &gt; rfc-2833-in-sdp</pre> <p>[RxDTMFOption]</p>	<p>Global parameter that enables the device to declare the RFC 2833 'telephony-event' parameter in the SDP. You can also configure this feature per specific calls, using IP Profiles ('Rx DTMF Option' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table,</p>

Parameter	Description
	<p>see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'First Tx DTMF Option'</p> <pre>configure voip &gt; gateway dtmf-suppress-service dtmf-and- dialing &gt; first-dtmf- option-type [FirstTxDTMFOption]</pre>	<p>Defines the first preferred transmit (Tx) DTMF negotiation method.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = (Default) No negotiation. DTMF digits are sent according to the [DTMFTransportType] and [RFC2833PayloadType] parameters. The RFC 2833 payload type is according to the [RFC2833PayloadType] parameter for transmit and receive.</li> <li>■ [1] <b>Info NORTEL</b> = Sends DTMF digits according to IETF Internet-Draft draft-choudhuri-sip-info-digit-00.</li> <li>■ [2] <b>NOTIFY</b> = Sends DTMF digits according to IETF Internet-Draft draft-mahy-sipping-signaled-digits-01.</li> <li>■ [3] <b>Info Cisco</b> = Sends DTMF digits according to Cisco format.</li> <li>■ [4] <b>RFC 2833</b> = The device handles DTMF as follows: <ul style="list-style-type: none"> <li>✓ Negotiates RFC 2833 payload type using local and remote SDPs.</li> <li>✓ Sends DTMF packets using RFC 2833 payload type according to the payload type in the received SDP.</li> <li>✓ Expects to receive RFC 2833 packets with the same payload type according to the RFC2833PayloadType parameter.</li> <li>✓ Removes DTMF digits in transparent mode (as part of the voice stream).</li> </ul> </li> <li>■ [5] <b>Info KOREA</b> = Sends DTMF digits according to Korea Telecom format.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When out-of-band DTMF transfer is used -- [1], [2], [3], or [5] -- the [DTMFTransportType] parameter is automatically set to [0] (i.e., DTMF digits are erased from the RTP stream).</li> <li>■ Digital interfaces: If an ISDN phone user presses digits (e.g., for interactive voice response / IVR applications such as retrieving voice mail messages), ISDN Information messages received by the device for each digit are sent in the voice channel to the IP network as DTMF signals, according to the settings of the parameter.</li> <li>■ For more information on DTMF transport, see <a href="#">Configuring DTMF Transport Types</a> on page 299.</li> <li>■ You can also configure the parameter per specific calls, using IP Profiles ('First Tx DTMF Option' parameter). To configure IP Profiles, see <a href="#">Configuring IP Profiles</a> on page 674.</li> </ul>
<p>'Second Tx DTMF Option'</p> <pre>configure voip &gt; gateway dtmf-supp-service dtmf-and- dialing &gt; second-dtmf- option-type [SecondTxDTMFOption]</pre>	<p>Defines the second preferred transmit (Tx) DTMF negotiation method. The first preferred method is configured by the FirstTxDTMFOption parameter. For a description of the optional values for the parameter, see the FirstTxDTMFOption parameter above.</p> <p><b>Note:</b> You can also configure the parameter per specific calls, using IP Profiles ('Second Tx DTMF Option' parameter). To configure IP Profiles, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
[AdditionalOutOfBandDtmfFormat]	<p>Enables the device to simultaneously send DTMF tones (signals) in SIP messages such as INFO messages (out-of-band) and in RTP media streams (in-band) with a special payload type (as defined in RFC 2833), when the</p>

Parameter	Description
	<p>FirstTxDTMFOption parameter is configured to 4. The parameter must be configured to the method for transporting DTMF digits over the IP network to the remote endpoint. For more information on DTMF transport, see <a href="#">Configuring DTMF Transport Types</a> on page 299.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) DTMF is sent according to FirstTxDTMFOption.</li> <li>■ [1] = Nortel</li> <li>■ [2] = Cisco</li> <li>■ [3] = Threecom</li> <li>■ [4] = Korea</li> </ul>
<pre>configure voip &gt; gateway dtmf-suppress-service dtmf-and- dialing &gt; auto-dtmf-mute [DisableAutoDTMFMute]</pre>	<p>Enables the automatic muting of DTMF digits when out-of-band DTMF transmission is used.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Automatic mute is used.</li> <li>■ [1] = No automatic mute of in-band DTMF.</li> </ul> <p>When the parameter is set to [1], the DTMF transport type is set according to the parameter [DTMFTransportType] and the DTMF digits aren't muted if out-of-band DTMF mode is selected -- [FirstTxDTMFOption] set to [1], [2] or [3]. This enables the sending of DTMF digits in-band (transparent of RFC 2833) in addition to out-of-band DTMF messages.</p> <p><b>Note:</b> This mode is usually not recommended.</p>
<p>'Enable Digit Delivery to IP'</p> <pre>configure voip &gt; sip- definition settings &gt; digit-delivery-2ip [EnableDigitDelivery2IP]</pre>	<p>Enables the Digit Delivery feature, which sends DTMF digits to the destination IP address after the Tel-to-IP call is answered.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>To enable this feature, modify the called number to include at least one 'p' character. The device uses the digits before the 'p' character in the initial INVITE message. After</p>

Parameter	Description
	<p>the call is answered, the device waits for the required time (number of 'p' multiplied by 1.5 seconds), and then sends the rest of the DTMF digits using the method chosen (in-band or out-of-band).</p> <p><b>Note:</b> The called number can include several 'p' characters (1.5 seconds pause), for example, 1001pp699, 8888p9p300.</p>
<p>'Enable Digit Delivery to Tel'</p> <pre>configure voip &gt; sip- definition settings &gt; digit-delivery-2tel</pre> <p>[EnableDigitDelivery]</p>	<p>Global parameter enabling the Digit Delivery feature, which sends DTMF digits of the called number to the Tel side (analog port or B-channel for digital interfaces) after the call is answered (i.e., line is off-hooked for FXS, or seized for FXO) for IP-to-Tel calls.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('Enable Digit Delivery' parameter). For a detailed description of the parameter and To configure the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
<p>'Replace Number Sign With Escape'</p> <pre>configure voip &gt; sip- definition settings &gt; replace-nb-sign-w-esc</pre> <p>[ReplaceNumberSignWithEscapeChar]</p>	<p>Determines whether to replace the number sign (#) with the escape character (%23) in outgoing SIP messages for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = (Default) Disabled.</li> <li>■ [1] Check box selected = Enabled. All number signs #, received in the dialed DTMF digits are replaced in the outgoing SIP Request-URI and To headers with the escape sign %23.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the parameter [IsSpecialDigits] is set 1.</li> <li>■ The parameter is applicable only to analog interfaces.</li> </ul>

Parameter	Description
<p>'Special Digit Representation'</p> <pre>configure voip &gt; gateway dtmf-supp-service dtmf-and- dialing &gt; special-digit-rep</pre> <p>[UseDigitForSpecialDTMF]</p>	<p>Defines the representation for 'special' digits ('*' and '#') that are used for out-of-band DTMF signaling (using SIP INFO/NOTIFY).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Special</b> = (Default) Uses the strings '*' and '#'.</li> <li>■ [1] <b>Numeric</b> = Uses the numerical values 10 and 11.</li> </ul>
<pre>isdn-keypad-mode</pre> <p>[ISDNKeypadMode]</p>	<p>Enables the device to send DTMF digits received in the called party number from the IP side, as Keypad facility IE in ISDN INFORMATION messages to PSTN.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Don't send - all digits are sent as DTMF to PSTN (i.e., not sent as Keypad).</li> <li>■ [1] = During Call Establishment - DTMF digits after * or # (inclusive) are sent as Keypad only during call establishment and call disconnect. During an established call, all digits are sent as DTMF.</li> <li>■ [2] = Always - DTMF digits after * or # (inclusive) are always sent as Keypad (call establishment, connect, and disconnect).</li> </ul> <p>For more information, see <a href="#">Interworking Keypad DTMFs for SIP-to-ISDN Calls</a> on page 1028.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature is not applicable to re-INVITE messages.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>

## Digit Collection and Dial Plan Parameters

The digit collection and dial plan parameters are described in the table below.

**Table 73-42:Digit Collection and Dial Plan Parameters**

Parameter	Description
<p>'Dial Plan Index'</p> <pre>configure voip &gt; gateway dtmf- supp-service dtmf-and-dialing &gt; dial-plan-index</pre> <p>[DialPlanIndex]</p>	<p>Defines the Dial Plan index to use in the external Dial Plan file. The Dial Plan file is loaded to the device as a .dat file (converted using the DConvert utility). The Dial Plan index can be defined globally or per Tel Profile.</p> <p>The valid value range is 0 to 7, where 0 denotes PLAN1, 1 denotes PLAN2, and so on. The default is -1, indicating that no Dial Plan file is used.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is configured to select a Dial Plan index, the settings of the parameter DigitMapping are ignored.</li> <li>■ If the parameter is configured to select a Dial Plan index from an external Dial Plan file, the device first attempts to locate a matching digit pattern in the Dial Plan file, and if not found, then attempts to locate a matching digit pattern in the Digit Map rules configured by the DigitMapping parameter.</li> <li>■ Digital interfaces: The parameter is also applicable to ISDN with overlap dialing.</li> <li>■ Digital interfaces: For E1 CAS MFC-R2 variants (which don't support terminating digit for the called party number, usually I-15), the parameter and the DigitMapping parameter are ignored. Instead, you can define a Dial Plan template per trunk using the parameter CasTrunkDialPlanName_x (or in the Trunk Settings page).</li> <li>■ The parameter can also be configured in a Tel Profile.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For more information on the Dial Plan file, see Digit Collection and Dial Plan Parameters.</li> </ul>
<pre>configure voip &gt; gateway manipulation settings &gt; tel2ip- src-nb-map-dial-index</pre> <p>[Tel2IPSourceNumberMappingDialPlanIndex]</p>	<p>Defines the Dial Plan index in the external Dial Plan file for the Tel-to-IP Source Number Mapping feature.</p> <p>The valid value range is 0 to 7, defining the Dial Plan index [Plan x] in the Dial Plan file. The default is -1 (disabled).</p> <p>For more information on this feature, see Digit Collection and Dial Plan Parameters.</p>
<p>'Digit Mapping Rules'</p> <pre>configure voip &gt; gateway dtmf- supp-service dtmf-and-dialing &gt; digitmapping</pre> <p>[DigitMapping]</p>	<p>Defines the digit map pattern. If the digit string (i.e., dialed number) matches one of the patterns in the digit map, the device stops collecting digits and establishes a call with the collected number. For digital interfaces: This is used to reduce the dialing period for ISDN overlap dialing.</p> <p>The digit map pattern can contain up to 52 options (rules), each separated by a vertical bar ( ). The maximum length of the entire digit pattern is 152 characters.</p> <p>For more information on digit maps, see <a href="#">Digit Mapping</a> on page 1026.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For ISDN interfaces, the digit map mechanism is applicable only when ISDN overlap dialing is used (ISDNRxOverlap is set to 1).</li> <li>■ If the [DialPlanIndex] parameter is configured (to select a Dial Plan index), then the device first attempts to locate a matching digit pattern in the Dial Plan file, and if not found, then attempts to locate a matching digit pattern in the Digit Map rules configured by the</li> </ul>

Parameter	Description
	[DigitMapping] parameter.
<p>'Max Digits in Phone Num'</p> <pre>configure voip &gt; gateway dtmf- supp-service dtmf-and-dialing &gt; mxdig-b4-dialing</pre> <p>[MaxDigits]</p>	<p>Defines the maximum number of collected destination number digits that can be received from the Tel side for analog interfaces or for digital interfaces, when ISDN Tel-to-IP overlap dialing is performed. When the number of collected digits reaches this maximum, the device uses these digits for the called destination number.</p> <p>The valid range is 1 to 49. The default is 5 for analog interfaces and 30 for digital interfaces.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Instead of using the parameter, you can configure digit maps.</li> <li>■ Analog: Dialing ends when any of the following scenarios occur: <ul style="list-style-type: none"> <li>✓ Maximum number of digits is dialed</li> <li>✓ Interdigit timeout expires (configured by the [TimeBetweenDigits] parameter)</li> <li>✓ Pound (#) key is pressed</li> <li>✓ Digit map pattern is matched</li> </ul> </li> </ul>
<p>'Inter Digit Timeout for Overlap Dialing'</p> <pre>configure voip &gt; gateway dtmf- supp-service dtmf-and-dialing &gt; time-btwn-dial-digs</pre> <p>[TimeBetweenDigits]</p>	<p>Defines a timeout between digits (i.e., inter-digit timeout).</p> <p><b>Analog:</b> Defines the time (in seconds) that the device waits between digits dialed by the user.</p> <p><b>ISDN Overlap Dialing:</b> Defines the time (in seconds) that the device waits between digits received from the PSTN or IP during overlap dialing.</p> <p>When this timeout expires, the device stops waiting for more digits, and uses the collected digits to dial the called</p>

Parameter	Description
	<p>destination number.</p> <p>The valid range is 1 to 10. The default is 4.</p>
<p>'Enable Special Digits'</p> <pre>configure voip &gt; gateway dtmf- supp-service dtmf-and-dialing &gt; special-digits</pre> <p>[IsSpecialDigits]</p>	<p>Enables the use of the asterisk (*) and pound (#) symbols in dialed telephone numbers.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Uses '*' or '#' to terminate number collection (see the [UseDigitForSpecialDTMF] parameter).</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Allows '*' and '#' for telephone numbers dialed by a user or for the endpoint telephone number.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ These symbols can always be used as the first digit of a dialed number even if you disable the parameter.</li> <li>■ The parameter is applicable only to analog interfaces.</li> </ul>

## Voice Mail Parameters

The voice mail parameters are described in the table below. For more information on the Voice Mail application, refer to the *CPE Configuration Guide for Voice Mail*.

**Table 73-43:Voice Mail Parameters**

Parameter	Description
<p>'Voice Mail Interface'</p> <pre>configure voip &gt; gateway voice-mail-setting &gt; vm- interface</pre> <p>[VoiceMailInterface]</p>	<p>Enables the device's Voice Mail application and determines the communication method between the device and PBX.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> (default)</li> <li>■ [1] <b>DTMF</b></li> <li>■ [2] <b>SMDI</b></li> <li>■ [3] <b>QSIG</b></li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [4] <b>SETUP Only</b> = Applicable only to ISDN.</li> <li>■ [5] <b>MATRA/AASTRA QSIG</b></li> <li>■ [6] <b>QSIG SIEMENS</b> = QSIG MWI activate and deactivate messages include Siemens Manufacturer Specific Information (MSI)</li> <li>■ [8] <b>ETSI</b> = Euro ISDN, according to ETS 300 745-1 V1.2.4, section 9.5.1.1. Enables MWI interworking from IP to Tel , typically used for BRI phones.</li> <li>■ [9] <b>NI2</b> = ISDN PRI trunks set to NI-2. This is used for interworking the SIP Message Waiting Indication (MWI) NOTIFY message to ISDN PRI NI-2 Message Waiting Notification (MWN) that is sent in the ISDN Facility IE message. This option is applicable when the device is connected to a PBX through an ISDN PRI trunk configured to NI-2.</li> </ul> <p><b>Note:</b> To disable voice mail per Trunk Group, you can use a Tel Profile with the EnableVoiceMailDelay parameter set to disabled (0). This eliminates the phenomenon of call delay on Trunks not implementing voice mail when voice mail is enabled using this global parameter.</p>
'Enable VoiceMail URI' voicemail-uri [EnableVMURI]	<p>Enables the interworking of target and cause for redirection from Tel to IP and vice versa, according to RFC 4468.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>Digital interfaces: Upon receipt of an ISDN Setup message with Redirect values, the device maps the Redirect phone number to the SIP 'target' parameter and the Redirect number reason to the SIP 'cause' parameter in the Request-URI.</p> <p>Redirecting Reason &gt;&gt; SIP Response Code</p>

Parameter	Description
	<p>Unknown &gt;&gt; 404</p> <p>User busy &gt;&gt; 486</p> <p>No reply &gt;&gt; 408</p> <p>Deflection &gt;&gt; 487/480</p> <p>Unconditional &gt;&gt; 302</p> <p>Others &gt;&gt; 302</p> <p>If the device receives a Request-URI that includes a 'target' and 'cause' parameter, the 'target' is mapped to the Redirect phone number and the 'cause' is mapped to the Redirect number reason.</p>
[WaitForBusyTime]	<p>Defines the time (in msec) that the device waits to detect busy and/or reorder tones. This feature is used for semi-supervised PBX call transfers (i.e., the LineTransferMode parameter is set to 2).</p> <p>The valid value range is 0 to 20000 (i.e., 20 sec). The default is 2000 (i.e., 2 sec).</p>
<p>'Line Transfer Mode'</p> <pre>configure voip &gt; gateway voice-mail-setting &gt; line- transfer-mode</pre> <p>[LineTransferMode]</p>	<p>Defines the call transfer method used by the device. The parameter is applicable to the following:</p> <ul style="list-style-type: none"> <li>■ Analog interfaces: FXO call transfer</li> <li>■ Digital interfaces: E1/T1 CAS call transfer if the TrunkTransferMode_x parameter is set to 3 (CAS Normal) or 1 (CAS NFA)</li> </ul> <p>The valid values are:</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) IP.</li> <li>■ [1] <b>Blind</b> = PBX blind transfer: <ul style="list-style-type: none"> <li>✓ Analog (FXO): After receiving a SIP REFER message from the IP side, the device (FXO) sends a hook-flash to the PBX, dials the digits (that are received in the Refer-To header), and then immediately releases the line (i.e., on-hook). The PBX performs the transfer internally.</li> <li>✓ E1/T1 CAS: When a SIP REFER</li> </ul> </li> </ul>

Parameter	Description
	<p>message is received, the device performs a blind transfer, by performing a CAS wink, waiting a user-defined time (configured by the WaitForDialTime parameter), dialing the Refer-To number, and then releasing the call. The PBX performs the transfer internally.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Semi Supervised</b> = PBX semi-supervised transfer: <ul style="list-style-type: none"> <li>✓ Analog (FXO): After receiving a SIP REFER message from the IP side, the device sends a hook-flash to the PBX, and then dials the digits (that are received in the Refer-To header). If no busy or reorder tones are detected (within the user-defined interval set by the WaitForBusyTime parameter), the device completes the call transfer by releasing the line. If these tones are detected, the transfer is cancelled, the device sends a SIP NOTIFY message with a failure reason in the NOTIFY body (such as 486 if busy tone detected), and generates an additional hook-flash toward the FXO line to restore connection to the original call.</li> <li>✓ E1/T1 CAS: The device performs a CAS wink, waits a user-defined time (configured by the WaitForDialTime parameter), and then dials the Refer-To number. If during the user-defined interval set by the WaitForBusyTime parameter, no busy or reorder tones are detected, the device completes the call transfer by releasing the line. If during this interval, the device detects these tones, the transfer operation is cancelled, the device sends a SIP NOTIFY message with a</li> </ul> </li> </ul>

Parameter	Description
	<p>failure reason (e.g., 486 if a busy tone is detected), and then generates an additional wink toward the CAS line to restore connection with the original call.</p> <p>■ [3] <b>Supervised</b> = PBX Supervised transfer:</p> <ul style="list-style-type: none"> <li>✓ Analog (FXO): After receiving a SIP REFER message from the IP side, the device sends a hook-flash to the PBX, and then dials the digits (that are received in the Refer-To header). The device waits for connection of the transferred call and then completes the call transfer by releasing the line. If speech is not detected, the transfer is cancelled, the device sends a SIP NOTIFY message with a failure reason in the NOTIFY body (such as 486 if busy tone detected) and generates an additional hook-flash toward the FXO line to restore connection to the original call.</li> <li>✓ E1/T1 CAS: The device performs a supervised transfer to the PBX. The device performs a CAS wink, waits a user-defined time (configured by the WaitForDialTime parameter), and then dials the Refer-To number. The device completes the call transfer by releasing the line only after detection of the transferred party answer. To enable answer supervision, you also need to do the following:             <ol style="list-style-type: none"> <li>1) Enable voice detection (i.e., set the EnableVoiceDetection parameter to 1).</li> <li>2) Set the EnabledSPIPMDetectors parameter to 1.</li> <li>3) Install the IPMDetector DSP option Feature License Key.</li> </ol> </li> </ul>

Parameter	Description
<b>SMDI Parameters</b>	
<b>'Enable SMDI'</b> <pre>configure voip &gt; gateway voice-mail-setting &gt; enable- smdi</pre> <b>[SMDI]</b>	<p>Enables Simplified Message Desk Interface (SMDI) interface on the device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Normal serial</li> <li>■ [1] <b>Enable (Bellcore)</b></li> <li>■ [2] <b>Ericsson MD-110</b></li> <li>■ [3] <b>NEC (ICS)</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When the RS-232 connection is used for SMDI messages (Serial SMDI), it cannot be used for other applications, for example, to access the Command Line Interface (CLI).</li> </ul>
<b>'SMDI Timeout'</b> <pre>configure voip &gt; gateway voice-mail-setting &gt; smdi- timeout-[msec]</pre> <b>[SMDITimeout]</b>	<p>Defines the time (in msec) that the device waits for an SMDI Call Status message before or after a Setup message is received. The parameter synchronizes the SMDI and analog CAS interfaces.</p> <p>If the timeout expires and only an SMDI message is received, the SMDI message is dropped. If the timeout expires and only a Setup message is received, the call is established.</p> <p>The valid range is 0 to 10000 (i.e., 10 seconds). The default is 2000.</p>
<b>Message Waiting Indication (MWI) Parameters</b>	
<b>'MWI Off Digit Pattern'</b> <pre>configure voip &gt; gateway voice-mail-setting &gt; mwi- off-dig-ptn</pre> <b>[MWIOffCode]</b>	<p>Defines the digit code used by the device to notify the PBX that there are no messages waiting for a specific extension. This code is added as prefix to the dialed number.</p> <p>The valid range is a 25-character string.</p>
<b>'MWI On Digit Pattern'</b> <pre>configure voip &gt; gateway</pre>	<p>Defines the digit code used by the device to notify the PBX of messages waiting for a</p>

Parameter	Description
<pre>voice-mail-setting &gt; mwi-on-dig-ptn</pre> <p>[MWIONCode]</p>	<p>specific extension. This code is added as prefix to the dialed number.</p> <p>The valid range is a 25-character string.</p>
<p>'MWI Suffix Pattern'</p> <pre>configure voip &gt; gateway voice-mail-setting &gt; mwi-suffix-pattern</pre> <p>[MWISuffixCode]</p>	<p>Defines the digit code used by the device as a suffix for 'MWI On Digit Pattern' and 'MWI Off Digit Pattern'. This suffix is added to the generated DTMF string after the extension number.</p> <p>The valid range is a 25-character string.</p>
<p>'MWI Source Number'</p> <pre>configure voip &gt; gateway voice-mail-setting &gt; mwi-source-number</pre> <p>[MWISourceNumber]</p>	<p>Defines the calling party's phone number used in the Q.931 MWI Setup message to PSTN. If not configured, the channel's phone number is used as the calling number.</p>
<pre>configure voip &gt; gateway dtmf-supp-service supp-service-settings &gt; mwi-sub-ipgrp-id</pre> <p>[MWISubscribeIPGroupID]</p>	<p>Defines the IP Group ID used when subscribing to an MWI server. The 'SIP Group Name' field value of the IP Groups table is used as the Request-URI host name in the outgoing MWI SIP SUBSCRIBE message. The request is sent to the IP address defined for the Proxy Set that is associated with the IP Group. The Proxy Set's capabilities such as proxy redundancy and load balancing are also applied to the message.</p> <p>For example, if the 'SIP Group Name' field of the IP Group is "company.com", the device sends the following SUBSCRIBE message:</p> <pre>SUBSCRIBE sip:company.com...</pre> <p>Instead of:</p> <pre>SUBSCRIBE sip:10.33.10.10...</pre> <p><b>Note:</b> If the parameter is not configured, the MWI SUBSCRIBE message is sent to the MWI server as defined by the [MWIServerIP] parameter.</p>
<p>'Notification IP Group Name'</p> <pre>configure voip &gt; gateway digital settings &gt; notification-ip-group-name</pre>	<p>Defines the IP Group to where the device sends SIP NOTIFY MWI messages.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This is used for MWI Interrogation. For</li> </ul>

Parameter	Description
[NotificationIPGroupName]	<p>more information on the interworking of QSIG MWI to IP, see <a href="#">Message Waiting Indication</a> on page 1051.</p> <ul style="list-style-type: none"> <li>To define the handling method of MWI Interrogation messages, use the 'MWI Interrogation Type' parameter in the Trunk Group Settings table (see <a href="#">Configuring Trunk Group Settings</a> on page 937).</li> </ul>
<p>'MWI Notification Timeout'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mwi-ntf- timeout</pre> <p>[MWINotificationTimeout]</p>	<p>Global parameter defining the maximum duration (timeout) that a message waiting indication (MWI) is displayed on endpoint equipment (phones' LED, screen notification or voice tone).</p> <p>You can also configure the feature for specific calls, using Tel Profiles ('MWI Notification Timeout' parameter). For a detailed description of the parameter or for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only to FXS interfaces.</li> <li>If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
<pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mwi-qsig- party-num</pre> <p>[MWIQsigMsgCentredIDPartyNumber]</p>	<p>Defines the Message Centred ID party number used for QSIG MWI messages. If not configured (default), the parameter is not included in MWI (activate and deactivate) QSIG messages.</p> <p>The valid value is a string.</p>
<p><b>Digit Patterns</b> The following digit pattern parameters apply only to voice mail applications that use the DTMF communication method. For available pattern syntaxes, refer to the <i>CPE Configuration Guide for Voice Mail</i>.</p>	
<p>'Forward on Busy Digit Pattern (Internal)'</p> <pre>configure voip &gt; gateway</pre>	<p>Defines the digit pattern used by the PBX to indicate 'call forward on busy' when the</p>

Parameter	Description
<code>voice-mail-setting &gt; fwd-busy-dig-ptrn-int</code> <b>[DigitPatternForwardOnBusy]</b>	<p>original call is received from an internal extension.</p> <p>The valid range is a 120-character string.</p>
<p>'Forward on No Answer Digit Pattern (Internal)'</p> <code>configure voip &gt; gateway voice-mail-setting &gt; fwd-no-ans-dig-pat-int</code> <b>[DigitPatternForwardOnNoAnswer]</b>	<p>Defines the digit pattern used by the PBX to indicate 'call forward on no answer' when the original call is received from an internal extension.</p> <p>The valid range is a 120-character string.</p>
<p>'Forward on Do Not Disturb Digit Pattern (Internal)'</p> <code>configure voip &gt; gateway voice-mail-setting &gt; fwd-dnd-dig-ptrn-int</code> <b>[DigitPatternForwardOnDND]</b>	<p>Defines the digit pattern used by the PBX to indicate 'call forward on do not disturb' when the original call is received from an internal extension.</p> <p>The valid range is a 120-character string.</p>
<p>'Forward on No Reason Digit Pattern (Internal)'</p> <code>configure voip &gt; gateway voice-mail-setting &gt; fwd-no-rsn-dig-ptrn-int</code> <b>[DigitPatternForwardNoReason]</b>	<p>Defines the digit pattern used by the PBX to indicate 'call forward with no reason' when the original call is received from an internal extension.</p> <p>The valid range is a 120-character string.</p>
<p>'Forward on Busy Digit Pattern (External)'</p> <code>configure voip &gt; gateway voice-mail-setting &gt; fwd-busy-dig-ptrn-ext</code> <b>[DigitPatternForwardOnBusyExt]</b>	<p>Defines the digit pattern used by the PBX to indicate 'call forward on busy' when the original call is received from an external line (not an internal extension).</p> <p>The valid range is a 120-character string.</p>
<p>'Forward on No Answer Digit Pattern (External)'</p> <code>configure voip &gt; gateway voice-mail-setting &gt; fwd-no-ans-dig-pat-ext</code> <b>[DigitPatternForwardOnNoAnswerExt]</b>	<p>Defines the digit pattern used by the PBX to indicate 'call forward on no answer' when the original call is received from an external line (not an internal extension).</p> <p>The valid range is a 120-character string.</p>
<p>'Forward on Do Not Disturb Digit Pattern (External)'</p> <code>configure voip &gt; gateway voice-mail-setting &gt; fwd-</code>	<p>Defines the digit pattern used by the PBX to indicate 'call forward on do not disturb' when the original call is received from an external line (not an internal extension).</p>

Parameter	Description
dnd-dig-ptn-ext [DigitPatternForwardOnDNDExt]	The valid range is a 120-character string.
'Forward on No Reason Digit Pattern (External)' configure voip > gateway voice-mail-setting > fwd-no-rsn-dig-ptn-ext [DigitPatternForwardNoReasonExt]	Defines the digit pattern used by the PBX to indicate 'call forward with no reason' when the original call is received from an external line (not an internal extension).  The valid range is a 120-character string.
'Internal Call Digit Pattern' configure voip > gateway voice-mail-setting > int-call-dig-ptn [DigitPatternInternalCall]	Defines the digit pattern used by the PBX to indicate an internal call.  The valid range is a 120-character string.
'External Call Digit Pattern' configure voip > gateway voice-mail-setting > ext-call-dig-ptn [DigitPatternExternalCall]	Defines the digit pattern used by the PBX to indicate an external call.  The valid range is a 120-character string.
'Disconnect Call Digit Pattern' configure voip > gateway voice-mail-setting > disc-call-dig-ptn [TelDisconnectCode]	Defines a digit pattern that when received from the Tel side, indicates the device to disconnect the call.  The valid range is a 25-character string.
'Digit To Ignore Digit Pattern' configure voip > gateway voice-mail-setting > dig-to-ignore-dig-pattern [DigitPatternDigitToIgnore]	Defines a digit pattern that if received as Src (S) or Redirect (R) numbers is ignored and not added to that number.  The valid range is a 25-character string.

## Supplementary Services Parameters

This subsection describes the device's supplementary telephony services parameters.

### Caller ID Parameters

The caller ID parameters are described in the table below.

**Table 73-44: Caller ID Parameters**

Parameter	Description
<p>'Enable Caller ID'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; enable-caller-id</pre> <p>[EnableCallerID]</p>	<p>Global parameter that enables Caller ID.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <ul style="list-style-type: none"> <li>✓ FXS: The calling number and display text (from IP) are sent to the device's port.</li> <li>✓ FXO and CAS: The device detects the Caller ID signal received from the Tel and sends it to the IP in the SIP INVITE message (as the 'Display' element).</li> </ul> <p>To configure the Caller ID string per port, see <a href="#">Configuring Caller Display Information</a> on page 1097. To enable or disable caller ID generation / detection per port, see <a href="#">Configuring Caller ID Permissions</a> on page 1101.</p>
<p>'Caller ID Type'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; caller-id-type</pre> <p>[CallerIDType]</p>	<p>Determines the standard used for detection (FXO) and generation (FXS) of Caller ID, and detection (FXO) / generation (FXS) of MWI (when specified) signals:</p> <ul style="list-style-type: none"> <li>■ [0] <b>Standard Bellcore</b> = (Default) Caller ID and MWI</li> <li>■ [1] <b>Standard ETSI</b> = Caller ID and MWI</li> <li>■ [2] <b>Standard NTT</b></li> <li>■ [4] <b>Standard BT</b> = Britain</li> <li>■ [16] <b>Standard DTMF Based ETSI</b></li> <li>■ [17] <b>Standard Denmark</b> = Caller ID and MWI</li> <li>■ [18] <b>Standard India</b></li> <li>■ [19] <b>Standard Brazil</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to analog interfaces.</li> <li>■ Typically, the Caller ID signals are generated / detected between the first and second rings. However, sometimes the Caller ID is detected before the first ring signal. In such a scenario, set the [RingsBeforeCallerID] parameter to 0.</li> <li>■ Caller ID detection for Britain [4] is not supported on the device's FXO ports. Only FXS ports can generate the Britain [4] Caller ID.</li> </ul>

Parameter	Description									
	<ul style="list-style-type: none"><li>■ To select the Bellcore Caller ID sub standard, use the [BellcoreCallerIDTypeOneSubStandard] parameter. To select the ETSI Caller ID substandard, use the [ETSCallerIDTypeOneSubStandard] parameter.</li><li>■ To select the Bellcore MWI sub standard, use the [BellcoreVMWITypeOneStandard] parameter. To select the ETSI MWI sub standard, use the [ETSIVMWITypeOneStandard] parameter.</li><li>■ If you define Caller ID Type as NTT [2], you need to define the NTT DID signaling form (FSK or DTMF) using the [NTTDIDSignallingForm] parameter.</li></ul>									
'Enable FXS Caller ID Category Digit For Brazil Telecom' fxs-callid-cat-brazil [AddCPCPrefix2BrazilCallerID]	<p>Enables the interworking of Calling Party Category (cpc) code from SIP INVITE messages to FXS Caller ID first digit.</p> <ul style="list-style-type: none"><li>■ [0] <b>Disable</b> (default)</li><li>■ [1] <b>Enable</b></li></ul> <p>When the parameter is enabled, the device sends the Caller ID number (calling number) with the cpc code (received in the SIP INVITE message) to the device's FXS port. The cpc code is added as a prefix to the caller ID (after IP-to-Tel calling number manipulation). For example, assuming that the incoming INVITE contains the following From (or P-Asserted-Id) header:</p> <pre>From:&lt;sip:+551137077801;cpc=payphone@10.20.7.35&gt;;tag=53700</pre> <p>The calling number manipulation removes "+55" (leaving 10 digits), and then adds the prefix 7, the cpc code for payphone user. Therefore, the Caller ID number that is sent to the FXS port, in this example is 71137077801.</p> <p>If the incoming INVITE message doesn't contain the 'cpc' parameter, nothing is added to the Caller ID number.</p> <table><tr><th>CPC Value in Received INVITE</th><th>CPC Code Prefixed to Caller ID (Sent to FXS Endpoint)</th><th>Description</th></tr><tr><td>cpc=unknown</td><td>1</td><td>Unknown user</td></tr><tr><td>cpc=subscribe</td><td>1</td><td>-</td></tr></table>	CPC Value in Received INVITE	CPC Code Prefixed to Caller ID (Sent to FXS Endpoint)	Description	cpc=unknown	1	Unknown user	cpc=subscribe	1	-
CPC Value in Received INVITE	CPC Code Prefixed to Caller ID (Sent to FXS Endpoint)	Description								
cpc=unknown	1	Unknown user								
cpc=subscribe	1	-								

Parameter	Description																		
	<table><tr><td>cpc=ordinary</td><td>1</td><td>Ordinary user</td></tr><tr><td>cpc=priority</td><td>2</td><td>Pre-paid user</td></tr><tr><td>cpc=test</td><td>3</td><td>Test user</td></tr><tr><td>cpc=operator</td><td>5</td><td>Operator</td></tr><tr><td>cpc=data</td><td>6</td><td>Data call</td></tr><tr><td>cpc=payphone</td><td>7</td><td>Payphone user</td></tr></table> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>■ The parameter is applicable only to FXS interfaces.</li><li>■ For the parameter to be enabled, you must also set the parameter EnableCallingPartyCategory to 1.</li></ul>	cpc=ordinary	1	Ordinary user	cpc=priority	2	Pre-paid user	cpc=test	3	Test user	cpc=operator	5	Operator	cpc=data	6	Data call	cpc=payphone	7	Payphone user

cpc=priority	2	Pre-paid user																	
cpc=test	3	Test user																	
cpc=operator	5	Operator																	
cpc=data	6	Data call																	
cpc=payphone	7	Payphone user																	
[EnableCallerIDTypeTwo]	<p>Disables the generation of Caller ID type 2 when the phone is off-hooked. Caller ID type 2 (also known as off-hook Caller ID) is sent to a currently busy telephone to display the caller ID of the waiting call.</p> <ul style="list-style-type: none"><li>■ [0] = Caller ID type 2 isn't played.</li><li>■ [1] = (Default) Caller ID type 2 is played.</li></ul> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>																		
<pre>configure voip &gt; interface fxs-fxo &gt; caller-id-timing- mode [AnalogCallerIDTimingMod e]</pre>	<p>Determines when Caller ID is generated.</p> <ul style="list-style-type: none"><li>■ [0] = (Default) Caller ID is generated between the first two rings.</li><li>■ [1] = The device attempts to find an optimized timing to generate the Caller ID according to the selected Caller ID type.</li></ul> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>■ The parameter is applicable only to FXS interfaces.</li><li>■ If the parameter is set to 1 and used with distinctive ringing, the Caller ID signal doesn't change the distinctive ringing timing.</li></ul>																		

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; bellcore-callerid- type-one-sub- standard</pre> <p>[BellcoreCallerIDTypeOneSubStandard]</p>	<p>Determines the Bellcore Caller ID sub-standard.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Between rings.</li> <li>■ [1] = Not ring related.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; etsi-callerid-type- one-sub-standard</pre> <p>[ETSCallerIDTypeOneSubStandard]</p>	<p>Determines the ETSI FSK Caller ID Type 1 sub-standard (FXS only).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) ETSI between rings.</li> <li>■ [1] = ETSI before ring DT_AS.</li> <li>■ [2] = ETSI before ring RP_AS.</li> <li>■ [3] = ETSI before ring LR_DT_AS.</li> <li>■ [4] = ETSI not ring related DT_AS.</li> <li>■ [5] = ETSI not ring related RP_AS.</li> <li>■ [6] = ETSI not ring related LR_DT_AS.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>'Asserted Identity Mode' asserted-identity-m</pre> <p>[AssertedIdMode]</p>	<p>Determines whether the SIP header P-Asserted-Identity or P-Preferred-Identity is added to the sent INVITE, 200 OK, or UPDATE request for Caller ID (or privacy). These headers are used to present the calling party's Caller ID, which is composed of a Calling Number and a Calling Name (optional).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disabled</b> = (Default) P-Asserted-Identity and P-Preferred-Identity headers are not added.</li> <li>■ [1] <b>Add P-Asserted-Identity</b></li> <li>■ [2] <b>Add P-Preferred-Identity</b></li> </ul>

Parameter	Description
	<p>The used header also depends on the calling Privacy (allowed or restricted). These headers are used together with the Privacy header. If Caller ID is restricted (i.e., P-Asserted-Identity is not sent), the Privacy header includes the value 'id' ('Privacy: id'). Otherwise, for allowed Caller ID, 'Privacy: none' is used. If Caller ID is restricted (received from Tel or for analog interfaces, configured on the device), the From header is set to &lt;anonymous@anonymous.invalid&gt;.</p> <p>Digital Interfaces: The 200 OK response can contain the connected party CallerID - Connected Number and Connected Name. For example, if the call is answered by the device, the 200 OK response includes the P-Asserted-Identity with Caller ID. The device interworks (in some ISDN variants), the Connected Party number and name from Q.931 Connect message to SIP 200 OK with the P-Asserted-Identity header. In the opposite direction, if the ISDN device receives a 200 OK with P-Asserted-Identity header, it interworks it to the Connected party number and name in the Q.931 Connect message, including its privacy.</p>
<p>'Use Destination As Connected Number'</p> <pre>configure voip &gt; sip-definition settings &gt; use-dst- as-connected-num [UseDestinationAsConnect edNumber]</pre>	<p>Enables the device to include the Called Party Number, from outgoing Tel calls (after number manipulation), in the SIP P-Asserted-Identity header. The device includes the SIP P-Asserted-Identity header in 180 Ringing and 200 OK responses for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For this feature to function, you also need to enable the device to include the P-Asserted-Identity header in 180/200 OK responses, by setting the [AssertedIDMode] parameter to <b>Add P-Asserted-Identity</b>.</li> <li>■ If the received Q.931 Connect message contains a Connected Party Number, this number is used in the P-Asserted-Identity header in 200 OK response.</li> <li>■ The parameter is applicable to FXO, ISDN and CAS interfaces.</li> </ul>
'Caller ID Transport Type'	Defines the device's behavior for Caller ID detection.

Parameter	Description
<pre>configure voip &gt; media fax-modem &gt; caller-ID- transport-type [CallerIDTransportType]</pre>	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = The caller ID signal is not detected - DTMF digits remain in the voice stream.</li> <li>■ [3] <b>Mute</b> = The caller ID signal is detected from the Tel side and then erased from the voice stream.</li> </ul> <p><b>Note:</b> This option is applicable only to Gateway calls.</p> <ul style="list-style-type: none"> <li>■ [4] <b>SetBySoftware</b> = (Default) The behavior as defined for <b>Mute</b> is applied to Gateway calls. The behavior as defined for <b>Disable</b> is applied to SBC calls.</li> </ul> <p><b>Note:</b> Caller ID detection is applicable only to FXO interfaces.</p>

### Call Waiting Parameters

The call waiting parameters are described in the table below.

**Table 73-45:Call Waiting Parameters**

Parameter	Description
<pre>'Enable Call Waiting' configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; call-waiting [EnableCallWaiting]</pre>	<p>Enables the Call Waiting feature.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul> <ul style="list-style-type: none"> <li>✓ Digital interfaces: If enabled and the device initiates a Tel-to-IP call to a destination that is busy, it plays a call waiting ringback tone to the caller. The tone is played only if the destination returns a 182 "Queued" SIP response.</li> <li>✓ FXS interfaces: If enabled, when an FXS interface receives a call on a busy endpoint, it responds with a 182 response (and not with a 486 busy). The device plays a call waiting indication signal. When hook-flash is detected, the device switches to the waiting call. The device that initiated the waiting call plays a call waiting ringback tone to the calling party after a 182 response is received.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device's Call Progress Tones (CPT) file must include a Call Waiting ringback tone-- for analog interfaces: (caller side) and a call waiting tone (called side, FXS</li> </ul>

Parameter	Description
	<p>only).</p> <ul style="list-style-type: none"> <li>■ FXS interfaces: The [EnableHold] parameter must be enabled on both the calling and the called side.</li> <li>■ Analog interfaces: You can use the table parameter [CallWaitingPerPort] to enable Call Waiting per port.</li> <li>■ Analog interfaces: For information on the Call Waiting feature, see <a href="#">Enabling Call Waiting</a> on page 1050.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; send- 180-for-call- waiting [Send180ForCallWaiting]</pre>	<p>Determines the SIP response code for indicating Call Waiting.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Use 182 Queued response to indicate call waiting.</li> <li>■ [1] = Use 180 Ringing response to indicate call waiting.</li> </ul>
<p>'Number of Call Waiting Indications'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; nb-of-cw-ind [NumberOfWaitingIndications]</pre>	<p>Defines the number of call waiting indications that are played to the called telephone that is connected to the device for Call Waiting.</p> <p>The valid range is 1 to 100 indications. The default is 2.</p> <p><b>Note:</b> The parameter is applicable only to FXS ports.</p>
<p>'Time Between Call Waiting Indications'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; time-between-cw [TimeBetweenWaitingIndications]</pre>	<p>Defines the time (in seconds) between consecutive call waiting indications for call waiting.</p> <p>The valid range is 1 to 100. The default is 10.</p> <p><b>Note:</b> The parameter is applicable only to FXS ports.</p>
<p>'Time Before Waiting Indications'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt;</pre>	<p>Defines the interval (in seconds) before a call waiting indication is played to the port that is currently in a call.</p> <p>The valid range is 0 to 100. The default time is 0 seconds.</p> <p><b>Note:</b> The parameter is applicable only to FXS ports.</p>

Parameter	Description
time-b4-cw-ind [TimeBeforeWaitingIndications]	
'Waiting Beep Duration' configure voip > gateway dtmf-supp- service supp- service-settings > waiting-beep-dur [WaitingBeepDuration]	<p>Defines the duration (in msec) of call waiting indications that are played to the port that is receiving the call.</p> <p>The valid range is 100 to 65535. The default is 300.</p> <p><b>Note:</b> The parameter is applicable only to FXS ports.</p>
[FirstCallWaitingToneID]	<p>Defines the index of the first Call Waiting Tone in the CPT file. This feature enables the called party to distinguish between different call origins (e.g., external versus internal calls).</p> <p>There are three ways to use the distinctive call waiting tones:</p> <ul style="list-style-type: none"> <li>■ Playing the call waiting tone according to the SIP Alert-Info header in the received 180 Ringing SIP response. The value of the Alert-Info header is added to the value of the FirstCallWaitingToneID parameter.</li> <li>■ Playing the call waiting tone according to PriorityIndex in the ToneIndex table parameter.</li> <li>■ Playing the call waiting tone according to the parameter "CallWaitingTone#" of a SIP INFO message.</li> </ul> <p>The device plays the tone received in the 'play tone CallWaitingTone#' parameter of an INFO message plus the value of the parameter minus 1.</p> <p>The valid range is -1 to 1,000. The default is -1 (i.e., not used).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to analog interfaces.</li> <li>■ It is assumed that all Call Waiting Tones are defined in sequence in the CPT file.</li> <li>■ SIP Alert-Info header examples: <ul style="list-style-type: none"> <li>✓ Alert-Info:&lt;Bellcore-dr2&gt;</li> <li>✓ Alert-Info:&lt;http://.../Bellcore-dr2&gt; (where "dr2"</li> </ul> </li> </ul>

Parameter	Description
	<p>defines call waiting tone #2)</p> <ul style="list-style-type: none"> <li>The SIP INFO message is according to Broadsoft's application server definition. Below is an example of such an INFO message:</li> </ul> <pre>INFO sip:06@192.168.13.2:5060 SIP/2.0 Via:SIP/2.0/UDP 192.168.13.40:5060;branch=z9hG4bK0400664 22630 From: &lt;sip:4505656002@192.168.13.40:5060&gt;;tag= 1455352915 To: &lt;sip:06@192.168.13.2:5060&gt; Call-ID:0010-0008@192.168.13.2 CSeq:342168303 INFO Content-Length:28 Content-Type:application/broadsoft play tone CallWaitingTone1</pre>

## Call Forwarding Parameters

The call forwarding parameters are described in the table below.

