

# Mediant 800 Gateway & E-SBC

Version 7.6

## Notice

Information contained in this document is believed to be accurate and reliable at the time of publishing. However, due to ongoing product improvements and revisions, AudioCodes cannot guarantee accuracy of published material after the Date Published nor can it accept responsibility for errors or omissions. Updates to this document can be downloaded from <https://www.audiocodes.com/library/technical-documents>.

This document is subject to change without notice.

Date Published: May-11-2025

## WEEE EU Directive

Pursuant to the WEEE EU Directive, electronic and electrical waste must not be disposed of with unsorted waste. Please contact your local recycling authority for disposal of this product.

## Security Vulnerabilities

All security vulnerabilities should be reported to [vulnerability@audiocodes.com](mailto:vulnerability@audiocodes.com).

## Customer Support

Customer technical support and services are provided by AudioCodes or by an authorized AudioCodes Service Partner. For more information on how to buy technical support for AudioCodes products and for contact information, please visit our website at <https://www.audiocodes.com/services-support/maintenance-and-support>.

## Documentation Feedback

AudioCodes continually strives to produce high quality documentation. If you have any comments (suggestions or errors) regarding this document, please fill out the Documentation Feedback form on our website at <https://online.audiocodes.com/documentation-feedback>.

## Stay in the Loop with AudioCodes

## Notes and Warnings

The device is an indoor unit and therefore, must be installed only **INDOORS**.

Configuration and usage of this device must be in accordance with your local security regulations, telephony regulations, or any other related regulations.

The scope of this document doesn't fully cover security aspects for deploying the device in your environment. Security measures should be done in accordance with your organization's security policies. For basic security guidelines, refer to the *Recommended Security Guidelines* document.

Throughout this manual, unless otherwise specified, the term *device* refers to your AudioCodes product.

Before configuring the device, ensure that it is installed correctly as instructed in the *Hardware Installation Manual*.

**OPEN SOURCE SOFTWARE.** Portions of the software may be open source software and may be governed by and distributed under open source licenses, such as the terms of the GNU General Public License (GPL), the terms of the Lesser General Public License (LGPL), BSD and LDAP. If any open source software is provided in object code, and its accompanying license requires that it be provided in source code as well, the Buyer may receive such source code by contacting AudioCodes.

- This device includes software developed by the OpenSSL Project for use in the OpenSSL Toolkit (<http://www.openssl.org/>).
- This device includes cryptographic software written by Eric Young ([eay@cryptsoft.com](mailto:eay@cryptsoft.com)).

- Some of the features described in this document are licensed features and are available only if the installed License Key contains these features.

DHCP Server Functionality .....	327
Configuring the DHCP Server .....	327
Configuring the Vendor Class Identifier .....	333
Configuring Additional DHCP Options .....	334
Configuring Static IP Addresses for DHCP Clients .....	337

Viewing and Deleting DHCP Clients .....	338
<b>SIPREC SIP-based Media Recording .....</b>	<b>339</b>
SIPREC Overview .....	339
SIP Message Flow for SIPREC .....	341
SIPREC for SRTP Calls .....	345
SIPREC for Real-Time Text .....	346
Sending SIPREC to Multiple SRSs .....	346
Load Balancing SIPREC SRSs using IP Group Set .....	348
Configuring SIP Recording Rules .....	349
Starting a SIPREC Session using Message Conditions .....	354
Configuring Format of SIPREC Metadata .....	355
Configuring Video Recording Synchronization .....	355
On-demand SIPREC .....	356
On-Demand SIPREC using SIP INFO Messages .....	356
On-Demand SIPREC using SIP 200 OK Responses .....	359
On-Demand SIPREC using REST .....	361
Configuring SIP User Part for SRS .....	363
Sending DTMF Digits Notifications using SIP INFO Messages to SRS .....	364
Interworking SIP-based Media Recording with Third-Party Vendors .....	365
SIPREC with Genesys Equipment .....	365
SIPREC with Avaya Equipment .....	365
Customizing Recorded SIP Messages Sent to SRS .....	366
<b>RADIUS-based Services .....</b>	<b>369</b>
Enabling RADIUS Services .....	369
Configuring RADIUS Servers .....	369
Configuring RADIUS Packet Retransmission .....	373
Configuring the RADIUS Vendor ID .....	373
Securing RADIUS Messages with Message-Authenticator Attribute .....	374
RADIUS-based User Login Authentication .....	374
Setting Up a Third-Party RADIUS Server .....	375
Configuring RADIUS-based User Authentication .....	377
Securing RADIUS Communication .....	378
RADIUS-based User Authentication in URL .....	378
RADIUS-based CDR Accounting .....	378
<b>LDAP-based Services .....</b>	<b>378</b>
Enabling the LDAP Service .....	381
Enabling LDAP-based User Login Authentication .....	381
Configuring LDAP Server Groups .....	382
Configuring LDAP Servers .....	385
Configuring LDAP DN (Base Paths) per LDAP Server .....	392
Configuring the LDAP Search Filter Attribute .....	393
Configuring Access Level per Management Groups Attributes .....	394
Configuring the Device's LDAP Cache .....	396
Refreshing LDAP Cache for LDAP Server Groups .....	399
Clearing LDAP Cache .....	400

Configuring Fallback Options to Local Users Table .....	400
LDAP-based Login Authentication Example .....	401
Enabling LDAP Searches for Numbers with Characters .....	405
Routing for Microsoft Teams or Skype for Business using Microsoft Entra ID .....	406
Querying Microsoft Entra ID and Routing Priority .....	407
Configuring Routing Rules based on Microsoft Entra ID .....	410
Querying Microsoft Entra ID for Calling Name .....	413
OAuth 2.0 Based Authentication Services .....	414
Configuring OAuth 2.0 Servers .....	414
OAuth-based User Login Authentication and Authorization .....	417
Setting Up Microsoft Entra ID for User Login OAuth Authentication .....	418
Device Configuration Summary .....	423
Microsoft Entra ID Login to Device's Web Interface .....	426
Microsoft Entra ID Login to Device's CLI .....	426
Microsoft Entra ID Login to Device's REST API .....	426
Configuring OAuth Servers for User Login Authentication .....	429
Enabling OAuth-based User Login Authentication .....	430
OAuth 2.0 Based SIP Message Authentication .....	433
Authenticating SIP Messages using Device's OAuth 2.0 Server with Microsoft Entra ID .....	433
Authenticating SIP Messages with External OAuth 2.0 Server .....	434
Remote Web Services .....	438
Configuring Remote Web Services .....	438
Configuring Remote HTTP Hosts .....	447
Enabling Topology Status Services .....	450
Enabling Registration Status Services .....	450
Centralized Routing by ARM (AudioCodes Routing Manager) .....	451
Configuring QoS-based Routing by ARM .....	455
Configuring an HTTP GET Web Service .....	456
Configuring HTTP POST Web Service .....	459
Least Cost Routing .....	461
Overview of LCR .....	461
Configuring LCR .....	464
Configuring Cost Groups .....	464
Assigning Cost Groups to Routing Rules .....	468
HTTP-based Proxy Services .....	468
Enabling the HTTP Proxy Application .....	470
Debugging Remote HTTP Services .....	470
Caching HTTP Responses .....	471
Configuring a DNS Server for HTTP Services .....	471
Configuring HTTP Proxy Servers .....	472
Configuring HTTP Locations .....	475
Configuring TCP-UDP Proxy Servers .....	479
Configuring Upstream Groups .....	483
Configuring Upstream Hosts .....	485
Configuring HTTP Directive Sets .....	487

Configuring HTTP Directives .....	489
Configuring an HTTP-based OVOC Service .....	490
Troubleshooting NGINX Configuration .....	495
Configuring a Public IP Address for NGINX NAT Traversal .....	496
Configuring LDAP Authentication for NGINX HTTP Reverse Proxy .....	496
E9-1-1 Support for Microsoft Teams and Skype for Business .....	498
About E9-1-1 Services .....	499
Microsoft Skype for Business and E9-1-1 .....	500
Gathering Location Information of Skype for Business Clients for 911 Calls .....	500
Adding ELINs to the Location Information Server .....	502
Passing Location Information to the PSTN Emergency Provider .....	503
AudioCodes ELIN Device for Teams / Skype for Business E9-1-1 Calls to PSTN .....	504
Detecting and Handling E9-1-1 Calls .....	505
Pre-empting Existing Calls for E9-1-1 Calls .....	508
PSAP Callback for Dropped E9-1-1 Calls .....	508
Selecting ELIN for Multiple Calls within Same ERL .....	509
Location Based Emergency Routing .....	510
Configuring AudioCodes ELIN Device .....	510
Enabling the E9-1-1 Feature .....	510
Configuring the E9-1-1 Callback Timeout .....	511
Enabling SIP Release Cause Code Response for Failed E9-1-1 Calls .....	511
Configuring SBC IP-to-IP Routing Rule for E9-1-1 .....	512
Configuring Location-Based Emergency Routing .....	512
Viewing the ELIN Table .....	514
Microsoft Skype for Business Presence of Third-Party Endpoints .....	514
Configuring Skype for Business Server for Presence .....	517
Configuring the Device for Microsoft Teams Presence .....	518
Microsoft Teams with Local Media Optimization .....	520

# 1 Introduction

This User's Manual describes how to configure and manage your AudioCodes Mediant 800 Gateway & E-SBC (hereafter, referred to as *device*).

## Product Overview

AudioCodes Mediant 800 Gateway & E-SBC (hereafter referred to as *device*) offers a complete connectivity solution for small-to-medium sized enterprises. The device connects IP-PBXs to any SIP trunking service provider. It offers superior performance in connecting any SIP to SIP environment, legacy TDM-based PBX systems to IP networks, and IP-PBXs to the PSTN.

The device supports a wide range of voice coders and is capable of transcoding between narrowband and wideband voice coders, providing SIP normalization, fax handling, gain control and numerous additional media processing features. It offers certified interoperability with leading unified communications solutions and SIP trunking providers.

The device provides robust protection for the IP communications infrastructure, preventing Denial of Service, fraud and service theft and guarding against cyber-attacks and other service-impacting events.

The device offers active/standby high availability and maintains high voice quality to deliver reliable enterprise VoIP communications. Advanced call routing mechanisms, network voice quality monitoring and branch survivability capabilities (including PSTN fallback with E911) result in minimum communications downtime.

Typical applications:

- SIP trunking
- Hosted PBX & UC as a Service
- IP contact centers
- Remote and mobile worker support
- SIP mediation between UC and IP-PBX systems

Key Features:

- Rich and powerful SIP normalization and routing mechanisms for seamless interoperability
- Hybrid SBC that connects to PSTN / PBX trunks for fallback and gradual enterprise migration to SIP
- Support for analog (FXO and FXS) and digital (PRI and BRI) interfaces
- Perimeter defense against denial of service, fraud and eavesdropping
- VoIP quality monitoring and enforcement
- High Availability using two-box redundancy
- Media processing for transcoding, gain control, DTMF/fax, etc.

- Optional Open Solution Network (OSN) platform for hosting value-added applications

## Typographical Conventions

This document uses the following typographical conventions:

**Table 1-1: Typographical Conventions**

Convention	Description	Example
Text enclosed by a single quotation mark ('...')	Indicates Web interface parameters.	From the 'Debug Level' drop-down list, select <b>Basic</b> .
<b>Boldface font</b>	Indicates one of the following Web-based management interface elements: <ul style="list-style-type: none"> <li>■ A button</li> <li>■ A selectable value</li> <li>■ The navigational path to a Web page</li> </ul>	Click the <b>Add</b> button.
Text enclosed by double quotation marks ("...")	Indicates values that you need to enter (type) in the Web interface.	In the 'IP Address' field, enter "10.10.1.1".
Courier font	Indicates CLI commands or ini-based file configuration.	At the CLI prompt, type the following: <div># configure system</div>
Text enclosed by square brackets [...]	Indicates ini file parameters and values.	Configure the [GWDebugLevel] parameter to [1].
	Indicates a note bulletin providing important or useful information.	-
	Indicates a warning bulletin alerting you to potentially serious problems if a specific action is not taken.	-

## Configuration Concepts and Terminology

Before using your device, it is recommended that you familiarize yourself with the basic configuration concepts and terminology. An understanding of the basic concepts and

terminology will help you configure and manage your device more effectively and easily.

## SBC Application Concepts and Terms

The objective of your configuration is to enable the device to forward calls between telephony endpoints in the SIP-based Voice-over-IP (VoIP) network. The endpoints (SIP entities) can be servers such as SIP proxy servers and IP PBXs, or end users such as IP phones. In the SIP world, the endpoints are referred to as SIP user agents (UA). The UA that initiates the call is referred to as the user agent client (UAC); the UA that accepts the call is referred to as the user-agent server (UAS).

The following table describes the main configuration concepts and terminology.