**Table 73-46:Call Forwarding Parameters**

Parameter	Description
<p>'Enable Call Forward'</p> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; call-forward [EnableForward]</pre>	<p>Enables call forwarding.</p> <ul style="list-style-type: none"> <li>[0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>[1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled.</li> </ul> <p>For FXS interfaces: You must configure the Call Forward table (FwdInfo parameter) to use the Call Forward feature (see <a href="#">Configuring Call Forward</a> on page 1099. The device uses SIP 302 (Moved Temporarily) responses for call forwarding.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>To use this service, the devices at both ends must support call forwarding.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For the device to respond to SIP 3xx responses with a new SIP request (forwarding the original request), enable the parameter.</li> </ul>
<b>Call Forward Reminder Ring Parameters</b> <b>Note:</b> <ul style="list-style-type: none"> <li>■ These parameters are applicable only to FXS interfaces.</li> <li>■ For a description of this feature, see <a href="#">Call Forward Reminder Ring</a> on page 1043.</li> </ul>	
<b>'Enable NRT Subscription'</b> <code>configure voip &gt; gateway dtmf-suppress-service supp-service-settings &gt; nrt-subscription</code> <code>[EnableNRTSubscription]</code>	Enables endpoint subscription for Ring reminder event notification feature. <ul style="list-style-type: none"> <li>■ [0] Check box cleared = (Default) Disabled</li> <li>■ [1] Check box selected = Enable d</li> </ul>
<b>'AS Subscribe IP Group Name'</b> <code>configure voip &gt; gateway dtmf-suppress-service supp-service-settings &gt; as-subs-ipgroupname</code> <code>[ASSubscribeIPGroupName]</code>	Defines the IP Group (by name) that represents the Application server for Subscription.
<b>'NRT Subscribe Retry Time'</b> <code>configure voip &gt; gateway dtmf-suppress-service supp-service-settings &gt; nrt-sub-retry-time</code> <code>[NRTSubscribeRetryTime]</code>	Defines the Retry period (in seconds) for Dialog subscription if a previous request failed.  The valid value range is 10 to 7200. The default is 120.
<b>'Call Forward Ring Tone ID'</b> <code>configure voip &gt; gateway dtmf-suppress-service supp-service-settings &gt; cfe-ring-tone-id</code> <code>[CallForwardRingToneID]</code>	Defines the ringing tone type played when call forward notification is accepted.  The valid value range is 1 to 5. The default is 1.

### Message Waiting Indication Parameters

The message waiting indication (MWI) parameters are described in the table below.

**Table 73-47:MWI Parameters**

Parameter	Description
<p>'Enable MWI'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; enable-mwi</pre> <p>[EnableMWI]</p>	<p>Enables Message Waiting Indication (MWI).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The device supports only the receipt of SIP MWI NOTIFY messages (the device doesn't generate these messages).</li> <li>■ For more information on MWI, see <a href="#">Message Waiting Indication</a> on page 1051.</li> </ul>
<p>'MWI Analog Lamp'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mwi- analog-lamp</pre> <p>[MWIAnalogLamp]</p>	<p>Global parameter enabling the visual display of MWI.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('MWI Analog Lamp' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<p>'MWI Display'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; enable-mwi</pre> <p>[MWIDisplay]</p>	<p>Global parameter enabling the sending of MWI information to the phone display.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('MWI Display' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>The parameter is applicable only to FXS interfaces.</li> </ul>
<p>'Subscribe to MWI'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; subscribe-to-mwi</pre> <p>[EnableMWISubscription]</p>	<p>Enables subscription to an MWI server.</p> <ul style="list-style-type: none"> <li>[0] <b>No</b> (default)</li> <li>[1] <b>Yes</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>To configure the MWI server address, use the [MWIServerIP] parameter.</li> <li>To configure whether the device subscribes per endpoint or per the entire device, use the parameter [SubscriptionMode].</li> </ul>
<p>'MWI Server IP Address'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mwi- srvr-ip-addr</pre> <p>[MWIServerIP]</p>	<p>Defines the MWI server's IP address. If provided, the device subscribes to this IP address. The MWI server address can be configured as a numerical IP address or as a domain name. If not configured, the Proxy IP address is used instead.</p>
<p>'MWI Server Transport Type'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mwi- srvr-transp-type</pre> <p>[MWIServerTransportType]</p>	<p>Defines the transport layer used for outgoing SIP dialogs initiated by the device to the MWI server.</p> <ul style="list-style-type: none"> <li>[-1] <b>Not Configured</b> (default)</li> <li>[0] <b>UDP</b></li> <li>[1] <b>TCP</b></li> <li>[2] <b>TLS</b></li> </ul> <p><b>Note:</b> When set to 'Not Configured', the value of the parameter [SIPTransportType] is used.</p>
<p>'MWI Subscribe Expiration Time'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mwi- subs-expr-time</pre> <p>[MWIExpirationTime]</p>	<p>Defines the MWI subscription expiration time in seconds.</p> <p>The default is 7200 seconds. The range is 10 to 2,000,000.</p>
<p>'MWI Subscribe Retry Time'</p> <pre>configure voip &gt; gateway</pre>	<p>Defines the subscription retry time (in seconds) after last subscription failure.</p> <p>The default is 120 seconds. The range is 10 to</p>

Parameter	Description
<pre>dtmf-suppress-service suppress- service-settings &gt; mwi- subs-rtry-time</pre> <p>[SubscribeRetryTime]</p>	2,000,000.
<p>'Subscription Mode'</p> <pre>configure voip &gt; sip- definition proxy-and- registration &gt; subscription-mode</pre> <p>[SubscriptionMode]</p>	<p>Defines the method the device uses to subscribe to an MWI server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Per Endpoint</b> = (Default) Each endpoint subscribes separately - typically used for FXS interfaces.</li> <li>■ [1] <b>Per Gateway</b> = Single subscription for the entire device - typically used for FXO interfaces.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; etsi-vmwi-type-one- standard</pre> <p>[ETSIVMWITypeOneStandard]</p>	<p>Defines the ETSI Visual Message Waiting Indication (VMWI) Type 1 sub-standard.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) ETSI VMWI between rings</li> <li>■ [1] = ETSI VMWI before ring DT_AS</li> <li>■ [2] = ETSI VMWI before ring RP_AS</li> <li>■ [3] = ETSI VMWI before ring LR_DT_AS</li> <li>■ [4] = ETSI VMWI not ring related DT_AS</li> <li>■ [5] = ETSI VMWI not ring related RP_AS</li> <li>■ [6] = ETSI VMWI not ring related LR_DT_AS</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; interface fxs-fxo &gt; bellcore-vmwi-type-one- standard</pre> <p>[BellcoreVMWITypeOneStandard]</p>	<p>Defines the Bellcore VMWI sub-standard.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Between rings.</li> <li>■ [1] = Not ring related.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

### Call Hold Parameters

The call hold parameters are described in the table below.

Table 73-48: Call Hold Parameters

Parameter	Description
<b>'Enable Hold'</b> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; hold [EnableHold]</pre>	<p>Global parameter that enables the following:</p> <ul style="list-style-type: none"> <li>■ Analog interfaces: Call Hold feature</li> <li>■ Digital interfaces: Interworking of the Hold/Retrieve supplementary service from ISDN to SIP.</li> </ul> <p>You can also configure this feature per specific calls, using IP Profiles ('Hold'). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<b>'Hold Format'</b> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; hold- format [HoldFormat]</pre>	<p>Defines the format of the SDP in the sent re-INVITE hold request.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0.0.0.0</b> = (Default) The SDP 'c=' field contains the IP address "0.0.0.0" and the 'a=inactive' attribute.</li> <li>■ [1] <b>Send Only</b> = The SDP 'c=' field contains the device's IP address and the 'a=sendonly' attribute.</li> <li>■ [2] <b>x.y.z.t</b> = The SDP 'c=' field contains the device's IP address and the 'a=inactive' attribute.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device doesn't send any RTP packets when it is in hold state.</li> <li>■ Digital interfaces: The parameter is applicable only to QSIG and Euro ISDN protocols.</li> </ul>
<b>'Held Timeout'</b> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; held- timeout [HeldTimeout]</pre>	<p>Defines the maximum duration (in seconds) that the device allows for a call to remain on hold. This parameter applies to Tel-to-IP calls, where the Tel side places the IP side on hold.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) The IP side remains on hold until the Tel side (which placed the call on hold) retrieves the call (SIP re-INVITE message).</li> <li>■ [0 - 2400] = If the IP side is still on hold when this duration expires, the device disconnects the call (sends a SIP BYE message to the IP side). For example, if configured to 60 and the Tel side places the IP side (Alice) on hold and makes a new call to Bob, if the call with Bob gets to 61, the</li> </ul>

Parameter	Description
	<p>device disconnects the call with Alice.</p> <p><b>Note:</b> When the Tel side puts the call on hold (hookflash), the device plays a dial tone to the Tel side (dial tone timeout starts according to the 'Dial Tone Duration' parameter, which is 16 sec. by default), expecting the Tel side to do some action (e.g., make another call, conferencing, or call transfer). If the 'Dial Tone Duration' parameter expires as no DTMF digits were collected (i.e., Tel side did nothing), the device plays a congestion tone to the Tel side (and if the Tel side goes on-hook, the phone rings and if the Tel side then goes off-hook, the IP side is retrieved).</p>
<p>'Call Hold Reminder Ring Timeout'</p> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; call- hold-remnd-rng [CHRRTimeout]</pre>	<p>Defines the duration (in seconds) that the Call Hold Reminder Ring is played. If a user hangs up while a call is still on hold or there is a call waiting, then the FXS interface immediately rings the extension for the duration specified by the parameter. If the user off-hooks the phone, the call becomes active.</p> <p>The valid range is 0 to 600. The default is 30.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ You can disable the Reminder Ring feature using the [DisableReminderRing] parameter.</li> </ul>
<p>'Reminder Ring'</p> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; dis- reminder-ring [DisableReminderRing]</pre>	<p>Disables the reminder ring, which notifies the FXS user of a call on hold or a waiting call when the phone is returned to on-hook position.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The reminder ring feature is active. If a call is on hold or there is a call waiting and the phone is changed from offhook to onhook, the phone rings (for a duration defined by the [CHRRTimeout] parameter) to "remind" you of the call hold or call waiting.</li> <li>■ [1] <b>Yes</b> = Disables the reminder ring. If a call is on hold or there is a call waiting and the phone is changed from offhook to onhook, the call is released (and the device sends a SIP BYE to the IP).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The parameter is typically used for MLPP, allowing</li> </ul>

Parameter	Description
	preemption to clear held calls.
<pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; dtmf- during-hold [PlayDTMFduringHold]</pre>	<p>Determines whether the device sends DTMF signals (or DTMF SIP INFO message) when a call is on hold.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable.</li> <li>■ [1] = Enable - If the call is on hold, the device stops playing the Held tone (if it is played) and sends DTMF: <ul style="list-style-type: none"> <li>✓ To Tel side: plays DTMF digits according to the received SIP INFO message(s). (The stopped held tone is not played again.)</li> <li>✓ To IP side: sends DTMF SIP INFO messages to an IP destination if it detects DTMF digits from the Tel side.</li> </ul> </li> </ul>

### Call Transfer Parameters

The call transfer parameters are described in the table below.

**Table 73-49:Call Transfer Parameters**

Parameter	Description
<p>'Enable Transfer'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; enable-transfer [EnableTransfer]</pre>	<p>Enables the Call Transfer feature.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. <ul style="list-style-type: none"> <li>✓ Digital interfaces: The device responds to a REFER message with the Referred-To header to initiate a call transfer.</li> <li>✓ Analog interfaces: If the transfer service is enabled, the user can activate Transfer using hook-flash signaling. If this service is enabled, the remote party performs the call transfer.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To use call transfer, the devices at both ends must support this option.</li> <li>■ To use call transfer, configure the [EnableHold] parameter to 1.</li> </ul>
'Transfer Prefix'	Defines the string that is added as a prefix to the

Parameter	Description
<pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; transfer-prefix [xferPrefix]</pre>	<p>transferred/forwarded called number when the REFER/3xx message is received.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The number manipulation rules apply to the user part of the Refer-To and Contact URI before it is sent in the INVITE message.</li> <li>■ The parameter can be used to apply different manipulation rules to differentiate the transferred/forwarded call number from the originally dialed number.</li> </ul>
<p>'Transfer Prefix IP 2 Tel'</p> <pre>configure voip &gt; gateway digital settings &gt; xfer- prefix-ip2tel [XferPrefixIP2Tel]</pre>	<p>Defines the prefix that is added to the destination number received in the SIP Refer-To header (for IP-to-Tel calls). The parameter is applicable only to FXO and CAS blind transfer modes (i.e., LineTransferMode = 1, 2 or 3, and TrunkTransferMode = 1 or 3 for CAS).</p> <p>The valid range is a string of up to 9 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter is also applicable to ISDN Blind Transfer, according to AT&amp;T Toll Free Transfer Connect Service (TR 50075) "Courtesy Transfer-Human-No Data". To support this transfer mode, you need to configure the parameter [XferPrefixIP2Tel] to "*8" (without quotation marks) and the parameter [TrunkTransferMode] to "5" (without quotation marks).</p>
<p>'Enable Semi-Attended Transfer'</p> <pre>semi-att-transfer [EnableSemiAttendedTransfer]</pre>	<p>Defines what the device does when a transfer is initiated while in Alerting state.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. Sends a SIP REFER message with the Replaces header.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Sends a SIP CANCEL message and after a SIP 487 response is received, sends a REFER without the Replaces header.</li> </ul>
<p>'Blind'</p> <pre>configure voip &gt; gateway</pre>	<p>Defines the keypad sequence to activate blind transfer for established Tel-to-IP calls. The Tel</p>

Parameter	Description
<pre> analog keypad-features &gt; blind-transfer [KeyBlindTransfer] </pre>	<p>user can perform blind transfer by dialing the [KeyBlindTransfer] digits, followed by a transferee destination number.</p> <p>After the KeyBlindTransfer DTMF digits sequence is dialed, the current call is put on hold (using a Re-INVITE message), a dial tone is played to the channel, and then the phone number collection starts.</p> <p>After the destination phone number is collected, it is sent to the transferee in a SIP REFER request in a Refer-To header. The call is then terminated and a confirmation tone is played to the channel. If the phone number collection fails due to a mismatch, a reorder tone is played to the channel.</p> <p><b>Note:</b> For analog interfaces, it is possible to configure whether the KeyBlindTransfer code is added as a prefix to the dialed destination number, by using the parameter KeyBlindTransferAddPrefix.</p>
<pre> configure voip &gt; gateway digital settings &gt; blind- xfer-add-prefix [KeyBlindTransferAddPrefix] </pre>	<p>Determines whether the device adds the Blind Transfer code (defined by the KeyBlindTransfer parameter) to the dialed destination number.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> The parameter is applicable only to analog interfaces.</p>
<pre> configure voip &gt; gateway digital settings &gt; blind- xfer-disc-tmo [BlindTransferDisconnectTimeout] </pre>	<p>Defines the duration (in milliseconds) for which the device waits for a disconnection from the Tel side after the Blind Transfer Code (KeyBlindTransfer) has been identified. When this timer expires, a SIP REFER message is sent toward the IP side. If the parameter is set to 0, the REFER message is immediately sent.</p> <p>The valid value range is 0 to 1,000,000. The default is 0.</p>
<p>'QSIG Path Replacement Mode'</p> <pre> configure voip &gt; gateway </pre>	<p>Enables QSIG transfer for IP-to-Tel and Tel-to-IP calls.</p>

Parameter	Description
<pre>digital settings &gt; qsig- path-replacement</pre> <p>[QSIGPathReplacementMode]</p>	<ul style="list-style-type: none"> <li>■ [0] <b>IP2QSIGTransfer</b> = (Default) Enables IP-to-QSIG transfer.</li> <li>■ [1] <b>QSIG2IPTransfer</b> = Enables QSIG-to-IP transfer.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<pre>configure voip &gt; gateway digital settings &gt; replace-tel2ip-calnum-to</pre> <p>[ReplaceTel2IPCallingNumTimeout]</p>	<p>Defines the maximum duration (timeout) to wait between call Setup and Facility with Redirecting Number for replacing the calling number (for Tel-to-IP calls).</p> <p>The valid value range is 0 to 10,000 msec. The default is 0.</p> <p>The interworking of the received Setup message to a SIP INVITE is suspended when the parameter is set to any value greater than 0. This means that the redirecting number in the Setup message is not checked. When a subsequent Facility with Call Transfer Complete/Update is received with a non-empty Redirection Number, the Calling Number is replaced with the received redirect number in the sent INVITE message.</p> <p>If the timeout expires, the device sends the INVITE without changing the calling number.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The suspension of the INVITE message occurs for all calls.</li> <li>■ The parameter is applicable only to QSIG.</li> </ul>
<p>'Call Transfer using re-INVITES'</p> <pre>configure voip &gt; sip- definition settings &gt; enable-call-transfer- using-reinvites</pre> <p>[EnableCallTransferUsingReinvites]</p>	<p>Enables call transfer using SIP re-INVITE requests.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. Call transfer is done using REFER messages.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Call transfer is done by sending re-INVITE messages (instead of REFER).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device uses two DSP channels per transferred call. Therefore, make sure that the device's License Key includes a license for DSP</li> </ul>

Parameter	Description
	<p>resources ('DSP Channels').</p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>

### Three-Way Conferencing Parameters

The three-way conferencing parameters are described in the table below.

**Table 73-50:Three-Way Conferencing Parameters**

Parameter	Description
<p>'Enable 3-Way Conference'</p> <pre>configure voip &gt; gateway dtmf-suppress-service supp- service-settings &gt; enable-3w-conf</pre> <p>[Enable3WayConference]</p>	<p>Enables the 3-Way Conference feature.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>'3-Way Conference Mode'</p> <pre>configure voip &gt; gateway dtmf-suppress-service supp- service-settings &gt; 3w- conf-mode</pre> <p>[3WayConferenceMode]</p>	<p>Defines the mode of operation for three-way conferencing.</p> <ul style="list-style-type: none"> <li>■ [0] AudioCodes <b>Media Server</b> = (Default) The conference-initiating INVITE sent by the device, uses the ConferenceID concatenated with a unique identifier as the Request-URI. This same Request-URI is set as the Refer-To header value in the REFER messages that are sent to the two remote parties. This conference mode is used when operating with AudioCodes IPMedia conferencing server.</li> <li>■ [1] <b>Non-AudioCodes Media Server</b> = The conference-initiating INVITE sent by the device, uses only the ConferenceID as the Request-URI. The Conference server sets the Contact header of the 200 OK response to the actual unique identifier (Conference URI) to be used by the participants. This Conference URI is then included by the device in the Refer-To header value in the REFER messages sent by the device to the remote parties. The remote parties join the conference by sending INVITE messages to the conference using this conference URI.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>On Board</b> = On-board, three-way conference. The conference is established on the device without the need of an external Conference server. You can limit the number of simultaneous, on-board 3-way conference calls, by using the [MaxInBoardConferenceCalls] parameter. The device utilizes resources from idle ports to establish the conference call. You can designate ports that you do not want to use as resources for on-board, conference calls initiated by other ports. This is configured using the [3WayConfNoneAllocateablePorts] parameter.</li> <li>■ [3] <b>Huawei Media Server</b> = The conference is managed by an external, third-party Conferencing server. The conference-initiating INVITE sent by the device, uses only the ConferenceID as the Request-URI. The Conferencing server sets the Contact header of the 200 OK response to the actual unique identifier (Conference URI) to be used by the participants. The Conference URI is included in the URI of the REFER with a Replaces header sent by the device to the Conferencing server. The Conferencing server then sends an INVITE with a Replaces header to the remote participants.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS and BRI interfaces.</li> <li>■ Three-way conferencing using an external conference server is supported only by FXS interfaces.</li> <li>■ When using an external Conferencing server, a conference call with up to six participants can be established.</li> </ul>
'Max. 3-Way Conference' configure voip > gateway dtmf-supp-service supp- service-settings > mx-	<p>Defines the maximum number of simultaneous, on-board three-way conference calls.</p> <p>The valid range is 0 to 5. The default is 2.</p>

Parameter	Description
<code>3w-conf-onboard</code> <code>[MaxInBoardConferenceCalls]</code>	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For enabling on-board, three-way conferencing, use the <code>[3WayConferenceMode]</code> parameter.</li> <li>■ For more information on on-board three-way conferencing, see <a href="#">Three-Way Conferencing</a> on page 1056.</li> <li>■ The parameter is applicable only to FXS and BRI interfaces.</li> </ul>
<p>'Non Allocatable Ports'</p> <code>[3WayConfNoneAllocateablePort s]</code>	<p>Defines the ports that are not allocated as resources for on-board three-way conference calls that are initiated by other ports. Ports that are not configured with this parameter (and that are idle) are used by the device as a resources for establishing these type of conference calls if there are no DSP resources available.</p> <p>The valid range is up to 8 ports. To add multiple ports, use the comma separator. For example, for not allowing the use of ports 2, 4 and 6 as resources, configure the parameter to "2,4,6" (without quotation marks). The order of the entered values is not relevant (i.e., the example above can be entered as 6,2,4). The default is 0.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>■ To enable on-board, three-way conferencing, use the <code>3WayConferenceMode</code> and <code>MaxInBoardConferenceCalls</code> parameters.</li> <li>■ This parameter is applicable only to FXS interfaces.</li> </ul>
<p>'Establish Conference Code'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; estb- conf-code</pre> <code>[ConferenceCode]</code>	<p>Defines the DTMF digit pattern, which upon detection generates the conference call when three-way conferencing is enabled (<code>Enable3WayConference</code> is set to 1).</p> <p>The valid range is a 25-character string. The default is "!" (Hook-Flash).</p> <p><b>Note:</b> If the <code>[FlashKeysSequenceStyle]</code> parameter is set to 1 or 2, the setting of the <code>[ConferenceCode]</code> parameter is overridden.</p>
'Conference ID'	Defines the Conference Identification string.

Parameter	Description
<pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; conf- id</pre> <p>[ConferenceID]</p>	<p>The valid value is a string of up to 16 characters. The default is "conf".</p> <p>The device uses this identifier in the Conference-initiating INVITE that is sent to the media server when the Enable3WayConference parameter is set to 1.</p>
<p>'Use Different RTP port After Hold'</p> <pre>configure voip &gt; sip- definition settings &gt; dfrnt-port-after-hold</pre> <p>[UseDifferentRTPportAfterHold]</p>	<p>Enables the use of different RTP ports for the two calls involved in a three-way conference call made by the FXS endpoint in the initial outgoing INVITE requests.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The FXS endpoint makes the first and second calls on the same RTP port in the initial outgoing INVITE request. If a three-way conference is then made, the device sends a re-INVITE to the held call to retrieve it and to change the RTP port to a different port number.</li> </ul> <p>For example: A first calls B on port 6000 and places B on hold. A then calls C, also on port 6000. The device sends a re-INVITE to the held call to retrieve it and changes the port to 6010.</p> <ul style="list-style-type: none"> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The FXS endpoint makes the first and second calls on different RTP ports in the initial outgoing INVITE request. If a three-way conference is then made, the device sends a re-INVITE to the held call to retrieve it, without changing the port of the held call.</li> </ul> <p>For example: A first calls B on port 6000 and places B on hold. A then calls C on port 6010. The device sends a re-INVITE to the held call to retrieve it (without changing the port, i.e., remains 6010).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When this feature is enabled and only one RTP port is available, only one call can be made by the FXS endpoint, as there is no free RTP port for a second call.</li> <li>■ When this feature is enabled and you are using</li> </ul>

Parameter	Description
	<p>the Call Forking feature, every forked call is sent with a different RTP port. As the device can fork a call to up to 10 destinations, the device requires at least 10 free RTP ports.</p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>

## MLPP and Emergency Call Parameters

The Multilevel Precedence and Preemption (MLPP) and emergency E911 call parameters are described in the table below.

**Table 73-51:MLPP and Emergency E911 Call Parameters**

Parameter	Description
<p>'Call Priority Mode'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; call- prio-mode</pre> <p>[CallPriorityMode]</p>	<p>Global parameter defining call priority handling. You can also configure the feature per specific calls, using Tel Profiles ('Call Priority Mode' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
<b>Emergency E911 Parameters</b>	
<p>'E911 Gateway'</p> <pre>configure voip &gt; sip- definition settings &gt; e911-gateway</pre> <p>[E911Gateway]</p>	<p>Enables Enhanced 9-1-1(E9-1-1) support for ELIN handling in a Microsoft Skype for Business environment and routing to a PSTN-based emergency service provider.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>NG911 Callback Gateway</b> = Enables the ELIN Gateway.</li> <li>■ [2] <b>Location Based Manipulations</b> = Enables ELIN Gateway and location-based manipulation. For more information, see <a href="#">Location Based Emergency Routing</a> on page 510.</li> </ul>

Parameter	Description
	<p>For more information on E9-1-1 in a Skype for Business environment, see <a href="#">E9-1-1 Support for Microsoft Teams and Skype for Business</a> on page 498.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
'E911 Callback Timeout' configure voip > sip-definition settings > e911-callback-timeout [E911CallbackTimeout]	<p>Defines the maximum interval within which the PSAP can use the ELIN to call back the E9-1-1 caller. This interval starts from when the initial call established with the PSAP is terminated.</p> <p>The valid range is 1 to 60 (minutes). The default is 30.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
'Emergency Special Release Cause' configure voip > sip- definition settings > emrg-spcl-rel-cse [EmergencySpecialReleaseCause]	<p>Enables the device to send a SIP 503 "Service Unavailable" response if an emergency call cannot be established (i.e., rejected). This can occur, for example, due to the PSTN (for example, the destination is busy or not found) or ELIN Gateway (for example, lack of resources or an internal error).</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
[Enable911PSAP]	<p>Global parameter enabling the support for the E911 DID protocol, according to the Bellcore GR-350-CORE standard.</p> <p>You can also configure the feature per specific calls, using Tel Profiles. For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
'Emergency Number'	Defines a list of "emergency" numbers.

Parameter	Description
<pre>configure voip &gt; sip- definition settings &gt; emerg-nbs</pre> <p>[EmergencyNumbers]</p>	<p>FXS interfaces: When one of these numbers is dialed, the outgoing INVITE message includes the SIP Priority and Resource-Priority headers. If the user places the phone on-hook, the call is not disconnected. Instead, a Hold Re-INVITE request is sent to the remote party. Only if the remote party disconnects the call (i.e., a BYE is received) or a timer expires (configured by the [EmergencyRegretTimeout] parameter) is the call terminated.</p> <p>FXO, CAS, and ISDN interfaces: These emergency numbers are used for the preemption of E911 IP-to-Tel calls when there are unavailable or busy channels. In this scenario, the device terminates one of the busy channels and sends the emergency call to this channel. This feature is enabled by configuring the [CallPriorityMode] parameter to 2 ("Emergency"). For a description of this feature, see <a href="#">Pre-empting Existing Calls for E911 IP-to-Tel Calls</a> on page 1067.</p> <p>The list can include up to four different numbers, where each number can be up to four digits long. For example:</p> <pre>EmergencyNumbers = '100', '911', '112'</pre> <p><b>Note:</b> The parameter is applicable only to Tel-to-IP calls. For IP-to-Tel calls, use the [EmergencyCallAlertInfoUri] parameter to identify emergency calls.</p>
<pre>configure voip &gt; sip- definition settings &gt; emerg-alert-info-uri</pre> <p>[EmergencyCallAlertInfoUri]</p>	<p>Defines the URI of the SIP Alert-Info header, for the device to consider (identify) the incoming SIP INVITE message as an emergency call.</p> <p>By default, no value is defined. If you don't configure a value, the device doesn't consider any IP-to-Tel call as an emergency call (even if the Alert-Info header is present in the incoming SIP message).</p> <p><b>Note:</b> The parameter is applicable only to IP-to-Tel calls. For Tel-to-IP calls, use the [EmergencyNumbers] parameter to identify emergency calls.</p>

Parameter	Description
<pre>configure voip &gt; sip- definition settings &gt; reload-timeout-for- emergency-call</pre> <p>[ReloadTimeoutForEmergencyCall]</p>	<p>Enables the device to block device resets that are triggered through CLI (<code>reload</code> command) during active emergency calls and for a period (configured by this parameter) after the call ends (regardless of whether it was successfully established or not).</p> <p>The valid value is -1 to 3600 (in seconds). A value of -1 disables the feature and allows restarts during and after emergency calls.</p> <p><b>Note:</b> The parameter is applicable to IP-to-Tel and Tel-to-IP emergency calls.</p>
<p>'Emergency Calls Regret Timeout'</p> <pre>configure voip &gt; sip- definition settings &gt; emerg-calls-regrt-t-out</pre> <p>[EmergencyRegretTimeout]</p>	<p>Defines the time (in minutes) that the device waits before tearing-down an emergency call (configure by the [EmergencyNumbers] or [EmergencyCallAlertInfoUri] parameters). Until this time expires, an emergency call can only be disconnected by the remote party, typically, by a Public Safety Answering Point (PSAP).</p> <p>The valid range is 1 to 30. The default is 10.</p> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>
<b>Multilevel Precedence and Preemption (MLPP) Parameters</b>	
<p>'MLPP Default Namespace'</p> <pre>configure voip &gt; gateway digital settings &gt; mlpp- dflt-namespace</pre> <p>[MLPPDefaultNamespace]</p>	<p>Determines the namespace used for MLPP calls received from the ISDN side without a Precedence IE and destined for an Application server. This value is used in the Resource-Priority header of the outgoing SIP INVITE request.</p> <ul style="list-style-type: none"> <li>■ [1] <b>DSN</b> (default)</li> <li>■ [2] <b>DOD</b></li> <li>■ [3] <b>DRSN</b></li> <li>■ [5] <b>UC</b></li> <li>■ [7] <b>CUC</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the ISDN message contains a Precedence IE, the device automatically interworks the "network identity" digits in the IE to the network domain subfield in the Resource-</li> </ul>

Parameter	Description
	<p>Priority header. For more information, see <a href="#">Multilevel Precedence and Preemption</a> on page 1068.</p> <ul style="list-style-type: none"> <li>The parameter is applicable only to digital interfaces.</li> </ul>
[ResourcePriorityNetworkDomains]	<p>Defines up to 32 user-defined MLPP network domain names (namespaces). This value is used in the AS-SIP Resource-Priority header of the outgoing SIP INVITE request. The parameter is used in combination with the MLPPDefaultNamespace parameter, where you need to enter the table row index as its value. The parameter is also used for mapping the Resource-Priority field value of the SIP Resource-Priority header to the ISDN Precedence Level IE. The mapping is configured by the field, EnableIp2TelInterworking:</p> <ul style="list-style-type: none"> <li>Disabled: The network-domain field in the Resource-Priority header is set to "0 1 0 0" (i.e., "routine") in the Precedence Level field.</li> <li>Enabled: The network-domain field in the Resource-Priority header is set in the Precedence Level field according to Table 5.3.2.12-4 (Mapping of RPH r-priority Field to ISDN Precedence Level Value).</li> </ul> <p>The domain name can be a string of up to 10 characters.</p> <p>The format of this table ini file parameter is as follows:</p> <pre> FORMAT Index = Name, EnableIp2TelInterworking; ResourcePriorityNetworkDomains 1 = dsn, 0; ResourcePriorityNetworkDomains 2 = dod, 0; ResourcePriorityNetworkDomains 3 = drsn, 0; ResourcePriorityNetworkDomains 5 = uc, 1; ResourcePriorityNetworkDomains 7 = cuc, 0; [ \ResourcePriorityNetworkDomains ] </pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Indices 1, 2, 3, 5, and 7 cannot be modified</li> </ul>

Parameter	Description
	<p>and are defined for DSN, DOD, DRSN, UC, and CUC, respectively.</p> <ul style="list-style-type: none"> <li>■ If the <code>MLPPDefaultNamespace</code> parameter is set to -1, interworking from PSTN NI digits is done automatically.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'Default Call Priority'</p> <pre>configure voip &gt; gateway digital settings &gt; dflt- call-prio</pre> <p>[SIPDefaultCallPriority]</p>	<p>Determines the default call priority for MLPP calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = (Default) ROUTINE</li> <li>■ [2] <b>2</b> = PRIORITY</li> <li>■ [4] <b>4</b> = IMMEDIATE</li> <li>■ [6] <b>6</b> = FLASH</li> <li>■ [8] <b>8</b> = FLASH-OVERRIDE</li> <li>■ [9] <b>9</b> = FLASH-OVERRIDE-OVERRIDE</li> </ul> <p>If the incoming SIP INVITE request doesn't contain a valid priority value in the SIP Resource-Priority header, the default value is used in the Precedence IE (after translation to the relevant ISDN Precedence value) of the outgoing ISDN Setup message.</p> <p>If the incoming Setup message doesn't contain a valid Precedence Level value, the default value is used in the Resource-Priority header of the outgoing SIP INVITE request. In this scenario, the character string is sent without translation to a numerical value.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'MLPP DiffServ'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; mlpp- diffserv</pre> <p>[MLPPDiffserv]</p>	<p>Defines the DiffServ value (differentiated services code point/DSCP) used in IP packets containing SIP messages that are related to MLPP calls. The parameter defines DiffServ for incoming and, for digital interfaces, outgoing MLPP calls with the Resource-Priority header.</p> <p>The valid range is 0 to 63. The default is 50.</p>

Parameter	Description
<p>'Preemption Tone Duration'</p> <pre>configure voip &gt; gateway digital settings &gt; preemp-tone-dur</pre> <p>[PreemptionToneDuration]</p>	<p>Defines the duration (in seconds) in which the device plays a preemption tone to the Tel and IP sides if a call is preempted.</p> <p>The valid range is 0 to 60. The default is 3.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If set to 0, no preemption tone is played.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'MLPP Normalized Service Domain'</p> <pre>configure voip &gt; gateway digital settings &gt; mlpp- norm-ser-dmn</pre> <p>[MLPPNormalizedServiceDomain]</p>	<p>Defines the MLPP normalized service domain string. If the device receives an MLPP ISDN incoming call, it uses the parameter (if different from 'FFFFFF') as a Service domain in the SIP Resource-Priority header in outgoing INVITE messages. If the parameter is configured to 'FFFFFF', the Resource-Priority header is set to the MLPP Service Domain obtained from the Precedence IE.</p> <p>The valid value is 6 hexadecimal digits. The default is '000000'.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the MLPP NI-2 ISDN variant with CallPriorityMode set to 1.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; mlpp- nwrk-id</pre> <p>[MLPPNetworkIdentifier]</p>	<p>Defines the MLPP network identifier (i.e., International prefix or Telephone Country Code/TCC) for IP-to-ISDN calls, according to the UCR 2008 and ITU Q.955 specifications.</p> <p>The valid range is 1 to 999. The default is 1 (i.e., USA).</p> <p>The MLPP network identifier is sent in the Facility IE of the ISDN Setup message. For example:</p> <ul style="list-style-type: none"> <li>■ MLPPNetworkIdentifier set to default (i.e., USA, 1):</li> </ul> <pre>PlaceCall- MLPPNetworkID:0100 MlppServiceDomain:123abc,</pre>

Parameter	Description
	<p>MlppPrecLevel:5</p> <p>Fac(1c): 91 a1 15 02 01 05 02 01 19 30 0d 0a 01 05 0a 01 01 04 05 01 00 12 3a bc</p> <p>■ MLPPNetworkIdentifier set to 490:</p> <p>PlaceCall- MLPPNetworkID:9004 MlppServiceDomain:123abc, MlppPrecLevel:5</p> <p>Fac(1c): 91 a1 15 02 01 0a 02 01 19 30 0d 0a 01 05 0a 01 01 04 05 90 04 12 3a bc</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'MLPP Default Service Domain'</p> <p>configure voip &gt; gateway digital settings &gt; mlpp- dflt-srv-domain</p> <p>[MLPPDefaultServiceDomain]</p>	<p>Defines the MLPP default service domain string. If the device receives a non-MLPP ISDN incoming call (without a Precedence IE), it uses the parameter (if different than "FFFFFF") as a Service domain in the SIP Resource-Priority header in outgoing (Tel-to-IP calls) INVITE messages. The parameter is used in conjunction with the parameter SIPDefaultCallPriority.</p> <p>If MLPPDefaultServiceDomain is set to 'FFFFFF', the device interworks the non-MLPP ISDN call to non-MLPP SIP call, and the outgoing INVITE doesn't contain the Resource-Priority header.</p> <p>The valid value is a 6 hexadecimal digits. The default is "000000".</p> <p><b>Note:</b></p> <p>■ The parameter is applicable only to the MLPP NI-2 ISDN variant with CallPriorityMode set to 1.</p> <p>■ The parameter is applicable only to digital interfaces.</p>
<p>'Precedence Ringing Type'</p> <p>precedence-ringing</p> <p>[PrecedenceRingingType]</p>	<p>Defines the index of the Precedence Ringing tone in the Call Progress Tones (CPT) file. This tone is used when the parameter CallPriorityMode is set to 1 and a Precedence call is received from the IP side.</p>

Parameter	Description				
	<p>The valid range is -1 to 16. The default is -1 (i.e., plays standard ringing tone).</p> <p><b>Note:</b> The parameter is applicable only to analog interfaces.</p>				
<pre>configure voip &gt; gateway digital settings &gt; e911-mlpp-bhvr</pre> <p>[E911MLPPBehavior]</p>	<p>Defines the E911 (or Emergency Telecommunication Services/ETS) MLPP Preemption mode:</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Standard Mode - ETS calls have the highest priority and preempt any MLPP call.</li> <li>■ [1] = Treat as routine mode - ETS calls are handled as routine calls.</li> </ul> <p><b>Note:</b> The parameter is applicable only to analog interfaces.</p>				
<pre>resource-prio-req</pre> <p>[RPRequired]</p>	<p>Defines if the device adds the SIP 'resource-priority' tag to the SIP Require header of INVITE messages for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable. The device excludes the SIP 'resource-priority' tag from the SIP Require header.</li> <li>■ [1] = (Default) Enable. The device adds the SIP 'resource-priority' tag to the SIP Require header.</li> </ul> <p><b>Note:</b> The parameter is applicable only to MLPP priority call handling (i.e., only when the CallPriorityMode parameter is configured to [1]).</p>				
<p><b>Multiple Differentiated Services Code Points (DSCP) per MLPP Call Priority Level (Precedence) Parameters</b></p> <p>The MLPP service allows placement of priority calls, where properly validated users can preempt (terminate) lower-priority phone calls with higher-priority calls. For each MLPP call priority level, the DSCP can be set to a value from 0 to 63. The Resource Priority value in the Resource-Priority SIP header can be one of the following:</p> <table border="1"> <thead> <tr> <th>MLPP Precedence Level</th><th>Precedence Level in Resource-Priority SIP Header</th></tr> </thead> <tbody> <tr> <td>0 (lowest)</td><td>routine</td></tr> </tbody> </table>		MLPP Precedence Level	Precedence Level in Resource-Priority SIP Header	0 (lowest)	routine
MLPP Precedence Level	Precedence Level in Resource-Priority SIP Header				
0 (lowest)	routine				

Parameter		Description
2	priority	
4	immediate	
6	flash	
8	flash-override	
9 (highest)	flash-override-override	
'RTP DSCP for MLPP Routine' <code>configure voip &gt; gateway</code> <code>digital settings &gt; dscp-</code> <code>4-mlpp-rtn</code> <b>[MLPPRoutineRTPDSCP]</b>		Defines the RTP DSCP for MLPP Routine precedence call level.  The valid range is -1 to 63. The default is -1.  <b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter <code>PremiumServiceClassMediaDiffServ</code> or as defined in IP Profiles per call.
'RTP DSCP for MLPP Priority' <code>configure voip &gt; gateway</code> <code>digital settings &gt; dscp-</code> <code>4-mlpp-prio</code> <b>[MLPPPriorityRTPDSCP]</b>		Defines the RTP DSCP for MLPP Priority precedence call level.  The valid range is -1 to 63. The default is -1.  <b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter <code>PremiumServiceClassMediaDiffServ</code> or as defined in IP Profiles per call.
'RTP DSCP for MLPP Immediate' <code>configure voip &gt; gateway</code> <code>digital settings &gt; dscp-</code> <code>4-mlpp-immed</code> <b>[MLPPImmediateRTPDSCP]</b>		Defines the RTP DSCP for MLPP Immediate precedence call level.  The valid range is -1 to 63. The default is -1.  <b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter <code>PremiumServiceClassMediaDiffServ</code> or as defined in IP Profiles per call.
'RTP DSCP for MLPP Flash' <code>configure voip &gt; gateway</code> <code>digital settings &gt; dscp-</code> <code>4-mlpp-flsh</code> <b>[MLPPFlashRTPDSCP]</b>		Defines the RTP DSCP for MLPP Flash precedence call level.  The valid range is -1 to 63. The default is -1.  <b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter <code>PremiumServiceClassMediaDiffServ</code> or as defined in IP Profiles per call.

Parameter	Description
'RTP DSCP for MLPP Flash Override' configure voip > gateway digital settings > dscp- 4-mlpp-flsh-ov [MLPPFlashOverRTPDSCP]	Defines the RTP DSCP for MLPP Flash-Override precedence call level.  The valid range is -1 to 63. The default is -1. <b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.
'RTP DSCP for MLPP Flash-Override-Override' configure voip > gateway digital settings > dscp- 4-mlpp-flsh-ov-ov [MLPPFlashOverOverRTPDSCP]	Defines the RTP DSCP for MLPP Flash-Override-Override precedence call level.  The valid range is -1 to 63. The default is -1. <b>Note:</b> If set to -1, the DiffServ value is taken from the global parameter PremiumServiceClassMediaDiffServ or as defined in IP Profiles per call.

### Call Cut-through Parameters

The call cut-through parameters are described in the table below.

**Table 73-52:Call Cut-Through Parameters**

Parameter	Description
'Enable Calls Cut Through' configure voip > sip- definition settings > calls-cut- through [CutThrough]	Global parameter enabling FXS endpoints to receive incoming IP calls while the port is in off-hook state.  You can also configure the feature per specific calls, using Tel Profiles ('IP-to-Tel Cut-Through Call Mode' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
cut-through- anable [DigitalCutThrough]	Global parameter enabling PSTN CAS channels/endpoints to receive incoming IP calls even if the B-channels are in off-hook state.  You can also configure the feature per specific calls, using Tel Profiles ('Digital Cut Through' parameter). For a detailed

Parameter	Description
	<p>description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> <li>■ The parameter is applicable only to digital interfaces (CAS).</li> </ul>

### Direct Inward Dialing Parameters

The Direct Inward Dialing (DID) parameters are described in the table below.

**Table 73-53:DID Parameters**

Parameter	Description
<p>'DID Wink'</p> <pre>configure voip &gt; sip-definition settings &gt; did- wink-enbl</pre> <p>[EnabledDIDWink]</p>	<p>Global parameter enabling Direct Inward Dialing (DID) using Wink-Start signaling, typically used for signaling between an E-911 switch and the PSAP.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('DID Wink' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to FXS and FXO interfaces.</li> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
<p>'Time Between DID Winks'</p> <pre>configure voip &gt; sip-definition settings &gt; time- between-did-winks</pre> <p>[TimeBetweenDIDWinks]</p>	<p>Defines the interval (in msec) for wink signaling:</p> <ul style="list-style-type: none"> <li>■ Double-wink signaling [2]: interval between the first and second wink</li> <li>■ Wink and Polarity signaling [3]: interval between wink and polarity change</li> </ul> <p>The valid range is 100 to 2000. The default is 1000.</p> <p><b>Note:</b> See the EnableDIDWink parameter for configuring the wink signaling type.</p>
<p>'Delay Before DID Wink'</p>	<p>Defines the time interval (in msec) between the detection of</p>

Parameter	Description
<pre>configure voip &gt; sip-definition settings &gt; delay- b4-did-wink</pre> <p>[DelayBeforeDIDWink]</p>	<p>the off-hook and the generation of the DID Wink.</p> <p>The valid range is 0 to 1,000. The default is 0.</p> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>
<pre>NTT-DID-signaling- form</pre> <p>[NTTDIDSignallingForm]</p>	<p>Determines the type of DID signaling support for NTT (Japan) modem: DTMF- or Frequency Shift Keying (FSK)-based signaling. The devices can be connected to Japan's NTT PBX using 'Modem' DID lines. These DID lines are used to deliver a called number to the PBX.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) FSK-based signaling</li> <li>■ [1] = DTMF-based signaling</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>
<pre>configure voip &gt; gateway analog &gt; enable-did</pre> <p>[EnableDID]</p>	<p>This table parameter enables support for Japan NTT 'Modem' DID per FXS port. FXS interfaces can be connected to Japan's NTT PBX using 'Modem' DID lines. These DID lines are used to deliver a called number to the PBX. The DID signal can be sent alone or combined with an NTT Caller ID signal.</p> <p>The format of the ini file table parameter is as follows:</p> <pre>[EnableDID] FORMAT Index = IsEnable; Port, Module; [\EnableDID]</pre> <p>where:</p> <ul style="list-style-type: none"> <li>■ <i>IsEnable</i> = Enables [1] or disables [0] (default) Japan NTT Modem DID support.</li> <li>■ <i>Port</i> = Port number.</li> <li>■ <i>Module</i> = Module number.</li> </ul> <p>For example:  EnableDID 0 = 1,1,2; (DID is enabled on Port 1 of Module 2)</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable DID for all FXS ports, use the corresponding global parameter [EnableDID], below.</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>configure voip &gt; sip-definition</pre>	<p>Enables support for Japan NTT 'Modem' DID for all FXS ports.</p>

Parameter	Description
<pre>settings &gt; enable- did</pre> <p>[EnableDID]</p>	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable DID per FXS port, use the corresponding table parameter [EnableDID] (above).</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; wink-time</pre> <p>[WinkTime]</p>	<p>Defines the time (in msec) elapsed between two consecutive polarity reversals. The parameter can be used for DID signaling, for example, E911 lines to the Public Safety Answering Point (PSAP), according to the Bellcore GR-350-CORE standard (see the parameter [Enable911PSAP]).</p> <p>The valid range is 0 to 4,294,967,295. The default is 200.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

### ISDN BRI Parameters

The ISDN BRI call forwarding service parameters are described in the table below.