**Table 1-2: Configuration Concepts and Terminology**

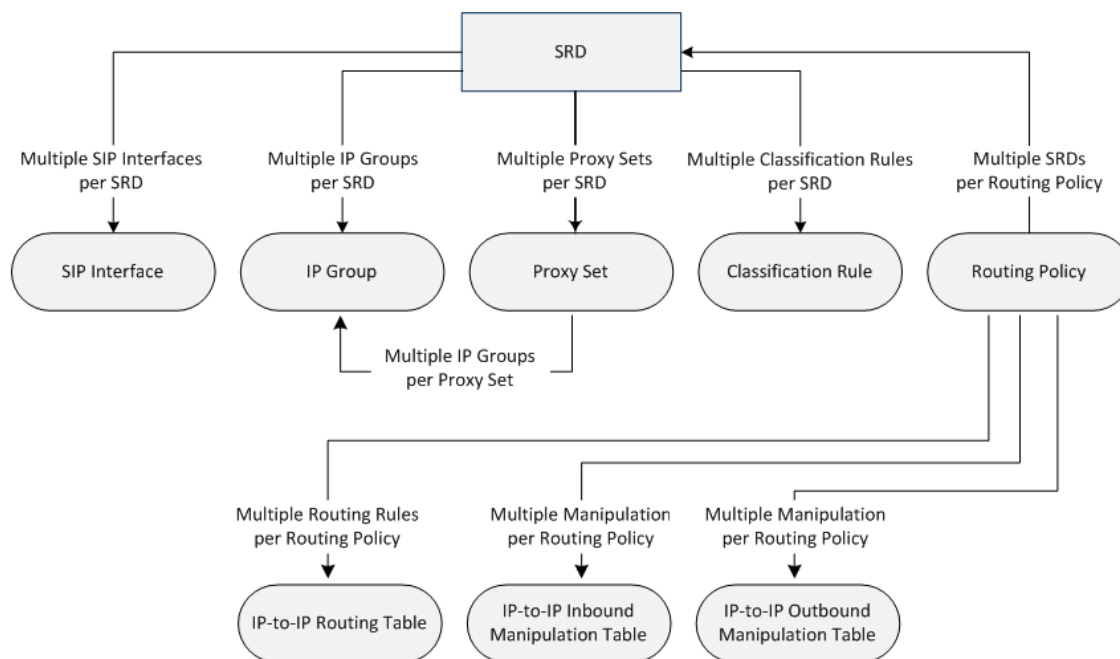

Configuration Terms	Description
IP Group	An IP Group is a logical representation of the SIP entity (UA) with which the device receives and sends calls. The SIP entity can be a server (e.g., IP PBX or SIP Trunk) or it can be a group of users (e.g., LAN IP phones). For servers, the IP Group is typically used to define the address of the entity (by its associated Proxy Set). IP Groups are used in IP-to-IP routing rules to denote the source and destination of the call.
Proxy Set	A Proxy Set defines the actual address (IP address or FQDN) of SIP entities that are servers (e.g., IP PBX). As the IP Group represents the SIP entity, to associate an address with the SIP entity, the Proxy Set is assigned to the IP Group. You can assign the same Proxy Set to multiple IP Groups (belonging to the same SRD).
SIP Interface	A SIP Interface represents a Layer-3 network. It defines a local listening port for SIP signaling traffic on a local, logical IP network interface. The term <i>local</i> implies that it's a logical port and network interface on the device. The SIP Interface is used to receive and send SIP messages with a specific SIP entity (IP Group). Therefore, you can create a SIP Interface for each SIP entity in the VoIP network with which your device needs to communicate. For example, if your VoIP network consists of three SIP entities -- a SIP Trunk, a LAN IP PBX, and remote WAN users -- a SIP Interface can be created for each of these Layer-3 networks.  The SIP Interface is associated with the SIP entity, by assigning it to an SRD that is in turn, assigned to the IP Group of the SIP entity.
Media Realm	A Media Realm defines a local UDP port range for RTP (media) traffic on any one of the device's logical IP network interfaces. The Media Realm is used to receive and send media traffic with a specific SIP entity (IP Group).

Configuration Terms	Description
	<p>The Media Realm can be associated with the SIP entity, by assigning the Media Realm to the IP Group of the SIP entity, or by assigning it to the SIP Interface associated with the SIP entity.</p>
SRD	<p>An SRD is a logical representation of your entire SIP-based VoIP network (Layer 5) containing groups of SIP users and servers. The SRD is in effect, the foundation of your configuration to which all other previously mentioned configuration entities are associated. For example, if your VoIP network consists of three SIP entities -- a SIP Trunk, a LAN IP PBX, and remote WAN users -- the three SIP Interfaces defining these Layer-3 networks would all assigned to the same SRD. Typically, only a single SRD is required and this is the recommended configuration topology. As the device provides a default SRD, in a single SRD topology, the device automatically assigns the SRD to newly created configuration entities. Thus, in such scenarios, there is no need to get involved with SRD configuration.</p> <p>Multiple SRDs are required only for multi-tenant deployments, where it "splits" the device into multiple logical devices. For multiple SRDs, the SRD can be configured with a Sharing Policy. The Sharing Policy simply means whether the SRD's resources (SIP Interfaces, IP Groups, and Proxy Sets) can be used by other SRDs. For example, if all tenants route calls with the same SIP Trunking service provider, the SRD of the SIP Trunk would be configured as a <i>Shared</i> Sharing Policy. SRDs whose resources are not shared, would be configured with an <i>Isolated</i> Sharing Policy.</p>
IP Profile	<p>An IP Profile is an optional configuration entity that defines a wide range of call settings for a specific SIP entity (IP Group). The IP Profile includes signaling and media related settings, for example, jitter buffer, silence suppression, voice coders, fax signaling method, SIP header support (local termination if not supported), and media security method. The IP Profile is in effect, the interoperability "machine" of the device, enabling communication between SIP endpoints that "speak" different call "languages".</p> <p>The IP Profile is associated with the SIP entity, by assigning the IP Profile to the IP Group of the SIP entity.</p>
Classification	<p>Classification is the process that identifies the incoming call (SIP dialog request) as belonging to a specific SIP entity (IP Group).</p> <p>There are three chronological classification stages, where each stage is done only if the previous stage fails. The device first attempts to classify</p>

Configuration Terms	Description
	<p>the SIP dialog by checking if it belongs to a user that is already registered in the device's registration database. If this stage fails, the device checks if the source IP address is defined for a Proxy Set and if yes, it classifies it to the IP Group associated with the Proxy Set. If this fails, the device classifies the SIP dialog using the Classification table, which defines various characteristics of the incoming dialog that if matched, classifies the call to a specific IP Group. The main characteristics of the incoming call is the SIP Interface that is associated with the SRD for which the Classification rule is configured.</p>
IP-to-IP Routing	<p>IP-to-IP routing rules define the routes for routing calls between SIP entities. As the SIP entities are represented by IP Groups, the routing rules typically employ IP Groups to denote the source and destination of the call. For example, to route calls from the IP PBX to the SIP Trunk, the routing rule can be configured with the IP PBX as the source IP Group and the SIP Trunk as the destination IP Group.</p> <p>Instead of IP Groups, various other source and destination methods can be used. For example, the source can be a source host name while the destination can be an IP address or based on an LDAP query.</p>
Inbound and Outbound Manipulation	<p>Inbound and Outbound Manipulation lets you manipulate the user part of the SIP URI in the SIP message for a specific entity (IP Group). Inbound manipulation is done on messages received from the SIP entity; outbound manipulation is done on messages sent to the SIP entity.</p> <p>Inbound manipulation lets you manipulate the user part of the SIP URI for source (e.g., in the SIP From header) and destination (e.g., in the Request-URI line) in the incoming SIP dialog request. Outbound manipulation lets you manipulate the user part of the Request-URI for source (e.g., in the SIP From header) or destination (e.g., in the SIP To header) or calling name, in outbound SIP dialog requests.</p> <p>The Inbound and Outbound manipulation are associated with the SIP entity, by configuring the rules with incoming characteristics such as source IP Group and destination host name. The manipulation rules are also assigned a Routing Policy, which in turn, is assigned to IP-to-IP routing rules. As most deployments require only one Routing Policy, the default Routing Policy is automatically assigned to the manipulation rules and to the routing rules.</p>
Routing Policy	<p>Routing Policy logically groups routing and manipulation (inbound and outbound) rules to a specific SRD. It also enables Least Cost Routing (LCR) for routing rules and associates an LDAP server for LDAP-based</p>

Configuration Terms	Description
	routing. However, as multiple Routing Policies are required only for multi-tenant deployments, for most deployments only a single Routing Policy is required. When only a single Routing Policy is required, handling of this configuration entity is not required as a default Routing Policy is provided, which is automatically associated with all relevant configuration entities.
Call Admission Control	Call Admission Control (CAC) lets you configure the maximum number of permitted concurrent calls (SIP dialogs) per IP Group, SIP Interface, SRD, or user.
Accounts	Accounts are used to register or authenticate a "served" SIP entity (e.g., IP PBX) with a "serving" SIP entity (e.g., a registrar or proxy server). The device does this on behalf of the "served" IP Group. Authentication (SIP 401) is typically relevant for INVITE messages forwarded by the device to a "serving" IP Group. Registration is for REGISTER messages, which are initiated by the device on behalf of the "serving" SIP entity.