**Table 73-54:BRI Call Forwarding Services Parameters**

Parameter	Description
<b>BRI-to-SIP Supplementary Services Codes for Call Forward</b> For more information, see <a href="#">Remote Handling of BRI Call Forwarding</a> on page 1046.	
<p>'Call Forward Unconditional'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settingscfu- code</pre> <p>[SuppServCodeCFU]</p>	<p>Defines the prefix code for activating Call Forward Unconditional sent to the softswitch.</p> <p>The valid value is a string. By default, no value is defined.</p> <p><b>Note:</b> The string must be enclosed by a single quotation mark (e.g., '*72').</p>
<p>'Call Forward Unconditional Deactivation'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settingscfu- deactivation-code</pre> <p>[SuppServCodeCFUDeact]</p>	<p>Defines the prefix code for deactivating Call Forward Unconditional Deactivation sent to the softswitch.</p> <p>The valid value is a string. By default, no value is defined.</p> <p><b>Note:</b> The string must be enclosed by a single quotation mark (e.g., '*72').</p>

Parameter	Description
<b>'Call Forward on Busy'</b> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settingscfb- code</pre> <b>[SuppServCodeCFB]</b>	<p>Defines the prefix code for activating Call Forward on Busy sent to the softswitch.</p> <p>The valid value is a string. By default, no value is defined.</p> <p><b>Note:</b> The string must be enclosed by a single quotation mark (e.g., '*72').</p>
<b>'Call Forward on Busy Deactivation'</b> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settingscfb- deactivation-code</pre> <b>[SuppServCodeCFBDeact]</b>	<p>Defines the prefix code for deactivating Call Forward on Busy Deactivation sent to the softswitch.</p> <p>The valid value is a string. By default, no value is defined.</p> <p><b>Note:</b> The string must be enclosed by a single quotation mark (e.g., '*72').</p>
<b>'Call Forward on No Reply'</b> <pre>configure voip &gt; gateway dtmf-supp- service supp- service- settingscfnr-code</pre> <b>[SuppServCodeCFNR]</b>	<p>Defines the prefix code for activating Call Forward on No Reply sent to the softswitch.</p> <p>The valid value is a string. By default, no value is defined.</p> <p><b>Note:</b> The string must be enclosed by a single quotation mark (e.g., '*72').</p>
<b>'Call Forward on No Reply Deactivation'</b> <pre>configure voip &gt; gateway dtmf-supp- service supp- service- settingscfnr- deactivation-code</pre> <b>[SuppServCodeCFNRDeact]</b>	<p>Defines the prefix code for deactivating Call Forward on No Reply Deactivation sent to the softswitch.</p> <p>The valid value is a string. By default, no value is defined.</p> <p><b>Note:</b> The string must be enclosed by a single quotation mark (e.g., '*72').</p>
<pre>configure voip &gt; gateway dtmf-supp- service supp- service-settingsuse- facility-in-req</pre> <b>[UseFacilityInRequest]</b>	<p>Enables the device to indicate the type of call forwarding service in the Request-URI of the outgoing SIP INVITE message, using a proprietary header parameter, "facility=&lt;call forward service&gt;".</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul>

Parameter	Description
[BRICallForwardHandling]	<p>Enables the device to handle BRI call forwarding.</p> <ul style="list-style-type: none"> <li>■ [0] Disable = (Default) BRI call forwarding is handled by a remote server. The device interworks Facility message from the BRI endpoint to SIP messages sent to the server. For more information, see <a href="#">Remote Handling of BRI Call Forwarding</a> on page 1046.</li> <li>■ [1] Enable = BRI call forwarding is handled by the device. For more information, see <a href="#">Local Handling of BRI Call Forwarding</a> on page 1048.</li> </ul>

## PSTN Parameters

This subsection describes the device's PSTN parameters.

### General Parameters

The general PSTN parameters are described in the table below.

**Table 73-55:General PSTN Parameters**

Parameter	Description
[ISDNTimerT310]	<p>Defines the T310 override timer for DMS, Euro ISDN, and ISDN NI-2 variants. An ISDN timer is started when a Q.931 Call Proceeding message is received. The timer is stopped when a Q.931 Alerting, Connect, or Disconnect message is received from the other end. If no ISDN Alerting, Progress, or Connect message is received within the duration of T310 timer, the call clears.</p> <p>The valid value range is 0 to 600 seconds. The default is 0 (i.e., use the default timer value according to the protocol's specifications).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When both the parameters [ISDNDmsTimerT310] and [ISDNTimerT310] are configured, the value of the parameter [ISDNTimerT310] prevails.</li> </ul>
[ISDNDMSTimerT310]	Defines the override T310 timer for the DMS-100

Parameter	Description
	<p>ISDN variant. T310 defines the timeout between the receipt of a Proceeding message and the receipt of an Alerting/Connect message.</p> <p>The valid range is 10 to 30. The default is 10 (seconds).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Instead of configuring the parameter, it is recommended to use the parameter [ISDNTimerT310].</li> <li>■ The parameter is applicable only to Nortel DMS and Nortel MERIDIAN PRI variants (ProtocolType = 14 and 35).</li> </ul>
[ISDNTimerT301]	<p>Defines the override T301 timer (in seconds). The T301 timer is started when a Q.931 Alert message is received. The timer is stopped when a Q.931 Connect/Disconnect message is received from the other side. If no Connect or Disconnect message is received within the duration of T301, the call is cleared.</p> <p>The valid range is 0 to 2400. The default is 0 (i.e., the default T301 timer value - 180 seconds - is used). If set to any value other than 0, it overrides the timer with this value.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to the ISDN QSIG protocol variant and the Network side of the NTT ISDN protocol variant.</li> <li>■ This timer is also affected by the [PSTNAlertTimeout] parameter.</li> </ul>
[ISDNJapanNTTTimerT3JA]	<p>Defines the T3_JA timer (in seconds). The parameter overrides the internal PSTN T301 timeout on the Users Side (TE side). If an outgoing call from the device to ISDN is not answered during this timeout, the call is released.</p> <p>The valid value is -1 to 300. The default is 0 (meaning 50 sec). The value -1 means that no timer</p>

Parameter	Description
	<p>is activated.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This timer is also affected by the [PSTNAlertTimeout] parameter.</li> <li>■ The parameter is applicable only to the Japan NTT PRI variant (ProtocolType = 16).</li> </ul>
[TrunkLifeLineType]	<p>Defines the scenarios upon which the device activates PSTN Fallback for digital interfaces. When PSTN Fallback is triggered, the device automatically routes incoming Tel calls to the PSTN (instead of to the IP).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) PSTN Fallback is activated upon the loss of power to the device, for example, due to a power outage or the unplugging of the device's power cable.</li> </ul> <p>PSTN Fallback is provided by two ports, where one port is connected to the PBX, for example, and the other to the PSTN. When PSTN Fallback is triggered, for example, due to a power outage, the device automatically connects the two ports using a metallic relay switch. In such a scenario, calls originating from the PBX are routed directly to the PSTN (instead of the IP network). For more information on PSTN Fallback cabling, refer to the <i>Hardware Installation Manual</i>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to the digital interfaces.</li> <li>■ PSTN Fallback is supported only on specific hardware configurations and where dual digital ports are provided. For more information, refer to the <i>Hardware Installation Manual</i>.</li> <li>■ The PSTN Fallback feature has no relation to the PSTN Fallback License Key.</li> </ul>
[AdminState]	Defines the administrative state for all trunks.

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] = Lock the trunk; stops trunk traffic to configure the trunk protocol type.</li> <li>■ [1] = Shutting down (read only).</li> <li>■ [2] = (Default) Unlock the trunk; enables trunk traffic.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ When the device is locked from the Web interface, the parameter changes to 0.</li> <li>■ To define the administrative state per trunk, use the [TrunkAdministrativeState] parameter.</li> </ul>
[TrunkAdministrativeState_x]	<p>Defines the administrative state per trunk, where x denotes the trunk number.</p> <ul style="list-style-type: none"> <li>■ [0] = Lock the trunk; stops trunk traffic to configure the trunk protocol type.</li> <li>■ [1] = shutting down (read only).</li> <li>■ [2] = (Default) Unlock the trunk; enables trunk traffic.</li> </ul>
[TDMHairPinning]	<p>Defines static TDM hairpinning (cross-connection) performed at initialization. The connection is between trunks with an option to exclude a single B-channel in each trunk. Format example: T0-T1/B3,T2-T3,T4-T5/B2.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to PRI.</li> </ul>
[TDMHairPinningAlarmIndication]	<p>Enables two trunks that are connected through TDM hairpinning to signal the Far-End about the presence of PSTN alarms. When the trunk with TDM hairpinning receives a PSTN alarm, its' connected trunk sends an AIS alarm to its' Far-End.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to PRI.</li> </ul>
<p>'TDM Tunneling'</p> <pre>configure voip &gt; gateway digital settings &gt; tdm- tunneling</pre> <p>[EnableTDMoverIP]</p>	<p>Enables TDM tunneling for all calls (trunks).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = Enables TDM tunneling. For more information, see <a href="#">TDM Tunneling</a> on page 914.</li> <li>■ [2] <b>Private Wire</b> = Enables TDM tunneling for private wire services. For more information, see <a href="#">Configuring Private Wire Interworking</a> on page 919.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to ISDN PRI.</li> <li>■ To enable TDM tunneling per trunk, use the [EnableTDMOverIPforTrunk] parameter.</li> </ul>
[EnableTDMOverIPforTrunk]	<p>Enables TDM tunneling for a specific trunk. For a description of the parameter, see the [EnableTDMoverIP] parameter.</p>
<pre>configure voip &gt; gateway digital settings &gt; iso8859-charset</pre> <p>[ISO8859CharacterSet]</p>	<p>Defines the ISO 8859 character set type (languages) for representing the alphanumeric string of the calling name (caller ID) in the forwarded message, for IP-to-Tel and Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] = No Accented - proprietary method where incoming INVITE messages with any accented characters (e.g., á, é, í, ó, and ü), which are represented in a 2-byte unicode character, are translated to Latin-only, which are normal one-byte ASCII characters (a, e, i, o, and u, respectively).</li> <li>■ [1] = Western European (Default)</li> <li>■ [2] = Central European</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [3] = South European</li> <li>■ [4] = North European</li> <li>■ [5] = Cyrillic</li> <li>■ [6] = Arabic</li> <li>■ [7] = Hebrew</li> <li>■ [8] = Turkish</li> </ul>
'Time to Wait before Dialing' [WaitForDialTime]	<p>Defines the delay after hook-flash is generated and until dialing begins.</p> <p>The valid range (in milliseconds) is 0 to 20,000 (i.e., 20 seconds). The default is 1,000 (i.e., 1 second).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to call transfer (i.e., the [TrunkTransferMode] parameter is set to 3) on CAS protocols.</li> <li>■ The parameter is also applicable to analog interfaces. For more information, see <a href="#">FXO and FXS Parameters</a> on page 2049.</li> </ul>

### TDM Bus and Clock Timing Parameters

The TDM Bus parameters are described in the table below.

**Table 73-56:TDM Bus and Clock Timing Parameters**

Parameter	Description
TDM Bus Parameters	
Digital PCM	
'PCM Law Select' <pre>configure voip &gt; media tdm &gt; pcm-law-select</pre> [PCMLawSelect]	<p>Defines the type of pulse-code modulation (PCM) companding algorithm law in input and output TDM bus.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Alaw</b></li> <li>■ [3] <b>MuLaw</b></li> </ul> <p>The default value is automatically selected according to the Protocol Type of the selected trunk (E1 defaults to A-Law; T1</p>

Parameter	Description
	<p>defaults to Mu-Law). If the Protocol Type is set to NONE, the default is MuLaw.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ Typically, A-Law is used for E1 spans; Mu-Law for T1/J1 spans.</li> <li>■ Typically, A-Law is used for most BRI variants.</li> </ul>
<p>'Idle PCM Pattern'</p> <pre>configure voip &gt; media tdm &gt; idle-pcm-pattern</pre> <p>[IdlePCMPattern]</p>	<p>Defines the PCM Pattern that is applied to the PSTN timeslot (B-channel) when the channel is idle.</p> <p>The range is 0 to 255. The default is set internally according to the Law select 1 (0xFF for Mu-Law; 0x55 for A-law).</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>'Idle ABCD Pattern'</p> <pre>configure voip &gt; media tdm &gt; idle-abcd-pattern</pre> <p>[IdleABCDPattern]</p>	<p>Defines the ABCD (CAS) Pattern that is applied to the CAS signaling bus when the channel is idle.</p> <p>The valid range is 0x0 to 0xF. The default is -1 (i.e., default pattern is 0000).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when using PSTN interface with the RAW_CAS protocol.</li> </ul>
General	
<p>'TDM Bus Clock Source'</p> <pre>configure voip &gt; media tdm &gt; tdm-bus-clock-source</pre> <p>[TDMBusClockSource]</p>	<p>Defines the clock source to which the device synchronizes.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Internal</b> = (Default) Generate clock from local source.</li> <li>■ [4] <b>Network</b> = Recover clock from PSTN line.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
<p>'TDM Bus Local Reference'</p> <pre>configure voip &gt; media tdm &gt; pstn-bus-local-reference</pre> <p>[TDMBusPSTNLocalReference]</p>	<p>Defines the physical Trunk ID from which the device recovers (receives) its clock synchronization.</p> <p>The range is 1 to the maximum number of Trunks. The default is 1.</p> <p><b>Note:</b> The parameter is applicable only if the [TDMBusClockSource] parameter is configured to 4 and the [TDMBusPSTNAutoClockEnable] parameter to 0.</p>
<p>'TDM Bus PSTN Auto FallBack Clock'</p> <pre>configure voip &gt; media tdm &gt; pstn-bus-auto-clock</pre> <p>[TDMBusPSTNAutoClockEnable]</p>	<p>Enables the PSTN trunk Auto-Fallback Clock feature.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. Recovers the clock from the trunk line configured by the [TDMBusPSTNLocalReference] parameter.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Recovers the clock from any connected synchronized slave trunk line. If this trunk loses its synchronization, the device attempts to recover the clock from the next trunk. Note that initially, the device attempts to recover the clock from the trunk defined by the [TDMBusPSTNLocalReference] parameter.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only if the [TDMBusClockSource] parameter is configured to 4.</li> </ul>
'TDM Bus PSTN Auto Clock Reverting'	Enables the PSTN trunk Auto-Fallback

Parameter	Description
<pre>configure voip &gt; media tdm &gt; pstn-bus-auto-clock-reverting</pre> <p>[TDMBusPSTNAutoClockRevertingEnable]</p>	<p>Reverting feature. If enabled and a trunk returning to service has an AutoClockTrunkPriority parameter value that is higher than the priority of the local reference trunk (configured by the [TDMBusPSTNLocalReference] parameter), the local reference reverts to the trunk with the higher priority that has returned to service for the device's clock source.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only when the [TDMBusPSTNAutoClockEnable] parameter is set to 1.</li> </ul>

### CAS Parameters

The Common Channel Associated (CAS) parameters are described in the table below.

CAS is applicable only to ISDN PRI interfaces.

**Table 73-57: CAS Parameters**

Parameter	Description
[CASOrientedBoard]	<p>Enables DSP resource allocation for CAS.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable.</li> <li>■ [1] = Enable.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ Enable the parameter before configuring CAS.</li> </ul>

Parameter	Description
'CAS Transport Type' <code>cas-transport-type</code> [CASTransportType]	<p>Determines the ABCD signaling transport type over IP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>CAS Events Only</b> = (Default) Disable CAS relay.</li> <li>■ [1] <b>CAS RFC2833 Relay</b> = Enable CAS relay mode using RFC 2833.</li> </ul> <p>The CAS relay mode can be used with the TDM tunneling feature to enable tunneling over IP for both voice and CAS signaling bearers.</p>
[CASAddressingDelimiters]	<p>Enables the addition of delimiters to the received address or received ANI digits string.</p> <ul style="list-style-type: none"> <li>■ [0] = (default) Disable. The address and ANI strings remain without delimiters.</li> <li>■ [1] = Enable. Delimiters such as '*', '#', and 'ST' are added to the received address or received ANI digits string.</li> </ul>
<code>configure voip &gt; interface e1-t1</code> <code>&gt; cas-delimiters-types</code> [CASDelimitersPaddingUsage]	<p>Defines the digits string delimiter padding usage per trunk.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Default address string padding: '*XXX#' (where XXX is the digit string that begins with '*' and ends with '#', when using padding).</li> <li>■ [1] = Special use of asterisks delimiters: '*XXX*YYY*' (where XXX is the address, YYY is the source phone number, and '*' is the only delimiter padding).</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[CASFileName_x]	<p>Defines the CAS file name (e.g., 'E_M_WinkTable.dat') that defines the CAS protocol, where x denotes the CAS file ID (0-7). It is possible to define up to</p>

Parameter	Description
	<p>eight different CAS files by repeating the parameter. Each CAS file can be associated with one or more of the device's trunks, using the parameter CASTableIndex_x.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[CASTablesNum]	<p>Defines the number of loaded CAS protocol configurations files.</p> <p>The valid range is 1 to 8.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<b>CAS State Machines Parameters</b> <b>Note:</b> To configure the CAS State Machine table using the Web interface, see <a href="#">Configuring CAS State Machines</a> on page 911. The CAS state machine can be configured only through the Web-based management tool.	
'Generate Digit On Time' [CASStateMachineGenerateDigitOnTime]	<p>Generates digit on-time (in msec).</p> <p>The value must be a positive value. The default is -1.</p>
'Generate Inter Digit Time' [CASStateMachineGenerateInterDigitTime]	<p>Generates digit off-time (in msec).</p> <p>The value must be a positive value. The default is -1.</p>
'DTMF Max Detection Time' [CASStateMachineDTMFMaxOnDetectionTime]	<p>Detects digit maximum on time (according to DSP detection information event) in msec units.</p> <p>The value must be a positive value. The default is -1.</p>
'DTMF Min Detection Time' [CASStateMachineDTMFMinOnDetectionTime]	<p>Detects digit minimum on time (according to DSP detection information event) in msec units. The digit time length must be longer than this value to receive a detection. Any number may be used, but the value must be less than CasStateMachineDTMFMaxOnDetection Time.</p> <p>The value must be a positive value. The default is -1.</p>

Parameter	Description
'MAX Incoming Address Digits' [CASStateMachineMaxNumOfIncomingAddress Digits]	Defines the limitation for the maximum address digits that need to be collected. After reaching this number of digits, the collection of address digits is stopped. The value must be an integer. The default is -1.
'MAX Incoming ANI Digits' [CASStateMachineMaxNumOfIncomingANIDigits]	Defines the limitation for the maximum ANI digits that need to be collected. After reaching this number of digits, the collection of ANI digits is stopped. The value must be an integer. The default is -1.
'Collect ANI' [CASStateMachineCollectANI]	In some cases, when the state machine handles the ANI collection (not related to MFCR2), you can enable the state machine to collect ANI or discard ANI. <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = Don't collect ANI.</li> <li>■ [1] <b>Yes</b> = Collect ANI.</li> <li>■ [-1] <b>Default</b> = Default value.</li> </ul>
'Digit Signaling System' [CASStateMachineDigitSignalingSystem]	Defines which Signaling System to use in both directions (detection\generation). <ul style="list-style-type: none"> <li>■ [0] <b>DTMF</b> = DTMF signaling.</li> <li>■ [1] <b>MF</b> = (Default) MF signaling.</li> <li>■ [-1] <b>Default</b> = Default value.</li> </ul>

### ISDN Parameters

The ISDN parameters are described in the table below.

**Table 73-58:ISDN Parameters**

Parameter	Description
configure voip > gateway digital settings > ign- isdn-disc-w-pi [KeepISDNCallOnDisconnectWithPI]	Enables the device to ignore ISDN Disconnect messages with Progress Indicator (PI) information element (IE) values 1 or 8. <ul style="list-style-type: none"> <li>■ [1] = The call (in connected state) is not released if a Q.931 Disconnect with PI (PI = 1</li> </ul>

Parameter	Description
	<p>or 8) message is received during the call.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) The call is disconnected.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; pi-4- setup-msg</pre> <p>[PIForSetupMsg]</p>	<p>Defines if and which Progress Indicator (PI) information element (IE) is added to the sent ISDN Setup message. Some ISDN protocols such as NI-2 or Euro ISDN can optionally contain PI = 1 or PI = 3 in the Setup message.</p> <ul style="list-style-type: none"> <li>■ [0] = PI is not added (default).</li> <li>■ [1] = PI 1 is added to a sent ISDN Setup message - call is not end-to-end ISDN.</li> <li>■ [3] = PI 3 is added to a sent ISDN Setup message - calling equipment is not ISDN.</li> </ul>
<pre>no-sdp-for-isdn-pi</pre> <p>[NoSdpForIsdnPi]</p>	<p>Defines the value of the Progress Indicator (PI) information element (IE) that if present in the received ISDN Progress message, the device sends SIP 180 messages <b>without</b> an SDP body (for Tel-to-IP calls).</p> <p>The valid value is a bit field, allowing you to specify more than one PI. The default is 0, meaning that SDP is included in the outgoing SIP 180 message, regardless of PI value.</p>
<p>'B-channel Negotiation'</p> <pre>configure voip &gt; gateway digital settings &gt; b-ch- negotiation</pre> <p>[BchannelNegotiation]</p>	<p>Defines the ISDN B-channel negotiation mode for all trunks.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Preferred</b></li> <li>■ [1] <b>Exclusive</b> (default)</li> <li>■ [2] <b>Any</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For some ISDN variants, when 'Any' (2) is selected, the Setup message excludes the Channel Identification IE.</li> <li>■ The 'Any' (2) option is applicable only if the following conditions are met: <ul style="list-style-type: none"> <li>✓ The parameter TerminationSide is set to 0 ('User side').</li> <li>✓ The PSTN protocol type (ProtocolType) is</li> </ul> </li> </ul>

Parameter	Description
	<p>configured as Euro ISDN.</p> <ul style="list-style-type: none"> <li>■ To configure B-channel negotiation mode per trunk, see the [BChannelNegotiationForTrunk] parameter.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; isdn- channel-id-format</pre> <p>[ISDNChannelIDFormat]</p>	<p>Defines the channel number format in the Channel Identification IE when sending Q.931 ISDN messages.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Channel Number</li> <li>■ [1] = Slotmap</li> </ul> <p>The device's handling of the Channel Identification format is as follows:</p> <ul style="list-style-type: none"> <li>■ Device as Network Termination (NT): <ul style="list-style-type: none"> <li>✓ Device-to-PBX: The device includes the configured Channel Identification format (Slotmap or Channel Number) in the outgoing ISDN Setup. The PBX can respond (Call Proceeding, Alert or Connect) with its own Channel Identification, which the device adopts. However, if the PBX doesn't include information for the Channel Identification, the device adopts the one that it offered in the Setup.</li> <li>✓ PBX-to-Device: The device adopts the same Channel Identification received in the Setup from the PBX (and notifies this to the PBX in the Call Proceeding). However, If the PBX didn't include information for the Channel Identification, the device adopts the configured format (and notifies this to the PBX in Call Proceeding).</li> </ul> </li> <li>■ Device as Terminal Equipment (TE): <ul style="list-style-type: none"> <li>✓ Device-to-PBX: The device includes the configured Channel Identification format (Slotmap or Channel Number), and notifies this to the PBX in the Setup.</li> </ul> </li> </ul>

Parameter	Description
	<p>✓ PBX-to-Device: The device includes the configured Channel Identification format (Slotmap or Channel Number), and notifies this to the PBX in the Call Proceeding.</p> <p><b>Note:</b> The parameter is applicable only to the NTT ISDN and Euro ISDN protocols.</p>
el-t1 isdn-channel-id-format-for-trunk [ISDNChannelIDFormatForTrunk]	<p>Defines the channel number format in the Channel Identification IE when sending Q.931 ISDN messages, per Trunk.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) According to the global parameter [ISDNChannelIDFormat].</li> <li>■ [0] = Channel Number</li> <li>■ [1] = Slotmap</li> </ul> <p>For more information, refer to the [ISDNChannelIDFormat] parameter.</p>
[PSTNExtendedParams]	<p>Determines the bit map for special PSTN behavior parameters:</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Applicable for NI-2 ISDN and QSIG "Networking Extensions". This bit (i.e., bit #0) is responsible for the Invoke ID size:               <ul style="list-style-type: none"> <li>✓ If this bit is not set (default), then the Invoke ID size is always one byte, with a value of 01 to 7f.</li> <li>✓ If this bit is set, then the Invoke ID size is one or two bytes according to the Invoke ID value.</li> </ul> </li> <li>■ [2] = Applicable to the ROSE format (according to the old QSIG specifications). This bit (i.e., bit #1) is responsible for the QSIG octet 3. According to the ECMA-165 new version, octet 3 in all QSIG supplementary services Facility messages should be 0x9F = Networking Extensions. However, according to the old version, the value should be 0x91 = ROSE:               <ul style="list-style-type: none"> <li>✓ If this bit is not set (default): 0x9F =</li> </ul> </li> </ul>

Parameter	Description
	<p>Networking Extensions.</p> <ul style="list-style-type: none"> <li>✓ If this bit is set: 0x91 = ROSE.</li> <li>■ [3] = Use options [0] and [2] above.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<b>BRI Parameters</b>	
<pre>configure voip &gt; interface bri &gt; tei-config-p2p [BriTEIConfigP2P_x]</pre>	<p>Defines the BRI terminal endpoint identifier (TEI) when in point-to-point (P2P) mode.</p> <p>The valid value is 0 to 63, 127. The default is 0.</p> <ul style="list-style-type: none"> <li>■ Network Side: <ul style="list-style-type: none"> <li>✓ 0-63: Only one specified static TEI is accepted.</li> <li>✓ 127: Any possible TEI is accepted. Dynamic TEI allocation procedure is supported.</li> </ul> </li> <li>■ User Side: <ul style="list-style-type: none"> <li>✓ 0-63: Static TEI is used.</li> <li>✓ 127: The TEI is obtained through dynamic TEI request procedure.</li> </ul> </li> </ul>
<pre>configure voip &gt; interface bri &gt; tei-config-p2mp [BriTEIConfigP2MP_x]</pre>	<p>Defines the BRI TEI when in point-to-multipoint (P2MP) mode.</p> <p>The valid value is 0 to 63, 127. The default is 127.</p> <ul style="list-style-type: none"> <li>■ Network Side: Not applicable - in Network side in P2MP configuration, any TEI must be accepted.</li> <li>■ User Side: <ul style="list-style-type: none"> <li>✓ 0-63: Static TEI is used.</li> <li>✓ 127: Dynamic TEI allocation is supported (TEI request procedure initiated).</li> </ul> </li> </ul>
<pre>configure voip &gt; interface bri &gt; tei-assign-trigger [BriTEIAssignTrigger_x]</pre>	<p>Defines when TEI assignment procedure is triggered (when dynamic TEI allocation is configured).</p> <p>The valid values are (bit-field parameter):</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Bit #0: BRI Layer 1 (physical) is activated.</li> <li>■ Bit #1: BRI port configuration has completed.</li> <li>■ Bit #2: Call setup is initiated.</li> </ul> <p>The default is 0x04 (Bit #2).</p> <p><b>Note:</b> The parameter is applicable only to the User side and for dynamic TEI assignment.</p>
<pre>configure voip &gt; interface bri &gt; tei-remove-trigger [BriTEIRemoveTrigger_x]</pre>	<p>Defines when to clear existing dynamic TEI(s) assignment.</p> <p>The valid values are (bit-field parameter):</p> <ul style="list-style-type: none"> <li>■ Bit #0: BRI layer 1 is deactivated (disconnected).</li> <li>■ Bit #1: BRI Layer 2 (data link) is released (disconnected).</li> </ul> <p>The default is 0x00 (no one bit is configured).</p>
<pre>configure voip &gt; gateway digital settings &gt; trunk- restart-mode-on-powerup [TrunkRestartModeOnPowerUp]</pre>	<p>Defines if the device sends the RESTART message upon power up.</p> <ul style="list-style-type: none"> <li>■ [0] = No RESTART message is sent.</li> <li>■ [1] = (Default) Per trunk - device sends only one RESTART message for the whole trunk.</li> <li>■ [2] = Per B-channel - device sends a RESTART message for each B-channel of the trunk.</li> </ul> <p><b>Note:</b> The parameter is applicable only to BRI QSIG and ISDN.</p>

## ISDN and CAS Interworking Parameters

The ISDN and CAS interworking parameters are described in the table below.

**Table 73-59:ISDN and CAS Interworking Parameters**

Parameter	Description
<b>ISDN Parameters</b>	
'Send Local Time To ISDN Connect' [SendLocalTimeToISDNCon]	Determines the device's handling of the date and time sent in the ISDN Connect message (Date / Time IE) upon receipt of SIP 200 OK messages.

Parameter	Description
nect]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) If the SIP 200 OK includes the Date header, the device sends its value in the ISDN Connect Date / Time IE. If the 200 OK doesn't include this header, it doesn't add the Date / Time IE to the sent ISDN Connect message.</li> <li>■ [1] <b>Enable</b> = If the SIP 200 OK includes the Date header, the device sends its value (i.e. date and time) in the ISDN Connect Date / Time IE. If the 200 OK doesn't include this header, the device uses its internal, local date and time for the Date / Time IE, which it adds to the sent ISDN Connect message.</li> <li>■ [2] <b>Always Send Local Date and Time</b> = The device always sends its local date and time (obtained from its internal clock) to PBXs in ISDN Q.931 Connect messages (Date / Time IE). It does this regardless of whether or not the incoming SIP 200 OK includes the Date header. If the SIP 200 OK includes the Date header, the device ignores its value.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature is applicable only to Tel-to-IP calls.</li> <li>■ For IP-to-Tel calls, the parameter is not applicable. Only if the incoming ISDN Connect message contains the Date / Time IE does the device add the Date header to the sent SIP 200 OK message.</li> </ul>
<p>'Min Routing Overlap Digits'</p> <pre>configure voip &gt; gateway dtmf-supp- service dtmf-and- dialing &gt; min-dg- b4-routing</pre> <p>[MinOverlapDigitsForRouting]</p>	<p>Defines the minimum number of overlap digits to collect (for ISDN overlap dialing) before sending the first SIP message for routing Tel-to-IP calls.</p> <p>The valid value range is 0 to 49. The default is 1.</p> <p><b>Note:</b> The parameter is applicable when the ISDNRxOverlap parameter is set to [2] or [3].</p>
<p>'ISDN Overlap IP to Tel Dialing'</p> <pre>configure voip &gt; gateway dtmf-supp- service dtmf-and-</pre>	<p>Enables ISDN overlap dialing for IP-to-Tel calls. This feature is part of ISDN-to-SIP overlap dialing according to RFC 3578.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Through SIP</b> = The device sends the first received</li> </ul>

Parameter	Description
<pre>dialing &gt; isdn-tx- overlap</pre> <p>[ISDNTxOverlap]</p>	<p>digits from the initial INVITE to the Tel side in an ISDN Setup message. For each subsequently received re-INVITE message of the same dialog session, the device sends the collected digits to the Tel side in ISDN Info Q.931 messages. For each received re-INVITE, the device sends a SIP 484 Address Incomplete response to maintain the current dialog session and to receive additional digits from subsequent re-INVITES.</p> <p>■ [2] <b>Through SIP INFO</b> = The device sends the first received digits from the initial INVITE to the Tel side in an ISDN Setup message and then responds to the IP side with a SIP 183. For each subsequently received SIP INFO message with additional digits of the same dialog session, the device sends the collected digits to the Tel side in ISDN Info Q.931 messages. For each received SIP INFO, the device sends a SIP 200 OK response to maintain the current dialog session and to receive additional digits from subsequent INFOs.</p> <p><b>Note:</b> When IP-to-Tel overlap dialing is enabled, to send ISDN Setup messages without the Sending Complete IE, the ISDNOutCallsBehavior parameter must be set to USER SENDING COMPLETE (2).</p>
<pre>'Mute DTMF In Overlap' configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; mute-dtmf-in- overlap</pre> <p>[MuteDTMFInOverlap]</p>	<p>Enables the muting of in-band DTMF detection until the device receives the complete destination number from the ISDN (for Tel-to-IP calls). In other words, the device doesn't accept DTMF digits received in the voice stream from the PSTN, but only accepts digits from ISDN Info messages.</p> <p>■ [0] <b>Don't Mute</b> (default).</p> <p>■ [1] <b>Mute DTMF in Overlap Dialing</b> = The device ignores in-band DTMF digits received during ISDN overlap dialing (disables the DTMF in-band detector).</p> <p><b>Note:</b> The parameter is applicable to ISDN Overlap mode only when dialed numbers are sent using Q.931 Information messages.</p>
<p>[ConnectedNumberType]</p>	<p>Defines the Numbering Type of the ISDN Q.931 Connected Number IE that the device sends in the Connect message to the ISDN (for Tel-to-IP calls). This is interworked from the P-Asserted-Identity header in SIP 200 OK.</p> <p>The default is [0] (i.e., unknown).</p>

Parameter	Description
<pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt; connected-number- type</pre> <p>[ConnectedNumberPlan]</p>	<p>Defines the Numbering Plan of the ISDN Q.931 Connected Number IE that the device sends in the Connect message to the ISDN (for Tel-to-IP calls). This is interworked from the P-Asserted-Identity header in SIP 200 OK.</p> <p>The default is [0] (i.e., unknown).</p>
<p>'Enable ISDN Tunneling Tel to IP'</p> <pre>configure voip &gt; gateway digital settings &gt; isdn- tnl-tel2ip</pre> <p>[EnableISDNTunnelingTel2IP]</p>	<p>Enables ISDN Tunneling.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default).</li> <li>■ [1] <b>Using Header</b> = Enable ISDN Tunneling from ISDN to SIP using a proprietary SIP header.</li> <li>■ [2] <b>Using Body</b> = Enable ISDN Tunneling from ISDN to SIP using a dedicated message body.</li> </ul> <p>When ISDN Tunneling is enabled, the device sends all ISDN messages using the correlated SIP messages. The ISDN Setup message is tunneled using SIP INVITE, all mid-call messages are tunneled using SIP INFO, and ISDN Disconnect/Release message is tunneled using SIP BYE messages. The raw data from the ISDN is inserted into a proprietary SIP header (X-ISDNTunnelingInfo) or a dedicated message body (application/isdn) in the SIP messages.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For this feature to function, configure the [ISDNDuplicateQ931BuffMode] parameter to 128 (i.e., duplicate all messages).</li> <li>■ ISDN tunneling is applicable for all ISDN variants as well as QSIG.</li> </ul>
<p>'Enable ISDN Tunneling IP to Tel'</p> <pre>configure voip &gt; gateway digital settings &gt; isdn- tnl-ip2tel</pre> <p>[EnableISDNTunnelingIP2Tel]</p>	<p>Enables ISDN Tunneling for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable ISDN Tunneling from IP to ISDN</b></li> </ul> <p>When ISDN Tunneling is enabled, the device extracts raw data received in the proprietary SIP header, x-isdntunnelinginfo, or a dedicated message body (application/isdn) in the SIP message and then sends the data in an ISDN message to the PSTN.</p> <p>If the raw data in this SIP header is suffixed with the string "ADDE", then the raw data is extracted and added as</p>

Parameter	Description
	<p>Informational Elements (IE) in the outgoing Q.931 message. The tunneling of the x-isdntunnelinginfo SIP header with IEs is converted from INVITE, 180, and 200 OK SIP messages to Q.931 SETUP, ALERT, and CONNECT respectively.</p> <p>For example, if the following SIP header is received,  x-isdntunnelinginfo: ADDE1C269FAA 06  800100820100A10F020136  0201F0A00702010102021F69</p> <p>then it is added as an IE to the outgoing Q.931 message as 1C269FAA 06 800100820100A10F020136 0201F0A00702010102021F69, where, for example, "1C269F" is a 26 byte length Facility IE.</p> <p><b>Note:</b> The feature is similar to that of the AddIEinSetup parameter. If both parameters are configured, the AddIEinSetup parameter is ignored.</p>
<p>'Enable QSIG Tunneling'</p> <pre>configure voip &gt; gateway digital settings &gt; qsig- tunneling</pre> <p>[EnableQSIGTunneling]</p>	<p>Global parameter that enables QSIG tunneling-over-SIP for all calls. You can also configure this feature per specific calls, using IP Profiles ('QSIG Tunneling' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<pre>configure voip &gt; gateway digital settings &gt; qsig- tunneling-mode</pre> <p>[QSIGTunnelingMode]</p>	<p>Defines the format of encapsulated QSIG message data in the SIP message MIME body.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) ASCII presentation of Q.931 QSIG message.</li> <li>■ [1] = Binary encoding of Q.931 QSIG message (according to ECMA-355, RFC 3204, and RFC 2025).</li> </ul> <p><b>Note:</b> The parameter is applicable only if the QSIG Tunneling feature is enabled, using the [EnableQSIGTunneling] parameter.</p>
<p>'Enable Hold to ISDN'</p> <pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt;</pre>	<p>Enables SIP-to-ISDN interworking of the Hold/Retrieve supplementary service.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>

Parameter	Description
<code>hold-to-isdn</code> <code>[EnableHold2ISDN]</code>	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to Euro ISDN variants - from TE (user) to NT (network).</li> <li>■ The parameter is applicable to QSIG BRI.</li> <li>■ If the parameter is disabled, the device plays a held tone to the Tel side when a SIP request with 0.0.0.0 or "inactive" in SDP is received. An appropriate CPT file with the held tone should be used.</li> </ul>
<p>'ISDN SubAddress Format'</p> <code>configure voip &gt;</code> <code>gateway digital</code> <code>settings &gt; isdn-</code> <code>subaddr-frmt</code> <code>[ISDNSubAddressFormat]</code>	<p>Determines the encoding format of the SIP Tel URI parameter 'isub', which carries the encoding type of ISDN subaddresses. This is used to identify different remote ISDN entities under the same phone number (ISDN Calling and Called numbers) for interworking between ISDN and SIP networks.</p> <ul style="list-style-type: none"> <li>■ [0] <b>ASCII</b> = (Default) IA5 format that allows up to 20 digits. Indicates that the 'isub' parameter value needs to be encoded using ASCII characters.</li> <li>■ [1] <b>BCD</b> = (Binary Coded Decimal) - allows up to 40 characters (digits and letters). Indicates that the 'isub' parameter value needs to be encoded using BCD when translated to an ISDN message.</li> <li>■ [2] <b>User Specified</b></li> </ul> <p>For IP-to-Tel calls, if the incoming SIP INVITE message includes subaddress values in the 'isub' parameter for the Called Number (in the Request-URI) and/or the Calling Number (in the From header), these values are mapped to the outgoing ISDN Setup message.</p> <p>If the incoming ISDN Setup message includes 'subaddress' values for the Called Number and/or the Calling Number, these values are mapped to the outgoing SIP INVITE message's 'isub' parameter in accordance with RFC 4715.</p>
<code>configure voip &gt;</code> <code>gateway dtmf-supp-</code> <code>service supp-</code> <code>service-settings &gt;</code> <code>ignore-isdn-</code> <code>subaddress</code> <code>[IgnoreISDNSubaddress]</code>	<p>Determines whether the device ignores the Subaddress from the incoming ISDN Called and Calling numbers when sending to IP.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) If an incoming ISDN Q.931 Setup message contains a Called/Calling Number Subaddress, the Subaddress is interworked to the SIP 'isub' parameter</li> </ul>

Parameter	Description
	<p>according to RFC.</p> <ul style="list-style-type: none"> <li>■ [1] = The device removes the ISDN Subaddress and doesn't include the 'isub' parameter in the Request-URI and doesn't process INVITEs with the parameter.</li> </ul>
[ISUBNumberOfDigits]	<p>Defines the number of digits (from the end) that the device takes from the called number (received from the IP) for the isub number (in the sent ISDN Setup message). This feature is applicable only for IP-to-ISDN calls.</p> <p>The valid value range is 0 to 36. The default is 0.</p> <p>This feature operates as follows:</p> <ol style="list-style-type: none"> <li>1. If an isub parameter is received in the Request-URI, for example, INVITE sip:9565645;<b>isub</b>=1234@host-domain:user=phone SIP/2.0 then the isub value is sent in the ISDN Setup message as the destination subaddress.</li> <li>2. If the isub parameter is not received in the user part of the Request-URI, the device searches for it in the URI parameters of the To header, for example, To: "Alex" &lt;sip: 9565645@host.domain;<b>isub</b>=1234&gt; If present, the isub value is sent in the ISDN Setup message as the destination subaddress.</li> <li>3. If the isub parameter is not present in the Request-URI header nor To header, the device does the following: <ul style="list-style-type: none"> <li>✓ If the called number (that appears in the user part of the Request-URI) starts with zero (0), for example, INVITE sip:<b>0</b>5694564@host.domain:user=phone SIP/2.0 then the device maps this called number to the destination number of the ISDN Setup message, and the destination subaddress in this ISDN Setup message remains empty.</li> <li>✓ If the called number (that appears in the user part of the Request-URI) doesn't start with zero, for example, INVITE sip:5694564@host.domain:user=phone SIP/2.0 then the device maps this called number to the destination number of the ISDN Setup message, and</li> </ul> </li> </ol>

Parameter	Description
	<p>the destination subaddress in this ISDN Setup message then contains y digits from the end of the called number. The y number of digits can be configured using the ISUBNumberOfDigits parameter. The default value of ISUBNumberOfDigits is 0, thus, if the parameter is not configured, and 1) and 2) scenarios (described above) have not provided an isub value, the subaddress remains empty.</p>
<p>'Default Cause Mapping From ISDN to SIP'</p> <pre>configure voip &gt; gateway digital settings &gt; dflt- cse-map-isdn2sip [DefaultCauseMapISDN2IP]</pre>	<p>Defines a single default ISDN release cause that is used (in ISDN-to-IP calls) instead of all received release causes, except when the following Q.931 cause values are received: Normal Call Clearing (16), User Busy (17), No User Responding (18), or No Answer from User (19). The range is any valid Q.931 release cause (0 to 127). The default is 0 (i.e., not configured - static mapping is used).</p>
<p>'Enable Calling Party Category'</p> <pre>configure voip &gt; gateway digital settings &gt; ni2-cpc [EnableCallingPartyCategory]</pre>	<p>Enables the mapping of the calling party category (CPC) between the incoming PSTN message and outgoing SIP message, and vice versa (i.e., for IP-to-Tel and Tel-to-IP calls). The CPC characterizes the station used to originate a call (e.g., a payphone or an operator).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. CPC is not relayed between SIP and PSTN.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>The CPC is denoted in the PSTN message as follows:</p> <ul style="list-style-type: none"> <li>■ ISDN PRI NI-2: In the Originating Line Information (OLI) Information Element (IE) of the ISDN Setup message.</li> <li>■ MFC-R2: ANI II digits. The device supports the Brazilian and Argentinian variants. This regional support is configured using the CallingPartyCategoryMode.</li> </ul> <p>The CPC is denoted in the SIP INVITE message using the 'cpc=' parameter in the From or P-Asserted-Identity headers. For example, the 'cpc=' parameter in the below INVITE message is set to "payphone":</p> <pre>INVITE sip:bob@biloxi.example.com SIP/2.0  To: "Bob" &lt;sip:bob@biloxi.example.com&gt; From:</pre>

Parameter	Description																																																																				
	<p>&lt;tel:+17005554141;cpc=payphone&gt;;tag=1928301774</p> <p>The table below shows the mapping of CPC between SIP and PSTN:</p> <table> <tr> <th rowspan="2">SIP CPC</th><th rowspan="2">NI-2 PRI</th><th colspan="2">MFC-R2</th></tr> <tr> <th>Argentina</th><th>Brazil</th></tr> <tr> <td>ordinary</td><td>23</td><td>II-1</td><td>II-1</td></tr> <tr> <td>priority</td><td>n/a</td><td>II-2</td><td>II-2</td></tr> <tr> <td>data</td><td>n/a</td><td>II-6</td><td>II-6</td></tr> <tr> <td>test</td><td>n/a</td><td>II-3</td><td>II-3</td></tr> <tr> <td>operator</td><td>35</td><td>II-5</td><td>II-5</td></tr> <tr> <td>payphone</td><td>70</td><td>II-4</td><td>II-7</td></tr> <tr> <td>unknown</td><td>n/a</td><td>II-1</td><td>II-1</td></tr> <tr> <td>subscriber</td><td>23</td><td>n/a</td><td>II-1</td></tr> <tr> <td>cellular</td><td>61</td><td>II-13</td><td>n/a</td></tr> <tr> <td>locutorio</td><td>n/a</td><td>II-11</td><td>n/a</td></tr> <tr> <td>servicio-publico</td><td>n/a</td><td>II-12</td><td>n/a</td></tr> <tr> <td>red-privada-virtual / private-virtual-network</td><td>n/a</td><td>II-14</td><td>n/a</td></tr> <tr> <td>linea-especial / special-operator-handling-required</td><td>n/a</td><td>II-15</td><td>n/a</td></tr> <tr> <td>operadora-con-intervencion / telco-operator-handled-call</td><td>n/a</td><td>II-5</td><td>n/a</td></tr> <tr> <td>prison</td><td>29</td><td>n/a</td><td>n/a</td></tr> </table>			SIP CPC	NI-2 PRI	MFC-R2		Argentina	Brazil	ordinary	23	II-1	II-1	priority	n/a	II-2	II-2	data	n/a	II-6	II-6	test	n/a	II-3	II-3	operator	35	II-5	II-5	payphone	70	II-4	II-7	unknown	n/a	II-1	II-1	subscriber	23	n/a	II-1	cellular	61	II-13	n/a	locutorio	n/a	II-11	n/a	servicio-publico	n/a	II-12	n/a	red-privada-virtual / private-virtual-network	n/a	II-14	n/a	linea-especial / special-operator-handling-required	n/a	II-15	n/a	operadora-con-intervencion / telco-operator-handled-call	n/a	II-5	n/a	prison	29	n/a	n/a