The associations between the configuration entities are summarized in the following figure:

The main configuration entities and their involvement in the call processing is summarized in following figure. The figure is used only as an example to provide basic understanding of the configuration terminology. Depending on configuration and network topology, the call process may include additional stages or a different order of stages.

1. The device determines the SIP Interface on which the incoming SIP dialog is received and thus, determines its associated SRD.
2. The device classifies the dialog to an IP Group (origin of dialog), using a specific Classification rule that is associated with the dialog's SRD and that matches the incoming characteristics of the incoming dialog defined for the rule.
3. IP Profile and inbound manipulation can be applied to incoming dialog.
4. The device routes the dialog to an IP Group (destination), using the IP-to-IP Routing table. The destination SRD (and thus, SIP Interface and Media Realm) is the one assigned to the IP Group. Outbound manipulation can be applied to the outgoing dialog.

## Gateway Application Concepts and Terms

The objective of your configuration is to enable the device to forward calls between the IP-based endpoints and PSTN-based endpoints. The PSTN-based endpoints can be analog endpoints such as FXS (plain old telephone service or POTS) or FXO (e.g., PBX) or digital endpoints such as ISDN trunks. The IP-based endpoints (SIP entities) can be servers such as SIP proxy servers and IP PBXs, or end users such as LAN IP phones. In the SIP world, the endpoints are referred to as SIP user agents (UA). The UA that initiates the call is referred to as the user agent client (UAC); the UA that accepts the call is referred to as the user-agent server (UAS).

The following table describes the main configuration concepts and terminology.

**Table 1-3: Configuration Concepts and Terminology**

Configuration Terms	Description
IP Groups	An IP Group is a logical representation of the SIP entity (UA) with which the device receives and sends calls. The SIP entity can be a server (e.g., IP PBX or SIP Trunk) or it can be a group of users (e.g., LAN IP phones). For servers, the IP Group is typically used to define the address of the entity (by its associated Proxy Set). IP Groups are typically used in Tel-to-IP routing rules to denote the destination of the call.
Proxy Sets	A Proxy Set defines the actual address (IP address or FQDN) of

Configuration Terms	Description
	SIP entities that are servers (e.g., IP PBX). As the IP Group represents the SIP entity, to associate an address with the SIP entity, the Proxy Set is assigned to the IP Group.
SIP Interfaces	<p>A SIP Interface represents a Layer-3 network for the IP-based SIP entity. It defines a local listening port for SIP signaling traffic on a local, logical IP network interface. The term <i>local</i> implies that it's a logical port and network interface on the device. The SIP Interface is used to receive and send SIP messages with a specific SIP entity (IP Group). Therefore, you can create a SIP Interface for each SIP entity in the VoIP network with which your device needs to communicate.</p> <p>The SIP Interface is associated with the SIP entity, by assigning the SIP Interface to an SRD that is in turn, assigned to the IP Group of the SIP entity.</p>
Media Realms	<p>A Media Realm defines a local UDP port range for RTP (media) traffic on any one of the device's logical IP network interfaces. The Media Realm is used to receive and send media traffic with a specific SIP entity (IP Group).</p> <p>The Media Realm can be associated with the SIP entity, by assigning the Media Realm to the IP Group of the SIP entity, or by assigning it to the SIP Interface associated with the SIP entity.</p>
SRDs	<p>An SRD is a logical representation of your entire VoIP network. The SRD is in effect, the foundation of your configuration to which all other previously mentioned configuration entities are associated.</p> <p>Typically, only a single SRD is required and this is the recommended configuration topology. As the device provides a default SRD, in a single SRD topology, the device automatically assigns the SRD to newly created configuration entities. Thus, in such scenarios, there is no need to get involved with SRD configuration.</p> <p>Multiple SRDs are required only for multi-tenant deployments.</p>
IP Profiles	<p>An IP Profile is an optional configuration entity that defines a wide range of call settings for a specific SIP entity (IP Group). The IP Profile includes signaling and media related settings, for example, jitter buffer, silence suppression, voice coders, fax signaling method, SIP header support (local termination if not supported), and media security method. The IP Profile is in effect, the interoperability "machine" of the device, enabling</p>

Configuration Terms	Description
	<p>communication with SIP endpoints supporting different call "languages".</p> <p>The IP Profile is associated with the SIP entity, by assigning the IP Profile to the IP Group of the SIP entity.</p>
Tel Profiles	<p>A Tel Profile is an optional configuration entity that defines a wide range of call settings for a specific PSTN-based endpoint. The IP Profile includes settings such as message waiting indication (MWI), input gain, voice volume and fax signaling method.</p> <p>The Tel Profile is associated with the PSTN-based endpoint, by assigning it to the Trunk Group belonging to the endpoint.</p>
Tel-to-IP Routing Rules	<p>Tel-to-IP routing rules are used to route calls from PSTN-based endpoints to an IP destination (SIP entity). The PSTN side can be denoted by a specific Trunk Group, or calling or called telephone number prefix and suffix. The SIP entity can be denoted by an IP Group or other IP destinations such as IP address, FQDN, E.164 Telephone Number Mapping (ENUM service), and Lightweight Directory Access Protocol (LDAP).</p>
IP-to-Tel (Trunk Group) Routing Rules	<p>An IP-to-Tel Routing rule is used to route specific incoming IP calls to a specific Trunk Group. The specific channel pertaining to the Trunk Group to which the call is routed can also be configured.</p>
Accounts	<p>An Account is used to register or authenticate PSTN-based endpoints with a SIP entity (e.g., a registrar or proxy server). The device does this on behalf of the PSTN-based endpoint. Authentication (SIP 401) is typically relevant for INVITE messages forwarded by the device to a SIP entity. Registration is for REGISTER messages, which are initiated by the device on behalf of the PSTN-based endpoint.</p>

The following figure shows the main configuration entities and their involvement in call processing. The figure is used only as an example to provide basic understanding of the configuration terminology. Depending on configuration and network topology, the call process may include additional stages or a different order of stages.

# Part I

## Getting Started with Initial Connectivity

## 2 Overview

This part describes how to initially access the device's management interface and change its default IP address to correspond with your networking scheme.

## 3 Default IP Address

The device is shipped with a factory default networking address for operations, administration, maintenance, and provisioning (OAMP), through its LAN interface, as listed in the table below. You can use this address to initially access the device from any of its management tools (embedded Web server, REST API, OVOC, or Telnet/SSH). You can also access the device through the console CLI, by connecting the device's serial (RS-232) port to a PC.

**Table 3-1: Default VoIP LAN IP Address for OAMP**

IP Address	Value
IP Address	192.168.0.2
Prefix Length	24 (255.255.255.0)
Default Gateway	0.0.0.0
VLAN	1
Ethernet Group	GROUP_1
Port	GE_4_1

## 4 Configuring OAMP Interface

You can change the device's default OAMP IP address to suit your networking scheme. You can configure up to two OAMP interfaces, each with a different IP version (IPv4 or IPv6).