'Calling Party Category Mode'  configure voip > gateway digital settings > cpc- mode  [CallingPartyCategoryMode]	<p>Defines the regional Calling Party Category (CPC) mapping variant between SIP and PSTN for MFC-R2.</p> <ul style="list-style-type: none"><li>■ [0] <b>None</b> (default)</li><li>■ [1] <b>Brazil R2</b></li><li>■ [2] <b>Argentina R2</b></li></ul> <p><b>Note:</b></p> <ul style="list-style-type: none"><li>■ To enable CPC mapping, set the EnableCallingPartyCategory parameter to 1.</li><li>■ The parameter is applicable only to the E1 MFC-R2 variant.</li></ul>								
'Remove CLI when Restricted'  configure voip > gateway digital settings > rmv- cli-when-restr  [RemoveCLIWhenRestricted]	<p>Determines (for IP-to-Tel calls) whether the Calling Number and Calling Name IEs are removed from the ISDN Setup message if the presentation is set to Restricted.</p> <ul style="list-style-type: none"><li>■ [0] <b>No</b> = (Default) IE's are not removed.</li><li>■ [1] <b>Yes</b> = IE's are removed.</li></ul>								
'Remove Calling Name'  configure voip > gateway digital settings > rmv- calling-name  [RemoveCallingName]	<p>Enables the device to remove the Calling Name from SIP-to-ISDN calls for all trunks.</p> <ul style="list-style-type: none"><li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li><li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li></ul> <p><b>Note:</b> Some PSTN switches / PBXs may not be configured to support the receipt of the “Calling Name” information. These switches might respond to an ISDN Setup message (including the Calling Name) with an ISDN "REQUESTED_FAC_NOT_SUBSCRIBED" failure. The parameter can be set to Enable (1) to remove the “Calling Name” from SIP-to-ISDN calls and allow the call to proceed.</p>								

Parameter	Description
<p>'CID Notification'</p> <pre>configure voip &gt; gateway digital settings &gt; cid- notification</pre> <p>[CIDNotification]</p>	<p>Enables presentation in the outgoing SIP message when the presentation indicator in the Calling Party Number information element of the incoming ISDN message has the value "number not available due to interworking".</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device restricts presentation in the outgoing SIP message. The device sends the SIP message with "anonymous" in the From header (e.g., From: "anonymous" &lt;sip:anonymous@anonymous.invalid&gt;).</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device allows presentation in the outgoing SIP message (e.g., From: "Bob" &lt;sip:12345@10.33.1.6&gt;;tag=1c172113195).</li> </ul> <p><b>Note:</b> The parameter is applicable only to Tel-to-IP calls.</p>
<p>'CID Not Included Notification'</p> <pre>configure voip &gt; gateway digital settings &gt; cid- not-included- notification</pre> <p>[CIDNotIncludedNotification]</p>	<p>Enables presentation in the outgoing SIP message when the Calling Party Number information element of the incoming ISDN message doesn't include the presentation indicator.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled. The device restricts presentation in the outgoing SIP message. The device sends the SIP message with "anonymous" in the From header (e.g., From: "anonymous" &lt;sip:anonymous@anonymous.invalid&gt;).</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. The device allows presentation in the outgoing SIP message (e.g., From: "Bob" &lt;sip:12345@10.33.1.6&gt;;tag=1c172113195).</li> </ul> <p><b>Note:</b> The parameter is applicable only to Tel-to-IP calls.</p>
[ConnectOnProgressInd]	<p>Enables the play of announcements from IP to Tel without the need to answer the Tel-to-IP call. It can be used with PSTN networks that don't support the opening of a TDM channel before an ISDN Connect message is received.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Connect message isn't sent after SIP 183 Session Progress message is received.</li> <li>■ [1] = Connect message is sent after SIP 183 Session Progress message is received.</li> </ul>
<pre>configure voip &gt; gateway dtmf-supp- service supp- service-settings &gt;</pre>	<p>Enables the device to send an ISDN Service message per trunk upon device restart. The message (transmitted on the trunk's D-channel) indicates the availability of the trunk's B-channels (i.e., trunk in service).</p>

Parameter	Description
<code>snd-isdn-ser-aftr-restart</code> [SendISDNServiceAfterRestart]	<ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul>
<code>configure voip &gt; sip-definition proxy-and-registration &gt; redirect-in-facility</code> [SupportRedirectInFacility]	<p>Determines whether the Redirect Number is retrieved from the Facility IE.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Not supported.</li> <li>■ [1] = Supports partial retrieval of Redirect Number (number only) from the Facility IE in ISDN Setup messages. This is applicable to Redirect Number according to ECMA-173 Call Diversion Supplementary Services.</li> </ul> <p><b>Note:</b> To enable this feature, configure the [ISDNDuplicateQ931BuffMode] parameter to 1.</p>
[EnableCIC]	<p>Enables the relay of the Carrier Identification Code (CIC) to the ISDN.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled - CIC is not relayed to the ISDN.</li> <li>■ [1] = Enabled - CIC (received in the INVITE Request-URI) is relayed to the ISDN in the Transit Network Selection (TNS) IE of the Setup message. For example: INVITE sip:555666;cic=2345@100.2.3.4 sip/2.0.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature is supported only for SIP-to-ISDN calls.</li> <li>■ The parameter AddCicAsPrefix can be used to add the CIC as a prefix to the destination phone number for routing IP-to-Tel calls.</li> </ul>
<b>'AoC Support'</b> <code>configure voip &gt; gateway dtmf-supp-service supp-service-settings &gt; aoc-support</code> [EnableAOC]	<p>Enables the interworking of ISDN Advice of Charge (AOC) messages to SIP.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information on AOC, see <a href="#">Advice of Charge Services for Euro ISDN</a> on page 1079.</p>
<b>'Add IE in SETUP'</b> <code>configure voip &gt;</code>	<p>Global parameter that defines an optional Information Element (IE) data (in hex format) to add to ISDN Setup</p>

Parameter	Description
<pre>gateway digital settings &gt; add-ie- in-setup</pre> <p>[AddIEInSetup]</p>	<p>messages. You can also configure this feature per specific calls, using IP Profiles ('Add IE In Setup' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<pre>'Trunk Groups to Send IE' configure voip &gt; gateway digital settings &gt; trkgrps-to-snd-ie</pre> <p>[SendIEonTG]</p>	<p>Defines Trunk Group IDs (up to 50 characters) from where the optional ISDN IE (defined by the parameter AddIEInSetup) is sent. For example: '1,2,4,10,12,6'.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You can configure different IE data for Trunk Groups by defining the parameter for different IP Profile IDs (using the parameter IPProfile), and then assigning the required IP Profile ID in the IP-to-Tel Routing table (PSTNPrefix).</li> <li>When IP Profiles are used for configuring different IE data for Trunk Groups, the parameter is ignored.</li> </ul>
<pre>'Enable User-to-User IE for Tel to IP' configure voip &gt; gateway digital settings &gt; uui-ie- for-tel2ip</pre> <p>[EnableUUITel2IP]</p>	<p>Enables transfer of User-to-User (UU) IE from ISDN to SIP.</p> <ul style="list-style-type: none"> <li>[0] <b>Disable</b> (default)</li> <li>[1] <b>Enable</b></li> </ul> <p>The device supports the following ISDN-to-SIP interworking: Setup to SIP INVITE, Connect to SIP 200 OK, User Information to SIP INFO, Alerting to SIP 18x response, and Disconnect to SIP BYE response messages.</p> <p><b>Note:</b> The interworking of ISDN User-to-User IE to SIP INFO is applicable only to the Euro ISDN, QSIG, and 4ESS ISDN variants.</p>
<pre>'User-to-User IE for IP-to- Tel' configure voip &gt; gateway digital settings &gt; uui-ie- for-ip2tel</pre> <p>[EnableUUIIP2Tel]</p>	<p>Enables interworking of SIP user-to-user information (UUI) to User-to-User IE in ISDN Q.931 messages.</p> <ul style="list-style-type: none"> <li>[0] Check box cleared <input type="checkbox"/> = (Default) Disabled. Received UUI is not sent in ISDN message.</li> <li>[1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device interworks UUI from SIP to ISDN messages. The device supports the following SIP-to-ISDN interworking of UUI:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ SIP INVITE to Q.931 Setup</li> <li>✓ SIP REFER to Q.931 Setup</li> <li>✓ SIP 200 OK to Q.931 Connect</li> <li>✓ SIP INFO to Q.931 User Information</li> <li>✓ SIP 18x to Q.931 Alerting</li> <li>✓ SIP BYE to Q.931 Disconnect</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The interworking of ISDN User-to-User IE to SIP INFO is applicable only to the Euro ISDN, QSIG, and 4ESS ISDN variants.</li> <li>■ To interwork the UUIE header from SIP-to-ISDN messages with the 4ESS ISDN variant, the [ISDNGeneralCCBehavior] parameter must be set to 16384.</li> </ul>
[Enable911LocationIdIP2Tel]	<p>Enables interworking of Emergency Location Identification from SIP to PRI.</p> <ul style="list-style-type: none"> <li>■ [0] = Disabled (default)</li> <li>■ [1] = Enabled</li> </ul> <p>When enabled, the From header received in the SIP INVITE is translated into the following ISDN IE's:</p> <ul style="list-style-type: none"> <li>■ Emergency Call Control.</li> <li>■ Generic Information - to carry the Location Identification Number information.</li> <li>■ Generic Information - to carry the Calling Geodetic Location information.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the NI-2 ISDN variant.</p>
configure voip > gateway digital settings > early- answer-timeout [EarlyAnswerTimeout]	<p>Global parameter that defines the duration (in seconds) that the device waits for an ISDN Connect message from the called party (Tel side), started from when it sends a Setup message. You can also configure this feature per specific calls, using IP Profiles ('Early Answer Timeout' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see</p>

Parameter	Description														
	<p><a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>														
<p>'Trunk Transfer Mode'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; trk-xfer- mode-type</pre> <p>[TrunkTransferMode]</p>	<p>Determines the trunk transfer method (for all trunks) when a SIP REFER message is received. Parameter	Description
	<p>Trunk (RLT) (DMS-100), Two B Channel Transfer (TBCT) (NI2), Explicit Call Transfer (ECT) (EURO ISDN), and Path Replacement (QSIG). When a SIP REFER message is received, the device performs a transfer by sending Facility messages to the PBX with the necessary information on the call's legs to be connected. The different ISDN variants use slightly different methods (using Facility messages) to perform the transfer.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>✓ For RLT ISDN transfer, the parameter <code>SendISDNTransferOnConnect</code> must be set to 1.</li> <li>✓ The parameter <code>SendISDNTransferOnConnect</code> can be used to define if the TBCT/ECT transfer is performed after receipt of Alerting or Connect messages. For RLT, the transfer is always done after receipt of Connect (<code>SendISDNTransferOnConnect</code> is set to 1).</li> <li>✓ This transfer can be performed between B-channels from different trunks or Trunk Groups, by using the parameter <code>EnableTransferAcrossTrunkGroups</code>.</li> <li>✓ The device initiates the ECT process after receiving a SIP REFER message only for trunks that are configured to User side.</li> </ul> <p>■ [3] = Supports CAS Normal transfer. When a SIP REFER message is received, the device performs a Blind Transfer by executing a CAS Wink, dialing the Refer-to number to the switch, and then releasing the call.</p> <p>■ [4] = Supports QSIG Single Step transfer PRI and BRI:</p> <ul style="list-style-type: none"> <li>✓ IP-to-Tel: When a SIP REFER message is received, the device performs a transfer by sending a Facility message to the PBX, initiating Single Step transfer. Once a success return result is received, the transfer is completed.</li> <li>✓ Tel-to-IP: When a Facility message initiating Single Step transfer is received from the PBX, a SIP REFER message is sent to the IP side.</li> </ul> <p>■ [5] = IP-to-Tel Blind Transfer mode supported for ISDN PRI and BRI protocols and implemented according to AT&amp;T Toll Free Transfer Connect Service (TR 50075)</p>

Parameter	Description
	<p>“Courtesy Transfer-Human-No Data”. When the device receives a SIP REFER message, it performs a blind transfer by first dialing the DTMF digits (transfer prefix) defined by the parameter XferPrefixIP2Tel (configured to “*8” for AT&amp;T service), and then (after 500 msec) the device dials the DTMF of the number (referred) from the Refer-To header sip:URI userpart. If the hostpart of the Refer-To sip:URI contains the device's IP address, and if the Trunk Group selected according to the IP-to-Tel Routing table is the same Trunk Group as the original call, then the device performs the in-band DTMF transfer; otherwise, the device sends the INVITE according to regular transfer rules.</p> <p>After completing the in-band transfer, the device waits for the ISDN Disconnect message. If the Disconnect message is received during the first 5 seconds, the device sends a SIP NOTIFY with 200 OK message; otherwise, the device sends a NOTIFY with 4xx message.</p> <ul style="list-style-type: none"> <li>■ [6] = Supports AT&amp;T toll free out-of-band blind transfer for trunks configured with the 4ESS ISDN protocol. AT&amp;T courtesy transfer is a supplementary service which enables a user (e.g., user “A”) to transform an established call between it and user “B” into a new call between users “B” and “C”, whereby user “A” doesn't have a call established with user “C” prior to call transfer. The device handles this feature as follows: <ul style="list-style-type: none"> <li>✓ IP-to-Tel (user side): When a SIP REFER message is received, the device initiates a transfer by sending a Facility message to the PBX.</li> <li>✓ Tel-to-IP (network side): When a Facility message initiating an out-of-band blind transfer is received from the PBX, the device sends a SIP REFER message to the IP side (if the EnableNetworkISDNTransfer parameter is set to 1).</li> </ul> </li> </ul> <p><b>Note:</b> To configure trunk transfer mode per trunk, use the parameter TrunkTransferMode_x.</p>
[TrunkTransferMode_x]	Determines the trunk transfer mode per trunk (where x denotes the Trunk number). To configure trunk transfer mode for all trunks and for a description of the parameter options, refer to the parameter TrunkTransferMode.

Parameter	Description
[EnableTransferAcrossTrunkGroups]	<p>Determines whether the device allows ISDN ECT, RLT or TBCT IP-to-Tel call transfers between B-channels of different Trunk Groups.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable - ISDN call transfer is only between B-channels of the same Trunk Group.</li> <li>■ [1] = Enable - the device performs ISDN transfer between any two PSTN calls (between any Trunk Group) handled by the device.</li> </ul> <p>Note: The ISDN transfer also requires that you configure the parameter TrunkTransferMode_x to 2.</p>
[TransferCapabilityForDataCalls]	<p>Defines the ISDN Transfer Capability for data calls.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) ISDN Transfer Capability for data calls is 64k unrestricted (data).</li> <li>■ [1] = ISDN Transfer Capability for data calls is determined according to the ISDNTransferCapability parameter.</li> </ul>
'ISDN Transfer On Connect' configure voip > gateway digital settings > isdn- trsfr-on-conn [SendISDNTransferOnConnect]	<p>The parameter is used for the ECT/TBCT/RLT/Path Replacement ISDN transfer methods. Usually, the device requests the PBX to connect an incoming and outgoing call. The parameter determines if the outgoing call (from the device to the PBX) must be connected before the transfer is initiated.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Alert</b> = (Default) Enables ISDN Transfer if the outgoing call is in Alerting or Connect state.</li> <li>■ [1] <b>Connect</b> = Enables ISDN Transfer only if the outgoing call is in Connect state.</li> </ul> <p><b>Note:</b> For RLT ISDN transfer (TrunkTransferMode = 2 and ProtocolType = 14 DMS-100), the parameter must be set to 1.</p>
configure voip > gateway dtmf-supp- service supp- service-settings > isdn-xfer- complete-timeout [ISDNTransferCompleteTimeout]	<p>Defines the timeout (in seconds) for determining ISDN call transfer (ECT, RLT, or TBCT) failure. If the device doesn't receive any response to an ISDN transfer attempt within this user-defined time, the device identifies this as an ISDN transfer failure and subsequently performs a hairpin TDM connection or sends a SIP NOTIFY message with a SIP 603 response (depending whether hairpin is enabled or disabled, using the parameter DisableFallbackTransferToTDM).</p>

Parameter	Description
	The valid range is 1 to 10. The default is 4.
'Network ISDN Transfer' configure voip > sip-definition settings > network-isdn-xfer [EnableNetworkISDNTransf er]	<p>Determines whether the device allows interworking of network-side received ECT/TBCT Facility messages (NI-2 TBCT - Two B-channel Transfer and ETSI ECT - Explicit Call Transfer) to SIP REFER.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled. Rejects ISDN transfer requests.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. The device sends a SIP REFER message to the remote call party if ECT/TBCT Facility messages are received from the ISDN side (e.g., from a PBX).</li> </ul>
[DisableFallbackTransferTo TDM]	<p>Enables "hairpin" TDM transfer upon ISDN (ECT, RLT, or TBCT) call transfer failure. When this feature is enabled and an ISDN call transfer failure occurs, the device sends a SIP NOTIFY message with a SIP 603 Decline response.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) The device performs a hairpin TDM transfer upon ISDN call transfer.</li> <li>■ [1] = Hairpin TDM transfer is disabled.</li> </ul>
configure voip > gateway digital settings > isdn- ignore-18x- without-sdp [ISDNIgnore18xWithoutSD P]	<p>Enables interworking SIP 18x without SDP and ISDN Q.931 Progress/Alerting messages.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable. Incoming SIP 18x messages without SDP are replied by the device by PRACK (if required), but the device doesn't interwork these SIP messages with Q.931 Progress or Alerting messages (i.e., doesn't send to PSTN).</li> <li>■ [1] = (Default) Enable. The device interworks 18x SIP messages with Q.931 Progress and Alerting messages (if required) and sends them to the PSTN.</li> </ul>
configure voip > gateway digital settings > isdn- send-progress-for- te [ISDNSendProgressForTE]	<p>Defines whether the device sends Q.931 Progress messages to the ISDN trunk if the trunk is configured as User side (TE) and/or Network (NT) side, for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable. The device sends Progress messages to the trunk only if the trunk is configured as NT.</li> <li>■ [1] = (Default) Enable. The device sends Q.931 Progress messages to the trunk if the trunk is configured as TE or NT.</li> </ul>

Parameter	Description
	<p><b>Note:</b> To configure the trunk's ISDN termination side (TE or NT), use the 'ISDN Termination Side' parameter.</p>
<p>'Enable QSIG Transfer Update'</p> <pre>configure voip &gt; gateway digital settings &gt; qsig- xfer-update</pre> <p>[EnableQSIGTransferUpdate]</p>	<p>Determines whether the device interworks QSIG Facility messages with CallTransferComplete or CallTransferUpdate invoke application protocol data units (APDU) to SIP UPDATE messages with P-Asserted-Identity and optional Privacy headers. This feature is supported for IP-to-Tel and Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Ignores QSIG Facility messages with CallTransferComplete or CallTransferUpdate invokes.</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For example, assume A and C are PBX call parties and B is the SIP IP phone:</p> <ol style="list-style-type: none"> <li>1. A calls B; B answers the call.</li> <li>2. A places B on hold and calls C; C answers the call.</li> <li>3. A performs a call transfer (the transfer is done internally by the PBX); B and C are connected to one another.</li> </ol> <p>In the above example, the PBX updates B that it is now talking with C. The PBX updates this by sending a QSIG Facility message with CallTransferComplete invoke APDU. The device interworks this message to a SIP UPDATE message containing a P-Asserted-Identity header with the number and name derived from the QSIG CallTransferComplete RedirectionNumber and RedirectionName.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For IP-to-Tel calls, the RedirectionNumber and RedirectionName in the CallTransferComplete invoke is derived from the P-Asserted-Identity and Privacy headers in the received SIP INFO message.</li> <li>■ To include the P-Asserted-Identity header in outgoing SIP UPDATE messages, set the AssertedIDMode parameter to <b>Add P-Asserted-Identity</b>.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; isdn- ntt-noid-</pre>	<p>Defines SIP-ISDN interworking between NTT Japan's No-ID cause in the Facility information element (IE) of the ISDN Setup message, and the calling party number (display name) in the From header of the SIP INVITE message. The No ID</p>

Parameter	Description
<code>interworking-mode</code> <code>[ISDNttNoidInterworking Mode]</code>	<p>cause in the Facility IE indicates one of four reasons (see list of mapping below), for example, why the call was blocked.</p> <ul style="list-style-type: none"> <li>■ [0] =(Default) No interworking of No-ID cause.</li> <li>■ [1] = Interwork No-ID cause only from IP to Tel.</li> <li>■ [2] = Interwork No-ID cause only from Tel to IP.</li> <li>■ [3] = Interwork No-ID cause from IP-to-Tel side and Tel-to-IP side.</li> </ul> <p>The following lists the mapping between the SIP display name in the From header and the cause of the Facility IE in the ISDN Setup message (SIP:ISDN):</p> <ul style="list-style-type: none"> <li>■ Unavailable: IE[03]=1c 11 91 a1 0e 02 01 00 06 06 02 83 38 66 01 01 0a 01 00</li> <li>■ Anonymous: IE[03]=1c 11 91 a1 0e 02 01 00 06 06 02 83 38 66 01 01 0a 01 01</li> <li>■ Interaction with other service: IE[03]=1c 11 91 a1 0e 02 01 00 06 06 02 83 38 66 01 01 0a 01 02</li> <li>■ Coin line/payphone: IE[03]=1c 11 91 a1 0e 02 01 00 06 06 02 83 38 66 01 01 0a 01 03</li> </ul> <p>Below shows an example of an ISDN No-ID cause mapped to SIP for "Interaction with other service":</p> <div style="background-color: #f0f0f0; padding: 10px; border-radius: 5px;"> <p>From: "Interaction with other service"          &lt;sip:anonymous@anonymous.invalid;pstn-params=9082828088&gt;;tag=gK09696ce6</p> </div> <p><b>Note:</b> The parameter is applicable only to Trunks configured with the JAPAN NTT ISDN PRI (T1) protocol variant (i.e., [ProtocolType] parameter configured to 16).</p>
<code>is-cas-sndhook-flsh</code> <code>[CASSendHookFlash]</code>	<p>Enables sending Wink signal toward CAS trunks.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p>If the device receives a mid-call SIP INFO message with flashhook event body (as shown below) and the parameter is set to 1, the device generates a wink signal toward the CAS trunk. The CAS wink signal is done by changing the A bit from 1 to 0, and then back to 1 for 450 msec.</p>

Parameter	Description
	<pre>INFO sip:4505656002@192.168.13.40:5060 SIP/2.0 Via: SIP/2.0/UDP 192.168.13.2:5060 From: &lt;sip:06@192.168.13.2:5060&gt; To: &lt;sip:4505656002@192.168.13.40:5060&gt;;tag= 132878796-1040067870294 Call-ID: 0010-0016-D69A7DA8- 1@192.168.13.2 CSeq:2 INFO Content-Type: application/broadsoft Content-Length: 17 event flashhook</pre> <p><b>Note:</b> The parameter is applicable only to T1 CAS protocols.</p>
<pre>configure voip &gt; gateway digital settings &gt; cug- data-mode [CugDataMode]</pre>	<p>Enables interworking between the ISDN Closed User Group (CUG) supplementary service and SIP, for Tel-to-IP calls. The CUG supplementary service enables users to form groups, where members of a specific closed user group can communicate among themselves but not, in general, with users outside the group. If the parameter is enabled and the device receives an ISDN Setup message whose Facility IE indicates CUG (cUGCall invoke), it adds an XML body containing CUG information (CUG index and outgoing access) to the outgoing SIP INVITE message.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable. The device doesn't add the XML body containing CUG information to the outgoing SIP INVITE message.</li> <li>■ [1] = Enable. The device adds the XML body containing CUG information to the outgoing SIP INVITE message.</li> </ul> <p>The following shows an example of an added XML body containing CUG information:</p> <pre>&lt;?xml version="1.0" encoding="utf-8"?&gt; &lt;xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema" xmlns="http://uri.etsi.org/ngn/params/xml/simserv</pre>

Parameter	Description

## Tone Parameters

This subsection describes the device's tone parameters.

### Telephony Tone Parameters

The telephony tone parameters are described in the table below.

**Table 73-60:Tone Parameters**

Parameter	Description
'Maximum simultaneous streaming calls' <code>max-streaming-calls</code> <code>[MaxStreamingCalls]</code>	<p>Defines the maximum number of concurrent call parties that have been placed on hold to which the device can play Music on Hold (MoH) that originates from an external media player.</p> <p>The maximum is 20. The default is 0.</p> <p>For more information, see <a href="#">Configuring MoH from External Audio Source</a> on page 1034.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ Each FXS port supports up to 20 concurrent MoH sessions.</li> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
'SIP Hold Behavior' <code>configure voip &gt; sip-definition settings &gt; sip-hold-behavior</code> <code>[SIPHoldBehavior]</code>	<p>Enables the device to handle incoming re-INVITE messages with the "a=sendonly" attribute in the SDP, in the same way as if an "a=inactive" is received in the SDP. When enabled, the device plays a held tone to the Tel phone and responds with a SIP 200 OK containing the "a=recvonly" attribute in the SDP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to analog interfaces.</p>
'Dial Tone Duration' <code>configure voip &gt; gateway dtmf-suppress-service dtmf-and-dialing &gt; dt-duration</code> <code>[TimeForDialTone]</code>	<p>Defines the duration (in seconds) that the dial tone is played.</p> <p>Digital interfaces: The device plays the tone to an ISDN terminal. The parameter is applicable for overlap dialing if you configure the <code>[ISDNInCallsBehavior]</code> parameter to 65536. The dial tone is played if the ISDN Setup message doesn't include the called number. The valid range is 0 to 60. The default is 5.</p> <p>Analog interfaces: The device's FXS interfaces play the dial tone after the phone is picked up (off-</p>

Parameter	Description
	<p>hook). FXO interfaces play the dial tone after the port is seized in response to ringing (from PBX/PSTN). The valid range is 0 to 60. The default time is 16.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Analog interfaces: During play of dial tone, the device waits for DTMF digits.</li> <li>■ Analog interfaces: The parameter is not applicable when Automatic Dialing is enabled.</li> </ul>
<p>'Stutter Tone Duration'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; sttr- tone-duration [StutterToneDuration]</pre>	<p>Defines the duration (in msec) of the confirmation tone. A stutter tone is played (instead of a regular dial tone) when a Message Waiting Indication (MWI) is received. The stutter tone is composed of a confirmation tone (Tone Type #8), which is played for the defined duration (StutterToneDuration) followed by a stutter dial tone (Tone Type #15). Both these tones are defined in the CPT file.</p> <p>The range is 1,000 to 60,000. The default is 2,000 (i.e., 2 seconds).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ If you want to configure the duration of the confirmation tone to longer than 16 seconds, you must increase the value of the parameter TimeForDialTone accordingly.</li> <li>■ The MWI tone overrides the call forwarding reminder tone. For more information on MWI, see <a href="#">Message Waiting Indication</a> on page 1051.</li> </ul>
<p>'FXO AutoDial Play BusyTone'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; fxo- autodial-play-bsytn [FXOAutoDialPlayBusyTone]</pre>	<p>Enables the device to play a busy / reorder tone to the PSTN side if a Tel-to-IP call is rejected by a SIP error response (4xx, 5xx or 6xx). If a SIP error response is received, the device seizes the line (off-hook), and then plays a busy / reorder tone to the PSTN side (for the duration defined by the parameter TimeForReorderTone). After playing the tone, the line is released (on-hook).</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXO interfaces.</p>
<p>'Hotline Dial Tone Duration'</p> <pre>configure voip &gt; gateway dtmf-supp-service dtmf- and-dialing &gt; hotline-dt- dur</pre> <p>[HotLineToneDuration]</p>	<p>Defines the duration (in seconds) of the hotline dial tone. If no digits are received during this duration, the device initiates a call to a user-defined number (configured in the Automatic Dialing table - TargetOfChannel - see <a href="#">Configuring Automatic Dialing</a> on page 1095).</p> <p>The valid range is 0 to 60. The default is 16.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to analog interfaces.</li> <li>■ You can define the Hotline duration per FXS /FXO port using the Automatic Dialing table.</li> </ul>
<p>'Reorder Tone Duration'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; reorder-tone-duration</pre> <p>[TimeForReorderTone]</p>	<p>Defines the duration (in seconds) that the device plays a busy or reorder tone before releasing the line.</p> <p>You can also configure this feature per specific calls, using Tel Profiles ('Time For Reorder Tone' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the device ignores this global parameter for calls associated with the Tel Profile.</p>
<p>'Time Before Reorder Tone'</p> <pre>configure voip &gt; gateway advanced &gt; time-b4- reordr-tn</pre> <p>[TimeBeforeReorderTone]</p>	<p>Defines the delay interval (in seconds) from when the device receives a SIP BYE message (i.e., remote party terminates call) until the device starts playing a reorder tone to the FXS phone.</p> <p>The valid range is 0 to 60. The default is 0.</p> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>
<p>'Cut Through Reorder Tone Duration'</p> <pre>configure voip &gt; gateway</pre>	<p>Defines the duration (in seconds) of the reorder tone played to the Tel side after the IP call party</p>

Parameter	Description
<code>digital settings &gt; cut-thru-reord-dur</code> <code>[CutThroughTimeForReOrderTone]</code>	<p>releases the call, for the Cut-Through feature. After the tone stops playing, an incoming call is immediately answered if:</p> <ul style="list-style-type: none"> <li>■ Analog interfaces: The FXS is off-hooked.</li> <li>■ Digital interfaces: The PSTN is connected.</li> </ul> <p>The valid values are 0 to 30. The default is 0 (i.e., no reorder tone is played).</p> <p><b>Note:</b> To enable the Cut-Through feature:</p> <ul style="list-style-type: none"> <li>■ CAS channels: DigitalCutThrough parameter</li> <li>■ FXS channels: CutThrough parameter</li> </ul>
<p>'Enable Comfort Tone'</p> <code>comfort-tone</code> <code>[EnableComfortTone]</code>	<p>Defines if the device plays a comfort tone (Tone Type #18) to the FXS /FXO endpoint after the SIP INVITE message is sent and before a SIP 18x response is received.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> The parameter is applicable to FXS and FXO interfaces.</p>
<code>[WarningToneDuration]</code>	<p>Defines the duration (in seconds) for which the offhook warning tone is played to the user. The valid range is -1 to 2,147,483,647. The default is 600.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ A negative value indicates that the tone is played infinitely.</li> <li>■ The parameter is applicable only to analog interfaces.</li> </ul>
<p>'Play Busy Tone to Tel'</p> <code>configure voip &gt; sip-definition settings &gt; play-bsy-tone-2tel</code> <code>[PlayBusyTone2ISDN]</code>	<p>Enables the device to play a busy or reorder tone to the PSTN after a Tel-to-IP call is released.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Don't Play</b> = (Default) Immediately sends an ISDN Disconnect message.</li> <li>■ [1] <b>Play when Disconnecting</b> = Sends an ISDN Disconnect message with PI = 8 and plays a busy or reorder tone to the PSTN (depending on the release cause).</li> </ul>

Parameter	Description
	<p>■ [2] <b>Play before Disconnect</b> = Delays the sending of an ISDN Disconnect message for a user-defined time (configured by the TimeForReorderTone parameter) and plays a busy or reorder tone to the PSTN. This is applicable only if the call is released from the IP [Busy Here (486) or Not Found (404)] before it reaches the Connect state; otherwise, the Disconnect message is sent immediately and no tones are played.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<pre>configure voip &gt; gateway digital settings &gt; q850- reason-code-2play-user- tone</pre> <p>[Q850ReasonCode2PlayUserTone]</p>	<p>Defines an ISDN Q.8931 release cause code(s), which if mapped to the SIP release reason received from the IP side, causes the device to play a user-defined tone from the installed PRT file to the Tel side. For example, if the received SIP release cause is 480 Temporarily Unavailable and you configure the parameter with Q.931 release code 18 (No User Responding), the device plays the user-defined tone to the Tel side.</p> <p>The user-defined tone is configured when creating the PRT file, using AudioCodes DConvert utility. The tone must be assigned to the "acSpecialConditionTone" (Tone Type 21) option in DConvert.</p> <p>The parameter can be configured with up to 10 release codes. When configuring multiple codes, separate the codes by commas (without spaces). For example:</p> <pre>Q850ReasonCode2PlayUserTone = 1, 18, 24</pre> <p>If the SIP release reason received from the IP side is mapped to the Q.931 release code specified by the parameter, the device plays the user-defined tone. Otherwise, if not specified and the release code is 17 (User Busy), the device plays the busy tone and for all other release codes, the device plays the reorder tone.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ To enable the feature, the 'Play Busy Tone to Tel' (PlayBusyTone2ISDN) parameter must be enabled (set to 1 or 2).</li> </ul>
'Play Ringback Tone to Tel' configure voip > sip- definition settings > play-rbt2tel [PlayRBTone2Tel]	<p>Defines the playing method of the ringback tone to the Tel side.</p> <p>Digital interfaces: The parameter applies to all trunks that are not configured by the [PlayRBTone2Trunk] parameter, which defines ringback tone per Trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Don't Play</b> =               <ul style="list-style-type: none"> <li>✓ Analog Interfaces: Ringback tone is not played.</li> <li>✓ Digital Interfaces: The device doesn't play a ringback tone. No Progress Indicator (PI) is sent to the ISDN, unless the [ProgressIndicator2ISDN_x] parameter is configured differently.</li> </ul> </li> <li>■ [1] <b>Play on Local</b> =               <ul style="list-style-type: none"> <li>✓ Analog interfaces: Plays a ringback tone to the Tel side of the call when a SIP 180/183 response is received.</li> <li>✓ Digital interfaces:                   <ul style="list-style-type: none"> <li>● CAS: The device plays a local ringback tone to the PSTN upon receipt of a SIP 180 Ringing response (with or without SDP). Note that the receipt of a 183 response doesn't cause the device to play a ringback tone, unless the [SIP183Behaviour] parameter is configured to 1.</li> <li>● ISDN: The device behaves according to the [LocalISDNRBSrc] parameter:                       <ol style="list-style-type: none"> <li>1) If the device receives a SIP 180</li> </ol> </li> </ul> </li> </ul> </li> </ul>

Parameter	Description
	<p>Ringing response (with or without SDP) and the [LocalISDNRBSource] parameter is configured to 1, it plays a ringback tone and sends an ISDN Alert with PI = 8, unless the [ProgressIndicator2ISDN_x] parameter is configured differently.</p> <p>2) If the [LocalISDNRBSource] parameter is configured to 0, the device doesn't play a ringback tone and an Alert message without PI is sent to the ISDN. In this case, the PBX / PSTN plays the ringback tone to the originating terminal. Note that the receipt of a 183 response doesn't cause the device to play a ringback tone; the device sends a Progress message, unless [SIP183Behaviour] is configured to 1. If the [SIP183Behaviour] parameter is configured to 1, the 183 response is handled the same way as a 180 Ringing response.</p> <p>■ [2] <b>Prefer IP</b> = (Default):</p> <ul style="list-style-type: none"> <li>✓ Analog interfaces: Plays a ringback tone to the Tel side only if a 180/183 response without SDP is received. If 180/183 with SDP message is received, the device cuts through the voice channel and doesn't play the ringback tone.</li> <li>✓ Digital interfaces: The device plays a ringback tone according to 'Early Media'. If a SIP 180 response is received and the voice channel is already open (due to a previous 183 early media response or due to an SDP in the current 180 response), the device configured for ISDN or CAS doesn't play the ringback tone; PI = 8 is sent in an ISDN Alert message, unless the [ProgressIndicator2ISDN_x] parameter is configured differently.</li> </ul> <p>When there are multiple 18x responses, if</p>

Parameter	Description
	<p>a 18x response without SDP is received after the remote media is played (due to a previously received 18x with SDP), the device plays the local media instead of the remote, until a new 18x with SDP is received.</p> <ul style="list-style-type: none"> <li>• CAS: If a 180 response is received, but the 'early media' voice channel is not opened, the device plays a ringback tone to the PSTN.</li> <li>• ISDN: If a 180 response is received, but the 'early media' voice channel is not opened, the device configured for ISDN operates according to the [LocalISDNRBSource] parameter:             <ol style="list-style-type: none"> <li>1) [LocalISDNRBSource] configured to 1: The device plays a ringback tone and sends an ISDN Alert with PI = 8 to the ISDN (unless the [ProgressIndicator2ISDN_x] parameter is configured differently).</li> <li>2) [LocalISDNRBSource] configured to 0: The device doesn't play a ringback tone. No PI is sent in the ISDN Alert message, unless the [ProgressIndicator2ISDN_x] parameter is configured differently. In this case, the PBX / PSTN plays a ringback tone to the originating terminal. Note that the receipt of a 183 response results in an ISDN Progress message, unless [SIP183Behaviour] is configured to 1. If [SIP183Behaviour] is configured to 1 (183 is handled the same way as a 180 with SDP), the device sends an Alert message with PI = 8 without playing a ringback tone..</li> </ol> </li> </ul> <p>■ [3] <b>Play Local Until Remote Media Arrive</b> = The device plays a ringback tone according to the received media. The behavior is similar to</p>

Parameter	Description
	<p>option [2]. If a SIP 180 response is received and the voice channel is already open (due to a previous 183 early media response or due to an SDP in the current 180 response), the device plays a local ringback tone if there are no prior received RTP packets. The device stops playing the local ringback tone as soon as it starts receiving RTP packets. At this stage, if the device receives additional 18x responses, it doesn't resume playing the local ringback tone.</p> <p><b>Note:</b> For ISDN trunks, this option is applicable only if the [LocalISDNRBSource] parameter is configured to 1.</p>
<p>'Play Ringback Tone to IP'</p> <pre>configure voip &gt; sip- definition settings &gt; play-rbt-2ip</pre> <p>[PlayRBTone2IP]</p>	<p>Global parameter that enables the device to play a ringback tone to the IP side for IP-to-Tel calls. You can also configure this feature per specific calls, using IP Profiles ('Play RB Tone to IP' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Play Local RBT on ISDN Transfer'</p> <pre>configure voip &gt; gateway digital settings &gt; play- l-rbt-isdn-trsfr</pre> <p>[PlayRBTOnISDNTransfer]</p>	<p>Determines whether the device plays a local ringback tone for ISDN's Two B Channel Transfer (TBCT), Release Line Trunk (RLT), or Explicit Call Transfer (ECT) call transfers to the originator when the second leg receives an ISDN Alerting or Progress message.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Don't Play</b> (default)</li> <li>■ [1] <b>Play</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For Blind transfer, the local ringback tone is played to first call PSTN party when the second leg receives the ISDN Alerting or Progress message.</li> <li>■ For Consulted transfer, the local ringback tone</li> </ul>

Parameter	Description
	<p>is played when the second leg receives ISDN Alerting or Progress message if the Progress message is received after a SIP REFER.</p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the parameter SendISDNTransferOnConnect is set to 1.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'MFC R2 Category'</p> <pre>configure voip &gt; gateway digital settings &gt; mfcr2- category</pre> <p>[R2Category]</p>	<p>Defines the tone for MFC R2 calling party category (CPC). The parameter provides information on the calling party such as National or International call, Operator or Subscriber and Subscriber priority.</p> <p>The value range is 1 to 15 (defining one of the MFC R2 tones). The default is 1.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>

### Tone Detection Parameters

The signal tone detection parameters are described in the table below.

**Table 73-61:Tone Detection Parameters**

Parameter	Description
<pre>dtmf-detector-enable</pre> <p>[DTMFDetectorEnable]</p>	<p>Enables the detection of DTMF signaling.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable</li> <li>■ [1] = (Default) Enable</li> </ul>
<pre>mfr1-detector-enable</pre> <p>[MFR1DetectorEnable]</p>	<p>Enables the detection of MF-R1 signaling.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul>
<pre>mf-transport-type</pre> <p>[MFTransportType]</p>	<p>Defines the method for sending MF digits over the network to the remote side.</p> <ul style="list-style-type: none"> <li>■ [0] = (Mute) MF digits are erased from the audio stream and are not relayed to the remote side. Instead, silence is sent in the RTP stream.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] = (Transparent) MF digits are left in the audio stream and MF relay is disabled.</li> <li>■ [3] = (Default) (RFC 2833 Relay) MF digits are relayed to the remote side using the RFC 2833 Relay syntax.</li> </ul>
[R1DetectionStandard]	<p>Determines the MF-R1 protocol used for detection.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) ITU</li> <li>■ [1] = R1.5</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
user-defined-tones-detector-enable [UserDefinedToneDetectorEnable]	<p>Enables the detection of User Defined Tones signaling, applicable for Special Information Tone (SIT) detection.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul>
sit-detector-enable [SITDetectorEnable]	<p>Enables SIT detection according to the ITU-T recommendation E.180/Q.35.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p>Digital interfaces: To disconnect IP-to-ISDN calls when a SIT tone is detected, configure the following parameters:</p> <ul style="list-style-type: none"> <li>■ [SITDetectorEnable = 1]</li> <li>■ [UserDefinedToneDetectorEnable = 1]</li> <li>■ [ISDNDisconnectOnBusyTone = 1] (applicable for Busy, Reorder and SIT tones)</li> </ul> <p>Digital interfaces: Another parameter for handling the SIT tone is [SITQ850Cause], which defines the Q.850 cause value specified in the SIP Reason header that is included in a 4xx response when a SIT tone is detected on an IP-to-Tel call.</p> <p>To disconnect IP-to-Tel calls when a SIT tone is detected, configure the following parameters:</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [SITDetectorEnable = 1]</li> <li>■ [UserDefinedToneDetectorEnable = 1]</li> <li>■ [DisconnectOnBusyTone = 1] (applicable for busy, reorder, and SIT tones)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The IP-to-ISDN call is disconnected on detection of a SIT tone only in call alert state. If the call is in connected state, the SIT doesn't disconnect the call. Detection of busy or reorder tones disconnect these calls also in call connected state.</li> <li>■ For IP-to-CAS calls, detection of busy, reorder, or SIT tones disconnect the call in any call state.</li> </ul>
udt-detector-frequency-deviation [UDTDetectorFrequencyDeviation]	Defines the deviation (in Hz) allowed for the detection of each signal frequency. The valid range is 1 to 50. The default is 50. <b>Note:</b> For the parameter to take effect, a device restart is required.
cpt-detector-frequency-deviation [CPTDetectorFrequencyDeviation]	Defines the deviation (in Hz) allowed for the detection of each CPT signal frequency. The valid range is 1 to 30. The default is 10. <b>Note:</b> For the parameter to take effect, a device restart is required.

## Metering Tone Parameters

The metering tone parameters are described in the table below.

**Table 73-62: Metering Tone Parameters**

Parameter	Description
'Generate Metering Tones' configure voip > gateway analog metering-tones > gen-mtr-tones	Defines the method for configuring metering tones that are generated to the Tel side. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Metering tones are not</li> </ul>

Parameter	Description
[PayPhoneMeteringMode]	<p>generated.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Charge Code Table</b> = Metering tones are generated by the device according to the Charge Code table (see <a href="#">Configuring Charge Codes</a> on page 1082) and sent to the Tel side.</li> <li>■ [2] <b>SIP Interval Provided</b> = (Proprietary method of TELES Communications Corporation) Advice-of-Charge service toward the PSTN. Periodic generation of AOC-D and AOC-E toward the PSTN. Calculation is based on seconds. The time interval is calculated according to the scale and tariff provided in the proprietary formatted file included in SIP INFO messages, which is always sent before 200 OK. The device ignores tariffs sent after the call is established. <p><b>Note:</b> This option is applicable only to digital interfaces.</p> </li> <li>■ [3] <b>SIP RAW Data Provided</b> = (Proprietary method of Cirpack) Advice-of-Charge service toward the PSTN. The received AOC-D messages contain a subtotal. When receiving AOC-D in raw format, provided in the header of SIP INFO messages, the device parses AOC-D raw data to obtain the number of units. This number is sent in the Facility message with AOC-D. In addition, the device stores the latest number of units in order to send them in AOC-E IE when the call is disconnected. <p><b>Note:</b> This option is applicable only to digital interfaces.</p> </li> <li>■ [4] <b>SIP RAW Data Incremental Provided</b> = (Proprietary method of Cirpack) Advice-of-Charge service toward the PSTN. The AOC-D message in the payload is an increment. When receiving AOC-D in raw format, provided in the header of SIP INFO messages, the device parses AOC-D raw data to obtain the number of units. This number is sent in the Facility message with AOC-D. The device generates the AOC-E. Parsing every AOC-D received and summing the values</li> </ul>

Parameter	Description
	<p>is required to obtain the total sum (that is placed in the AOC-E).</p> <p><b>Note:</b> This option is applicable only to digital interfaces.</p> <p>■ [5] <b>SIP-to-Tel Interworking</b> = Enables IP-to-Tel AOC, using the AudioCodes proprietary SIP header, AOC.</p> <p><b>Note:</b> This option is applicable only to digital interfaces.</p> <p><b>Note:</b> The parameter is applicable only to FXS and ISDN Euro trunks for sending AOC Facility messages (see <a href="#">Advice of Charge Services for Euro ISDN</a> on page 1079).</p>
<p>'Analog Metering Type'</p> <pre>configure voip &gt; interface fxs-fxo &gt; metering-type [MeteringType]</pre>	<p>Defines the metering method for generating pulses (sinusoidal metering burst frequency) by the FXS port.</p> <p>■ [0] <b>12 KHz sinusoidal bursts</b> (default)</p> <p>■ [1] <b>16 kHz sinusoidal bursts</b></p> <p>■ [2] <b>Polarity Reversal pulses</b></p> <p><b>Note:</b></p> <p>■ For the parameter to take effect, a device restart is required.</p> <p>■ The parameter is applicable only to FXS interfaces.</p>
<p>'Analog TTX Voltage Level'</p> <p>[AnalogTTXVoltageLevel ]</p>	<p>Determines the metering signal/pulse voltage level (TTX).</p> <p>■ [0] <b>0V</b> = 0 Vrms sinusoidal bursts.</p> <p>■ [1] <b>0.5V</b> = (Default) 0.5 Vrms sinusoidal bursts.</p> <p>■ [2] <b>1V</b> = 1 Vrms sinusoidal bursts</p> <p><b>Note:</b></p> <p>■ For the parameter to take effect, a device restart is required.</p> <p>■ The parameter is applicable only to FXS interfaces.</p>

Parameter	Description
[ISDNAoCAmountPerInterval]	<p>Defines the amount (units) charged per interval. The default is 1.</p> <p><b>Note:</b> The parameter is applicable only to the Euro ISDN protocol (Advice of Charge supplementary services).</p>
[ISDNAoCMinIntervalGeneration]	<p>Defines the interval for sending the AOC messages. The default is 0 (meaning that the interval is according to the Charge Codes table).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Euro ISDN protocol (Advice of Charge supplementary services).</li> <li>■ The parameter doesn't affect the interval charge amount.</li> <li>■ The parameter is ignored if its' value is less than the interval configured in the Charge Codes table ('Interval' parameter).</li> </ul>

## Telephone Keypad Key Sequence Parameters

The telephony keypad key sequence parameters are described in the table below.

**Table 73-63:Telephone Keypad Key Sequence Parameters**

Parameter	Description
<p>'Call Pickup Key'</p> <pre>configure voip &gt; sip- definition settings &gt; call-pickup-key</pre> <p>[KeyCallPickup]</p>	<p>Defines the key sequence on the phone's keypad for performing a call pick-up. Call pick-up allows the FXS endpoint to answer another telephone's incoming call by pressing this user-defined sequence of digits. When the user dials these digits (e.g., #77), incoming calls from another phone is forwarded to the user's phone.</p> <p>The valid value is a string of up to 15 characters (0-9, #, and *). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Call pick-up is configured only for FXS endpoints pertaining to the same Trunk Group.</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>

Parameter	Description
<pre>configure voip &gt; gateway analog keypad-features key-port-configure</pre> <p>[KeyPortConfigure]</p>	<p>Defines the key sequence on the phone's keypad for configuring a phone number for the FXS phone that is connected to the device's FXS port.</p> <p>To configure the phone number:</p> <ol style="list-style-type: none"> <li>1. Press the keys on the keypad to enter the configured key sequence.</li> <li>2. Press the keys on the keypad to enter the phone number.</li> <li>3. Press the number sign key (#) to complete configuration.</li> </ol> <p>For example, if you configured the parameter to "*81" and you want the phone number to be 9764004, press the following keys on the keypad: *819764004#.</p> <p>To delete the phone number, simply press the configured key sequence with the # key at the end (e.g., *81#).</p> <p>The valid value is a string of up to 16 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You must assign the FXS port to a Trunk Group (in the Trunk Groups table) that is dedicated <b>only</b> to this port. The Trunk Group can be configured with or without a phone number, which you can change or delete by using this parameter.</li> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>configure voip &gt; gateway analog fxs-setting &gt; prefix-to-ext-line</pre> <p>[Prefix2ExtLine]</p>	<p>Defines a prefix (e.g., digit 9 dialed for an external line) that when dialed, the device plays a secondary dial tone (i.e., stutter tone) to the FXS line and then starts collecting the subsequently dialed digits from the FXS line.</p> <p>The valid value is a string of up to three characters, which can include digits (0-9), #, and * (e.g., *72). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can enable the device to add this string as the prefix to the collected (and sent) digits, using</li> </ul>

Parameter	Description
	<p>the [AddPrefix2ExtLine] parameter.</p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> </ul>
<pre>configure voip &gt; gateway manipulation settings &gt; prefix-2-ext-line [AddPrefix2ExtLine]</pre>	<p>Enables the device to add the prefix string for accessing an external line (configured by the [Prefix2ExtLine] parameter) to the dialed (called) number as the prefix, which is sent to the IP destination (for Tel-to-IP calls).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disabled - the device doesn't add the prefix string for accessing the external line to the collected and sent dialed number. For example, if you configure the [Prefix2ExtLine] parameter to "9" and the FXS endpoint makes a call to destination number "123", the device collects and sends only the destination number digits "123" (i.e., without the prefix string) to the IP destination.</li> <li>■ [1] = Enables the device to add the prefix string for accessing the external line to the dialed number as the prefix, which is sent to the IP destination. For example, if you configure the [Prefix2ExtLine] parameter to "9" and the FXS endpoint makes a call to destination number "123", the device collects and sends all the dialed digits, including the prefix string "9", as "9123" to the IP destination.</li> <li>■ [2] = Same as option [1], but in addition, the device uses the prefix string for accessing the external line as the first digit in configured patterns of Digit Maps and/or Dial Plans. This option is useful in that it allows you to configure separate patterns for internal and external dialing. For example, if you configure the [Prefix2ExtLine] parameter to "9" and configure digit map patterns "2xxx 92xxxxxxx", the device considers dialed numbers between 2000 and 2999 (2xxx) as internal extensions (i.e., when "9" is not dialed for an external line), and if the first dialed digit (prefix) is "9" (for accessing the external line), considers dialed numbers</li> </ul>

Parameter	Description
	<p>between 20000000 and 299999999 (92xxxxxxx) as external numbers.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The parameter is applicable only to Tel-to-IP calls.</li> </ul>
<b>Hook Flash Parameters</b>	
<p>'Flash Keys Sequence Style'</p> <pre>configure voip &gt; gateway dtmf-supp-service supp- service-settings &gt; flash-key-seq-style [FlashKeysSequenceStyle]</pre>	<p>Defines the hook-flash key sequence for FXS interfaces.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Flash hook</b> = (Default) Only the phone's flash button is used for the following scenarios: <ul style="list-style-type: none"> <li>✓ During an existing call, if the user presses the flash button, the call is put on hold. A dial tone is heard and the user can then make a second call. Once the second call is established, on-hooking transfers the first (held) call to the second call.</li> <li>✓ During an existing call, if there is a second incoming call, pressing the flash button places the existing call on hold and answers the waiting call. Pressing flash again toggles between these two calls.</li> </ul> </li> <li>■ [1] <b>Sequence 1</b> = Sequence of flash button with a digit: <ul style="list-style-type: none"> <li>✓ Flash + 1: Holds a call or toggles between two existing calls</li> <li>✓ Flash + 2: Makes a call transfer.</li> <li>✓ Flash + 3: Makes a three-way conference call if the three-way conferencing is enabled (i.e., the [Enable3WayConference] parameter is configured to 1 and [3WayConferenceMode] to 2).</li> </ul> </li> <li>■ [2] <b>Sequence 2</b> = Sequence of flash button with a digit: <ul style="list-style-type: none"> <li>✓ Flash only: Places the call on hold.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Flash + 1: <ul style="list-style-type: none"> <li>• When the device handles two calls (an active and a held call) and this key sequence is pressed, it sends a SIP BYE message to the active call, and the previously held call becomes the active call.</li> <li>• When there is an active call and an incoming waiting call, if this key sequence is pressed, the device disconnects the active call and the waiting call becomes the active call.</li> </ul> </li> <li>✓ Flash + 2: Places a call on hold and answers a call-waiting call, or toggles between active and on-hold calls.</li> <li>✓ Flash + 3: Makes a three-way conference call. This is applicable only if the [Enable3WayConference] parameter is configured to 1 and [3WayConferenceMode] to 2. Note that the device ignores the setting of the [ConferenceCode] parameter.</li> <li>✓ Flash + 4: Makes a call transfer.</li> </ul> <p><b>Note:</b> The parameter is applicable only to FXS interfaces.</p>
'Flash Keys Sequence Timeout' flash-key-seq-tmout [FlashKeysSequenceTimeout]	Defines the flash keys sequence timeout (in msec) that the device waits for digits after the user presses the flash button (flash hook + digit - when the [FlashKeysSequenceStyle] parameter is configured to 1 or 2).  The valid range is 100 to 5,000. The default is 2,000.
<b>Keypad Feature - Call Forward Parameters</b>	
'Forward Unconditional' configure voip > gateway analog keypad-features > fwd-unconditional [KeyCFUnCond]	Defines the key sequence on the keypad to activate the immediate call forward option.

Parameter	Description
<b>'Forward No Answer'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>fwd-no-answer</code> <b>[KeyCFNoAnswer]</b>	Defines the key sequence on the keypad to activate the forward on no answer option.
<b>'Forward On Busy'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>fwd-on-busy</code> <b>[KeyCFBusy]</b>	Defines the key sequence on the keypad to activate the forward on busy option.
<b>'Forward On Busy or No Answer'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>fwd-busy-or-no-ans</code> <b>[KeyCFBusyOrNoAnswer]</b>	Defines the key sequence on the keypad to activate the forward on 'busy or no answer' option.
<b>'Do Not Disturb'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>fwd-dnd</code> <b>[KeyCFDoNotDisturb]</b>	Defines the key sequence on the keypad to activate the Do Not Disturb option (immediately reject incoming calls).  <b>Note:</b> You can't configure a call forwarding destination for this Do Not Disturb feature.
To activate the required call forward method, using the telephone: <ol style="list-style-type: none"> <li>1. Dial the user-defined sequence number on the keypad; a dial tone is heard.</li> <li>2. Dial the telephone number to which the call is forwarded (terminate the number with #); a confirmation tone is heard.</li> </ol>	
<b>'Forward Deactivate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>fwd-deactivate</code> <b>[KeyCFDeact]</b>	Defines the key sequence on the keypad to deactivate any of the call forward options. After the sequence is pressed, a confirmation tone is heard.
<b>Keypad Feature - Caller ID Restriction Parameters</b>	
<b>'Restricted Caller ID Activate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>id-restriction-act</code> <b>[KeyCLIR]</b>	Defines the key sequence on the keypad to activate the restricted Caller ID option. After the sequence is pressed, a confirmation tone is heard.

Parameter	Description
<b>'Restricted Caller ID Deactivate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>id-restriction-deact</code> <b>[KeyCLIRDeact]</b>	Defines the key sequence on the keypad to deactivate the restricted Caller ID option. After the sequence is pressed, a confirmation tone is heard.
<b>Keypad Feature - Hotline Parameters</b>	
<b>'Hot-line Activate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>hotline-act</code> <b>[KeyHotLine]</b>	Defines the key sequence on the keypad to activate the delayed hotline option. To activate the delayed hotline option from the telephone: <ol style="list-style-type: none"> <li>1. Dial the user-defined sequence number on the keypad; a dial tone is heard.</li> <li>2. Dial the telephone number to which the phone automatically dials after a configurable delay (terminate the number with #); a confirmation tone is heard.</li> </ol>
<b>'Hot-line Deactivate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>hotline-deact</code> <b>[KeyHotLineDeact]</b>	Defines the key sequence on the keypad to deactivate the delayed hotline option. After the sequence is pressed, a confirmation tone is heard.
<b>Keypad Feature - Transfer Parameters</b> <b>Note:</b> See the description of the [KeyBlindTransfer] parameter for this feature.	
<b>Keypad Feature - Call Waiting Parameters</b>	
<b>'Call Waiting Activate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>cw-act</code> <b>[KeyCallWaiting]</b>	Defines the key sequence on the keypad to activate the Call Waiting option. After the sequence is pressed, a confirmation tone is heard.
<b>'Call Waiting Deactivate'</b> <code>configure voip &gt; gateway</code> <code>analog keypad-features &gt;</code> <code>cw-deact</code> <b>[KeyCallWaitingDeact]</b>	Defines the key sequence on the keypad to deactivate the Call Waiting option. After the sequence is pressed, a confirmation tone is heard.

Parameter	Description
<b>Keypad Feature - Reject Anonymous Call Parameters</b>	
'Reject Anonymous Call Activate' configure voip > gateway analog keypad-features > reject-anony-call- activate [KeyRejectAnonymousCall]	Defines the key sequence on the keypad to activate the reject anonymous call option, whereby the device rejects incoming anonymous calls. After the sequence is pressed, a confirmation tone is heard.
'Reject Anonymous Call Deactivate' configure voip > gateway analog keypad-features > reject-anony-call- deactivate [KeyRejectAnonymousCallDeact]	Defines the key sequence on the keypad that deactivates the reject anonymous call option. After the sequence is pressed, a confirmation tone is heard.

## FXO and FXS Parameters

The general FXO and FXS parameters are described in the table below.

**Table 73-64:General FXO and FXS Parameters**

Parameter	Description
'Update Port Info' configure voip > interface fxs-fxo > port- info [AnalogPortInfo_x]	<p>Defines a descriptive name for an analog port. This can be used to easily identify the port.</p> <p>The valid value is a string of up to 40 characters. By default, the value is undefined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the ini file parameter, the x denotes the port number.</li> <li>■ To configure a port description through the Web interface, see <a href="#">Configuring a Description for Telephony Ports</a> on page 1338.</li> </ul>
<b>FXS Parameters</b>	
'FXS Coefficient Type' configure voip > interface fxs-fxo > fxs- country-coefficients [FXSCountryCoefficients]	<p>Determines the FXS line characteristics (AC and DC) according to USA or Europe (TBR21) standards.</p> <ul style="list-style-type: none"> <li>■ [66] <b>Europe</b> = TBR21</li> <li>■ [70] <b>USA</b> = (Default) United States</li> </ul>

Parameter	Description
	<b>Note:</b> For the parameter to take effect, a device restart is required.
[EnablePulseDialDetection]	<p>Enables the device to detect pulse (rotary) dialing from analog equipment (e.g., telephones) connected to the device's FXS port interfaces.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<b>FXO Parameters</b>	
<p>'FXO Coefficient Type'</p> <pre>configure voip &gt; interface fxs-fxo &gt; fxo- country-coefficients</pre> <p>[FXOCountryCoefficients]</p>	<p>Determines the FXO line characteristics (AC and DC) according to USA or TBR21 standard.</p> <ul style="list-style-type: none"> <li>■ [66] <b>Europe</b> = TBR21</li> <li>■ [70] <b>USA</b> = (Default) United States</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; interface fxs-fxo &gt; fxo- dc-termination</pre> <p>[FXODCTermination]</p>	<p>Defines the FXO line DC termination (i.e., resistance).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) DC termination is set to 50 Ohms.</li> <li>■ [1] = DC termination set to 800 Ohms. The termination changes from 50 to 800 Ohms only when moving from onhook to offhook.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; interface fxs-fxo &gt; enable-fxo-current-limit</pre> <p>[EnableFXOCurrentLimit]</p>	<p>Enables limiting the FXO loop current to a maximum of 60 mA (according to the TBR21 standard).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) FXO line current limit is disabled.</li> <li>■ [1] = FXO loop current is limited to a maximum of 60 mA.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device</p>

Parameter	Description
	restart is required.
[EnableAnalogOverloadProtection]	<p>Enables electrical overload protection on FXO interfaces.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable.</li> <li>■ [1] = Enable. Port impedance is set to 800 Ohm for 1,500 msec to overcome the load. Overload threshold is 160 mA. If you configure the FXODCTermination parameter to 1, the threshold is set to 60 mA.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; gateway analog fxo-setting &gt; fxo- number-of-rings</pre> <p>[FXONumberOfRings]</p>	<p>Defines the number of rings before the device's FXO interface answers a call by seizing the line. The valid range is 0 to 10. The default is 0.</p> <p>When set to 0, the FXO seizes the line after one ring. When set to 1, the FXO seizes the line after two rings.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if automatic dialing is not used.</li> <li>■ If caller ID is enabled and if the number of rings defined by the parameter RingsBeforeCallerID is greater than the number of rings defined by the parameter, the greater value is used.</li> </ul>
<p>'Dialing Mode'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; dialing-mode</pre> <p>[IsTwoStageDial]</p>	<p>Global parameter defining the dialing mode for IP-to-Tel (FXO) calls.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('Two Stage Dial' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
'Waiting For Dial Tone'	Determines whether or not the device waits for a

Parameter	Description
<pre>configure voip &gt; gateway analog fxo-setting &gt; waiting-4-dial-tone [IsWaitForDialTone]</pre>	<p>dial tone before dialing the phone number for IP-to-Tel (FXO) calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b> (default)</li> </ul> <p>When one-stage dialing and the parameter are enabled, the device dials the phone number (to the PSTN/PBX line) only after it detects a dial tone. If the parameter is disabled, the device immediately dials the phone number after seizing the PSTN/PBX line without 'listening' for a dial tone.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The correct dial tone parameters must be configured in the CPT file.</li> <li>■ The device may take 1 to 3 seconds to detect a dial tone (according to the dial tone configuration in the CPT file). If the dial tone is not detected within 6 seconds, the device releases the call and sends a SIP 500 "Server Internal Error" response.</li> </ul>
<p>'Time to Wait before Dialing'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; time-wait-b4-dialing [WaitForDialTime]</pre>	<p>Defines the delay before the device starts dialing on the FXO line in the following scenarios:</p> <ul style="list-style-type: none"> <li>■ The delay between the time the line is seized and dialing begins during the establishment of an IP-to-Tel call. <p><b>Note:</b> Applicable only for one-stage dialing when the [IsWaitForDialTone] parameter is disabled.</p> </li> <li>■ The delay between detection of a Wink and the start of dialing during the establishment of an IP-to-Tel call (for DID lines, see the [EnableDIDWink] parameter).</li> <li>■ For call transfer: The delay after hook-flash is generated and dialing begins.</li> </ul> <p>The valid range (in milliseconds) is 0 to 20,000 (i.e., 20 seconds). The default is 1,000 (i.e., 1 second).</p>

Parameter	Description
<p>'Ring Detection Timeout'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; ring-detection-tout</pre> <p>[FXOBetweenRingTime]</p>	<p>Defines the timeout (in seconds) for detecting the second ring after the first detected ring.</p> <p>If automatic dialing is not used and Caller ID is enabled, the device seizes the line after detection of the second ring signal (allowing detection of caller ID sent between the first and the second rings). If the second ring signal is not received within this timeout, the device doesn't initiate a call to IP.</p> <p>If automatic dialing is used, the device initiates a call to IP when the ringing signal is detected. The FXO line is seized only if the remote IP party answers the call. If the remote party doesn't answer the call and the second ring signal is not received within this timeout, the device releases the IP call.</p> <p>The parameter is typically set to between 5 and 8. The default is 8.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only for Tel-to-IP calls.</li> <li>■ This timeout is calculated from the end of the ring until the start of the next ring. For example, if the ring cycle is two seconds on and four seconds off, the timeout value should be configured to five seconds (i.e., greater than the off time, e.g., four).</li> </ul>
<p>'Rings before Detecting Caller ID'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; rings-b4-det-callerid</pre> <p>[RingsBeforeCallerID]</p>	<p>Determines the number of rings before the device starts detecting Caller ID.</p> <ul style="list-style-type: none"> <li>■ [0] 0 = Before first ring.</li> <li>■ [1] 1 = (Default) After first ring.</li> <li>■ [2] 2 = After second ring.</li> </ul>
<p>'Guard Time Between Calls'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; guard-time-btwn-calls</pre> <p>[GuardTimeBetweenCalls]</p>	<p>Defines the time interval (in seconds) after a call has ended and a new call can be accepted for IP-to-Tel (FXO) calls.</p> <p>The valid range is 0 to 10. The default is 1.</p> <p><b>Note:</b> Occasionally, after a call ends and on-hook is applied, a delay is required before placing a new</p>

Parameter	Description
	call (and performing off-hook). This is necessary to prevent incorrect hook-flash detection or other glare phenomena.
<b>'FXO Double Answer'</b> <code>configure voip &gt; gateway</code> <code>analog fxo-setting &gt; fxo-dbl-ans</code> <b>[EnableFXODoubleAnswer]</b>	<p>Global parameter enabling the FXO Double Answer feature, which rejects (disconnects) incoming Tel-to-IP collect calls and signals (informs) this call denial to the PSTN.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('FXO Double Answer' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
<b>'FXO Ring Timeout'</b> <code>configure voip &gt; gateway</code> <code>analog fxo-setting &gt; fxo-ring-timeout</code> <b>[FXORingTimeout]</b>	<p>Defines the delay (in msec) before the device generates a SIP INVITE (call) to the IP side upon detection of a RING_START event from the Tel (FXO) side. This occurs instead of waiting for a RING_END event.</p> <p>This feature is useful for telephony services that employ constant ringing (i.e., no RING_END is sent). For example, Ringdown circuit is a service that sends a constant ringing current over the line, instead of cadence-based 2 second on, 4 second off. For example, when a telephone goes off-hook, a phone at the other end instantly rings.</p> <p>If a RING_END event is received before the timeout expires, the device doesn't initiate a call and ignores the detected ring. The device ignores RING_END events detected after the timeout expires.</p> <p>The valid value range is 0 to 50 (msec), in steps of 100-msec. For example, a value of 50 represents 5 sec. The default value is 0 (i.e., standard ring operation - the FXO interface sends an INVITE upon receipt of the RING_END event).</p> <p><b>Note:</b> The parameter can be configured for a Tel Profile.</p>

Parameter	Description
<pre>configure voip &gt; gateway analog fxo-setting &gt; fxo-voice-delay-on-200ok</pre> <p>[FXOVoiceDelayon200OK]</p>	<p>Defines the time (in msec) that the device waits before opening the RTP (voice) channel with the FXO endpoint, after receiving a 200 OK from the IP side. This delay may be useful in scenarios in which a 'click' noise is audible when the FXO interface (PBX) seizes the line. A delay in opening the voice channel eliminates this noise.</p> <p>The valid range is 0 (default) to 500, where 0 means that the device opens the voice channel immediately upon the receipt of the 200 OK.</p>
<pre>configure voip &gt; gateway analog fxo-setting &gt; fxo-consult-call-transfer</pre> <p>[FXOConsultCallTransfer]</p>	<p>Global parameter enabling FXO consultative call transfers (initiated by the PSAP operator) for emergency (NG9-1-1) calls, based on the NENA i3 Standard for Next Generation 9-1-1 (NENA-STA-010.2-2016).</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('FXO Consultative Call Transfer' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>

## Trunk Group and Routing Parameters

The routing parameters are described in the table below.

**Table 73-65: Routing Parameters**

Parameter	Description
<p>'Channel Select Mode'</p> <pre>ch-select-mode</pre> <p>[ChannelSelectMode]</p>	<p>Defines the method for allocating incoming IP-to-Tel calls to a channel. The parameter applies to the following:</p> <ul style="list-style-type: none"> <li>■ Trunks configured without a channel select mode in the Trunk Group Settings table (see <a href="#">Configuring Trunk Group Settings</a> on page 937).</li> <li>■ Channels and trunks configured without a Trunk Group ID.</li> </ul> <p>For all channels that are configured without a Trunk Group</p>

Parameter	Description
	<p>ID:</p> <ul style="list-style-type: none"> <li>■ [0] <b>By Dest Phone Number</b></li> <li>■ [1] <b>Cyclic Ascending</b> (default)</li> <li>■ [2] <b>Ascending</b></li> <li>■ [3] <b>Cyclic Descending</b></li> <li>■ [4] <b>Descending</b></li> <li>■ [5] <b>Dest Number + Cyclic Ascending</b></li> <li>■ [6] <b>By Source Phone Number</b></li> <li>■ [7] <b>Trunk Cyclic Ascending</b></li> <li>■ [8] <b>Trunk &amp; Channel Cyclic Ascending</b></li> <li>■ [9] <b>Ring to Hunt Group</b></li> </ul> <p><b>Note:</b> This option is applicable only to FXS interfaces.</p> <ul style="list-style-type: none"> <li>■ [10] <b>Select Trunk By Supplementary Service Table</b></li> </ul> <p><b>Note:</b> This option is applicable only to BRI interfaces.</p> <ul style="list-style-type: none"> <li>■ [11] <b>Dest Number + Ascending</b></li> </ul> <p>For a detailed description of the parameter's options, see <a href="#">Configuring Trunk Group Settings</a> on page 937.</p>
<p>'Default Destination Number'</p> <pre>configure voip &gt; gateway dtmf-supp- service dtmf-and- dialing &gt; dflt- dest-nb</pre> <p>[DefaultNumber]</p>	<p>For IP-to-Tel calls, the parameter defines the default destination (called) phone number if the received SIP message doesn't contain a called party number and a phone number ('Channels' parameter) is not configured in the Trunk Groups table (see <a href="#">Configuring Trunk Groups</a> on page 934). The final destination number is the value of this parameter plus the channel ID.</p> <p>For Tel-to-IP calls, the parameter defines the default source (calling) phone number if the received ISDN message doesn't contain a calling party number and a phone number ('Channels' parameter) is not configured in the Trunk Groups table.</p> <p>The parameter is used as a starting number for the channels of all the trunks.</p> <p>The default is 1000.</p> <p>For example, for a Tel-to-IP call, if you configure the parameter to "2000" and the 'Channels' parameter in the Trunks Groups table to "34", the source number is 2034.</p>

Parameter	Description
<p>'Source IP Address Input'</p> <pre>configure voip &gt; gateway routing settings &gt; src-ip- addr-input</pre> <p>[SourceIPAddressInput]</p>	<p>Defines which IP address the device uses to determine the source of incoming INVITE messages for IP-to-Tel routing.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configure</b> = (Default) The parameter is automatically set to SIP Contact header (1).</li> <li>■ [0] <b>SIP Contact Header</b> = The IP address in the Contact header of the incoming INVITE message is used.</li> <li>■ [1] <b>Layer 3 Source IP</b> = The actual IP address (Layer 3) from where the SIP packet is received is used.</li> </ul>
<p>'Use Source Number As Display Name'</p> <pre>configure voip &gt; sip-definition settings &gt; src-nb- as-disp-name</pre> <p>[UseSourceNumberAsDisplayNumber]</p>	<p>Defines the use of the Tel Source Number and Display Name for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) If a Tel Display Name is received, the Tel Source Number is used as the IP Source Number and the Tel Display Name is used as the IP Display Name. If no Display Name is received from the Tel side, the IP Display Name remains empty.</li> <li>■ [1] <b>Yes</b> = If a Tel Display Name is received, the Tel Source Number is used as the IP Source Number and the Tel Display Name is used as the IP Display Name. If no Display Name is received from the Tel side, the Tel Source Number is used as the IP Source Number and also as the IP Display Name.</li> <li>■ [2] <b>Overwrite</b> = The Tel Source Number is used as the IP Source Number and also as the IP Display Name (even if the received Tel Display Name is not empty).</li> <li>■ [3] <b>Original</b> = Similar to option [2], except that the operation is done before regular calling number manipulation.</li> </ul>
<p>'Use Display Name as Source Number'</p> <pre>configure voip &gt; sip-definition settings &gt; disp- name-as-src-nb</pre> <p>[UseDisplayNameAsSourceNumber]</p>	<p>Defines how the display name (caller ID) received from the IP side (in the SIP From header) effects the source number sent to the Tel side, for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) If a display name is received from the IP side, the source number of the IP side is used as the Tel source number.</li> <li>■ [1] <b>Yes</b> = If a display name is received from the IP side, the display name of the IP side is used as the Tel source number and Presentation is set to Allowed (0). If no display name is received from the IP side, the source</li> </ul>

Parameter	Description
	<p>number of the IP side is used as the Tel source number and Presentation is set to Restricted (1). For example:</p> <ul style="list-style-type: none"> <li>✓ If 'From: 100 &lt;sip:200@201.202.203.204&gt;' is received from the IP side, the outgoing source number (and display name) are set to "100" and Presentation is set to Allowed (0).</li> <li>✓ If 'From: &lt;sip:400@101.102.103.104&gt;' is received from the IP side, the outgoing source number is set to "400" and Presentation is set to Restricted (1).</li> </ul> <p>■ [2] <b>Preferred</b> = If a display name is received from the IP side, the display name of the IP side is used as the Tel source number. If no display name is received from the IP side, this setting doesn't affect the Tel source number.</p>
<p>'ENUM Resolution'</p> <pre>configure voip &gt; sip-definition settings &gt; enum- service-domain</pre> <p>[EnumService]</p>	<p>Defines the ENUM service for translating telephone numbers to IP addresses or domain names (FQDN), for example, e164.arpa, e164.customer.net, or NRENum.net. The valid value is a string of up to 50 characters. The default is "e164.arpa".</p> <p><b>Note:</b> ENUM-based routing is configured in the Tel-to-IP Routing table using the "ENUM" string value as the destination address to denote the parameter's value.</p>
<p>'Use Routing Table for Host Names and Profiles'</p> <pre>configure voip &gt; sip-definition settings &gt; rte-tbl- 4-host-names</pre> <p>[AlwaysUseRouteTable]</p>	<p>Enables the device to use the Tel-to-IP Routing table for obtaining the URI host name and optionally, an IP Profile (per call) even if a SIP proxy server is used.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter appears only if the 'Use Default Proxy' parameter is enabled.</li> <li>■ The domain name is used instead of a Proxy name or IP address in the INVITE SIP URI.</li> </ul>
<p>'Tel-to-IP Routing Mode'</p> <pre>configure voip &gt; gateway routing settings &gt; tel2ip-rte- mode</pre>	<p>Determines whether to route Tel calls to an IP destination before or after manipulation of the destination number. This applies to Tel-to-IP routing rules configured in the Tel-to-IP Routing table.</p>

Parameter	Description
[RouteModeTel2IP]	<ul style="list-style-type: none"> <li>■ <b>[0] Route calls before manipulation</b> = Calls are routed before the number manipulation rules are applied (default).</li> <li>■ <b>[1] Route calls after manipulation</b> = Calls are routed after the number manipulation rules are applied.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is not applicable if outbound proxy routing is used.</li> <li>■ For number manipulation, see <a href="#">Configuring Source-Destination Number Manipulation Rules</a> on page 983.</li> <li>■ To configure Tel-to-IP routing rules, see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946.</li> </ul>
<p>'IP-to-Tel Routing Mode'</p> <pre>configure voip &gt; gateway routing settings &gt; ip2tel- rte-mode</pre> <p>[RouteModeIP2Tel]</p>	<p>Determines whether to route IP calls to the Trunk Group before or after manipulation of the destination number (configured in <a href="#">Configuring Source-Destination Number Manipulation Rules</a> on page 983).</p> <ul style="list-style-type: none"> <li>■ <b>[0] Route calls before manipulation</b> = (Default) Calls are routed before the number manipulation rules are applied.</li> <li>■ <b>[1] Route calls after manipulation</b> = Calls are routed after the number manipulation rules are applied.</li> </ul>
<p>'IP Security'</p> <pre>configure voip &gt; sip-definition settings &gt; ip- security</pre> <p>[SecureCallsFromIP]</p>	<p>Defines the device's policy for accepting or blocking SIP calls (IP-to-Tel calls). This is useful in preventing unwanted SIP calls, SIP messages, and/or VoIP spam.</p> <ul style="list-style-type: none"> <li>■ <b>[0] Disable</b> = (Default) The device accepts all SIP calls.</li> <li>■ <b>[1] Secure Incoming calls</b> = The device accepts SIP calls only from IP addresses that are configured in the Tel-to-IP Routing table or Proxy Sets table, or IP addresses resolved by DNS servers from FQDN values configured in the Proxy Sets table. All other incoming calls are rejected.</li> <li>■ <b>[2] Secure All calls</b> = The device accepts SIP calls only from IP addresses (in dotted-decimal notation format) that are configured in the Tel-to-IP Routing table and rejects all other incoming calls. In addition, if an FQDN is configured in the Tel-to-IP Routing table or Proxy Sets</li> </ul>

Parameter	Description
	<p>table, the call is allowed to be sent only if the resolved DNS IP address appears in one of these tables; otherwise, the call is rejected. Therefore, the difference between this option and option [1] is that this option is concerned only about numerical IP addresses that are defined in the tables.</p> <p><b>Note:</b> If the parameter is set to [0] or [1], when using Proxies or Proxy Sets, it is unnecessary to configure the Proxy IP addresses in the routing table. The device allows SIP calls received from the Proxy IP addresses even if these addresses are not configured in the routing table.</p>
<p>'Filter Calls to IP'</p> <pre>configure voip &gt; sip-definition settings &gt; filter- calls-to-ip</pre> <p>[FilterCalls2IP]</p>	<p>Enables filtering of Tel-to-IP calls when a Proxy Set is used.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device doesn't filter calls when using a proxy.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>When the parameter is enabled and a proxy is used, the device first checks the Tel-to-IP Routing table before making a call through the proxy. If the number is not allowed (i.e., number isn't listed in the table or a call restriction routing rule of IP address 0.0.0.0 is applied), the call is released.</p> <p><b>Note:</b> When no proxy is used, the parameter must be disabled and filtering is according to the Tel-to-IP Routing table.</p>
<p>'Tel-to-IP Dial Plan Name'</p> <pre>configure voip &gt; gateway routing settings &gt; tel- dial-plan-name</pre> <p>[Tel2IPDialPlanName]</p>	<p>Assigns the Dial Plan (by name) to be used for tag-based IP-to-Tel routing rules. The Dial Plan's tags can be used as matching criteria (source and destination) for routing rules in the IP-to-Tel Routing table.</p> <p>For more information, see <a href="#">Using Dial Plans for IP-to-Tel or Tel-to-IP Call Routing</a> on page 849.</p>
<p>'IP-to-Tel Dial Plan Name'</p> <pre>configure voip &gt; gateway routing settings &gt; ip-dial- plan-name</pre> <p>[IP2TelDialPlanName]</p>	<p>Assigns the Dial Plan for tag-based Tel-to-IP routing rules. The Dial Plan's tags can be used as matching criteria (source and destination) for routing rules in the Tel-to-IP Routing table.</p> <p>For more information, see <a href="#">Using Dial Plans for IP-to-Tel or Tel-to-IP Call Routing</a> on page 849.</p>
'IP-to-Tel Tagging'	Defines the Dial Plan index in the Dial Plan file for called

Parameter	Description
<p>Destination Dial Plan Index'</p> <pre>configure voip &gt; gateway routing settings &gt; ip2tel- tagging-dst</pre> <p>[IP2TelTaggingDestDialPlanIndex]</p>	<p>prefix tags for representing called number prefixes in Inbound Routing rules.</p> <p>The valid values are 0 to 7, where 0 denotes PLAN1, 1 denotes PLAN2, and so on. The default is -1 (i.e., no dial plan file used).</p> <p>For more information on this feature, see Trunk Group and Routing Parameters.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'IP to Tel Tagging Source Dial Plan Index'</p> <pre>cconfigure voip &gt; gateway routing settings &gt; ip-to- tel-tagging-src</pre> <p>[IP2TelTaggingSourceDialPlanIndex]</p>	<p>Defines the Dial Plan index in the Dial Plan file for calling prefix tags for representing calling number prefixes in Inbound Routing rules.</p> <p>The valid values are 0 to 7, where 0 denotes PLAN1, 1 denotes PLAN2, and so on. The default is -1 (i.e., no dial plan file used).</p> <p>For more information on this feature, see Trunk Group and Routing Parameters.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<pre>configure voip &gt; gateway digital settings &gt; etsi- diversion</pre> <p>[EnableETSIDiversion]</p>	<p>Defines the method in which the Redirect Number is sent to the Tel side.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Q.931 Redirecting Number Information Element (IE).</li> <li>■ [1] = ETSI DivertingLegInformation2 in a Facility IE.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Add CIC'</p> <pre>configure voip &gt; gateway manipulation settings &gt; add-cic</pre> <p>[AddCicAsPrefix]</p>	<p>Determines whether to add the Carrier Identification Code (CIC) as a prefix to the destination phone number for IP-to-Tel calls. When the parameter is enabled, the 'cic' parameter in the incoming SIP INVITE can be used for IP-to-Tel routing decisions. It routes the call to the appropriate Trunk Group based on the parameter's value.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> (default)</li> <li>■ [1] <b>Yes</b></li> </ul> <p>Digital interfaces: The SIP 'cic' parameter enables the transmission of the 'cic' parameter from the SIP network to</p>

Parameter	Description
	<p>the ISDN. The 'cic' parameter is a three- or four-digit code used in routing tables to identify the network that serves the remote user when a call is routed over many different networks. The 'cic' parameter is carried in the SIP INVITE and maps to the ISDN Transit Network Selection Information Element (TNS IE) in the outgoing ISDN Setup message (if the EnableCIC parameter is set to 1). The TNS IE identifies the requested transportation networks and allows different providers equal access support, based on customer choice.</p> <p>For example, as a result of receiving the below INVITE, the destination number after number manipulation is</p> <pre>cic+167895550001: INVITE sip:5550001;cic=+16789@172.18.202.60:5060;user=phone SIP/2.0</pre> <p><b>Note:</b> After the cic prefix is added, the IP-to-Tel Routing table can be used to route this call to a specific Trunk Group. The Destination Number IP to Tel Manipulation table must be used to remove this prefix before placing the call to the Tel side.</p>
[FaxReroutingMode]	<p>Enables the re-routing of incoming Tel-to-IP calls that are identified as fax calls. If a CNG tone is detected on the Tel side of a Tel-to-IP call, the device adds the string, "FAX" as a prefix to the destination number before routing and manipulation. A routing rule in the Tel-to-IP Routing table having the value "FAX" (case-sensitive) as the destination number is then used to re-route the call to a fax destination and the destination number manipulation mechanism is used to remove the "FAX" prefix before sending the fax, if required. If the initial INVITE used to establish the voice call (not fax) was already sent, a CANCEL (if not connected yet) or a BYE (if already connected) is sent to release the voice call.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Rerouting without Delay</b> = Upon detection of a CNG tone, the device immediately releases the call of the initial INVITE and then sends a new INVITE to a specific IP Group or fax server according to the Tel-to-IP Routing table. To enable this feature, set the CNGDetectorMode</li> </ul>

Parameter	Description
	<p>parameter to 2 and the IsFaxUsed parameter to 1, 2, or 3.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Progress and Delay</b> = Incoming ISDN calls are delayed until a CNG tone detection or timeout, set by the FaxReroutingDelay parameter. If the EnableComfortTone parameter is set to 1, a Q.931 Progress message with Protocol Discriminator set to 1 is sent to the PSTN and a comfort tone is played accordingly to the PSTN. When the timeout expires, the device sends an INVITE to a specific IP Group or to a fax server, according to the Tel-to-IP Routing table rules.</li> </ul> <p><b>Note:</b> The option is applicable only to ISDN.</p> <ul style="list-style-type: none"> <li>■ [3] <b>Connect and Delay</b> = Incoming ISDN calls are delayed until a CNG tone detection or timeout, set by the FaxReroutingDelay parameter. A Q.931 Connect message is sent to the PSTN. If the EnableComfortTone parameter is set to 1, a comfort tone is played to the PSTN. When the timeout expires, the device sends an INVITE to a specific IP Group or to a fax server according to the Tel-to-IP Routing table rules.</li> </ul> <p><b>Note:</b> The option is applicable only to ISDN.</p> <p><b>Note:</b> The parameter has replaced the [EnableFaxRerouting] parameter ('Enable Fax Re-Routing'). For backward compatibility, the [EnableFaxRerouting] parameter set to 1 is equivalent to the [FaxReroutingMode] parameter set to 1.</p>
[FaxReroutingDelay]	<p>Defines the maximum time interval (in seconds) that the device waits for CNG detection before re-routing calls identified as fax calls to fax destinations (terminating fax machine).</p> <p>The valid value range is 1-10. The default is 5.</p>
<b>Call Forking Parameters</b>	
'Forking Handling Mode' forking-handling [ForkingHandlingMode]	<p>Defines how the device handles the receipt of multiple SIP 18x forking responses for Tel-to-IP calls. The forking 18x response is the response with a different SIP to-tag than the previous 18x response. These responses are typically generated (initiated) by Proxy / Application servers that perform call forking, sending the device's originating INVITE</p>

Parameter	Description
	<p>(received from SIP clients) to several destinations, using the same Call ID.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Parallel handling</b> = (Default) If SIP 18x with SDP is received, the device opens a voice stream according to the received SDP and disregards any subsequently received 18x forking responses (with or without SDP). If the first response is 180 without SDP, the device responds according to the PlayRBTone2TEL parameter and disregards the subsequent forking 18x responses.</li> <li>■ [1] <b>Sequential handling</b> = If 18x with SDP is received, the device opens a voice stream according to the received SDP. The device re-opens the stream according to subsequently received 18x responses with SDP, or plays a ringback tone if 180 response without SDP is received. If the first received response is 180 without SDP, the device responds according to the PlayRBTone2TEL parameter and processes the subsequent 18x forking responses.</li> </ul> <p><b>Note:</b> Regardless of the parameter setting, once a SIP 200 OK response is received, the device uses the RTP information and re-opens the voice stream, if necessary.</p>
<p>'Forking Timeout'</p> <pre>configure voip &gt; gateway advanced &gt; forking-timeout [ForkingTimeOut]</pre>	<p>Defines the timeout (in seconds) that is started after the first SIP 2xx response has been received for a User Agent when a Proxy server performs call forking (Proxy server forwards the INVITE to multiple SIP User Agents). The device sends a SIP ACK and BYE in response to any additional SIP 2xx received from the Proxy within this timeout. Once this timeout elapses, the device ignores any subsequent SIP 2xx.</p> <p>The number of supported forking calls per channel is 20. In other words, for an INVITE message, the device can receive up to 20 forking responses from the Proxy server.</p> <p>The valid range is 0 to 30. The default is 30.</p>
<p>'Tel-to-IP Call Forking Mode'</p> <pre>configure voip &gt; sip-definition settings &gt; tel2ip- call-forking-mode [Tel2IPCallForkingMode]</pre>	<p>Enables Tel-to-IP call forking, whereby a Tel call can be routed to multiple IP destinations.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = (Default) Disabled.</li> <li>■ [1] Check box selected = Enabled.</li> </ul> <p><b>Note:</b> Once enabled, routing rules must be assigned</p>

Parameter	Description
	Forking Groups in the Tel-to-IP Routing table.
'Forking Delay Time for SIP INVITE' configure voip > sip-definition settings > forking- delay-time-invite [ForkingDelayTimeForInvite]	Defines the interval (in seconds) to wait before sending INVITE messages to the other members of the forking group. The INVITE is immediately sent to the first member. The valid value range is 0 to 40. The default is 0 (i.e., sends immediately).

## IP Connectivity Parameters

The IP connectivity parameters are described in the table below.

**Table 73-66:IP Connectivity Parameters**

Parameter	Description
'Enable Tel-to-IP Alt Routing' configure voip > gateway routing settings > alt- routing-tel2ip [AltRoutingTel2IPEnable]	<p>Enables the device to check the connectivity status of IP destinations of configured Tel-to-IP routing rules in the Tel-to-IP Routing table. This can then be used to trigger alternative routing for Tel-to-IP calls if connectivity with an IP destination is down and an alternative routing rule has been configured.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Disables the IP Connectivity feature.</li> <li>■ [1] <b>Enable</b> = Enables the IP Connectivity feature.</li> <li>■ [2] <b>Status Only</b> = The IP Connectivity feature is disabled, but read-only information on the QoS of the IP destination is provided.</li> </ul> <p><b>Note:</b> If the parameter is enabled, the Busy Out feature (see [EnableBusyOut] parameter) doesn't function with the Proxy Set keep-alive mechanism. To use the Busy Out feature with the Proxy Set keep-alive mechanism (for IP Groups), disable the parameter.</p>
'Tel-to-IP Alt Routing Mode' configure voip > gateway routing settings > alt- rte-tel2ip-mode [AltRoutingTel2IPMode]	<p>Defines the IP Connectivity event(s) reason for triggering alternative routing.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = Alternative routing is disabled.</li> <li>■ [1] <b>Connectivity</b> = Alternative routing is done if</li> </ul>

Parameter	Description
	<p>SIP OPTIONS message to the initial destination fails.</p> <ul style="list-style-type: none"> <li>■ [2] <b>QoS</b> = Alternative routing is done if poor QoS is detected.</li> <li>■ [3] <b>Both</b> = (Default) Alternative routing is done if a SIP OPTIONS to the initial destination fails, poor QoS is detected, or the DNS host name is not resolved.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ QoS is quantified according to delay and packet loss calculated according to previous calls. QoS statistics are reset if no new data is received within two minutes.</li> <li>■ To receive quality information, displayed in the 'Quality Status' and 'Quality Info.' fields (see <a href="#">Viewing IP Connectivity</a> on page 1491) per destination, configure the parameter to <b>QoS</b> or <b>Both</b>.</li> </ul>
<p>'Tel-to-IP Alt Routing Keep-Alive Time'</p> <pre>configure voip &gt; gateway routing settings &gt; alt- rte-tel2ip-keep-alive [AltRoutingTel2IPKeepAliveTime]</pre>	<p>Defines the time interval (in seconds) between SIP OPTIONS keep-alive messages for the IP Connectivity feature (see <a href="#">IP Destinations Connectivity Feature</a> on page 969).</p> <p>The valid range is 5 to 2,000,000. The default is 60.</p>
<p>'Max Allowed Packet Loss for Alt Routing'</p> <pre>configure voip &gt; gateway routing settings &gt; mx- pkt-loss-4-alt-rte [IPConnQoSMaxAllowedPL]</pre>	<p>Defines the packet loss (in percentage) at which the IP connection is considered a failure and Alternative Routing mechanism is activated.</p> <p>The default is 20%.</p>
<p>'Max Allowed Delay for Alt Routing'</p> <pre>configure voip &gt; gateway routing settings &gt; mx- all-dly-4-alt-rte [IPConnQoSMaxAllowedDelay]</pre>	<p>Defines the transmission delay (in msec) at which the IP connection is considered a failure and the Alternative Routing mechanism is activated.</p> <p>The range is 100 to 10,000. The default is 250.</p>

## Alternative Routing Parameters

The alternative routing parameters are described in the table below.