You can change the device's default OAMP IP address, using any of the following methods:

- Embedded HTTP/S-based Web server (see [Changing OAMP Address through Web Interface](#) below)
- Embedded CLI (see [Changing OAMP Address through CLI](#) on the next page)
- ini file (see [Changing OAMP Address through ini File](#) on page 17)

If you are implementing the High Availability feature, see also [Overview of High Availability Mode](#) on page 1302 for initial setup.

### Changing OAMP Address through Web Interface

You can change the device's default OAMP networking address through the Web-based management tool (Web interface). The default IP address is used to initially access the device.

➤ **To change the default OAMP network address through Web interface:**

1. Connect Port 1 (left-most LAN port) located on the front panel directly to the network interface of your computer, using a straight-through Ethernet cable.

2. Change the IP settings of your computer to correspond with the default OAMP IP address and subnet mask of the device.
3. Access the Web interface:
  - a. On your computer, start a Web browser and in the URL address field, enter the default IP address of the device; the Web interface's Web Login screen appears:

- b. In the 'Username' and 'Password' fields, enter the case-sensitive, default login username ("Admin") and password ("Admin").
  - c. Click **Log In**.
4. Configure the Ethernet port(s) that you want to use for the OAMP interface:
  - a. In the Ethernet Groups table, configure an Ethernet Group by assigning it up to two ports (two ports provide optional, port-pair redundancy). For more information, see [Configuring Physical Ethernet Ports](#) on page 150.
  - b. In the Physical Ports table, configure port settings such as speed and duplex mode (see [Configuring Physical Ethernet Ports](#) on page 150).
  - c. In the Ethernet Devices table, configure an Ethernet Device by assigning it the Ethernet Group and a VLAN ID (see [Configuring Underlying Ethernet Devices](#) on page 156).
5. Modify the OAMP interface address to suite your network environment:
  - a. Open the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
  - b. Select the OAMP interface ("O+M+C"), and then click **Edit**.
  - c. From the 'Ethernet Device' drop-down list, select the Ethernet Device that you configured in the previous step.
  - d. Under the **IP Address** group, change the IP address to correspond with your network IP addressing scheme.
  - e. Under the **DNS** group, configure the DNS server, if required.
  - f. Click **Apply**; the new OAMP address is applied to the device and your connectivity to the device's Web interface at its previous OAMP address is now lost.
6. Change the IP settings of your computer to correspond with the new OAMP IP address and subnet mask that you assigned the device.
7. Access the device using the new OAMP IP address, and then on the Web interface's toolbar, click the **Save** button.
8. Re-cable the device to the desired network. You can now access the device's management interfaces using the new OAMP address.

## Changing OAMP Address through CLI

You can change the default OAMP IP address through the device's CLI. The procedure uses the regular CLI commands. Alternatively, you can use the CLI Wizard utility to set up your device with the initial OAMP settings. The utility provides a fast-and-easy method for initial configuration of the device through CLI. For more information, refer to the document *CLI Reference Guide*.

➤ **To configure the OAMP IP address through CLI:**

1. Connect the RS-232 port of the device to the serial communication port on your computer. For more information, refer to the device's *Hardware Installation Manual*.

2. Establish serial communication with the device using a terminal emulator program such as HyperTerminal, with the following communication port settings:
  - Baud Rate: 115,200 bps
  - Data Bits: 8
  - Parity: None
  - Stop Bits: 1
  - Flow Control: None
3. At the CLI prompt, type the username (default is "Admin" - case sensitive):

```
Username: Admin
```

4. At the prompt, type the password (default is "Admin" - case sensitive):

```
Password: Admin
```

5. At the prompt, type the following:

```
enable
```

6. At the prompt, type the password again:

```
Password: Admin
```

7. Access the Network configuration mode:

```
# configure network
```

8. Access the IP Interfaces table:

```
(config-network)# interface network-if 0  
(network-if-0)#
```

9. Configure the IP address:

```
(network-if-0)# ip-address <IP address>
```

10. Configure the prefix length:

```
(network-if-0)# prefix-length <prefix length / subnet mask, e.g., 16>
```

11. Configure the Default Gateway address:

```
(network-if-0)# gateway <IP address>
```

12. Apply your settings:

```
(network-if-0)# activate
```

13. Cable the device to your network. You can now access the device's management interface using this new OAMP IP address.

## Changing OAMP Address through ini File

You can change the device's default OAMP networking address by loading an ini file with the new OAMP address, through the device's Web interface.

### ➤ To change the default OAMP network address through ini file:

1. Create an ini file using a regular text-based editor program (such as Notepad) and save it with the file extension name **.ini** (e.g., myfile.ini).
2. Copy-and-paste the below ini file table parameter (InterfaceTable) into the ini file:

```
[ InterfaceTable ]  
FORMAT Index = ApplicationTypes, InterfaceMode, IPAddress, PrefixLength,  
Gateway, InterfaceName, PrimaryDNSServerIPAddress,
```

```
SecondaryDNSServerIPAddress, UnderlyingDevice;  
InterfaceTable 0 = 6, 10, <IP Address>, <Prefix Length>, <Default Gateway>,  
"O+M+C", 0.0.0.0, 0.0.0.0, "vlan 1";  
[ \InterfaceTable ]
```

3. Modify the <IP Address>, <Prefix Length>, and <Default Gateway> parameters (but remove the angle brackets).
4. Save the file.
5. Connect to the device's Web interface using the default OAMP address (see [Changing OAMP Address through Web Interface](#) on page 14).
6. Open the Configuration File page (**Setup** menu > **Administration** tab > **Maintenance** folder > **Configuration File**).
7. Under the INI File group, click the **Choose File** button to select the file, and then click **Upload INI File**; the device uploads the file and saves the configuration to flash memory with a device restart.
8. Disconnect the device from your PC and re-connect it to your network.
9. Access the device using the new OAMP interface address.

# Part II

## Management Tools

## 5 Overview

This part describes the various management tools that you can use to configure the device:

- Embedded HTTP/S-based Web server - see [Web-Based Management](#) on page 21
- Embedded Command Line Interface (CLI) - see [CLI-Based Management](#) on page 92
- Simple Network Management Protocol (SNMP) - see [SNMP-Based Management](#) on page 108
- Configuration *ini* file - see [INI File-Based Management](#) on page 127
- REST API - see [REST-Based Management](#) on page 132

- Some configuration settings can only be done using a specific management tool.
- For a list and description of all the configuration parameters, see [Configuration Parameters Reference](#) on page 1701.

## 6 Web-Based Management

The device provides an embedded Web server (hereafter referred to as *Web interface*), supporting fault management, configuration, accounting, performance, and security (FCAPS). The Web interface provides a user-friendly, graphical user interface (GUI), which can be accessed using any standard Web browser. Access to the Web interface can be controlled by various security mechanisms such as login username and password, read-write privileges, and limiting access to specific IP addresses.

- The Web interface allows you to configure most of the device's settings. However, additional configuration parameters may exist that are not available in the Web interface and which can only be configured using other management tools.
- Some Web interface pages and parameters are available only for certain hardware configurations or software features. The software features are determined by the installed License Key (see [License Key](#) on page 1362).

### Getting Acquainted with Web Interface

This section provides a description of the Web interface's graphical user interface (GUI).