**Table 73-67: Alternative Routing Parameters**

Parameter	Description
<p>'3xx Use Alt Route Reasons'</p> <pre>configure voip &gt; sip- definition settings &gt; 3xx-use-alt-route</pre> <p>[UseAltRouteReasonsFor3xx]</p>	<p>Defines the handling of received SIP 3xx responses regarding call redirection to listed contacts in the Contact header.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Upon receipt of a 3xx response, the device tries each contact, one by one, listed in the Contact headers, until a successful destination is found. However, if a contact responds with a 486 or 600, the device doesn't try to redirect the call to next contact, and drops the call.</li> <li>■ [1] <b>No if 6xx</b> = Upon receipt of a 3xx response, the device tries each contact, one by one, listed in the Contact headers. However, if a 6xx Global Failure response is received during this process (e.g., 600 Busy Everywhere) the device doesn't try to redirect the call to the next contact, and drops the call.</li> <li>■ [2] <b>Yes</b> = Upon receipt of a 3xx response, the device redirects the call to the first contact listed in the Contact header. If the contact responds with a SIP response that is defined in the Reasons for Tel-to-IP Alternative Routing table, the device tries to redirect the call to the next contact, and so on. If a contact responds with a response that is not configured in the table, the device doesn't try to redirect the call to the next contact, and drops the call.</li> </ul>
<p>'Redundant Routing Mode'</p> <pre>configure voip &gt; gateway routing settings &gt; redundant- routing-m</pre> <p>[RedundantRoutingMode]</p>	<p>Defines the type of redundant routing mechanism when a call can't be completed using the main route.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = No redundant routing is used. If the call can't be completed using the main route (using the active Proxy or the first matching rule in the Routing table), the call is disconnected.</li> <li>■ [1] <b>Routing Table</b> = (Default) Routing table is used to locate a redundant route.</li> <li>■ [2] <b>Proxy</b> = Proxy list is used to locate a redundant route.</li> </ul>

Parameter	Description
	<p><b>Note:</b> To implement the Redundant Routing Mode mechanism, you first need to configure the parameter [AltRouteCauseTEL2IP] (Reasons for Alternative Routing table), as described in <a href="#">Alternative Tel-to-IP Routing Based on SIP Responses</a> on page 973.</p>
'Disconnect Call With PI If Alt' [DisconnectCallwithPIIfAlt]	<p>Defines when the device sends the IP-to-Tel call to an alternative route (if configured) when it receives an ISDN Q.931 Disconnect message from the Tel side.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device forwards early media to the IP side if Disconnect includes PI, and disconnects the call when a Release message is received. Only after the call is disconnected does the device send the call to an alternative route.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device immediately sends the call to the alternative route.</li> </ul> <p>For more information, see <a href="#">Alternative Routing upon ISDN Disconnect</a> on page 981.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
configure voip > gateway manipulation settings > alt-map- tel-to-ip [EnableAltMapTel2IP]	<p>Enables different Tel-to-IP destination number manipulation rules per routing rule when several (up to three) Tel-to-IP routing rules are defined and if alternative routing using release causes is used. For example, if an INVITE message for a Tel-to-IP call is returned with a SIP 404 Not Found response, the call can be re-sent to a different destination number, configured by the [NumberMapTel2IP] parameter.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul>
[TR104FXOSwitchover]	<p>Enables the device to automatically switch the destination of an FXS call from the FXO (PSTN) to the IP (SIP Trunk) when the PSTN disconnects the FXS subscriber.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul> <p>For more information, see <a href="#">Alternative Routing from FXO</a></p>

Parameter	Description
	<p><a href="#">to IP</a> on page 982.</p> <p><b>Note:</b> The parameter is applicable only to analog interfaces.</p>
<p>'Alternative Routing Tone Duration'</p> <pre>configure voip &gt; gateway routing settings &gt; alt-rte- tone-duration</pre> <p>[AltRoutingToneDuration]</p>	<p>Defines the duration (in milliseconds) for which the device plays a tone to the endpoint on each attempt for Tel-to-IP alternative routing. When the device finishes playing the tone, a new SIP INVITE message is sent to the new IP destination. The tone played is the call forward tone (Tone Type #25 in the CPT file).</p> <p>The valid range is 0 to 20,000. The default is 0 (i.e., no tone is played).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to analog interfaces.</li> <li>■ The parameter is applicable only to Tel-to-IP alternative routing based on SIP responses (see <a href="#">Alternative Tel-to-IP Routing Based on SIP Responses</a> on page 973).</li> </ul>

## Number Manipulation Parameters

The number manipulation parameters are described in the table below.

**Table 73-68: Number Manipulation Parameters**

Parameter	Description
<pre>configure voip &gt; gateway manipulation settings &gt; map-ip- to-pstn-refer-to</pre> <p>[ManipulateIP2PSTNReferTo]</p>	<p>Enables the manipulation of the called party (destination) number according to the SIP Refer-To header received by the device for TDM (PSTN) blind transfer. The number in the SIP Refer-To header is manipulated for all types of blind transfers to the PSTN (CAS, FXO, TBCT, ECT, RLT, and QSIG ).</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul> <p>During the blind transfer, the device initiates a new call to the PSTN and the destination number of this call can be</p>

Parameter	Description
	<p>manipulated if the parameter is enabled. When enabled, the manipulation is done as follows:</p> <ol style="list-style-type: none"> <li>1. If you configure a value for the xfer-Prefix parameter, the value (string) is added as a prefix to the number in the Refer-To header.</li> <li>2. This called party number is then manipulated using the Destination Phone Number Manipulation for IP-to-Tel Calls table. The source number of the transferred call is taken from the original call, according to its initial direction: <ul style="list-style-type: none"> <li>✓ Source number of the original call if it is a Tel-to-IP call</li> <li>✓ Destination number of the original call if it is an IP-to-Tel call</li> </ul> <p>This source number can also be used as the value for the 'Source Phone Pattern' field in the Destination Phone Number Manipulation for IP-to-Tel Calls table. The local IP address is used as the value for the 'Source IP Address' field.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This manipulation doesn't affect IP-to-Trunk Group routing rules.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul> </li> </ol>
<p>'Use Endpoint Number as Calling Number Tel-to-IP'</p> <pre>configure voip &gt; gateway digital settings &gt; epn-as-cpn-tel2ip</pre> <p>[UseEPNumAsCallingNumTel2IP]</p>	<p>Enables the use of the B-channel number as the calling number (sent in the From field of the INVITE) instead of the number received in the Q.931 Setup message, for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>

Parameter	Description
	<p>For example, if the incoming calling party number in the Q.931 Setup message is "12345" and the B-channel number is 17, then the outgoing INVITE From header is set to "17" instead of "12345".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When enabled, this feature is applied before routing and manipulation on the source number.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'Use Endpoint Number as Calling Number IP-to-Tel'</p> <pre>configure voip &gt; gateway digital settings &gt; epn-as-cpn- ip2tel</pre> <p>[UseEPNumAsCallingNumIP2Tel]</p>	<p>Enables the use of the B-channel number as the calling party number (sent in the Q.931 Setup message) instead of the number received in the From header of the INVITE, for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For example, if the incoming INVITE From header contains "12345" and the destined B-channel number is 17, then the outgoing calling party number in the Q.931 Setup message is set to "17" instead of "12345".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When enabled, this feature is applied after routing and manipulation on the source number (i.e., just before sending to the Tel side).</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'Tel2IP Default Redirect Reason'</p> <pre>configure voip &gt; gateway manipulation settings &gt; tel-to- ip-dflt-redir-rsn</pre> <p>[Tel2IPDefaultRedirectReason]</p>	<p>Determines the default redirect reason for Tel-to-IP calls when no redirect reason (or "unknown") exists in the received Q931 ISDN Setup message. The device includes this default redirect reason in the SIP History-Info header of the outgoing</p>

Parameter	Description
	<p>INVITE.</p> <p>If a redirect reason exists in the received Setup message, the parameter is ignored and the device sends the INVITE message with the reason according to the received Setup message. If the parameter is not configured (-1), the outgoing INVITE is sent with the redirect reason as received in the Setup message (if none or “unknown” reason, then without a reason).</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) Received redirect reason is not changed</li> <li>■ [1] <b>Busy</b> = Call forwarding busy</li> <li>■ [2] <b>No Reply</b> = Call forwarding no reply</li> <li>■ [9] <b>DTE Out of Order</b> = Call forwarding DTE out of order</li> <li>■ [10] <b>Deflection</b> = Call deflection</li> <li>■ [15] <b>Systematic/Unconditional</b> = Call forward unconditional</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Redirect Number IP-to-Tel'</p> <pre>configure voip &gt; gateway routing settings &gt; redir-nb-si-2tel</pre> <p>[SetIp2TelRedirectScreeningInd]</p>	<p>Defines the value of the Redirect Number screening indicator in ISDN Setup messages.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> (default)</li> <li>■ [0] <b>User Provided</b></li> <li>■ [1] <b>User Passed</b></li> <li>■ [2] <b>User Failed</b></li> <li>■ [3] <b>Network Provided</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
'Set IP-to-Tel Redirect Reason'	Defines the redirect reason for IP-to-Tel

Parameter	Description
<pre>configure voip &gt; gateway manipulation settings &gt; ip2tel- redir-reason</pre> <p>[SetIp2TelRedirectReason]</p>	<p>calls. If redirect (diversion) information is received from the IP, the redirect reason is set to the value of the parameter before the device sends it on to the Tel.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> (default)</li> <li>■ [0] <b>Unkown</b></li> <li>■ [1] <b>Busy</b></li> <li>■ [2] <b>No Reply</b></li> <li>■ [3] <b>Network Busy</b></li> <li>■ [4] <b>Deflection</b></li> <li>■ [9] <b>DTE out of Order</b></li> <li>■ [10] <b>Forwarding DTE</b></li> <li>■ [13] <b>Transfer</b></li> <li>■ [14] <b>PickUp</b></li> <li>■ [15] <b>Systematic/Unconditional</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Set Tel-to-IP Redirect Reason'</p> <pre>configure voip &gt; gateway manipulation settings &gt; tel2ip- redir-reason</pre> <p>[SetTel2IpRedirectReason]</p>	<p>Defines the redirect reason for Tel-to-IP calls. If redirect (diversion) information is received from the Tel, the redirect reason is set to the value of the parameter before the device sends it on to the IP.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> (default)</li> <li>■ [0] <b>Unkown</b></li> <li>■ [1] <b>Busy</b></li> <li>■ [2] <b>No Reply</b></li> <li>■ [3] <b>Network Busy</b></li> <li>■ [4] <b>Deflection</b></li> <li>■ [9] <b>DTE out of Order</b></li> <li>■ [10] <b>Forwarding DTE</b></li> <li>■ [13] <b>Transfer</b></li> <li>■ [14] <b>PickUp</b></li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [15] <b>Systematic/Unconditional</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Send Screening Indicator to IP'</p> <pre>configure voip &gt; gateway digital settings &gt; send-screen- to-ip</pre> <p>[ScreeningInd2IP]</p>	<p>Overrides the calling party's number (CPN) screening indication in the received ISDN SETUP message for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) Not configured (interworking from ISDN to IP) or set to 0 for CAS.</li> <li>■ [0] <b>User Provided</b> = CPN set by user, but not screened (verified).</li> <li>■ [1] <b>User Passed</b> = CPN set by user, verified and passed.</li> <li>■ [2] <b>User Failed</b> = CPN set by user, and verification failed.</li> <li>■ [3] <b>Network Provided</b> = CPN set by network.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the Remote Party ID (RPID) header is enabled.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<p>'Send Screening Indicator to ISDN'</p> <pre>configure voip &gt; gateway digital settings &gt; send-screen- to-isdn</pre> <p>[ScreeningInd2ISDN]</p>	<p>Defines (overrides) the screening indicator of the calling party's number in the ISDN Setup message for IP-to-Tel ISDN calls. This is applicable only when the device includes one calling party number in the outgoing ISDN Setup message.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) Not configured (interworking from IP to ISDN).</li> <li>■ [0] <b>User Provided</b> = Screening indicator is set to "user provided, not screened".</li> <li>■ [1] <b>User Passed</b> = Screening indicator</li> </ul>

Parameter	Description
	<p>is set to "user provided, verified and passed".</p> <ul style="list-style-type: none"> <li>■ [2] <b>User Failed</b> = Screening indicator is set to "user provided, verified and failed".</li> <li>■ [3] <b>Network Provided</b> = Screening indicator is set to "network provided".</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital (ISDN) interfaces.</li> <li>■ If the device includes two calling party numbers in the outgoing ISDN Setup message, this parameter is ignored and the screening indicator of the first and second calling party numbers are configured by the [ScreeningInd2ISDN1] and [ScreeningInd2ISDN2] parameters, respectively.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; send-screen- to-isdn-1 [ScreeningInd2ISDN1]</pre>	<p>Defines (overrides) the screening indicator for the first calling party number when the device includes two calling party numbers in the outgoing ISDN Setup message for IP-to-Tel ISDN calls.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = Not configured (interworking from IP to ISDN).</li> <li>■ [0] <b>User Provided</b> = (Default) Screening indicator is set to "user provided, not screened".</li> <li>■ [1] <b>User Passed</b> = Screening indicator is set to "user provided, verified and passed".</li> <li>■ [2] <b>User Failed</b> = Screening indicator is set to "user provided, verified and failed".</li> <li>■ [3] <b>Network Provided</b> = Screening</li> </ul>

Parameter	Description
	<p>indicator is set to "network provided".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital (ISDN) interfaces.</li> <li>■ If the device includes only one calling party number in the outgoing ISDN Setup message, the screening indicator is configured by the [ScreeningInd2ISDN] parameter.</li> </ul>
<pre>configure voip &gt; gateway digital settings &gt; send-screen- to-isdn-2</pre> <p>[ScreeningInd2ISDN2]</p>	<p>Defines (overrides) the screening indicator for the second calling party number when the device includes two calling party numbers in the outgoing ISDN Setup message for IP-to-Tel ISDN calls.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = Not configured (interworking from IP to ISDN).</li> <li>■ [0] <b>User Provided</b> = Screening indicator is set to "user provided, not screened".</li> <li>■ [1] <b>User Passed</b> = Screening indicator is set to "user provided, verified and passed".</li> <li>■ [2] <b>User Failed</b> = Screening indicator is set to "user provided, verified and failed".</li> <li>■ [3] <b>Network Provided</b> = (Default) Screening indicator is set to "network provided".</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital (ISDN) interfaces.</li> <li>■ The SIP header in the incoming INVITE message from where the device obtains the second calling party number is configured by the</li> </ul>

Parameter	Description
	<p>[SecondCallingNumberSource] parameter.</p> <ul style="list-style-type: none"> <li>■ If the device includes only one calling party number in the outgoing ISDN Setup message, the screening indicator is configured by the [ScreeningInd2ISDN] parameter.</li> </ul>
<p>'Copy Destination Number to Redirect Number'</p> <pre>configure voip &gt; gateway digital settings &gt; cp-dst-nb-2- redir-nb</pre> <p>[CopyDest2RedirectNumber]</p>	<p>Enables the device to copy the called number (from the received ISDN message for digital interfaces) to the outgoing SIP Diversion header for Tel-to-IP calls (even if a Redirecting Number IE is not received in the ISDN Setup message for digital interfaces). Therefore, the called number is used as a redirect number. Call redirection information is typically used for Unified Messaging and voice mail services to identify the recipient of a message.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Don't copy</b> = (Default) Disable.</li> <li>■ [1] <b>Copy after phone number manipulation</b> = Copies the called number after manipulation. The device first performs Tel-to-IP destination phone number manipulation (i.e., on the SIP To header), and only then copies the manipulated called number to the SIP Diversion header for the Tel-to-IP call. Therefore, with this option, the called and redirect numbers are identical.</li> <li>■ [2] <b>Copy before phone number manipulation</b> = Copies the called number before manipulation. The device first copies the original called number to the SIP Diversion header, and then performs Tel-to-IP destination phone number manipulation. Therefore, this allows you to have different numbers for the</li> </ul>

Parameter	Description
	<p>called (i.e., SIP To header) and redirect (i.e., SIP Diversion header) numbers.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Digital interfaces: If the incoming ISDN-to-IP call includes a Redirect Number, this number is overridden by the new called number if the parameter is set to [1] or [2].</li> <li>■ Digital interfaces: You can also use this feature for IP-to-Tel calls, by configuring the parameter per IP Profile ('Copy Destination Number to Redirect Number'). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</li> </ul>
<pre>configure voip &gt; sip-definition settings &gt; rep-calling-w-redir [ReplaceCallingWithRedirectNumber]</pre>	<p>Enables the replacement of the calling number with the redirect number for ISDN-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = The calling name is removed and left blank. The outgoing INVITE message excludes the redirect number that was used to replace the calling number. The replacement is done only if a redirect number is present in the incoming Tel call.</li> <li>■ [2] = Manipulation is done on the new calling party number (after manipulation of the original calling party number, using the Tel2IPSourceNumberMappingDialPlan Index parameter), but before the regular calling or redirect number manipulation: <ul style="list-style-type: none"> <li>✓ If a redirect number exists, it replaces the calling party number. If there is no redirect number, the calling number is left unchanged.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ If there is a calling “display” name, it remains unchanged.</li> <li>✓ The redirect number remains unchanged and is included in the SIP Diversion header.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Add Trunk Group ID as Prefix'</p> <pre>configure voip &gt; gateway routing settings &gt; trkgrp-id- prefix</pre> <p>[AddTrunkGroupAsPrefix]</p>	<p>Determines whether the Trunk Group ID is added as a prefix to the destination phone number (i.e., called number) for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Don't add Trunk Group ID as prefix.</li> <li>■ [1] <b>Yes</b> = Add Trunk Group ID as prefix to called number.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This option can be used to define various routing rules.</li> <li>■ To use this feature, you must configure the Trunk Group IDs (see <a href="#">Configuring Trunk Groups</a> on page 934).</li> </ul>
<p>'Add Trunk ID as Prefix'</p> <pre>configure voip &gt; gateway routing settings &gt; trk-id-as- prefix</pre> <p>[AddPortAsPrefix]</p>	<p>Defines if the slot number / port number / Trunk ID is added as a prefix to the called (destination) number for Tel-to-IP calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> (Default)</li> <li>■ [1] <b>Yes</b></li> </ul> <p>If enabled, the device adds the following prefix to the called phone number: slot number (a single digit in the range of 1 to 6) and port number/Trunk ID (single digit in the range 1 to 8). For example, for the first trunk/channel located in the first slot, the number "11" is added as the prefix.</p> <p>This option can be used to define various routing rules.</p>

Parameter	Description
'Add Trunk Group ID as Prefix to Source' <code>trkgrp-id-pref2source</code> <code>[AddTrunkGroupAsPrefixToSource]</code>	Enables the device to add the Trunk ID (from where the call originated) as the prefix to the calling number (i.e. source number).  <input type="checkbox"/> [0] <b>No</b> (default) <input type="checkbox"/> [1] <b>Yes</b>
'Replace Empty Destination with B-channel Phone Number' <code>configure voip &gt; gateway routing settings &gt; empty-dst-w-bch-nb</code> <code>[ReplaceEmptyDstWithPortNumber]</code>	Determines whether the internal channel number is used as the destination number if the called number is missing.  <input type="checkbox"/> [0] <b>No</b> (default) <input type="checkbox"/> [1] <b>Yes</b>  <b>Note:</b> <input type="checkbox"/> The parameter is applicable only to Tel-to-IP calls and if the called number is missing. <input type="checkbox"/> The parameter is applicable only to digital interfaces.
<code>[CopyDestOnEmptySource]</code>	Determines whether the destination number is copied to the source number if no source number is present, for Tel-to-IP calls.  <input type="checkbox"/> [0] = (Default) Source Number is left empty. <input type="checkbox"/> [1] = If the Source Number of a Tel-to-IP call is empty, the Destination Number is copied to the Source Number.  <b>Note:</b> The parameter is applicable only to digital interfaces.
'Add NPI and TON to Calling Number' <code>configure voip &gt; gateway routing settings &gt; np-i-n-ton-to-cng-nb</code> <code>[AddNPIandTON2CallingNumber]</code>	Determines whether the Numbering Plan Indicator (NPI) and Type of Numbering (TON) are added to the Calling Number for Tel-to-IP calls.  <input type="checkbox"/> [0] <b>No</b> = (Default) Do not change the Calling Number.

Parameter	Description
	<p>■ [1] <b>Yes</b> = Add NPI and TON to the Calling Number ISDN Tel-to-IP call.</p> <p>For example: After receiving a Calling Number of 555, NPI of 1, and TON of 3, the modified number becomes 13555. This number can later be used for manipulation and routing.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Add NPI and TON to Called Number'</p> <pre>configure voip &gt; gateway routing settings &gt; npn-ntn- to-cld-nb</pre> <p>[AddNPIandTON2CalledNumber]</p>	<p>Determines whether NPI and TON are added to the Called Number for Tel-to-IP calls.</p> <p>■ [0] <b>No</b> = (Default) Do not change the Called Number.</p> <p>■ [1] <b>Yes</b> = Add NPI and TON to the Called Number of ISDN Tel-to-IP call.</p> <p>For example: After receiving a Called Number of 555, NPI of 1 and TON of 3, the modified number becomes 13555. This number can later be used for manipulation and routing.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Add NPI and TON to Redirect Number'</p> <pre>configure voip &gt; gateway digital settings &gt; npn-ntn-2- redirnb</pre> <p>[AddNPIandTON2RedirectNumber]</p>	<p>Determines whether the NPI and TON values are added as the prefix to the Redirect number in INVITE messages' Diversion or History-Info headers, for ISDN Tel-to-IP calls.</p> <p>■ [0] <b>Yes</b> (Default)</p> <p>■ [1] <b>No</b></p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'IP-to-Tel Remove Routing Table Prefix'</p> <pre>configure voip &gt; gateway routing settings &gt; ip2tel-rmv- rte-tbl</pre> <p>[RemovePrefix]</p>	<p>Determines whether or not the device removes the prefix, as configured in the IP-to-Tel Routing table (see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960) from the destination number for IP-to-Tel calls,</p>

Parameter	Description
	<p>before sending it to the Tel.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = (Default) Disabled.</li> <li>■ [1] Check box selected = Enabled.</li> </ul> <p>For example: To route an incoming IP-to-Tel call with destination number "21100", the IP-to-Tel Routing table is scanned for a matching prefix. If such a prefix is found (e.g., "21"), then before the call is routed to the corresponding Trunk Group, the prefix "21" is removed from the original number, and therefore, only "100" remains.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if number manipulation is done after call routing for IP-to-Tel calls (i.e., RouteModelIP2Tel parameter is set to 0).</li> <li>■ Similar operation (of removing the prefix) is also achieved by using the usual number manipulation rules.</li> </ul>
<p>'Swap Redirect and Called Numbers'</p> <pre>configure voip &gt; gateway digital settings &gt; swap-rdr-n- called-nb</pre> <p>[SwapRedirectNumber]</p>	<ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Don't change numbers.</li> <li>■ [1] <b>Yes</b> = Incoming ISDN call that includes a redirect number (sometimes referred to as 'original called number') uses the redirect number instead of the called number.</li> </ul> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<pre>configure voip &gt; gateway manipulation settings &gt; use- refer-by-for-calling-num</pre> <p>[UseReferredByForCallingNumber]</p>	<p>Determines whether the device uses the number from the URI in the SIP Referred-By header as the calling number in the outgoing Q.931 Setup message, when SIP REFER messages are received.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) No</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] = Yes</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to all ISDN (TBCT, RLT, ECT) and CAS blind call transfers (except for in-band) and when the device receives SIP REFER messages with a Referred-By header.</li> <li>■ This manipulation is done before regular IP-to-Tel source number manipulation.</li> <li>■ The parameter is applicable only to digital interfaces.</li> </ul>
<pre>configure voip &gt; gateway manipulation settings &gt; swap- tel-to-ip-phone-num</pre> <p>[SwapTel2IPCalled&amp;CallingNumbers]</p>	<p>Global parameter enabling the device to swap the calling and called numbers received from the Tel side (for Tel-to-IP calls).</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('Swap Tel To IP Phone Numbers' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</p>
<p>'Add Prefix to Redirect Number'</p> <pre>configure voip &gt; gateway digital settings &gt; add-pref-to- redir-nb</pre> <p>[Prefix2RedirectNumber]</p>	<p>Defines a string prefix that is added to the Redirect number received from the Tel side. This prefix is added to the Redirect Number in the SIP Diversion header.</p> <p>The valid range is an 8-character string. By default, no value is defined.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
<p>'Add Number Plan and Type to RPI Header'</p> <pre>np-n-type-to-rpi-hdr</pre> <p>[AddTON2RPI]</p>	<p>Determines whether the TON/PLAN parameters are included in the Remote-Party-ID (RPID) header.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b> (default)</li> </ul> <p>If the Remote-Party-ID header is enabled (EnableRPIHeader = 1) and AddTON2RPI = 1, it's possible to configure the calling and called number type and number plan using the Number Manipulation tables for Tel-to-IP calls.</p>
<p>'Source Manipulation Mode'</p> <pre>configure voip &gt; gateway routing settings &gt; src- manipulation</pre> <p>[SourceManipulationMode]</p>	<p>Determines the SIP headers containing the source number after manipulation:</p> <ul style="list-style-type: none"> <li>■ [0] <b>From and P-Asserted-Identity after Manipulation</b> = (Default) The SIP From and P-Asserted-Identity headers contain the source number after manipulation.</li> <li>■ [1] <b>Only From after Manipulation</b> = Only SIP From header contains the source number after manipulation, while the P-Asserted-Identity header contains the source number before manipulation.</li> </ul>
<pre>configure voip &gt; gateway manipulation settings &gt; prfm- ip-to-tel-dst-map</pre> <p>[PerformAdditionalIP2TELDestinationManipulation]</p>	<p>Enables additional destination number manipulation for IP-to-Tel calls. The additional manipulation is done on the initially manipulated destination number, and this additional rule is also configured in the manipulation table (NumberMapIP2Tel parameter). This enables you to configure only a few manipulation rules for complex number manipulation requirements (that generally require many rules).</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default)</li> <li>■ [1] = Enable</li> </ul>
<pre>configure voip &gt; gateway manipulation settings &gt; prfm- ip-to-tel-src-map</pre> <p>[PerformAdditionalIP2TELSourceManipulation]</p>	<p>Enables additional source number manipulation for IP-to-Tel calls. The additional manipulation is done on the</p>

Parameter	Description
n]	<p>initially manipulated source number, and this additional rule is also configured in the manipulation table (SourceNumberMapIP2Tel parameter). This enables you to configure only a few manipulation rules for complex number manipulation requirements (that generally require many rules).</p> <p>■ [0] = Disable (default)</p> <p>■ [1] = Enable</p>
<p>'Add Phone Context As Prefix'</p> <pre>configure voip &gt; gateway manipulation settings &gt; add-ph- cntxt-as-pref</pre> <p>[AddPhoneContextAsPrefix]</p>	<p>Determines whether the received Phone-Context parameter is added as a prefix to the outgoing called and calling numbers (in ISDN Setup messages for digital interfaces).</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>

## Answer and Disconnect Supervision Parameters

The answer and disconnect supervision parameters are described in the table below.

**Table 73-69:Answer and Disconnect Parameters**

Parameter	Description
<p>'Wait before PSTN Release-Ack'</p> <pre>configure voip &gt; gateway digital settings &gt; wait- befor-pstn-rel-ack</pre> <p>[TimeToWaitForPstnReleaseAck]</p>	<p>Defines a timeout (in milliseconds) that the device waits for the receipt of an ISDN Q.931 Release message from the PSTN side before releasing the channel. The Release ACK is typically sent by the PSTN in response to the device's Disconnect message to end the call. If the timeout expires and a Release message has not yet been received, the device releases the call channel.</p> <p>The valid value is 1 to 360,000. The default is 6,000.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>

Parameter	Description
<pre>configure voip &gt; interface e1-t1 &gt; isdn-japan-ntt- timer-t305</pre> <p>[ISDNJapanNttTimerT305]</p>	<p>Defines a timeout (in seconds) that the device waits before sending an ISDN Release message after it has sent a Disconnect message, if no SIP message (e.g., 4xx response) is received within the timeout. The parameter is applicable when the device's trunk is configured for the Japanese NTT ISDN PRI (T1) variant (i.e., [ProtocolType] is [16], as described in <a href="#">Configuring Trunk Settings</a> on page 878).</p> <p>The valid value is 0 to 480. The default is 0 (i.e., timeout is 30 seconds).</p> <p>For more information on this feature, see <a href="#">SIP-to-ISDN Disconnect Release Cause Code Mapping</a> on page 1012.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to digital interfaces (T1 NTT).</li> </ul>
<p>'Answer Supervision'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; answer-supervision</pre> <p>[EnableVoiceDetection]</p>	<p>Enables the sending of SIP 200 OK upon detection of speech, fax, or modem.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Yes</b> = The device sends a SIP 200 OK (in response to an INVITE message) when speech, fax, or modem is detected (from the Tel side, for analog interfaces).</li> <li>■ [0] <b>No</b> = (Default) The device sends a SIP 200 OK only after it completes dialing (to the Tel side, for analog interfaces).</li> </ul> <p>Typically, this feature is used only when early media, enabled by the [EnableEarlyMedia] parameter, is used to establish the voice path before the call is answered.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ FXO interfaces: The feature is applicable only to one-stage dialing (FXO).</li> <li>■ Digital interfaces:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ The parameter is applicable only when the protocol type is CAS.</li> <li>✓ To activate the feature, configure the [EnableDSIPMDetectors] parameter to 1.</li> </ul>
'GW Max Call Duration' configure voip > sip- definition settings > gw- mx-call-duration [GWMaxCallDuration]	<p>Defines the maximum duration (in minutes) per Gateway call. If this duration is reached, the device ends the call. This feature is useful for ensuring that device resources are available for new calls.</p> <p>The valid range is 0 to 35,791. A value of 0 means unlimited duration. The default is 0.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
configure voip > sip- definition settings > mn- call-duration [MinCallDuration]	<p>Defines the minimum call duration (in seconds) for the Tel side. If an established call is terminated by the IP side before this duration expires, the device terminates the call with the IP side, but delays the termination toward the Tel side until this timeout expires.</p> <p>The valid value range is 0 to 10 seconds, where 0 (default) disables this feature.</p> <p>For example: assume the minimum call duration is set to 10 seconds and an IP phone hangs up a call established with a BRI phone after 2 seconds. As the call duration is less than the minimum call duration, the device doesn't disconnect the call on the Tel side. However, it sends a SIP 200 OK immediately upon receipt of the BYE to disconnect from the IP phone. The call is disconnected from the Tel side only when the call duration is greater than or equal to the minimum call duration.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The parameter is applicable to IP-to-Tel and Tel-to-IP calls.</li> <li>■ The parameter is applicable only to ISDN</li> </ul>

Parameter	Description
	and CAS protocols.
<p>'Disconnect on Dial Tone'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; disc- on-dial-tone</pre> <p>[DisconnectOnDialTone]</p>	<p>Determines whether the device disconnects a call when a dial tone is detected from the PBX.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Call is not released.</li> <li>■ [1] <b>Enable</b> = Call is released if a dial tone is detected on the device's FXO port.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ This option is in addition to the mechanism that disconnects a call when either busy or reorder tones are detected.</li> </ul>
<p>'Send Digit Pattern on Connect'</p> <pre>configure voip &gt; sip- definition settings &gt; digit-pttrn-on-conn</pre> <p>[TelConnectCode]</p>	<p>Defines a digit pattern to send to the Tel side after a SIP 200 OK is received from the IP side. The digit pattern is a user-defined DTMF sequence that is used to indicate an answer signal (e.g., for billing).</p> <p>The valid value is up to 8 characters.</p> <p><b>Note:</b> The parameter is applicable only to FXO and CAS.</p>
<p>'Broken Connection Mode'</p> <pre>configure voip &gt; sip- definition settings &gt; disc- broken-conn</pre> <p>[DisconnectOnBrokenConnection]</p>	<p>Global parameter that defines the device's handling of calls if RTP or MSRP packets are not received within a user-defined timeout (configured by the 'Broken Connection Timeout' parameter) during an established call (i.e., packet flow suddenly stops during the call).</p> <p>You can also configure this feature per specific calls, using IP Profiles ('<a href="#">Broken Connection Mode</a>' on page 736'). For a detailed description of the global parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
'No RTP Mode'	Global parameter that defines the device's

Parameter	Description
<pre>configure voip &gt; sbc settings &gt; no-rtp-mode</pre> <p>[NoRTPMode]</p>	<p>handling of calls if RTP packets are not received (detected) during early media or upon call connect (i.e., never was RTP) within a timeout. The timeout is configured by the [NoRTPDetectionTimeout] parameter.</p> <p>You can also configure this feature per specific calls, using IP Profiles ('<a href="#">No RTP Mode</a>' on page 737' parameter). For a detailed description of the global parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Broken Connection Timeout'</p> <pre>configure voip &gt; sip- definition settings &gt; broken-connection-event- timeout</pre> <p>[BrokenConnectionEventTimeout]</p>	<p>Defines the timeout interval (in 100-msec units) after which a call is disconnected if RTP packets are not received during an established call (i.e., packet flow suddenly stops during the call). The valid range is from 3 (i.e., 3 x 100 = 300 msec) to approx. 2684354 (i.e., 74.5 hours). The default is 100 msec.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only when the 'Broken Connection Mode' parameter is configured to <b>Disconnect</b>.</li> <li>■ For this feature to function, you also need to disable silence suppression.</li> </ul>
<pre>configure voip &gt; sbc settings &gt; no-rtp- detection-timeout</pre> <p>[NoRTPDetectionTimeout]</p>	<p>Defines the timeout interval (in msec) after which a call is disconnected or re-routed if RTP packets are not received within the interval. The valid range is 0 to 50000. The default is 0, which means that this timeout feature is disabled and that the device doesn't disconnect the call due to packets not being received.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable to the 'Broken Connection Mode' and 'No RTP Mode' parameters.</li> <li>■ If a call is already established and RTP exists and at any stage during the call packets are not detected for a user-defined interval (configured by the 'Broken Connection Timeout' parameter), the device disconnects the call or routes it to an alternative destination, configured by the IP Profile parameter <a href="#">"Broken Connection Mode"</a> on page 736'.</li> <li>■ The parameter is not applicable to MSRP and direct media calls for the SBC application (see <a href="#">Direct Media Calls</a> on page 1135).</li> </ul>
'Timeout to Establish MSRP Connection' configure voip > sbc settings > msrp-connection- establish-timeout [MSRPConnectionEstablishTimeout]	<p>Defines the timeout (msec) for establishing MSRP connections.</p> <p>The timer starts from when the device opens the MSRP media socket (port). If the timeout expires and the connection wasn't established, the device does one of the following:</p> <ul style="list-style-type: none"> <li>■ Ends the SIP session.</li> <li>■ If you've enabled the Broken Connection feature, the device searches for an alternative route in the IP-to-IP Routing table. For more information, see the IP Profile's 'Broken Connection Mode' parameter in <a href="#">Configuring IP Profiles</a> on page 674.</li> </ul> <p>The valid value is 10000 to 120000. The default is 10000 (i.e., 10 sec).</p> <p>For more information, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p>
'Trunk Alarm Call Disconnect Timeout' trk-alm-call-disc-to [TrunkAlarmCallDisconnectTimeout]	<p>Defines the duration (in seconds) to wait after a digital trunk Red alarm (LOS / LOF) is raised, before the device disconnects the SIP call. If this timeout expires and the alarm is still raised, the device sends a SIP BYE message to terminate</p>

Parameter	Description
	<p>the call. If the alarm is cleared before this timeout expires, the call is not terminated, but continues as normal.</p> <p>The range is 1 to 3600. The default is 0 (20 for BRI, 20 for E1 and 40 for T1).</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Disconnect Call on Busy Tone Detection (ISDN)'</p> <pre>configure voip &gt; gateway digital settings &gt; disc-on- bsy-tone-i</pre> <p>[ISDNDisconnectOnBusyTone]</p>	<p>Defines if a call is disconnected upon detection of a busy tone.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. Do not disconnect call upon detection of busy tone.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Disconnect call upon detection of busy tone.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to ISDN protocols.</li> <li>■ IP-to-ISDN calls are disconnected on detection of SIT tones only in call alert state. If the call is in connected state, the SIT doesn't disconnect the calls. Detection of busy or reorder tones disconnects the IP-to-ISDN calls also in call connected state.</li> <li>■ For IP-to-CAS calls, detection of busy, reorder, or SIT tones disconnect the calls in any call state.</li> </ul>
<p>'Disconnect Call on Busy Tone Detection (CAS)'</p> <pre>configure voip &gt; gateway analog fxo-setting &gt; disc- on-bsy-tone-c</pre> <p>[DisconnectOnBusyTone]</p>	<p>Global parameter enabling call disconnection upon detection of a busy tone.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('Disconnect Call on Detection of Busy Tone' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the</li> </ul>

Parameter	Description
	<p>Gateway application.</p> <ul style="list-style-type: none"> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
<b>Polarity (Current) Reversal for Call Release (Analog Interfaces) Parameters</b>	
<pre>configure voip &gt; interface fxs-fxo &gt; default- linepolarity-state [SetDefaultLinePolarityState]</pre>	<p>Defines the FXO line polarity, required for DID signaling.</p> <ul style="list-style-type: none"> <li>■ [0] = Positive line polarity</li> <li>■ [1] = Negative line polarity</li> <li>■ [2] = (Default) Auto - The device detects the polarity upon power-up or upon insertion of the RJ-11 cable, and uses it as a reference polarity.</li> </ul> <p>Typically, if the RJ-11 cabling is connected correctly (without crossing, Tip to Tip, Ring to Ring), the Tip line is positive compared to the Ring line. In this case, set the parameter to 0. With this configuration, the device assumes that the idle line polarity is Tip line positive.</p> <p>When the device receives a SIP INVITE, it checks the FXO line polarity. If the polarity is "Reversed", it skips this FXO line and goes to the next line.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ To take advantage of this new feature, configure all FXO lines as a single Trunk Group with ascending or descending channel select mode, and configure routing rules to route incoming INVITE messages to this Trunk Group.</li> <li>■ The parameter is applicable only to FXO interfaces.</li> </ul>
'Polarity Reversal'	Global parameter enabling the Line Polarity Reversal feature for call release.

Parameter	Description
<pre>configure voip &gt; sip- definition settings &gt; polarity-rvrsl</pre> <p>[EnableReversalPolarity]</p>	<p>You can also configure the feature per specific calls, using Tel Profiles ('Enable Polarity Reversal' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to FXS and FXO interfaces.</li> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
<p>'Current Disconnect'</p> <pre>configure voip &gt; sip- definition settings &gt; current-disc</pre> <p>[EnableCurrentDisconnect]</p>	<p>Global parameter enabling call release upon detection of a Current Disconnect signal. You can also configure the feature per specific calls, using Tel Profiles ('Enable Current Disconnect' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to FXS and FXO interfaces.</li> <li>■ If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls associated with the Tel Profile.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; polarity- reversal-type</pre> <p>[PolarityReversalType]</p>	<p>Defines the voltage change slope during polarity reversal or wink.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Soft reverse polarity.</li> <li>■ [1] = Hard reverse polarity.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ Some Caller ID signals use reversal polarity or Wink signals, or both. In these cases, it is</li> </ul>

Parameter	Description
	<p>recommended to configure the parameter to [1] (Hard).</p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; current- disconnect-duration</pre> <p>[CurrentDisconnectDuration]</p>	<p>Defines the duration (in msec) of the current disconnect pulse.</p> <p>The range is 200 to 1500. The default is 900.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable for FXS and FXO interfaces.</li> <li>■ The FXO interface detection window is 100 msec below the parameter's value and 350 msec above the parameter's value. For example, if the parameter is set to 400 msec, then the detection window is 300 to 750 msec.</li> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
[CurrentDisconnectDefaultThreshold]	<p>Defines the line voltage threshold at which a current disconnect detection is considered.</p> <p>The valid range is 0 to 20 Volts. The default is 4 Volts.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ For the parameter to take effect, a device restart is required.</li> </ul>
<pre>configure voip &gt; interface fxs-fxo &gt; time-to-sample- analog-line-voltage</pre> <p>[TimeToSampleAnalogLineVoltage]</p>	<p>Defines the frequency at which the analog line voltage is sampled (after offhook), for detection of the current disconnect threshold.</p> <p>The valid range is 100 to 2500 msec. The default is 1000 msec.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ For the parameter to take effect, a device</li> </ul>

Parameter	Description
	restart is required.

## SBC Parameters

The SBC parameters are described in the table below.

**Table 73-70:SBC Parameters**

Parameter	Description
<b>SBC-specific Parameters</b>	
<code>configure voip &gt;</code> <code>application &gt; enable-sbc</code> [EnableSBCApplication]	<p>Enables the Session Border Control (SBC) application.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable</li> <li>■ [1] = Enable (default)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is enabled by default only if the License Key contains at least one of the SBC-related capacity features (e.g., "SBC-Signaling"); otherwise, the parameter is disabled.</li> </ul>
<b>SBC Parameters</b>	
<p>'Terminate Inbound OPTIONS'</p> <code>configure voip &gt; sbc</code> <code>settings &gt; sbc-terminate-</code> <code>options</code> [SBCTerminateOptions]	<p>Enables the device to terminate incoming in-dialog SIP OPTIONS messages or forward them to the outbound leg.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = Disable.</li> <li>■ [1] Check box selected =(Default) Enabled.</li> </ul>
<p>'Unclassified Calls'</p> <code>configure voip &gt; sbc</code> <code>settings &gt; unclassified-</code> <code>calls</code> [AllowUnclassifiedCalls]	<p>Determines whether incoming calls that cannot be classified (i.e. classification process fails) to a Source IP Group are rejected or processed.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Reject</b> = (Default) Call is rejected if classification fails.</li> <li>■ [1] <b>Allow</b> = If classification fails, the</li> </ul>

Parameter	Description
	<p>incoming packet is assigned to a source IP Group (and subsequently processed) as follows:</p> <ul style="list-style-type: none"> <li>✓ The source SRD is determined according to the SIP Interface to where the SIP-initiating dialog request is sent. The source IP Group is set to the default IP Group associated with this SRD.</li> <li>✓ If the source SRD is ID 0, then source IP Group ID 0 is chosen. In case of any other SRD, then the first IP Group associated with this SRD is chosen as the source IP Group or the call. If no IP Group is associated with this SRD, the call is rejected.</li> </ul>
<p>'SBC Max Call Duration'</p> <pre>configure voip &gt; sbc settings &gt; sbc-mx-call- duration</pre> <p>[SBCMaxCallDuration]</p>	<p>Defines the maximum duration (in minutes) per SBC call (global). If the duration is reached, the device terminates the call.</p> <p>The valid range is 0 to 35,791, where 0 is unlimited duration. The default is 0.</p> <p><b>Note:</b> You can also configure this feature per specific calls, using IP Profiles ('Max Call Duration' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674. If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'SBC No Answer Timeout'</p> <pre>configure voip &gt; sbc settings &gt; sbc-no-alert- timeout</pre> <p>[SBCAlertTimeout]</p>	<p>Defines the timeout (in seconds) for SIP INVITE messages sent by the device (outbound IP routing).</p> <p>The device starts the timeout when it sends the INVITE message and when (if) it receives the first SIP 18x response (e.g., 180 Ringing) from the called party. The timeout that is started when the INVITE message is sent, is <b>only</b> used if no 18x response is received.</p> <p>If the timeout expires and no additional SIP</p>

Parameter	Description
	<p>response (for example, 200 OK) was received during this interval, the device releases the call. The valid range is 0 to 3600 seconds. the default is 600.</p>
<pre>configure voip &gt; sbc settings &gt; num-of- subscribes</pre> <p>[NumOfSubscribes]</p>	<p>Defines the maximum number of concurrent SIP SUBSCRIBE sessions permitted on the device.</p> <p>The valid value is any value between 0 and the maximum supported SUBSCRIBE sessions. When set to -1, the device uses the default value. For more information, contact the sales representative of your purchased device.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<pre>configure voip &gt; sbc settings &gt; sbc-dialog- subsc-route-mode</pre> <p>[SBCInDialogSubscribeRouteMode]</p>	<p>Enables the device to route in-dialog, refresh SIP SUBSCRIBE requests to the "working" (has connectivity) proxy.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable – the device sends in-dialog, refresh SUBSCRIBES according to the address in the Contact header of the 200 OK response received from the proxy to which the initial SUBSCRIBE was sent (as per the SIP standard).</li> <li>■ [1] = Enable – the device routes in-dialog, refresh SUBSCRIBES to the "working" proxy (regardless of the Contact header). The "working" proxy (address) is determined by the device's keep-alive mechanism for the Proxy Set that was used to route the initial SUBSCRIBE.</li> </ul> <p><b>Note:</b> For this feature to be functional, ensure the following:</p> <ul style="list-style-type: none"> <li>■ Keep-alive mechanism is enabled for the Proxy Set ('Proxy Keep-Alive' parameter is set to any value other than <b>Disable</b>).</li> <li>■ Load-balancing between proxies is disabled ('Proxy Load Balancing Method' parameter is set to <b>Disable</b>).</li> </ul>

Parameter	Description
<p>'Backup Subscriptions'</p> <pre>config voip &gt; sbc settings &gt; backup-subscriptions</pre> <p>[BackupSubscriptions]</p>	<p>Defines which SIP SUBSCRIBE dialogs for registered users the device (operating in HA mode) backs up, based on transport protocol. Backing up SUBSCRIBE dialogs allows the redundant (now active) device to maintain user subscriptions and send relevant NOTIFY messages to the users (SIP UAs) after an HA switchover.</p> <ul style="list-style-type: none"> <li>■ [0] <b>All</b> = (Default) The device backs up all SUBSCRIBE dialogs (regardless of used transport protocol).</li> <li>■ [1] <b>UDP</b> = The device backs up only SUBSCRIBE dialogs that use UDP.</li> <li>■ [2] <b>None</b> = The device doesn't back up any SUBSCRIBE dialogs.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For SUBSCRIBE dialogs that use TCP or TLS connections, it may be beneficial to configure the parameter to <b>UDP</b> or <b>None</b>. For these registered users, the device needs to establish new TCP or TLS connections (typically initiated by the remote UA) after the switchover. Therefore, backing up these SUBSCRIBE dialogs is unnecessary, wasting valuable resources.</li> <li>■ The parameter is applicable only when the device operates in HA mode.</li> </ul>
<p>'Disconnect Subscriptions Mode'</p> <pre>config voip &gt; sbc settings &gt; disconnect-subscriptions</pre> <p>[DisconnectSubscriptionsMode]</p>	<p>Enables the device to disconnect (delete from storage) SUBSCRIBE dialogs associated with registered users, upon an unregister, upon register expiration, or upon a refresh register done from a different source IP address / port (like when the transport protocol is TCP or TLS).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device stores the SUBSCRIBE dialogs of registered users until the subscriptions' expiration times are reached.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device disconnects (deletes) SUBSCRIBE dialogs of registered users upon an unregister, upon a register expiration, or upon a refresh register done from a different source IP address / port.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<pre>configure voip &gt; sbc settings &gt; sbc-max-fwd- limit</pre> <p>[SBCMaxForwardsLimit]</p>	<p>Defines the Max-Forwards SIP header value. The Max-Forwards header is used to limit the number of servers (such as proxies) that can forward the SIP request. The Max-Forwards value indicates the remaining number of times this request message is allowed to be forwarded. The count is decremented by each server that forwards the request.</p> <p>The valid value range is 1-70. The default is 10. The parameter affects the Max-Forwards header in the received message as follows:</p> <ul style="list-style-type: none"> <li>■ If the received header's original value is 0, the message is not passed on and is rejected.</li> <li>■ If the received header's original value is less than the parameter's value, the header's value is decremented before being sent on.</li> <li>■ If the received header's original value is greater than the parameter's value, the header's value is replaced by the user-defined parameter's value.</li> </ul>
<p>'Play Tone on Connect Failure Behavior'</p> <pre>play-tone-on-connect- failure-behavior</pre> <p>[PlayToneOnConnectFailureBehavior]</p>	<p>Defines if the device connects or disconnects the call if it can't play the specified tone to the call party. This parameter relates to the feature that is described in <a href="#">Playing Tone upon Call Connect</a> on page 1299.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disconnect</b> (Default)</li> <li>■ [1] <b>Ignore</b></li> </ul>

Parameter	Description
<pre>configure voip &gt; sip- definition settings &gt; force-generate-to-tag [ForceGenerateToTag]</pre>	<p>Enables the device to generate the 'tag' parameter's value in the SIP To header. This is applied to the first SIP response, received from the called party, which the device sends to the dialog-initiating SIP user agent (caller). In other words, this device-generated To tag overwrites the original To tag generated by the called party. All SIP messages between the device and caller use this generated To tag, while all SIP messages between the device and called party use the To tag generated by the called party. As the device-generated To tag value is short (up to 12 characters), this feature may be useful for SIP UAs that cannot handle long tag values.</p> <p>An example of the To tag:  To: Alice@company.com; tag = 9777484849@10.10.1.110</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default). The device forwards the To tag transparently between the SIP UAs.</li> <li>■ [1] = Enable. The device generates the To tag in the response sent to the initiator of the SIP dialog.</li> </ul> <p><b>Note:</b> The feature is applicable only if the 'SBC Operation Mode' parameter is configured to <b>B2BUA</b>. This can be configured in the SRD and IP Groups table. However:</p> <ul style="list-style-type: none"> <li>■ The IP Group's 'SBC Operation Mode' parameter takes precedence over the SRD's 'SBC Operation Mode' parameter. For example, if the IP Group is configured for B2BUA but its' associated SRD is not, then the tag-generation feature can function.</li> <li>■ If the IP Group's 'SBC Operation Mode' parameter is not configured (-1), the tag-generation feature for the IP Group is functional only if its' associated SRD is configured for B2BUA.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For call routing between IP Groups, the feature can only function if both IP Groups are configured for B2BUA, or if one or both of them is not configured (-1), but the associated SRD is configured for B2BUA.</li> </ul>
<b>'Session-Expires'</b> <code>configure voip &gt; sbc</code> <code>settings &gt; sbc-sess-exp-</code> <code>time</code> <b>[SBCSessionExpires]</b>	<p>Defines the SBC session refresh timer (in seconds) in the Session-Expires header of outgoing INVITE messages.</p> <p>The valid value range is 90 (according to RFC 4028) to 86400. The default is 180.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>'Minimum Session-Expires'</b> <code>configure voip &gt; sbc</code> <code>settings &gt; min-session-</code> <code>expires</code> <b>[SBCMinSE]</b>	<p>Defines the minimum amount of time (in seconds) between session refresh requests in a dialog before the session is considered timed out. This value is conveyed in the SIP Min-SE header.</p> <p>The valid range is 0 (default) to 1,000,000, where 0 means that the device doesn't limit Session-Expires.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<code>configure voip &gt; sbc</code> <code>settings &gt; sbc-session-</code> <code>refresh-policy</code> <b>[SBCSessionRefreshingPolicy]</b>	<p>Defines the SIP user agent responsible for periodically sending refresh requests for established sessions (active calls). The session refresh allows SIP UAs or proxies to determine the status of the SIP session. When a session expires, the session is considered terminated by the UAs, regardless of whether a SIP BYE was sent by one of the UAs.</p> <p>The SIP Session-Expires header conveys the lifetime of the session, which is sent in re-INVITE or UPDATE requests (session refresh requests). The 'refresher=' parameter in the Session-Expires header (sent in the initial INVITE or subsequent 2xx response) indicates who sends the session refresh requests. If the parameter contains the value 'uac', the device performs the refreshes; if the parameter contains the value 'uas', the remote proxy</p>

Parameter	Description
	<p>performs the refreshes. An example of the Session-Expires header is shown below:</p> <pre>Session-Expires: 4000;refresher=uac</pre> <p>Thus, the parameter is useful when a UA doesn't support session refresh requests or doesn't support the indication of who performs session refresh requests. In such a scenario, the device can be configured to perform the session refresh requests.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Remote Refresher. The UA (proxy) performs the session refresh requests. The device indicates this to the UA by sending the SIP message with the 'refresher=' parameter in the Session-Expires header set to 'uas'.</li> <li>■ [1] = SBC Refresher. The device performs the session refresh requests. The device indicates this to the UA by sending the SIP message with the 'refresher=' parameter in the Session-Expires header set to 'uac'.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The time values of the Session-Expires (session refresh interval) and Min-SE (minimum session refresh interval) headers can be configured using the [SBCSessionExpires] and [SBCMinSE] parameters, respectively.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'User Registration Grace Time'</p> <pre>configure voip &gt; sbc settings &gt; sbc-usr-reg- grace-time</pre> <p>[SBCUserRegistrationGraceTime]</p>	<p>Defines additional time (in seconds) to add to the registration expiry time of users that are registered with the device.</p> <p>The valid value is 0 to 15,500,000. The default is 0.</p> <p>For more information, see <a href="#">Registration Refreshes</a> on page 1131.</p>
'DB Routing Search Mode'	Defines the method for searching a registered

Parameter	Description
configure voip > sbc settings > sbc-db-route-mode [SBCDBRoutingSearchMode]	<p>user in the device's User Registration database when a SIP INVITE message is received for routing to or from a user. If the registered user is found (i.e., destination URI in INVITE), the device routes the call to the user's corresponding contact address specified in the database.</p> <p>■ [0] <b>All permutations</b> = (Default)</p> <ul style="list-style-type: none"> <li>✓ <b>To User:</b> Device searches for the user in the database using the entire Request-URI (user@host). If not found, it searches for the user part of the Request-URI. For example, it first searches for "4709@joe.company.com" and if not found, it searches for "4709".</li> <li>✓ <b>From User:</b> Device searches for the user in the database using the entire From header AOR (user@host). If not found, it searches for the user part of the From header AOR. For example, it first searches for "4709@domain.com" and if not found, it searches for "4709".</li> </ul> <p>■ [1] <b>Dest URI dependant</b> =</p> <ul style="list-style-type: none"> <li>✓ <b>To User:</b> Device searches for the user in the database using the entire Request-URI (user@host) <b>only</b>. For example, it searches for "4709@joe.company.com".</li> <li>✓ <b>From User:</b> Device searches for the user in the database using the entire From header AOR (user@host) <b>only</b>. For example, for "From: &lt;sip:4709@domain.com&gt;", the device searches for "4709@domain.com".</li> </ul> <p><b>Note:</b> If the Request-URI contains the "tel:" URI or "user=phone" parameter, the device searches only for the user part.</p>

Parameter	Description
<p>'Skype Capabilities Header'</p> <pre>configure voip &gt; sip- definition settings &gt; skype-cap-hdr-enable</pre> <p>[DeclareAudcClient]</p>	<p>Enables the device to be identified by an AudioCodes SBC device as an AudioCodes analog device deployed in a Microsoft Skype for Business environment.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. Upon initial registration (REGISTER message) of the analog device with the SBC device, the SBC identifies the analog device as belonging to AudioCodes and enabled for operating in the Skype for Business environment. Once registered, all subsequent calls (i.e., INVITE messages) received from the analog device or destined to it are processed by the SBC.</li> </ul> <p><b>Note:</b> The parameter is applicable only to analog interfaces.</p>
<p>'Handle P-Asserted-Identity'</p> <pre>configure voip &gt; sbc settings &gt; p-assert-id</pre> <p>[SBCAssertIdentity]</p>	<p>Global parameter that defines the handling of the SIP P-Asserted-Identity header. You can also configure this feature per specific calls, using IP Profiles ('P-Asserted-Identity Header Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Keep original user in Register'</p> <pre>configure voip &gt; sbc settings &gt; keep-contact- user-in-reg</pre> <p>[SBCKeepContactUserinRegister]</p>	<p>Defines the device's handling of the SIP Contact header in REGISTER requests which it forwards as the outgoing message.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Do not keep user; override with unique identifier</b> = (Default) The device replaces the user part of the Contact header with a unique value, for example: <ul style="list-style-type: none"> <li>✓ Incoming Contact Header: &lt;sip:123@domain.com&gt;</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Outgoing Contact Header: &lt;sip:FEU1-7-1-3@SBC&gt;</li> <li>■ [1] <b>keep user without unique identifier</b> = The device retains the original user part value of the Contact header in the outgoing REGISTER request.</li> <li>■ [2] <b>Keep user; add unique identifier as URI parameter</b> = The device retains the original user part value of the Contact header in the outgoing REGISTER request. In addition, it adds the special URI parameter "ac-feu=&lt;identifier&gt;" to the Contact header, which is used to differentiate between two SIP entities with the same user part. The identifier value is generated by the device.</li> <li>✓ Incoming Contact Header: &lt;sip:123@domain.com&gt;</li> <li>✓ Outgoing Contact Header: &lt;sip:123@SBC;ac-feu=1-7-1-3&gt;</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to REGISTER messages received from User-type IP Groups which are sent to Server-type IP Groups.</li> <li>■ Depending on the 'Remote Representation Mode' parameter of the IP Profiles table ('Remote Representation Mode' parameter), the host part in the SIP Contact header can be replaced by the device's IP address or by the value of the 'SIP Group Name' parameter (configured in the IP Groups table).</li> </ul>
<p>'URI Comparison Excluded Parameters'</p> <pre>config-voip &gt; sbc settings &gt; uri-comparison-excluded-params</pre> <p>[SBCURIComparisonExcludedParams]</p>	<p>Defines which URI parameters are excluded when the device compares the URIs of two incoming dialog-initiating SIP requests (e.g., INVITEs) to determine if they were sent from a user that is registered in the device's registration database (registered AOR and</p>

Parameter	Description
	<p>corresponding Contact URI), during the Classification stage.</p> <p>The value of the parameter is a free-text string, which can't be empty. You can configure it to any sequence of parameters, separated by commas (e.g., transport, maddr, ttl). Alternatively, you can configure it to one of the following values (case-insensitive):</p> <ul style="list-style-type: none"> <li>■ <b>All = (Default)</b> The device excludes all URI parameters and ports in the comparison of the two URIs, except the canonical URI form ('gr' (gruu), 'user=phone', and AudioCodes proprietary 'ac-int' parameters).</li> </ul> <p>Therefore, if there are two different registrations of the same user whose Contacts are differentiated only by ports and/or a proprietary parameter, the device considers them to be the same single registration, even though they are different registrations.</p> <ul style="list-style-type: none"> <li>■ <b>All\&lt;parameter 1&gt;,&lt;parameter 2&gt;&lt;parameter 3&gt;, and so on</b> = The device excludes all URI parameters and ports in the comparison of the two URIs, except the following: <ul style="list-style-type: none"> <li>✓ Canonical URI form ('gr' (gruu), 'user=phone', and AudioCodes proprietary 'ac-int' parameters).</li> <li>✓ The specified parameters (&lt;parameter 1&gt;,&lt;parameter 2&gt;&lt;parameter 3&gt;, and so on).</li> </ul> </li> </ul> <p>Examples:</p> <ul style="list-style-type: none"> <li>✓ "ALL\x": <p><b>These URIs are not equal because their URI parameter 'x' has different values:</b></p> <p>sip:John@10.10.10.10;x=11111</p> <p>sip:John@10.10.10.10;x=22222</p> </li> </ul>

Parameter	Description
	<p><b>These URIs are not equal because only one of them contains 'user-r=phone' (i.e., different canonical forms):</b></p> <pre>sip:John@10.10.10.10;user-r=phone;x=11111</pre> <pre>sip:John@10.10.10.10;x=11111</pre> <p><b>These URIs are equal:</b></p> <pre>sip:John@10.10.10.10;x-x=11111;y=aaaaa</pre> <pre>sip:John@10.10.10.10;x-x=11111;y=bbbbbb</pre> <ul style="list-style-type: none"> <li>■ <b>None</b> = All URI parameters and ports are included in the comparison of the two URIs.</li> <li>■ <b>Port</b> = The ports of the URIs are excluded in the comparison of the two URIs, but all other URI parameters are included in the comparison. "port" can be combined with other URI parameters that you want excluded (e.g., port, transport, proprietary-param).</li> </ul> <p>For example, if two SIP requests are received with different Contact header values, as shown below (in bold) and the parameter is configured to <b>All</b>, then the device considers these requests as received from the same registered user as it disregards the port (5060 and 5070), 'transport', and 'ttl' parameters in its comparison. If configured to <b>None</b>, the device considers these requests as received from two different registered users.</p> <pre>Contact: &lt;sip:1000@172.17.142.105:5060 ;transport=tcp;ttl=10&gt;</pre> <pre>Contact: &lt;sip:1000@172.17.142.105:5070 ;transport=tls;ttl=20&gt;</pre> <p><b>Note:</b> The AudioCodes proprietary 'feu' string value for the user part must be included in the</p>

Parameter	Description
	Contact header of REGISTER requests that the device forwards to the registrar server when the parameter is configured to a non-default value (i.e., not <b>All</b> ). Therefore, if you configure the parameter to a non-default value, the [SBCKeepContactUserInRegister] parameter must not be configured to <b>Keep User Without Unique Identifier (1)</b> .
'SBC REFER Behavior' configure voip > sbc settings > sbc-refer-bhvr [SBCReferBehavior]	Global parameter that defines the handling of SIP REFER requests. You can also configure this feature per specific calls, using IP Profiles ('Remote REFER Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674. <b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.
configure voip > sbc settings > sbc-xfer-prefix [SBCXferPrefix]	When the SBCReferBehavior is set to 1, the device, while interworking the SIP REFER message, adds the prefix "T~&R-" to the user part of the URI in the Refer-To header. After this, the device can receive an INVITE with such a prefix (the INVITE is sent by the UA that receives the REFER message or 302 response). If the device receives an INVITE with such a prefix, it replaces the prefix with the value defined for the SBCXferPrefix parameter. By default, no value is defined. <b>Note:</b> This feature is also applicable to 3xx redirect responses. The device adds the prefix "T~&R-" to the URI user part in the Contact header if the SBC3xxBehavior parameter is set to 1.
configure voip > sbc settings > sbc-3xx-bhvt [SBC3xxBehavior]	Global parameter that defines the handling of SIP 3xx redirect responses. You can also configure this feature per specific calls, using IP Profiles ('Remote 3xx Mode' parameter). For a detailed description of the parameter and for

Parameter	Description
	<p>configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Enforce Media Order'</p> <pre>configure voip &gt; sbc settings &gt; enforce-media- order</pre> <p>[SBCEnforceMediaOrder]</p>	<p>Enables the device to include all previously negotiated media lines ('m=') within the current session in the SDP offer-answer exchange (RFC 3264).</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For example, assume a call (audio) has been established between two endpoints and one endpoint wants to subsequently send an image in the same call session. If the parameter is enabled, the endpoint includes the previously negotiated media type (i.e., audio) with the new negotiated media type (i.e., image) in its SDP offer:</p> <pre>v=0 o=bob 2890844730 2890844731 IN IP4 host.example.com s= c=IN IP4 host.example.com t=0 0 <b>m=audio</b> 0 RTP/AVP 0 m=image 12345 udpt1 t38</pre> <p>In this example, if the parameter is disabled, the only 'm=' line included in the SDP is the newly negotiated media (i.e., image).</p>
<p>'SBC Diversion URI Type'</p> <pre>configure voip &gt; sbc settings &gt; sbc-diversion- uri-type</pre> <p>[SBCDiversionUriType]</p>	<p>Defines the URI type to use in the SIP Diversion header of the outgoing SIP message.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) The device doesn't change the URI and leaves it as is.</li> <li>■ [1] <b>Sip</b> = The "sip" URI is used.</li> <li>■ [2] <b>Tel</b> = The "tel" URI is used.</li> </ul>

Parameter	Description
	<p><b>Note:</b> The parameter is applicable only if the Diversion header is used. The [SBCDiversiionMode] and [SBCHistoryInfoMode] parameters in the IP Profiles table determine the call redirection (diversion) SIP header to use - History-Info or Diversion.</p>
<pre>configure voip &gt; sbc general-setting &gt; sip- server-digest-algorithm</pre> <p>[SIPServerDigestAlgorithm]</p>	<p>Defines the cryptographic hash algorithm used in the outgoing authentication challenge (SIP 401 or 407) response when the device authenticates incoming SIP requests as an authentication server.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) MD5</li> <li>■ [1] = SHA-256</li> </ul>
<pre>configure voip &gt; sbc settings &gt; sbc-server-auth- mode</pre> <p>[SBCServerAuthMode]</p>	<p>Defines if authentication of the SIP client is done locally (by the device) or by a RADIUS server.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Authentication is done by the device (locally).</li> <li>■ [1] = Authentication is done by an RFC 5090 compliant RADIUS server.</li> <li>■ [2] = Authentication is done according to the Draft Stermann-aaa-sip-01 method.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Currently, option [1] is not supported.</li> <li>■ The parameter is overridden by the IP Group parameter 'SBC Server Authentication Type'.</li> </ul>
<p>'Lifetime of nonce'</p> <pre>configure voip &gt; sbc settings &gt; lifetime-of- nonce</pre> <p>[AuthNonceDuration]</p>	<p>Defines the lifetime (in seconds) that the current nonce is valid for server-based authentication. The device challenges a message that attempts to use a server nonce beyond this period. The parameter is used to provide replay protection (i.e., ensures that old communication streams are not used in replay attacks).</p> <p>The valid value range is 30 to 600. The default</p>

Parameter	Description
	is 300.
<p>'Authentication Challenge Method'</p> <pre>configure voip &gt; sbc settings &gt; auth-chlng-mthd</pre> <p>[AuthChallengeMethod]</p>	<p>Defines the type of server-based authentication challenge.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = (Default) Send SIP 401 "Unauthorized" with a WWW-Authenticate header as the authentication challenge response.</li> <li>■ [1] <b>1</b> = Send SIP 407 "Proxy Authentication Required" with a Proxy-Authenticate header as the authentication challenge response.</li> </ul>
<p>'Authentication Quality of Protection'</p> <pre>configure voip &gt; sbc settings &gt; auth-qop</pre> <p>[AuthQOP]</p>	<p>Defines the authentication and integrity level of quality of protection (QoP) for digest authentication offered to the client. When the device challenges a SIP request (e.g., INVITE), it sends a SIP 401 response with the Proxy-Authenticate header or WWW-Authenticate header containing the 'qop' parameter. The QoP offered in the 401 response can be 'auth', 'auth-int', both 'auth' and 'auth-int', or the 'qop' parameter can be omitted from the 401 response. In response to the 401, the client needs to send the device another INVITE with the cryptographic hash algorithm (configured by [SIPServerDigestAlgorithm] parameter) of the INVITE message and indicate the selected auth type.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = The device sends 'qop=auth' in the SIP response, requesting authentication (i.e., validates user by checking user name and password). This option doesn't authenticate the message body (i.e., SDP).</li> <li>■ [1] <b>1</b> = The device sends 'qop=auth-int' in the SIP response, indicating required authentication and authentication with integrity (e.g., checksum). This option restricts the client to authenticating the entire SIP message, including the body, if present.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>2</b> = (Default) The device sends 'qop=auth, auth-int' in the SIP response, indicating either authentication or integrity. This enables the client to choose 'auth' or 'auth-int'. If the client chooses 'auth-int', then the body is included in the authentication. If the client chooses 'auth', then the body is not authenticated.</li> <li>■ [3] <b>3</b> = No 'qop' parameter is offered in the SIP 401 challenge message.</li> </ul>
<p>'SBC User Registration Time'</p> <pre>configure voip &gt; sbc settings &gt; sbc-usr-rgstr- time</pre> <p>[SBCUserRegistrationTime]</p>	<p>Global parameter that defines the duration (in seconds) of the periodic registrations that occur between the user and the device (the device responds with this value to the user). You can also configure this feature per specific calls, using IP Profiles ('User Registration Time' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'SBC Proxy Registration Time'</p> <pre>configure voip &gt; sbc settings &gt; sbc-prxy-rgstr- time</pre> <p>[SBCProxyRegistrationTime]</p>	<p>Defines the duration (in seconds) for which the user is registered in the proxy database (after the device forwards the REGISTER message). This value is sent in the Expires header. When set to 0, the device sends the Expires header's value as received from the user to the proxy. The valid range is 0 to 2,000,000 seconds. The default is 0.</p>
<pre>configure voip &gt; sbc settings &gt; sbc-rand-expire</pre> <p>[SBCRandomizeExpires]</p>	<p>Enables the device to change the expiry time in the Expires header of SIP 200 OK responses for user registration or subscription requests. The feature is useful in scenarios where multiple users may refresh their registration or subscription simultaneously, causing the device to handle many such sessions at a given</p>

Parameter	Description
	<p>time. This may result in an overload of the device (reaching maximum session capacity), preventing the establishment of new calls or preventing the handling of some user registration or subscription requests. However, when this feature is enabled, the device assigns a random expiry time to each user registration or subscription, ensuring future user registration and subscription requests are more distributed over time (i.e., do not all occur simultaneously).</p> <p>The valid value is 0 (disabled) to 20 (any value from 1 to 20 is considered enabled). The default is enabled (10). If disabled (i.e., 0), the device doesn't change the expiry time. If enabled, the device assigns a random expiry time as follows:</p> <ul style="list-style-type: none"> <li>■ If the received expiry time is less than 610 sec, the device reduces the time by up to 10 sec. For example, if the received expiry time is 110 sec, the device reduces it to anywhere between 100 (i.e., 110 – 10) and 110 sec.</li> <li>■ If the received expiry time is greater than 610 sec, the device reduces the time to anywhere between 600 sec and the received expiry time. For example, if the received expiry time is 700 sec, the device reduces it to anywhere between 600 and 700 sec.</li> <li>■ Minimum expiry time: <ul style="list-style-type: none"> <li>✓ The minimum expiry time that the device can reduce REGISTER messages to is 30 sec and SUBSCRIBE messages to 120 sec. For example, if the received expiry time in a REGISTER message is 35 sec, the device reduces the time to any value between 30 and 35 sec (and not by 10 seconds -- between 25 and 35).</li> </ul> </li> </ul>

Parameter	Description
	<p>✓ If the received expiry time is less than the minimum (as stated above), the expiry time remains unchanged. For example, if the received expiry time in a REGISTER message is 18 sec, the device forwards the message with this same expiry time (i.e., 18).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature doesn't apply to refresh REGISTER or SUBSCRIBE messages.</li> <li>■ You can configure the device to change the received expiry time before forwarding it, using the SBCUserRegistrationTime parameter.</li> </ul>
<p>'SBC Survivability Registration Time'</p> <pre>configure voip &gt; sbc settings &gt; sbc-surv-rgstr- time</pre> <p>[SBCSurvivabilityRegistrationTime]</p>	<p>Defines the duration of the periodic registrations between the user and the device, when the device is in survivability state (i.e., when REGISTER requests cannot be forwarded to the proxy and are terminated by the device). When set to 0, the device uses the value set by the SBCUserRegistrationTime parameter for the device's response.</p> <p>The valid range is 0 to 2,000,000 seconds. The default is 0.</p>
<pre>configure voip &gt; sbc settings &gt; sas-notice</pre> <p>[SBCEnableSurvivabilityNotice]</p>	<p>Enables the device to notify Aastra IP phones that the device is currently operating in Survivability mode.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable</li> <li>■ [1] = Enable</li> </ul> <p>For more information, see <a href="#">Enabling Survivability Display on Aastra IP Phones</a> on page 1288.</p>
<p>'SBC Dialog-Info Interworking'</p> <pre>configure voip &gt; sbc settings &gt; sbc-dialog-info- interwork</pre> <p>[EnableSBCTDialogInfoInterworking]</p>	<p>Enables the interworking of dialog information (parsing of call identifiers in XML body) in SIP NOTIFY messages received from a remote application server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> </ul>

Parameter	Description
	<p>■ [1] <b>Enable</b></p> <p>For more information, see <a href="#">Interworking Dialog Information in SIP NOTIFY Messages</a> on page 1162.</p>
<pre>configure voip &gt; sbc settings &gt; sbc-keep-call-id</pre> <p>[SBCKeepOriginalCallId]</p>	<p>Global parameter that enables the device to use the same call identification (SIP Call-ID header value) received in incoming messages for the call identification in outgoing messages. The call identification value is contained in the SIP Call-ID header.</p> <p>You can also configure the feature per specific calls, using IP Profiles. For a detailed description of the parameter and for configuring the feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
<pre>configure voip &gt; sbc settings -&gt; sbc-terminate- options</pre> <p>[SBCTerminateOptions]</p>	<p>Defines the handling of in-dialog SIP OPTIONS messages.</p> <p>■ [0] = Disabled - the device forwards in-dialog SIP OPTIONS to the outbound peer.</p> <p>■ [1] = (Default) Enabled - the device terminates in-dialog SIP OPTIONS and sends a 200 OK response to the peer that sent the OPTIONS message.</p>
<p>'Routing Timeout'</p> <pre>configure voip &gt; sbc settings &gt; sbc-routing- timeout</pre> <p>[SbcRoutingTimeout]</p>	<p>Defines the maximum duration (in seconds) that the device is prepared to wait for a response from external servers when a routing rule is configured to query an external server (e.g., LDAP server) on whose response the device uses to determine the routing destination.</p> <p>The valid value is 0 to 60. The default is 10.</p> <p>For more information, see <a href="#">Configuring a Routing Response Timeout</a> on page 1214.</p>
<p>'SBC GRUU Mode'</p> <pre>configure voip &gt; sbc settings &gt; sbc-gruu-mode</pre> <p>[SBCGruuMode]</p>	<p>Determines the Globally Routable User Agent (UA) URI (GRUU) support, according to RFC 5627.</p> <p>■ [0] <b>None</b> = No GRUU is supplied to users.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>As Proxy</b> = (Default) The device provides same GRUU types as the proxy provided the device's GRUU clients.</li> <li>■ [2] <b>Temporary only</b> = Supply only temporary GRUU to users. (Currently not supported.)</li> <li>■ [3] <b>Public only</b> = The device provides only public GRUU to users.</li> <li>■ [4] <b>Both</b> = The device provides temporary and public GRUU to users. (Currently not supported.)</li> </ul> <p>The parameter allows the device to act as a GRUU server for its SIP UA clients, providing them with public GRUU's, according to RFC 5627. The public GRUU provided to the client is denoted in the SIP Contact header parameters, "pub-gruu". Public GRUU remains the same over registration expirations. On the other SBC leg communicating with the Proxy/Registrar, the device acts as a GRUU client.</p> <p>The device creates a GRUU value for each of its registered clients, which is mapped to the GRUU value received from the Proxy server. In other words, the created GRUU value is only used between the device and its clients (endpoints).</p> <p>Public-GRUU: sip:userA@domain.com;gr=unique-id</p>
<p>'BYE Authentication'</p> <pre>configure voip &gt; sbc settings &gt; sbc-bye-auth</pre> <p>[SBCEnableByeAuthentication]</p>	<p>Enables the device to authenticate a SIP BYE request before disconnecting the call. The device forwards the SIP authentication response (for the BYE request) to the request sender and waits for the user to authenticate it. The call is disconnected only if the authenticating server responds with a 200 OK. This feature prevents, for example, a scenario in which the SIP client receives a BYE request from a third-party imposter assuming the</p>

Parameter	Description
	<p>identity of a participant in the call. As a consequence, the call between the first and second parties is inappropriately disconnected.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<p>'SUBSCRIBE Trying'</p> <pre>configure voip &gt; sbc settings &gt; sbc-subs-try</pre> <p>[SBCSendTryingToSubscribe]</p>	<p>Enables the device to send a SIP 100 Trying response upon receipt of a SUBSCRIBE or NOTIFY message.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul>
<pre>configure voip &gt; sbc settings &gt; sbc-100trying- upon-reinvite</pre> <p>[SBC100TryingUponReinvite]</p>	<p>Enables the device to send a SIP 100 Trying response upon receipt of a re-INVITE request.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable</li> <li>■ [1] = Enable</li> </ul>
<pre>configure voip &gt; sbc settings &gt; session-expires- observer-mode</pre> <p>[SipSessionExpiresObserverMode]</p>	<p>Defines the observer session expiry method when the IP Profile parameter, 'Session Expires Mode' is configured to <b>Observer</b> (see <a href="#">Configuring IP Profiles</a> on page 674).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) With Grace Time. If the session is not refreshed on time according to the SIP Session-Expires header, the device adds a graceful session expiry time – 120 seconds if the client (UAC) was meant to do the refresh, or 60 seconds if the server (UAS) was meant to do the refresh. If the session is still not refreshed when this graceful time expires, the device disconnects the call (sends a SIP BYE).</li> <li>■ [1] = Strict. If the session is not refreshed on time according to RFC 4028 (Session-Expires header time minus the smaller of 32 or 1/3 of the time in Session-Expires header), the call is terminated. For example, if the Session-Expires header is</li> </ul>

Parameter	Description
	<p>150 sec., the expected refresh should be done at <math>150 - 32 = 118</math> sec. (as <math>1/3</math> of 150 is 50, which is greater than 32). If no refresh is received within this time (e.g., 118 sec.), the device disconnects the call (sends a SIP BYE). Note that the minimum Session Expires is 90 sec.; any received value less than this is set to 90.</p>
<p>'BroadWorks Survivability Feature'</p> <pre>configure voip &gt; sbc settings &gt; sbc-broadworks- survivability</pre> <p>[SBCExtensionsProvisioningMode]</p>	<p>Enables SBC user registration for interoperability with BroadSoft's BroadWorks server, to provide call survivability in case of connectivity failure with the BroadWorks server.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = (Default) Disabled - normal processing of REGISTER messages.</li> <li>■ [1] Check box selected = Enabled - registration method for BroadWorks server. In a failure scenario with BroadWorks, the device acts as a backup SIP proxy server, maintaining call continuity between the enterprise LAN users (subscribers) and between the subscribers and the PSTN (if provided).</li> </ul> <p><b>Note:</b> For a detailed description of this feature, see <a href="#">Enabling Auto-Provisioning of Subscriber-Specific Information of BroadWorks Server for Survivability</a> on page 1283.</p>
<p>'SBC Direct Media'</p> <pre>configure voip &gt; sip- interface &gt; sbc-direct- media</pre> <p>[SBCDirectMedia]</p>	<p>Enables the Direct Media feature (i.e., no Media Anchoring) for all SBC calls, whereby SIP signaling is handled by the device without handling the RTP/SRTP (media) flow between the user agents (UA). The RTP packets do not traverse the device. Instead, the two SIP UAs establish a direct RTP/SRTP flow between one another. Signaling continues to traverse the device with minimal intermediation and involvement to enable certain SBC abilities such as routing</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) All calls traverse the</li> </ul>

Parameter	Description
	<p>device (i.e., no direct media).</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = Direct media flow between endpoints for all SBC calls.</li> </ul> <p>For more information on direct media calls, see <a href="#">Direct Media Calls</a> on page 1135.</p>
<p>'Transcoding Mode'</p> <pre>configure voip &gt; sbc settings &gt; transcoding-mode</pre> <p>[TranscodingMode]</p>	<p>Global parameter that defines the voice transcoding mode (media negotiation). You can also configure this feature per specific calls, using IP Profiles ('Mediation Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Preferences Mode'</p> <pre>configure voip &gt; sbc settings &gt; sbc-preferences</pre> <p>[SBCPreferencesMode]</p>	<p>Defines the order of the Extension coders (coders added if there are no common coders between SDP offered coders and Allowed coders) and Allowed coders (configured in the Allowed Audio Coders Groups table) in the outgoing SIP message (in the SDP).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Doesn't Include Extensions</b> = (Default) Extension coders are added at the end of the coder list.</li> <li>■ [1] <b>Include Extensions</b> = Extension coders and Allowed coders are arranged according to their order of appearance in the Allowed Audio Coders Groups table.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if a Coders Group for Extension coders is assigned to the IP Profile ('Extension Coders Group' parameter).</li> </ul>
<p>'Reserve DSP on SDP Offer'</p> <pre>configure voip &gt; sbc</pre>	<p>Enables the device to allocate DSP resources for a call at the SDP Offer or SDP Answer stage.</p>

Parameter	Description
<pre>settings &gt; reserve-dsp-on-sdp-offer</pre> <p>[ReserveDSPOnSDPOffer]</p>	<ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = Disabled. The device allocates DSPs if available and required (e.g., for transcoding) for the call at the SDP Answer stage.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = (Default) Enabled. The device allocates and reserves DSPs (if available) for the call at the SDP Offer.</li> </ul> <p>For more information on this feature, see <a href="#">Allocating DSPs on SDP Offer or Answer</a> on page 1144.</p>
<p>'SBC RTCP Mode'</p> <pre>configure voip &gt; sbc</pre> <pre>settings &gt; sbc-rtcp-mode</pre> <p>[SBCRTCPMode]</p>	<p>Global parameter that defines the handling of RTCP packets. You can also configure this feature per specific calls, using IP Profiles ('RTCP Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<pre>configure voip &gt; sbc</pre> <pre>settings &gt; sbc-send-invite-to-all-contacts</pre> <p>[SBCSendInviteToAllContacts]</p>	<p>Enables call forking of INVITE message received with a Request-URI of a specific contact registered in the device's database, to all users under the same AOR as the contact.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Sends the INVITE only to the contact of the received Request-URI.</li> <li>■ [1] <b>Enable</b></li> </ul> <p>To configure call forking initiated by the device, see <a href="#">Initiating SIP Call Forking</a> on page 1281.</p>
<p>'SBC Shared Line Registration Mode'</p> <pre>configure voip &gt; sbc</pre> <pre>settings &gt; sbc-shared-line-reg-mode</pre> <p>[SBCSharedLineRegMode]</p>	<p>Enables the termination on the device of SIP REGISTER messages from secondary lines that belong to the Shared Line feature.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Device forwards the REGISTER messages as is (i.e., not</li> </ul>

Parameter	Description
	<p>terminated on the device).</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = REGISTER messages of secondary lines are terminated on the device.</li> </ul> <p><b>Note:</b> The device always forwards REGISTER messages of the primary line.</p>
<p>'SBC Forking Handling Mode'</p> <pre>configure voip &gt; sbc settings &gt; sbc-forking- handling-mode</pre> <p>[SBCForkingHandlingMode]</p>	<p>Defines the handling of SIP 18x responses that are received due to call forking of an INVITE.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Latch On First</b> = (Default) Only the first 18x is forwarded to the INVITE-initiating UA. If SIP 18x with SDP is received, the device opens a voice stream according to the received SDP and disregards any subsequent 18x forking responses (with or without SDP). If the first response is 180 without SDP, the device sends it to the other side.</li> <li>■ [1] <b>Sequential</b> = All 18x responses are forwarded, one at a time (sequentially) to the INVITE-initiating UA. If a 18x arrives with an offer only, then only the first offer is forwarded to the INVITE-initiating UA and subsequent 18x responses are discarded.</li> </ul>
<p>'Gateway Direct Route Prefix'</p> <pre>configure voip &gt; sbc settings &gt; gw-direct-route- prefix</pre> <p>[GWDirectRoutePrefix]</p>	<p>Defines the prefix destination Request-URI user part that is appended to the original user part for alternative IP-to-IP call routing from SBC to Gateway (Tel) interfaces.</p> <p>The valid value is a string of up to 16 characters. The default is "acgateway-&lt;original prefix destination number&gt;". For example, "acgateway-200".</p> <p>For more information, see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186.</p>
<pre>configure voip &gt; sbc settings &gt; sbc-media-sync</pre> <p>[EnableSBCMediaSync]</p>	<p>Enables synchronization of media between two SIP user agents when a call is established between them. Media synchronization means that the media is properly negotiated (SDP</p>

Parameter	Description
	<p>offer/answer) between the user agents. In some scenarios, the call is established despite the media not being synchronized. This may occur, for example, in call transfer (SIP REFER) where the media between the transfer target and transferee are not synchronized. The device performs media synchronization by sending a re-INVITE immediately after the call is established in order for the user agents to negotiate the media (SDP offer/answer).</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable. Media synchronization is performed only if the RTP mode (e.g., a=sendrecv, a=sendrecv, a=sendonly, a=recvonly, and a=inactive) between the user agents are different and synchronization is required.</li> <li>■ [1] = Enable. Media synchronization is performed if the media, including RTP mode or any other media such as coders, is different and has not been negotiated between the user agents.</li> <li>■ [2] = Never. Media synchronization is never performed.</li> </ul>
<p>'Remove SIPs from Non-Secured Transport'</p> <pre>configure voip &gt; sbc settings &gt; sbc-remove-sips- non-sec-transp</pre> <p>[SBCRemoveSIPsFromNonSecuredTransport]</p>	<p>Defines the SIP headers for which the device replaces "sips:" with "sip:" in the outgoing SIP-initiating dialog request (e.g., INVITE) when the destination transport type is unsecured (e.g., UDP). (The "sips:" URI scheme indicates secured transport, for example, TLS.)</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. The device replaces "sips:" with "sip:" for the Request-URI and Contact headers only (and retains "sips:" for all other headers).</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. The device replaces "sips:" with "sip:" for the Request-URI, Contact, From, To, P-Asserted, P-Preferred, and Route headers.</li> </ul>
'SBC Fax Detection Timeout'	Defines the duration (in seconds) for which the

Parameter	Description
<pre>configure voip &gt; sbc settings &gt; sbc-fax- detection-timeout</pre> <p>[SBCFaxDetectionTimeout]</p>	<p>device attempts to detect fax (CNG tone) immediately upon the establishment of a voice session. The interval starts from the establishment of the voice call.</p> <p>The valid value is 1 to any integer. The default is 10.</p> <p>The feature applies to faxes that are sent immediately after the voice channel is established (i.e., after 200 OK).</p> <p>You can configure the handling of fax negotiation by the device for specific calls, using IP Profiles ('Remote Renegotiate on Fax Detection' parameter). For more information, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
<p>'SIP Topology Hiding Mode'</p> <pre>configure voip &gt; sbc settings &gt; sip-topology- hiding-mode</pre> <p>[SIPTopologyHidingMode]</p>	<p>Enables the device to overwrite the host part in SIP headers with IP addresses, unless the relevant host name parameters of the IP Group ('SIP Group Name' and 'SIP Source Host Name') are configured:</p> <ul style="list-style-type: none"> <li>■ Headers concerned with the source of the message are overwritten with the IP address of the IP Interface from where the device sends the message.</li> <li>■ Headers concerned with the destination of the message are overwritten with the destination IP address.</li> </ul> <p>The parameter can be configured to one of the following values:</p> <ul style="list-style-type: none"> <li>■ <b>[0] By Host Name Parameters Only =</b> (Default) The device overwrites the host part in the SIP headers according to the configuration of the IP Group's 'SIP Group Name' and 'SIP Source Host Name' parameters. If these parameters are empty, the device doesn't overwrite the host part of the headers.</li> <li>■ <b>[1] Fallback to IP Addresses =</b> This option is applicable only to dialog-initiating requests and in-dialog REFER requests.</li> </ul>

Parameter	Description
	<p>✓ If the 'SIP Group Name' parameter of the destination IP Group is empty, the device overwrites the host part of the following destination-related SIP headers with the destination IP address: Request-URI and P-Called-Party-ID for all types of requests, and To header for non-REGISTER requests. If the 'SIP Group Name' parameter is configured, the device overwrites the host part in these headers with the configured value.</p> <p>✓ The source-related headers which are overwritten when the 'SIP Source Host Name' parameter is configured (From, P-Asserted-Identity, P-Preferred-Identity, Referred-By, P-Charge-Info, Remote-Party-ID, P-Associated-URI, Diversion, and History-info) are always overwritten. If the 'SIP Source Host Name' parameter of the destination IP Group is configured, the device overwrites the host part with the configured value. If the 'SIP Source Host Name' parameter of the destination IP Group is empty, the device overwrites the host part of the mentioned headers with the IP address of the device's IP Interface from where it sends the message.</p> <p>For more information on the IP Group parameters 'SIP Group Name' and 'SIP Source Host Name', see <a href="#">Configuring IP Groups</a> on page 591.</p>
<p>'Enable MSRP'</p> <pre>configure voip &gt; sbc settings &gt; enable-msrp [EnableMSRP]</pre>	<p>Enables Message Session Relay Protocol (MSRP).</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>For more information, see <a href="#">Configuring</a></p>

Parameter	Description
	<p><a href="#">Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<b>Push Notification Service</b>	
<pre>configure voip &gt; sbc settings &gt; pns-reminder- period</pre> <p>[PNSReminderPeriod]</p>	<p>Defines the time (in seconds) before the user's registration with the device expires, at which the device sends an HTTP message to the Push Notification Server to trigger it into sending a push notification to the user to remind the user to send a REGISTER refresh message to the device.</p> <p>The valid value range is 30 to 300. The default is 120.</p>
<pre>configure voip &gt; sbc settings &gt; pns-register- timeout</pre> <p>[PNSRegisterTimeout]</p>	<p>Defines the maximum time (in seconds) that the device waits for a SIP REGISTER refresh message from the user, before it forwards an incoming SIP dialog-initiating request (e.g., INVITE) to the user.</p> <p>The valid value range is 5 to 50. The default is 30.</p> <p>When the device receives an incoming SIP dialog-initiating request whose destination is the user, it sends an HTTP message to the Push Notification Server to trigger it into sending the user a push notification so that the user can send a REGISTER refresh message to the device. If the device receives the REGISTER refresh message within this timeout, it forwards the incoming SIP request to the user. If the timeout expires and the device still hasn't received the REGISTER refresh message, the device rejects the call.</p>

## Supplementary Services

The SBC supplementary services parameters are described in the table below.