#### Computer Requirements

The client computer accessing the device's Web interface requires the following prerequisites:

- A network connection to the device.
- One of the following Web browsers:
  - Microsoft® Edge (Version 100.0.1185.50 or later)
  - Mozilla Firefox® (Version 99.0.1 or later)
  - Google Chrome (Version 100.0.4896.127 or later)

The Web browser must be JavaScript-enabled.

- Recommended screen resolution: 1280 x 1024 pixels, or 1366 x 768 pixels

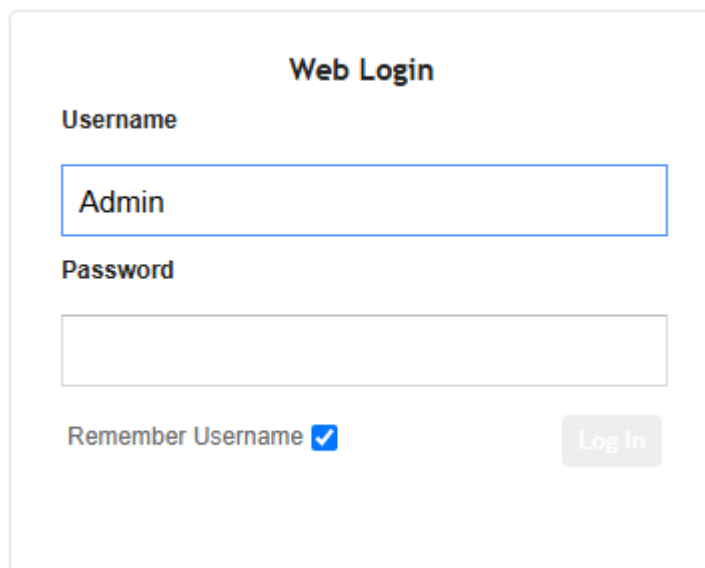

#### Logging into the Web Interface

The following procedure describes how to access the Web interface.

##### ➤ To log into Web interface:

1. Open a standard Web browser.

2. In the Web browser, enter the device's OAMP IP address (e.g., <http://10.1.10.10>); the Web interface's Web Login window appears:

A screenshot of the 'Web Login' form. The title 'Web Login' is centered at the top. Below it, the 'Username' label is followed by a text input field containing the text 'Admin'. Below the 'Username' field is the 'Password' label followed by an empty password input field. At the bottom left, there is a 'Remember Username' label followed by a checked checkbox. At the bottom right, there is a 'Log In' button.

3. In the 'Username' and 'Password' fields, enter your username and password, respectively.
4. If you want the Web browser to remember your username for future logins, select the 'Remember Username' check box. On your next login attempt, the 'Username' field will be automatically populated with your username.
5. Click **Log In**.

By default, autocompletion of the login username is enabled, whereby the 'Username' field predicts the rest of the username while you are typing, by displaying a drop-down list with previously entered usernames. To disable autocompletion, use the [WebLoginBlockAutoComplete] ini file parameter.

- The default login username and password is **Admin** and **Admin**, respectively. To change the login credentials, see [Configuring Local Management User Accounts](#) on page 55.
- The username and password is case-sensitive.
- You can only access the device's Web (and REST) interfaces through a configured Web Interface (see [Configuring Web Interfaces](#) on page 52).
- Depending on your Web browser's settings, a security warning box may be displayed. The reason for this is that the device's certificate is not trusted by your PC. The browser may allow you to install the certificate, thus skipping the warning box the next time you connect to the device. If you are using Windows Internet Explorer, click **View Certificate**, and then **Install Certificate**. The browser also warns you if the host name used in the URL is not identical to the one listed in the certificate. To resolve this, add the IP address and host name (ACL\_nnnnnn, where nnnnnn is the serial number of the device) to your hosts file, located at /etc/hosts on UNIX or C:\Windows\System32\Drivers\ETC\hosts on Windows; then use the host name in the URL (e.g., https://ACL\_280152). Below is an example of a host file:  
127.0.0.1 localhost  
10.31.4.47 ACL\_280152

## Areas of Web Interface

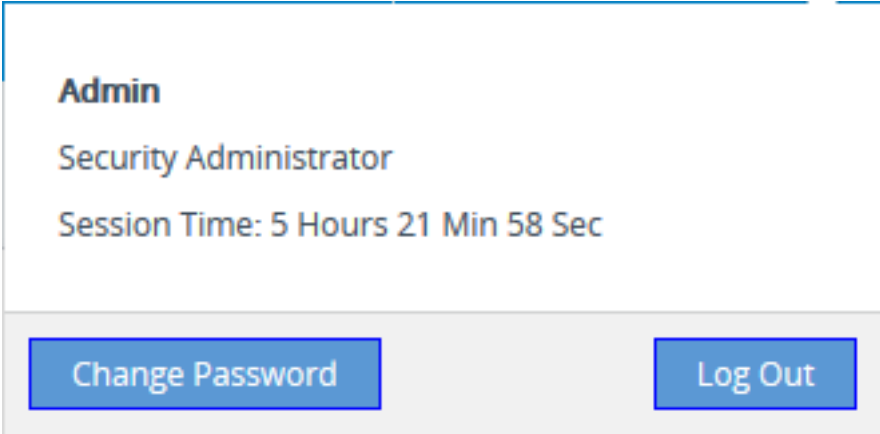

The main areas of the device's Web interface are shown in the figure below and described in the subsequent table:

**Table 6-1: Description of the Web GUI Areas**

Item#	Description
1	Company logo. To customize the logo, see <a href="#">Corporate Logo</a> on page 44. If you click the logo, the Topology View page opens (see <a href="#">Building and Viewing SIP Entities in Topology View</a> on page 654).
2	Menu bar with the following menus:

Item#	Description
	<ul style="list-style-type: none"> <li>■ <b>Setup</b> - access to pages concerned with device configuration.</li> <li>■ <b>Monitor</b> - access to pages concerned with status and performance monitoring.</li> <li>■ <b>Troubleshoot</b> - access to pages concerned with troubleshooting such as logs, debug recording, and call detail records.</li> </ul>
3	<p>Tab bar with tabs pertaining to the selected menu on the Menu bar:</p> <ul style="list-style-type: none"> <li>■ <b>Setup</b> menu: <ul style="list-style-type: none"> <li>✓ <b>IP Network</b> tab</li> <li>✓ <b>Signaling &amp; Media</b> tab</li> <li>✓ <b>Administration</b> tab</li> </ul> </li> <li>■ <b>Monitor</b> menu: <b>Monitor</b> tab</li> <li>■ <b>Troubleshoot</b> menu: <b>Troubleshoot</b> tab</li> </ul>
4	<p>Toolbar providing frequently required commands:</p> <ul style="list-style-type: none"> <li>■ <b>Save:</b> Saves configuration to the device's flash memory (without a restart). When you make a configuration change, the button is displayed with a red border, indicating that you need to save configuration.</li> <li>■ <b>Restart:</b> Opens the Maintenance Actions page, which is used for restarting the device (see <a href="#">Basic Maintenance</a> on page 1329) and for gracefully locking or unlocking the device (see <a href="#">Locking and Unlocking the Device</a> on page 1331). If you make a configuration change that takes effect only after a device restart, the button is displayed with a red border, indicating that you need to restart the device.</li> <li>■ <b>Actions:</b> Drop-down menu containing the following commands: <ul style="list-style-type: none"> <li>✓ <b>Configuration File:</b> Opens the Configuration File page, which is used for uploading or downloading ini, CLI Script, CLI Startup Script, and Configuration Package files (see <a href="#">Downloading and Uploading Configuration Files</a> on page 1386).</li> <li>✓ <b>Auxiliary Files:</b> Opens the Auxiliary Files page, which is used for uploading Auxiliary files (see <a href="#">Uploading Auxiliary Files through Web Interface</a> on page 1348).</li> <li>✓ <b>License Key:</b> Opens the License Key page, which is used for installing a new License Key file (see <a href="#">Installing License Key through Web Interface</a> on page 1364).</li> <li>✓ <b>Software Upgrade:</b> Starts the Software Upgrade Wizard for</li> </ul> </li> </ul>