**Table 73-71:SBC Supplementary Services Parameters**

Parameter	Description
<b>Emergency Call Preemption Parameters</b> For more information on SBC emergency call preemption, <a href="#">Configuring Call Preemption for SBC Emergency Calls</a> on page 1249.	
<b>'Preemption Mode'</b> <code>configure voip &gt; sbc</code> <code>settings &gt; sbc-</code> <code>preemption-mode</code> <b>[SBCPreemptionMode]</b>	Enables emergency SBC call preemption.  <input checked="" type="checkbox"/> [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. <input checked="" type="checkbox"/> [1] Check box selected <input checked="" type="checkbox"/> = Enabled.
<b>'Emergency Message Condition'</b> <code>configure voip &gt; sbc</code> <code>settings &gt; sbc-emerg-</code> <code>condition</code> <b>[SBCEmergencyCondition]</b>	Defines the index of the Message Condition rule in the Message Conditions table that is used to identify emergency calls.  <b>Note:</b> The device applies the rule only after call classification (but before inbound manipulation).
<b>'Emergency RTP DiffServ'</b> <code>configure voip &gt; sbc</code> <code>settings &gt; sbc-emerg-</code> <code>rtp-diffserv</code> <b>[SBCEmergencyRTPDiffserv]</b>	Defines DiffServ bits sent in the RTP for SBC emergency calls.  The valid value is 0 to 63. The default is 46.
<b>'Emergency Signaling DiffServ'</b> <code>configure voip &gt; sbc</code> <code>settings &gt; sbc-emerg-</code> <code>sig-diffserv</code> <b>[SBCEmergencySignalingDiffserv]</b>	Defines DiffServ bits sent in SIP signaling messages for SBC emergency calls. This is included in the SIP Resource-Priority header.  The valid value is 0 to 63. The default is 40.

## IP Media Parameters

The IP media parameters are described in the table below.

**Table 73-72:IP Media Parameters**

Parameter	Description
<b>'IPMedia Detectors'</b> <code>configure voip &gt; media ipmedia</code> <code>&gt; ipm-detectors-enable</code> <b>[EnableDSPIPMDetectors]</b>	Enables the device's DSP detectors for detection features such as AMD.  <input checked="" type="checkbox"/> [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  <input checked="" type="checkbox"/> [1] Check box selected <input checked="" type="checkbox"/> = Enabled.

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The DSP Detectors feature is available only if the device is installed with a License Key that includes this feature. For installing a License Key, see <a href="#">License Key</a> on page 1362.</li> <li>■ When enabled, the number of available channels is reduced.</li> </ul>
<p>'Number of Media Channels'</p> <pre>configure voip &gt; sbc settings &gt; media-channels</pre> <p>[MediaChannels]</p>	<p>Defines the maximum number of DSP channels that can be used for features requiring DSP resources, for example, coder transcoding, DTMF transcoding, and answer machine detection (AMD). This parameter limits the use of DSP channels as specified in the device's License Key.</p> <p>The default is -1, meaning that the maximum number of DSP channels is according to the License Key ('DSP Channels'). For more information on the License Key, see <a href="#">License Key</a> on page 1362.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Most SBC features that require DSP resources use two DSP channels. For example, if the device needs to perform coder transcoding between two endpoints where one uses the G.711 coder and the other G.729, and a maximum of 100 concurrent transcoding sessions need to be supported, the device uses 200 DSP channels. For this scenario, you would configure the parameter to 200.</li> <li>■ If you modify the parameter to a value that is less than the number of DSP channels currently being used by the device for active calls, the device</li> </ul>

Parameter	Description
	allows these calls to continue (doesn't terminate them).
<pre>configure voip &gt; media ip- media-settings &gt; http- streaming-playback-requests- timeout</pre> <p>[HttpStreamingPlaybackRequestsTimeout].</p>	<p>Defines a timeout for no packets received (e.g., due to playback underruns) from the text-to-speech (TTS) service provider can now be configured.</p> <p><b>Note:</b> The parameter is for AudioCodes <b>internal use only</b> and is applicable only when the device operates with AudioCodes VoiceAI Connect Enterprise.</p>
<b>Conferencing Parameters</b>	
<p>'Conference ID'</p> <pre>configure voip &gt; gateway dtmf- supp-service supp-service- settings &gt; conf-id</pre> <p>[ConferenceID]</p>	<p>Defines the Conference Identification string.</p> <p>The valid value is a string of up to 16 characters. The default is "conf".</p> <p><b>Note:</b> To join a conference, the INVITE URI must include the Conference ID string preceded by the number of the participants in the conference and terminated by a unique number. For example:</p> <pre>INVITE sip:4conf1234@10.1.10.10</pre> <p>INVITE messages with the same URI join the same conference.</p>
<b>Automatic Gain Control (AGC) Parameters</b>	
<p>'Enable AGC'</p> <pre>configure voip &gt; media ipmedia &gt; agc-enable</pre> <p>[EnableAGC]</p>	<p>Global parameter enabling the AGC feature.</p> <p>You can also configure the feature per specific calls, using Tel Profiles ('Enable AGC' parameter). For a detailed description of the parameter and for configuring the feature in the Tel Profiles table, see <a href="#">Configuring Tel Profile</a> on page 755.</p> <p><b>Note:</b> If the feature is configured for a specific Tel Profile, the settings of the global parameter is ignored for calls</p>

Parameter	Description
	<p>associated with the Tel Profile.</p> <p>For a description of AGC, see <a href="#">Automatic Gain Control (AGC)</a> on page 318.</p>
<p>'AGC Slope'</p> <pre>configure voip &gt; media ipmedia &gt; agc-gain-slope</pre> <p>[AGCGainSlope]</p>	<p>Determines the AGC convergence rate:</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = 0.25 dB/sec</li> <li>■ [1] <b>1</b> = 0.50 dB/sec</li> <li>■ [2] <b>2</b> = 0.75 dB/sec</li> <li>■ [3] <b>3</b> = 1.00 dB/sec (default)</li> <li>■ [4] <b>4</b> = 1.25 dB/sec</li> <li>■ [5] <b>5</b> = 1.50 dB/sec</li> <li>■ [6] <b>6</b> = 1.75 dB/sec</li> <li>■ [7] <b>7</b> = 2.00 dB/sec</li> <li>■ [8] <b>8</b> = 2.50 dB/sec</li> <li>■ [9] <b>9</b> = 3.00 dB/sec</li> <li>■ [10] <b>10</b> = 3.50 dB/sec</li> <li>■ [11] <b>11</b> = 4.00 dB/sec</li> <li>■ [12] <b>12</b> = 4.50 dB/sec</li> <li>■ [13] <b>13</b> = 5.00 dB/sec</li> <li>■ [14] <b>14</b> = 5.50 dB/sec</li> <li>■ [15] <b>15</b> = 6.00 dB/sec</li> <li>■ [16] <b>16</b> = 7.00 dB/sec</li> <li>■ [17] <b>17</b> = 8.00 dB/sec</li> <li>■ [18] <b>18</b> = 9.00 dB/sec</li> <li>■ [19] <b>19</b> = 10.00 dB/sec</li> <li>■ [20] <b>20</b> = 11.00 dB/sec</li> <li>■ [21] <b>21</b> = 12.00 dB/sec</li> <li>■ [22] <b>22</b> = 13.00 dB/sec</li> <li>■ [23] <b>23</b> = 14.00 dB/sec</li> <li>■ [24] <b>24</b> = 15.00 dB/sec</li> <li>■ [25] <b>25</b> = 20.00 dB/sec</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [26] <b>26</b> = 25.00 dB/sec</li> <li>■ [27] <b>27</b> = 30.00 dB/sec</li> <li>■ [28] <b>28</b> = 35.00 dB/sec</li> <li>■ [29] <b>29</b> = 40.00 dB/sec</li> <li>■ [30] <b>30</b> = 50.00 dB/sec</li> <li>■ [31] <b>31</b> = 70.00 dB/sec</li> </ul>
<b>'AGC Redirection'</b> configure voip > media ipmedia > agc-redirection [AGCRedirection]	Determines the AGC direction. <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = (Default) AGC works on signals from the TDM side.</li> <li>■ [1] <b>1</b> = AGC works on signals from the IP side.</li> </ul>
<b>'AGC Target Energy'</b> configure voip > media ipmedia > agc-target-energy [AGCTargetEnergy]	Defines the signal energy value (dBm) that the AGC attempts to attain. The valid range is 0 to -63 dBm. The default is -19 dBm.
<b>'AGC Minimum Gain'</b> configure voip > media ipmedia > agc-min-gain [AGCMinGain]	Defines the minimum gain (in dB) by the AGC when activated. The range is 0 to -31. The default is -20. <b>Note:</b> For the parameter to take effect, a device restart is required.
<b>AGC Maximum Gain</b> configure voip > media ipmedia > agc-max-gain [AGCMaxGain]	Defines the maximum gain (in dB) by the AGC when activated. The range is 0 to 18. The default is 15. <b>Note:</b> For the parameter to take effect, a device restart is required.
<b>'AGC Disable Fast Adaptation'</b> configure voip > media ipmedia > agc-disable-fast-adaptation [AGCDisableFastAdaptation]	Enables the AGC Fast Adaptation mode. <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <b>Note:</b> For the parameter to take effect, a device restart is required.
<b>Answer Detector (AD) Parameters</b> For more information on AD, see <a href="#">Configuring the Answer Detector Feature</a> on page 317.	

Parameter	Description
<b>'Enable Answer Detector'</b> <code>configure voip &gt; media ipmedia</code> <code>&gt; answer-detector-enable</code> <b>[EnableAnswerDetector]</b>	Enables the device's Answer Detector feature.  ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.
<b>'Answer Detector Activity Delay'</b> <code>configure voip &gt; media ipmedia</code> <code>&gt; answer-detector-activativity-delay</code> <b>[AnswerDetectorActivityDelay]</b>	Defines the time (in 100-msec resolution) between when the device activates the Answer Detector and when it actually starts to detect.  The valid range is 0 to 1023. The default is 0.
<b>'Answer Detector Silence Time'</b> <code>configure voip &gt; media ipmedia</code> <code>&gt; answer-detector-silence-time</code> <b>[AnswerDetectorSilenceTime]</b>	Defines the duration of silence (in 100-msec resolution) from when no speech input is detected by the Answer Detector until the device sends an End Of Speech event.  The valid range is 0 to 1023. The default is 10.
<b>'Answer Detector Redirection'</b> <code>configure voip &gt; media ipmedia</code> <code>&gt; answer-detector-redirection</code> <b>[AnswerDetectorRedirection]</b>	Enables the Answer Detector to apply to the IP network side instead of the PSTN side.  ■ [0] <b>No</b> = (Default) PSTN.  ■ [1] <b>Yes</b> = IP network.
<b>'Answer Detector Sensitivity'</b> <code>configure voip &gt; media ipmedia</code> <code>&gt; answer-detector-sensitivity</code> <b>[AnswerDetectorSensitivity]</b>	Defines the Answer Detector sensitivity. The range is 0 (most sensitive) to 7 (least sensitive). The default is 0.
<code>configure voip &gt; media ipmedia</code> <code>&gt; answer-detector-low-energy-sensitivity</code> <b>[AnswerDetectorLowEnergySensitivity]</b>	Enables low-energy sensitivity for the Answer Detector. This allows the Answer Detector to be more sensitive to signaling tones (e.g., Call Progress tones and DTMFs), thereby avoiding false detections of signaling tones as voice.  ■ [0] = (Default) Disable.  ■ [1] = Enable.

Parameter	Description
<b>Answering Machine Detector (AMD) Parameters</b> For more information on AMD, see <a href="#">Answering Machine Detection (AMD)</a> on page 311.	
'Answer Machine Detector Sensitivity Parameter Suite' <pre>configure voip &gt; media ipmedia &gt; amd-sensitivity-parameter-suite</pre> [AMDSensitivityParameterSuit]	<p>Global parameter that defines which AMD Parameter Suite to use.</p> <p>Each Parameter Suite contains a table with sensitivity levels. Some Parameter Suites are more sensitive to live voice while others are more sensitive to answering machines. The available Parameter Suites depends on the installed AMD Sensitivity file. The default, pre-installed AMD Sensitivity file, which is based on North American English, includes two Parameter Suites:</p> <ul style="list-style-type: none"> <li>■ <b>Parameter Suite #0:</b> Provides normal sensitivity and has 8 sensitivity levels (0-8). (See note below.)</li> <li>■ <b>Parameter Suite #1:</b> Provides high sensitivity and has 16 sensitivity levels (0-15).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the [AMDDetectionSensitivity] parameter to 3 (default), the device ignores the Parameter Suite #0 sensitivity table. In this case, the [AMDSensitivityLevel] parameter is not relevant and sensitivity is hard-coded and similar to sensitivity level 3 of Parameter Suite 0. If you configure the [AMDDetectionSensitivity] parameter to any value other than 3, use the [AMDSensitivityLevel] parameter to specify the sensitivity level of Parameter Suite 0.</li> <li>■ You can also configure this feature per specific calls using IP Profiles ('AMD Sensitivity Parameter Suite' parameter). For a detailed description</li> </ul>

Parameter	Description
	<p>of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674. If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<p>'Answer Machine Detector Sensitivity Level'</p> <pre>configure voip &gt; media ipmedia &gt; amd-sensitivity-level</pre> <p>[AMDSensitivityLevel]</p>	<p>Global parameter that defines the sensitivity level of the selected Parameter Suite (see 'Answer Machine Detector Sensitivity Parameter Suite' above) for detecting live voice over answering machine (tradeoff between them).</p> <p>A lower sensitivity level favors detection of answering machines while a higher level favors detection of live voice. For sensitivity levels and their tradeoff between live voice and answering machine detection, see the tables in <a href="#">Answering Machine Detection (AMD)</a> on page 311.</p> <p>You can also configure this feature per specific calls, using IP Profiles ('AMD Sensitivity Level' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This parameter is applicable to all Parameter Suites other than 0. For Parameter Suite 0, use the [AMDDetectionSensitivity] parameter.</li> <li>■ If you configure the parameter for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</li> </ul>
<p>'Answer Machine Detector Sensitivity'</p> <p>[AMDDetectionSensitivity]</p>	<p>Defines the sensitivity level of the device's core voice answer detector (VAD) that is used by the AMD algorithm to distinguish</p>

Parameter	Description
	<p>between voice and silence.</p> <p>The valid value range is 0 to 7. The default is 3.</p> <p>A lower value increases sensitivity, allowing detection of low-level speech parts, but may also lead to more false detections due to background noise. Conversely, a higher value decreases sensitivity and reduces the likelihood of false detections caused by background noise but may cause quieter speech parts to go undetected.</p> <p><b>Note:</b> It's recommended to keep the parameter at its default (unless your deployment requires a specific adjustment).</p>
'AMD Sensitivity File' [AMDSensitivityFileName]	<p>Defines the name of the installed AMD Sensitivity file, which contains the AMD Parameter Suites.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This file must be in binary format (.dat). You can use the DConvert utility to convert the original file format from XML to .dat.</li> <li>■ To install this file through the Web interface, see <a href="#">Uploading Auxiliary Files</a> on page 1347.</li> </ul>
[AMDSensitivityFileUrl]	<p>Defines the URL path to the AMD Sensitivity file for downloading from a remote server for the Automatic Update mechanism.</p>
[AMDMinimumVoiceLength]	<p>Defines the AMD minimum voice activity detection duration (in 5-ms units). Voice activity duration below this threshold is ignored and considered as non-voice.</p> <p>The valid value range is 10 to 100. The default is 42 (i.e., 210 ms).</p>
[AMDMaxGreetingTime]	<p>Global parameter that defines the</p>

Parameter	Description
	<p>maximum duration that the device can take to detect a greeting message.</p> <p>You can also configure this feature per specific calls, using IP Profiles ('AMD Max Greeting Time' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
[AMDMaxPostGreetingSilenceTime]	<p>Global parameter that defines the maximum duration of silence from after the greeting time is over, configured by [AMDMaxGreetingTime], until the device's AMD decision.</p> <p>You can also configure this feature per specific calls, using IP Profiles ('AMD Max Post Silence Greeting Time' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> If you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<pre>configure voip &gt; gateway digital settings &gt; amd-timeout</pre> [AMDDTimeout]	<p>Defines the timeout (in msec) between receiving Connect messages from the Tel side and sending AMD results.</p> <p>The valid range is 1 to 30,000. The default is 2,000 (i.e., 2 seconds).</p>
<p>'AMD Beep Detection Mode'</p> <pre>configure voip &gt; sip-definition settings &gt; amd-beep-detection</pre> [AMDBeepDetectionMode]	<p>Enables the AMD beep detection mode.</p> <p>This mode detects the beeps played at the end of an answering machine greeting message, by using the X-Detect header extension. The device sends a SIP INFO</p>

Parameter	Description
	<p>message containing the field values 'Type=AMD' and 'SubType=Beep'. This feature allows users of certain third-party Application servers to leave a voice message after an answering machine plays the "beep".</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disabled</b> (default)</li> <li>■ [1] <b>Start After AMD</b></li> <li>■ [2] <b>Start Immediately</b></li> </ul> <p><b>Note:</b> It's recommended to configure the parameter to <b>Start After AMD</b> because it reduces the probability of a false beep detection caused by voice that may have parts that sound similar to a beep.</p>
<p>'Answer Machine Detector Beep Detection Timeout'</p> <pre>configure voip &gt; media ipmedia &gt; amd-beep-detection-timeout</pre> <p>[AMDBeepDetectionTimeout]</p>	<p>Defines the AMD beep detection timeout (i.e., the duration that the beep detector functions from when detection is initiated). This is used for detecting beeps at the end of an answering machine message.</p> <p>The valid value is in units of 100 milliseconds, from 0 to 1638. The default is 200 (i.e., 20 seconds).</p>
<p>'Answer Machine Detector Beep Detection Sensitivity'</p> <pre>configure voip &gt; media ipmedia &gt; amd-beep-detection-sensitivity</pre> <p>[AMDBeepDetectionSensitivity]</p>	<p>Defines the AMD beep detection sensitivity for detecting beeps at the end of an answering machine message.</p> <p>The valid value is 0 to 3, where 0 (default) is the least sensitive.</p>
<pre>configure voip &gt; gateway digital settings &gt; early-amd</pre> <p>[EnableEarlyAMD]</p>	<p>Enables AMD detection to be activated upon receipt of an ISDN Alerting or Connect message.</p> <ul style="list-style-type: none"> <li>■ [0] = (Default) Disable - AMD is activated upon receipt of ISDN Connect message.</li> <li>■ [1] = Enable - AMD is activated upon receipt of ISDN Alerting message.</li> </ul>

Parameter	Description
	<b>Note:</b> The parameter is applicable only to the Gateway application (digital interfaces).
'AMD Mode' configure voip > sip-definition settings > amd-mode [AMDmode]	<p>Global parameter that enables the device to disconnect the call (IP-to-Tel for the Gateway application) upon detection of an answering machine (on the Tel side for the Gateway application). For more information on the Gateway implementation, see <a href="#">Enabling IP-to-Tel Call Disconnection upon Detection of Answering Machine</a> on page 317.</p> <p>For the SBC application: The parameter is typically used when the device is deployed with VoiceAI Connect.</p> <p>For the Gateway application, you can also configure this feature per specific calls, using IP Profiles ('AMD Mode' parameter). For a detailed description of the parameter and for configuring this feature in the IP Profiles table, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p><b>Note:</b> For the Gateway application, if you configure this feature for a specific IP Profile, the device ignores this global parameter for calls associated with the IP Profile.</p>
<b>Energy Detector Parameters</b>	
'Enable Energy Detector' configure voip > media ipmedia > energy-detector-enable [EnableEnergyDetector]	<p>Enables the Energy Detector feature. This feature generates events (notifications) when the signal received from the PSTN is higher or lower than a user-defined threshold, configured by the [EnergyDetectorThreshold] parameter.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>
'Energy Detector Quality Factor'	Defines the Energy Detector's sensitivity

Parameter	Description
<pre>configure voip &gt; media ipmedia &gt; energy-detector-sensitivity</pre> [EnergyDetectorQualityFactor]	<p>level.</p> <p>The valid range is 0 to 10, where 0 is the lowest sensitivity and 10 the highest sensitivity. The default is 4.</p>
<p>'Energy Detector Threshold'</p> <pre>configure voip &gt; media ipmedia &gt; energy-detector-threshold</pre> [EnergyDetectorThreshold]	<p>Defines the Energy Detector's threshold. A signal below or above this threshold invokes an 'Above' or 'Below' event.</p> <p>The threshold is calculated as follows: <math>-44 \text{ dBm} + (\text{EnergyDetectorThreshold} * 6)</math></p> <p>The valid value range is 0 to 7. The default is 3 (i.e., -26 dBm).</p>
<p><b>Pattern Detection Parameters</b></p> <p><b>Note:</b> For an overview on the pattern detector feature for TDM tunneling, see <a href="#">DSP Pattern Detector</a> on page 919.</p>	
<p>'Enable Pattern Detector'</p> [EnablePatternDetector]	<p>Enables the Pattern Detector (PD) feature.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p>
[PDPattern]	<p>Defines the patterns that can be detected by the Pattern Detector.</p> <p>The valid range is 0 to 0xFF.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[PDThreshold]	<p>Defines the number of consecutive patterns to trigger the pattern detection event.</p> <p>The valid range is 0 to 31. The default is 5.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>

## Services

This section describes services-related parameters.

## SIPREC Parameters

The SIPREC parameters are described in the table below.

**Table 73-73:SIPREC Parameters**

Parameter	Description
<p>'Forward Signaling to SIPREC'</p> <pre>configure voip &gt; sip- definition sip- recording settings &gt; fwd-signaling-to- siprec</pre> <p>[FwdSignalingToSIPRec]</p>	<p>Enables the device to send DTMF digits notifications using SIP INFO messages to the SIPREC SRS.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>DTMF SIP INFO</b></li> </ul> <p>For more information, see <a href="#">Sending DTMF Digits Notifications using SIP INFO Messages to SRS</a> on page 364.</p>
<p>'Recording Server (SRS) Destination Username'</p> <pre>configure voip &gt; sip- definition sip- recording settings &gt; siprec-server-dest- username</pre> <p>[SIPRecServerDestUsername]</p>	<p>Defines the SIP user part for the recording server. This user part is added in the SIP To header of the INVITE message that the device sends to the recording server. The valid value is a string of up to 50 characters. By default, no user part is defined.</p>
<p>'SIP Recording Metadata Format'</p> <pre>configure voip &gt; sip- definition sip- recording settings &gt; siprec-metadata-format</pre> <p>[SIPRecMetadataFormat]</p>	<p>Defines the format of the SIPREC recording metadata that the device generates in SIP messages sent to the SRS.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Legacy</b> = (Default) The device generates the recording metadata in a "legacy" format, whereby the user part of the participant URI (source or destination) is used as the ID.</li> <li>■ [1] <b>RFC 7865</b> = The device generates the recording metadata in a format according to RFC 7865, whereby all IDs (e.g., participant ID) are in Base64 format. This metadata format also includes additional XML tags with association information (e.g., "&lt;participantsessionassoc&gt;").</li> </ul>
<p>'SIP Recording Time Stamp Format'</p> <pre>configure voip &gt; sip- definition sip- recording settings &gt;</pre>	<p>Defines the format of the device's time (timestamp) in SIP messages that are sent to the SIP Recording Server (SRS).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Local Time</b> = (Default) The device's local time</li> </ul>

Parameter	Description
<pre>siprec-time-stamp</pre> <p>[SIPRecTimeStamp]</p>	<p>(without the UTC time zone) is used for the timestamp.</p> <ul style="list-style-type: none"> <li>■ [1] <b>UTC</b> = The device's UTC time is used for the timestamp.</li> </ul> <p><b>Note:</b> The timestamp is contained in the XML body of the SIP message. If the timestamp uses the UTC time, the time is suffixed with the letter "Z", for example:</p> <pre>&lt;associate-time&gt;2017-09-07T06:33:38Z&lt;/associate-time&gt;</pre>
<p>'Video Recording Sync Timeout'</p> <pre>configure voip &gt; sip- definition sip- recording settings &gt; video-rec-sync-timeout</pre> <p>[VideoRecordingSyncTimeout]</p>	<p>Defines the video synchronization timeout (in msec), which is applicable when the device also records the video stream of audio-video calls for SIPREC. If the SIP 200 OK from the SRS is not received within this timeout, the device connects the video stream between the UAs (instead of waiting for the 200 OK). The valid value is 100 to 5,000. The default is 2,000.</p>

## RADIUS and LDAP Parameters

This section describes the RADIUS and LDAP parameters.

### General Parameters

The general RADIUS and LDAP parameters are described in the table below.

**Table 73-74:General RADIUS and LDAP Parameters**

Parameter	Description
<p>'Use Local Users Table for Authentication'</p> <pre>configure system &gt; mgmt-auth &gt; use-local- users-db</pre> <p>[MgmtUseLocalUsersDatabase]</p>	<p>Defines when and if the device uses the Local Users table when an Authentication server (LDAP or RADIUS) is used for authenticating users attempting to log into the device's management interfaces (e.g., Web or CLI).</p> <ul style="list-style-type: none"> <li>■ [0] <b>When No Auth Server Defined</b> = (Default) If you haven't configured an Authentication server, the device uses the Local Users table (see <a href="#">Configuring Local Management User Accounts</a> on page 55) to authenticate the user.</li> </ul> <p>If you have configured an Authentication server, the device uses the server to authenticate the</p>

Parameter	Description
	<p>user.</p> <ul style="list-style-type: none"> <li>✓ If the user is not found in the server, the device denies access (i.e., doesn't fallback to Local Users table).</li> <li>✓ If there is no response from the server (connectivity timeout), the device either denies the user access or authenticates the user using the Local Users table (according to the 'Behavior upon Authentication Server Timeout' parameter).</li> </ul> <ul style="list-style-type: none"> <li>■ [1] <b>Always</b> = The device uses the Authentication server to authenticate the user.</li> <li>✓ If the user is not found in the server, the device uses the Local Users table to authenticate the user.</li> <li>✓ If there is no response from the server (connectivity timeout), the device either denies the user access or authenticates the user using the Local Users table (according to the 'Behavior upon Authentication Server Timeout' parameter).</li> </ul> <ul style="list-style-type: none"> <li>■ [2] <b>Always Before Auth Server</b> = The device uses the Local Users table to authenticate the user. If authentication fails, the device uses the Authentication server.</li> </ul> <p><b>Note:</b> If you haven't configured an Authentication server, the device always uses the Local Users table to authenticate the user.</p>
<p>'Behavior upon Authentication Server Timeout'</p> <pre>configure system &gt; mgmt-auth &gt; timeout- behavior</pre> <p>[MgmtBehaviorOnTimeout]</p>	<p>Defines the device's behavior when a connection timeout occurs with the LDAP/RADIUS Authentication server that is used for user login authentication.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Deny Access</b> = The device denies user access to its management interface.</li> <li>■ [1] <b>Verify Access Locally</b> = (Default) The device authenticates the user using its Local Users table.</li> </ul> <p><b>Note:</b> The parameter is applicable to LDAP- and RADIUS-based user login authentication.</p>

Parameter	Description
'Default Access Level' <pre>configure system &gt; mgmt-auth &gt; default- access-level</pre> [DefaultAccessLevel]	Defines the default access level for the device when the LDAP/RADIUS response doesn't include an access level attribute for determining the user's management access level. <ul style="list-style-type: none"> <li>■ [1] <b>No Access</b> = The device blocks these users.</li> <li>■ [50] <b>Monitor</b></li> <li>■ [100] <b>Administrator</b></li> <li>■ [200] <b>Security Administrator</b> (Default)</li> </ul> <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable to LDAP- and RADIUS-based management-user login authentication and authorization.</li> <li>■ If a user is not associated with any LDAP Group (at the LDAP server), the device automatically uses the value of this parameter as the access level.</li> </ul>

## RADIUS Parameters

The RADIUS parameters are described in the table below.

**Table 73-75:RADIUS Parameters**

Parameter	Description
<b>General RADIUS Parameters</b>	
'Enable RADIUS Access Control' <pre>configure system &gt; radius settings &gt; enable</pre> [EnableRADIUS]	Enables the RADIUS application. <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <b>Note:</b> For the parameter to take effect, a device restart is required.
'RADIUS VSA Vendor ID' <pre>configure system &gt; radius settings &gt; vsa- vendor-id</pre> [RadiusVSAVendorID]	Defines the vendor ID that the device accepts when parsing a RADIUS response packet.  The valid range is 0 to 0x7FFFFFFF. The default is 5003.
[MaxRADIUSSessions]	Defines the number of concurrent calls that can

Parameter	Description
	communicate with the RADIUS server (optional). The valid range is 0 to 240. The default is 240.
'RADIUS Packets Retransmission' [RADIUSRetransmission]	Defines the number of RADIUS retransmission retries when no response is received from the RADIUS server. See also the [RadiusTo] parameter. The valid range is 1 to 10. The default is 1.
'RADIUS Response Time Out' [RadiusTo]	Defines the time interval (in seconds) that the device waits for a response before it performs a RADIUS retransmission. See also the [RADIUSRetransmission] parameter. The valid range is 1 to 30. The default is 2.
configure system > radius settings > rad- pap-req-msg-auth-tx [RadiusPapRequireMsgAuthTx]	Enables the device (for PAP protocol used for user login) to always include RADIUS attribute 80 (Message-Authenticator) in outgoing RADIUS request messages (Access-Request packets) sent to the RADIUS server.  ■ [0] = (Default) The device doesn't include the attribute.  ■ [1] = The device includes the attribute.  For more information, see <a href="#">Securing RADIUS Messages with Message-Authenticator Attribute</a> on page 374.
configure system > radius settings > rad- req-msg-auth-rx [RadiusRequireMsgAuthRx]	Enables the requirement of RADIUS attribute 80 (Message-Authenticator) in incoming RADIUS messages from the RADIUS server.  ■ [0] = (Default) The device doesn't require the attribute.  ■ [1] = The device requires the attribute. If the attribute is not present, the device discards the incoming RADIUS message and denies user login.  For more information, see <a href="#">Securing RADIUS Messages with Message-Authenticator Attribute</a> on page 374.
<b>RADIUS Accounting Parameters</b>	
'RADIUS Accounting Type' configure voip > sip- definition settings > radius-accounting	Defines at what stage of the call RADIUS accounting messages are sent to the RADIUS accounting server.  ■ [0] <b>At Call Release</b> = (Default) Sent at call release

Parameter	Description
[RADIUSAccountingType]	<p>only.</p> <ul style="list-style-type: none"> <li>■ [1] <b>At Connect &amp; Release</b> = Sent at call connect and release.</li> <li>■ [2] <b>At Setup &amp; Release</b> = Sent at call setup and release.</li> </ul>
<p>'AAA Indications'</p> <pre>configure system &gt; cdr &gt; aaa-indications</pre> <p>[AAAIIndications]</p>	<p>Enables the Authentication, Authorization and Accounting (AAA) indications.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) No indications.</li> <li>■ [3] <b>Accounting Only</b> = Only accounting indications are used.</li> </ul>
<b>RADIUS User Authentication Parameters</b>	
<p>'Use RADIUS for Web/Telnet Login'</p> <pre>configure system &gt; radius settings &gt; enable-mgmt-login</pre> <p>[WebRADIUSLogin]</p>	<p>Enables RADIUS queries for Web and Telnet login authentication. When enabled, logging into the device's Web and Telnet embedded servers is done through a RADIUS server. The device communicates with a user-defined RADIUS server and verifies the given username and password against a remote database in a secure manner.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For RADIUS login authentication to function, you must also configure the [EnableRADIUS] parameter to 1 (Enable).</li> <li>■ RADIUS authentication requires HTTP basic authentication, where the username and password are transmitted in clear text over the network. Therefore, it's recommended to set the [HTTPSONly] parameter to 1 to force the use of HTTPS, since the transport is encrypted.</li> </ul>
<p>'Password Local Cache Mode'</p> <pre>configure system &gt; radius settings &gt; local-cache-mode</pre> <p>[RadiusLocalCacheMode]</p>	<p>Defines the device's mode of operation regarding the timer, configured by the [RadiusLocalCacheTimeout] parameter, which determines the validity of the username and password (verified by the RADIUS server).</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Absolute Expiry Timer</b> = When you access a Web page, the timeout doesn't reset, instead it continues decreasing.</li> <li>■ [1] <b>Reset Timer Upon Access</b> = (Default) Upon each access to a Web page, the timeout always resets (reverts to the initial value configured by the [RadiusLocalCacheTimeout] parameter).</li> </ul>
'Password Local Cache Timeout' configure system > radius settings > local-cache-timeout [RadiusLocalCacheTimeout]	Defines the duration (in seconds) that the locally stored username and password (verified by the RADIUS server) are valid. When this timeout expires, the username and password become invalid and must be re-verified with the RADIUS server. The valid range is 1 to 0xFFFFFFFF. The default is 900 (15 minutes). <ul style="list-style-type: none"> <li>■ [-1] = Never expires.</li> <li>■ [0] = Each request requires RADIUS authentication.</li> </ul>
'RADIUS VSA Access Level Attribute' configure system > radius settings > vsa- access-level [RadiusVSAAccessAttribute]	Defines the code that indicates the access level attribute in the Vendor Specific Attributes (VSA) section of the received RADIUS packet. The valid range is 0 to 255. The default is 35.

## LDAP Parameters

The Lightweight Directory Access Protocol (LDAP) parameters are described in the table below.

**Table 73-76:LDAP Parameters**

Parameter	Description
'LDAP Service' configure system > ldap settings > ldap-service [LDAPServiceEnable]	Enables the LDAP feature. <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
'LDAP Authentication Filter'	Defines the LDAP search filter attribute for

Parameter	Description
<pre>configure system &gt; ldap settings &gt; auth-filter</pre> [LDAPAuthFilter]	<p>searching the login username in the directory's subtree for LDAP-based user authentication and authorization.</p> <p>You must use the dollar (\$) sign to represent the username. For example, if you configure the parameter to "(sAMAccountName=)" and the user logs in with the username "SueM", the LDAP query is run for sAMAccountName=SueM.</p> <p><b>Note:</b> The number of characters of the parameter's value plus the length of the login username can't exceed 255. If the length exceeds this maximum, the device sends an error message to syslog.</p>
<p>'Use LDAP for Web/Telnet Login'</p> <pre>configure system &gt; ldap settings &gt; enable-mgmt- login</pre> [MgmtLDAPLogin]	<p>Enables LDAP-based management-user login authentication and authorization.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
[LDAPDebugMode]	<p>Enables debug messages for LDAP tasks and defines the debug level.</p> <p>The valid value range is 0 to 4. The default is 0 (i.e., disabled). The higher the value, the more detailed the information provided.</p>
<p>'LDAP Numeric Attributes'</p> <pre>ldap-numeric-attr</pre> [LDAPNumericAttributes]	<p>Defines up to five LDAP Attributes (separated by commas) for which the device uses for LDAP query searches in the AD for numbers that may have characters between the digits.</p> <p>For more information, see <a href="#">Enabling LDAP Searches for Numbers with Characters</a> on page 405.</p>
<p>'LDAP OCS Number Attribute Name'</p> <pre>configure voip &gt; sip- definition settings &gt; ldap- ocs-nm-attr</pre>	<p>Defines the name of the attribute that represents the user's Skype for Business number in the Microsoft AD database.</p> <p>The valid value is a string of up to 49 characters. The default is "msRTCSIP-Line".</p>

Parameter	Description
[MSLDAPOCSNumAttributeName]	
LDAP PBX Number Attribute Name configure voip > sip- definition settings > ldap- pbx-nm-attr [MSLDAPPBXNumAttributeName]	Defines the name of the attribute that represents the user PBX number in the Microsoft AD database.  The valid value is a string of up to 49 characters. The default is "telephoneNumber".
LDAP MOBILE Number Attribute Name configure voip > sip- definition settings > ldap- mobile-nm-attr [MSLDAPMobileNumAttributeName]	Defines the name of the attribute that represents the user Mobile number in the Microsoft AD database.  The valid value is a string of up to 49 characters. The default is "mobile".
LDAP PRIVATE Number Attribute Name configure voip > sip- definition settings > ldap- private-nm-attr [MSLDAPPrivateNumAttributeName]	Defines the name of the attribute that represents the user's private number in the AD. If this value equals the value of the MSLDAPPrimaryKey or MSLDAPSecondaryKey parameter, then the device queries the AD for the destination number in this private attribute name; otherwise, the parameter is not used as a search key.  The default is "msRTCSIP-PrivateLine".
'LDAP DISPLAY Name Attribute Name' configure voip > sip- definition settings > ldap- display-nm-attr [MSLDAPDisplayNameAttributeName]	Defines the attribute name that represents the Calling Name in the AD for LDAP queries based on calling number.  The valid value is a string of up to 49 characters. The default is "displayName".
LDAP Primary Key configure voip > sip- definition settings > ldap- primary-key [MSLDAPPrimaryKey]	Defines the name of the attribute used as a query search key for the destination number in the AD. This is used instead of the "PBX" attribute name (configured by the MSLDAPPBXNumAttributeName parameter).  The default is not configured.
LDAP Secondary Key configure voip > sip- definition settings > ldap- secondary-key [MSLDAPSecondaryKey]	Defines the name of the attribute used as the second query search key for the destination number in the AD, if the primary search key or PBX search is not found.

Parameter	Description
<p>'LDAP Cache Service'</p> <pre>configure system &gt; ldap settings &gt; ldap-cache- enable</pre> <p>[LDAPCacheEnable]</p>	<p>Enables the LDAP cache service.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> <li>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</li> </ul> <p>For more information on LDAP caching, see .</p> <p><b>Note:</b> For the parameter to take effect, a device restart is required.</p>
<p>'LDAP Cache Entry Timeout'</p> <pre>configure system &gt; ldap settings &gt; entry-timeout</pre> <p>[LDAPCacheEntryTimeout]</p>	<p>Defines the duration (in minutes) that an entry in the device's LDAP cache is valid. If the timeout expires, the cached entry is used only if there is no connectivity with the LDAP server.</p> <p>The valid range is 0 to 35791. The default is 1200. If 0, the LDAP entry is always valid.</p> <p>For more information on LDAP caching, see <a href="#">Configuring the Device's LDAP Cache</a> on page 396.</p>
<p>'LDAP Cache Entry Removal Timeout'</p> <pre>configure system &gt; ldap settings &gt; entry-removal- timeout</pre> <p>[LDAPCacheEntryRemovalTimeout]</p>	<p>Defines the duration (in hours) after which the LDAP entry is deleted from the device's LDAP cache.</p> <p>The valid range is 0 to 596. The default is 0 (i.e., the entry is never deleted).</p> <p>For more information on LDAP caching, see <a href="#">Configuring the Device's LDAP Cache</a> on page 396.</p>

## HTTP-based Services

The HTTP-based service parameters are described in the table below.

**Table 73-77:HTTP-based Service Parameters**

Parameter	Description
<p>'Gateway Routing Server'</p> <pre>configure voip &gt; gw routing general-setting &gt; gw-routing- server</pre> <p>[GWRoutingServer]</p>	<p>Enables routing by ARM.</p> <ul style="list-style-type: none"> <li>■ [0] Check box cleared = (Default) Disable.</li> <li>■ [1] Check box selected = Enabled.</li> </ul> <p>For more information on routing by ARM, see <a href="#">Centralized Routing by ARM</a></p>

Parameter	Description
	<p>(<a href="#">AudioCodes Routing Manager</a>) on page 451.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
<p>'Quality Status'</p> <pre>configure system &gt; http- services &gt; routing-qos-status</pre> <p>[RoutingServerQualityStatus]</p>	<p>Enables QoS-based routing by ARM. The device collects QoS metrics (media and signaling) and sends them to ARM.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>For more information, see <a href="#">Configuring QoS-based Routing by ARM</a> on page 455.</p>
<p>'Quality Status Rate'</p> <pre>configure system &gt; http- services &gt; routing-qos- status-rate</pre> <p>[RoutingServerQualityStatusRate]</p>	<p>Defines the rate (in sec) at which the device sends QoS reports to ARM.</p> <p>The valid range is 15-3600. The default is 60.</p> <p>For more information, see <a href="#">Configuring QoS-based Routing by ARM</a> on page 455.</p>
<p>'Topology Status'</p> <pre>configure system &gt; http- services &gt; routing-server- group-status</pre> <p>[RoutingServerGroupStatus]</p>	<p>Enables the reporting of the device's topology status (using the REST TopologyStatus API command) to remote HTTP hosts.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>For more information, see <a href="#">Configuring Remote Web Services</a> on page 438</p>
<p>'Routing Server Registration Status'</p> <pre>configure system &gt; http- services &gt; routing-server- registration-status</pre> <p>[RoutingServerRegistrationStatus]</p>	<p>Enables the synchronization of the device's registration database (using the REST registrationStatus API command) with remote HTTP hosts.</p> <p>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</p> <p>■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.</p> <p>For more information, see <a href="#">Configuring Remote Web Services</a> on page 438</p>

Parameter	Description
<b>Remote Monitoring</b> For more information, see <a href="#">Remote Monitoring of Device behind NAT</a> on page 1599.	
<b>'Remote Monitoring'</b> <code>configure system &gt; http-services &gt; remote-monitoring</code> <b>[RemoteMonitoringEnable]</b>	Enables the device to send monitoring reports to a remote monitoring server when the device is located behind NAT.  ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.
<b>'Reporting Period'</b> <code>configure system &gt; http-services &gt; remote-monitor-reporting-period</code> <b>[RemoteMonitoringPeriod]</b>	Defines the time interval (in seconds) between each remote monitoring report that is sent to the monitoring server.  The valid value is 30 to 65535. The default is 300.
<b>'Device Status'</b> <code>configure system &gt; http-services &gt; remote-monitor-status</code> <b>[RemoteMonitoringDeviceEnable]</b>	Enables the device to send a remote monitoring report of its status to the monitoring server.  ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.
<b>'Active Alarms'</b> <code>configure system &gt; http-services &gt; remote-monitor-alarms</code> <b>[RemoteMonitoringAlarmsEnable]</b>	Enables the device to send a remote monitoring report of currently active alarms to the monitoring server.  ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.
<b>'Performance Indicators'</b> <code>configure system &gt; http-services &gt; remote-monitor-kpi</code> <b>[RemoteMonitoringPMEEnable]</b>	Enables the device to send a remote monitoring report of performance monitoring statistics to the monitoring server.  ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.  ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.
<b>'Registration Status'</b> <code>configure system &gt; http-</code>	Enables the device to send a remote monitoring report of users registered with

Parameter	Description
<code>services &gt; remote-monitor-registration</code> [RemoteMonitoringSIPUsersEnable]	the device to the monitoring server. ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled.

## HTTP Proxy Parameters

The HTTP Proxy service parameters are described in the table below.

**Table 73-78:HTTP Proxy Service Parameters**

Parameter	Description
'HTTP Proxy Application' <code>configure network &gt; http-proxy &gt; http-proxy-app</code> [HTTPProxyApplication]	Enables the HTTP Proxy application. ■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled. ■ [1] Check box selected <input checked="" type="checkbox"/> = Enabled. <b>Note:</b> For the parameter to take effect, a device restart is required.
'HTTP Proxy Debug Level' <code>configure network &gt; http-proxy &gt; http-proxy-debug-level</code> [HTTPProxySyslogDebugLevel]	Enables debugging of HTTP services and filtering of messages sent to the syslog server by severity (debug) level. ■ [0] <b>No Debug</b> = (Default) Disable. ■ [1] <b>Info</b> = Enables debug and sends basic information in syslog. The logged information includes details of access requests (HTTP requests to read or write files). ■ [2] <b>Notice</b> = Enables debug and sends normal, but significant information in syslog. The logged information includes details of access requests (HTTP requests to read or write files). ■ [3] <b>Warning</b> = Enables debug and sends warning conditions in syslog.

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [4] <b>Error</b> = Enables debug and sends error conditions in syslog.</li> <li>■ [5] <b>Critical</b> = Enables debug and sends critical conditions in syslog.</li> <li>■ [6] <b>Alert</b> = Enables debug and sends conditions in syslog that require immediate action.</li> <li>■ [7] <b>Emergency</b> = Enables debug and sends conditions indicating unstable system in syslog.</li> </ul> <p><b>Note:</b> The NGINX Directive for this parameter is "error_log, access_log".</p>
'Primary DNS Server IP' <code>dns-primary-server</code> [HTTPPrimaryDNS]	Defines the primary DNS server (in dotted-decimal notation), which is used for translating domain names into IP addresses for the HTTP service.  By default, no IP address is defined.
'Secondary DNS Server IP' <code>dns-secondary-server</code> [HTTPSecondaryDNS]	Defines the secondary DNS server (in dotted-decimal notation), which is used for translating domain names into IP addresses for the HTTP service.  By default, no IP address is defined.
'HTTP Proxy Global Address' <code>configure network &gt; http-proxy &gt; http-proxy-global-address</code> [HttpProxyGlobalAddress]	Defines the device's public IP address for the HTTP Proxy service, when the device is located behind NAT.  The valid value is an IP address in dotted-decimal notation. The default is 0.0.0.0.  For more information, see <a href="#">Configuring a Public IP Address for NGINX NAT Traversal</a> on page 496.
'HTTP Cache Enable' [HTTPCacheEnable]	Enables the caching of HTTP responses.  <ul style="list-style-type: none"> <li>■ [0] Check box cleared <input type="checkbox"/> = (Default) Disabled.</li> </ul>

Parameter	Description
	 [1] Check box selected <input checked="" type="checkbox"/> = Enabled.

## 74 Capacity for Signaling, Media and User Registrations

For supported capacity (SIP signaling, media and user registrations), refer to the device's *Release Notes*, which can be downloaded from AudioCodes [website](#).

## 75 Technical Specifications

For technical specifications, refer to the device's Datasheet, which can be downloaded from AudioCodes [website](#).