Item#	Description
	<p>upgrading the device's software file (see <a href="#">Upgrading the Device's (.cmp) Software</a> on page 1339).</p> <ul style="list-style-type: none"> <li>✓ <b>Switchover:</b> Opens the High Availability Maintenance page, which is used for switching between Active and Redundant devices (see <a href="#">Initiating an HA Switchover</a> on page 1323).</li> <li>✓ <b>Configuration Wizard:</b> Opens the SBC Configuration Wizard, which is used for quick-and-easy device configuration (see <a href="#">SBC Configuration Wizard</a> on page 1424).</li> </ul> <p><b>Note:</b> If you have configured any IPv6 interfaces in the IP Interfaces table, the SBC Configuration Wizard is not supported and the <b>Configuration Wizard</b> command is not listed in the <b>Actions</b> menu.</p>
5	<p>Alarm bell icon displaying the number of currently active alarms sent by the device. The color of the number indicates the highest severity of all the active alarms. If you click the icon, the Active Alarms page opens (see <a href="#">Viewing Active Alarms</a> on page 1454). If the device is in HA mode, the icon displays the number of currently active alarms sent by both Active and Redundant devices as well as the highest severity of these active alarms.</p>
6	<p>Button displaying the username of the currently logged-in user. If you click the button, the following drop-down box appears:</p> <div data-bbox="491 1160 1375 1592">  </div> <ul style="list-style-type: none"> <li>■ Displays information of the logged-in user (see <a href="#">Viewing Currently Logged-In User Information</a> on page 73).</li> <li>■ <b>Change Password</b> button changes your login password (see <a href="#">Changing Login Password</a> on page 68).</li> <li>■ <b>Log Out</b> button logs you out of the Web session (see <a href="#">Logging Out the Web Interface</a> on page 43).</li> </ul>

Item#	Description
7	The  icon provides a drop-down list of links to documents related to your device (e.g., Installation Manual, User's Manual, Security Guidelines, and Release Notes). For private labeling (customizing Web interface), this icon is automatically hidden from the toolbar (see <a href="#">Displaying Referenced Document List</a> on page 52).
8	Product name of your device. <b>Note:</b> <ul style="list-style-type: none"> <li>■ If you configure a hostname for the device (see <a href="#">Configuring a Hostname for the Device</a> on page 144), the hostname is displayed instead of the product name.</li> <li>■ You can customize the product name, as described in <a href="#">Customizing the Product Name</a> on page 48.</li> </ul>
9	Navigation pane displaying the Navigation tree containing the commands (items) for opening the configuration pages (see <a href="#">Accessing Configuration Pages from Navigation Tree</a> below).
10	Search box for searching parameters and values (see <a href="#">Searching for Configuration Parameters</a> on page 41).
11	Work pane where configuration pages are displayed and configuration is done.

## Accessing Configuration Pages from Navigation Tree

Accessing configuration pages is a three-fold process that consists of selecting a menu on the menu bar, a tab on the tab bar, and then a page item in the Navigation pane. The Navigation pane provides the Navigation tree, which is a tree-like structure of folders and page items that open configuration pages in the Work pane. The hierarchical structure and organization of the items in the Navigation tree allow you to easily drill-down and locate the required item.

The Navigation tree consists of the following areas:

- **Home**  : (#1 in figure) First ("home") page displayed when a menu-tab combination is initially selected. For example, the home page of the **Setup** menu - **Administration** tab combination is the Time & Date page.
- **Folders:** (#2 in figure) Folders group items of similar functionality. To open and close a folder, simply click the folder name.
- **Items:** (#3 in figure) Items open configuration pages. In some cases, an item may be listed under a sub-item. An item can open a page containing stand-alone parameters or a table. If it opens a page with stand-alone parameters, the item is displayed in italics. If it opens a

page with a table, the item is displayed in regular font, or bold font to indicate an item that is commonly required.

The items of the Navigation tree depend on the menu-tab combination, selected from the menu bar and tab bar, respectively. The menus and their respective tabs are listed below:

■ **Setup menu:**

- IP Network tab
- Signaling & Media tab
- Administration tab

■ **Monitor menu:** Monitor tab

■ **Troubleshoot menu:** Troubleshoot tab

When you open the Navigation tree, folders containing commonly required items are opened by default, allowing quick access to their pages.

Items that open pages containing tables provide the following indications in the Navigation tree:

- **Number of configured rows.** For example, the item below indicates that two rows have been configured:

**Ethernet Groups (2)**

If you have filtered the Web interface display by SRD, the number reflects only the rows that are associated with the filtered SRD.

- **Invalid row configuration.** If you have configured a row with at least one invalid value, a red-colored icon is displayed next to the item, as shown in the following example:

Ethernet Groups (2) ●

If you hover your cursor over the icon, it displays the number of invalid rows (*lines*).

- **Association with an invalid row:** If you have associated a parameter of a row with a row of a different table that has an invalid configuration, the item appears with an arrow and a red-colored icon, as shown in the following example:

Ethernet Devices (2) ➔●

If you hover your cursor over the icon, it displays the number of rows in the table that are associated with invalid rows.

- **Folder containing an item with an invalid row:** If a folder contains an item with an invalid row (or associated with an invalid row), the closed folder displays a red-colored icon, as shown in the following example:

▶ CORE ENTITIES ●

If you hover your cursor over the icon, it displays the names of the items that are configured with invalid values. If you have filtered the Web interface display by SRD, only items with invalid rows that are associated with the filtered SRD are displayed.

#### ➤ To open a configuration page:

1. On the menu bar, click the required menu.
2. On the tab bar, click the required tab; the Navigation tree displays the items pertaining to the selected menu-tab combination.
3. In the Navigation pane, open the folder in which the required item is located. The folders are opened and closed by clicking the title of the folder. When opened, the folder's arrow is displayed as ▲; when closed, the arrow is displayed as ▶.
4. In the folder, click the required item; the page is displayed in the Work pane.

Depending on the access level (e.g., Monitor level) of your Web user account, certain pages may not be accessible or may be read-only (see [Configuring Local Management User Accounts](#) on page 55). For read-only privileges:

- Read-only pages with stand-alone parameters: "Read Only Mode" is displayed at the bottom of the page.
- Read-only pages with tables: Configuration buttons (e.g., **New** and **Edit**) are missing.

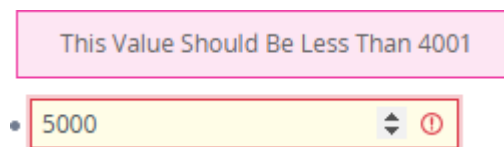

## Configuring Global Parameters

Parameters that are not contained in a table are referred to as *global* parameters.

- When entering a value for a parameter, the parameter's field is highlighted and a pop-up box appears, providing a short description of the parameter, for example, valid values.

- When you enter an invalid value, the field is displayed with a red border and a pop-up box describes the problem. In such cases, do one of the following:
  - Click the **Cancel** button (located at the bottom of the page) so that the parameter reverts to its previous value.
  - Enter a valid value.

- When you change a parameter's value from default and then click **Apply**, a dot is displayed next to the parameter's field or check box. In other words, if a dot isn't displayed, the parameter is at its default value.

- When you change a value of a parameter that is displayed with a lightning-bolt ⚡ icon (see below), you need to save your settings to flash memory with a device **restart** for changes to take effect.

When you change such a parameter and then click **Apply**, the **Restart** button on the toolbar is displayed in a red border, indicating you that you need to restart the device, which you can do by clicking the button:

- Common parameters are displayed in bold font.
- Fields of parameters that configure passwords provide a toggle icon that shows (eye) or hides (eye crossed out) the password when you type it in the field:

The Web interface always hides (by asterisks \*or dots) passwords once they have been configured (i.e., you've clicked **Apply**). Therefore, the toggle eye icon doesn't show them even when clicked.

- Parameters that enable or disable a functionality provide a check box. When selected (i.e., marked), functionality is enabled; when cleared (empty), functionality is disabled. The following shows an example of an enabled functionality:

- Parameters with numerical values provide a field with a spin box. Clicking the up arrow increases the number while clicking the down arrow decreases it.

- To get help on a parameter, hover your mouse over the parameter's field or check box to display a pop-up box with a brief description of the parameter.

The following procedure describes how to configure stand-alone parameters.

➤ **To configure a stand-alone parameter:**

1. Modify the parameter's value as desired.
2. Click **Apply**; the changes are saved to the device's volatile memory (RAM).
3. Save the changes to the device's non-volatile memory (flash):
  - If a device restart is not required:
    - i. On the toolbar, click **Save**; a confirmation message box appears:

*Save Configuration*

Configuration will be saved. Do you wish to continue?

No

Yes

- ii. Click **Yes** to confirm.
- If a device restart is required:
  - i. On the toolbar, click **Restart**; the Maintenance Actions page opens.

- ii. Click **Restart**; the device saves the changes to flash and then restarts.

For more information, see [Restarting the Device](#) on page 1329.

When you click **Apply**, changes are saved only to the device's volatile memory. If the device later undergoes a hardware reset, a software restart (without saving to flash), or powers down, the changes revert to their previous settings. Therefore, make sure that you save your configuration to the device's flash memory.

## Configuring Tables

A typical configuration table is shown below and subsequently described:

The screenshot shows the 'Proxy Sets' configuration page. It includes a table with columns: INDEX, NAME, SRD, GATEWAY IPv4 SIP INTERFACE, PROXY KEEP-ALIVE TIME [SEC], REDUNDANCY MODE, and PROXY HOT SWAP. Below the table, there are configuration details for the selected item, including GENERAL, REDUNDANCY, KEEP ALIVE, and ADVANCED sections. Numbered callouts 1 through 8 highlight specific UI elements as described in the image.

Table 6-2: General Description of Configuration Tables

Item#	Button	Description
1	-	Page title (i.e., name of table). The page title also displays the number of configured rows as well as the number of invalid rows. For more information on invalid rows, see <a href="#">Invalid Value Indications</a> on page 35.
2	+ New	Adds a new row to the table (see <a href="#">Adding Table Rows</a> on the next page).
	Edit	Modifies the selected row (see <a href="#">Editing Table Rows</a> on page 34).

Item#	Button	Description
		Adds a new row with similar settings as the selected row (i.e., clones the row). For more information, see <a href="#">Cloning SRDs</a> on page 569. <b>Note:</b> The button appears only in the SRDs table.
		Deletes the selected row (see <a href="#">Deleting Table Rows</a> on page 34).
		Changes the index position of a selected row (see <a href="#">Changing Table Row Position</a> on page 38).
	Action	Drop-down menu providing commands (e.g., <b>Register</b> and <b>Un-Register</b> ). <b>Note:</b> The button appears only in certain tables (e.g., Accounts table).
3	-	Added table rows displaying only some of the table parameters (columns).
4	-	Detailed view of a selected row, displaying all parameters.
5	-	Link to open the "child" table of the "parent" table. A link appears only if the table has a "child" table. The "child" table is opened for the selected row.
6	-	Navigation bar for scrolling through the table's pages (see <a href="#">Viewing Table Rows</a> on page 37).
7	-	Search tool for searching parameters and values (see <a href="#">Searching Values in Tables</a> on page 39).
8		Modifies the selected row (see <a href="#">Editing Table Rows</a> on page 34).

### Adding Table Rows

The following procedure describes how to add table rows, using the table's **New** button. By default, the row is added to the end of the table and assigned the next available index number (see note in Step 2).

#### ➤ To add a row using the New button:

1. On the table's toolbar, click the **New** button; a dialog box appears, displaying the parameters of the table.

2. Configure the parameters as desired, and then click **Apply**; the row is added at the end of the table.

If you don't configure an index number ('Index' parameter), the row is automatically assigned the next available index number in the table. If you configure an index number, use the next available index number, or any subsequent number up to the table's maximum index (capacity).

For example, assume the last existing row is at index 4 and the table's capacity is 10 rows (i.e., indices 0-9):

- If you add a row without specifying an index number, the row is automatically assigned index 5.
- If you want to specify an index number, you can use 5 through 9.
- If you added the row and assigned it index 8, the next time you add a row, it's automatically assigned index 5 or you can specify one of the following the index numbers: 5, 6, 7, or 9.

3. If the **Save** button on the Web interfaces toolbar is surrounded by a red border (see figure below), save your settings to flash memory. If you don't save to flash, your configuration is discarded after the device restarts (without a save to flash) or powers off.

- Commonly required parameters are displayed in **bold font**.
- If you change the value of a parameter (before clicking **Apply**), the parameter's field is highlighted, as shown in the example below:

6010

- If you configure a parameter to an invalid value, the device indicates this using special display properties, as described in [Invalid Value Indications](#) on page 35.
- For configuring parameters that reference rows from other tables, see [Parameter Values Referencing Table Rows](#) on page 40.

## Inserting Table Rows

Some tables (e.g., the Firewall table in [Configuring Firewall Rules](#) on page 253) allow you to insert a new row anywhere in the table, using the table's **Insert** button. Unlike the table's **New** button, which by default, adds the row at the next available index number (see [Adding Table Rows](#) on the previous page), inserting a row allows you to add the row anywhere in the table.

### ➤ To insert a new row:

1. Click the 'Index' column header so that the table rows are sorted in ascending or descending order; the **Insert** button on the table's toolbar becomes available.
2. Select an existing row in the table before which you want to insert the new row.
3. On the table's toolbar, click the **Insert** button; a dialog box appears, displaying the parameters belonging to the table.

4. Configure the parameters as desired, and then click **Apply**; the row is added to the table before the row that you selected in Step 2. The new row adopts the index number of the selected row, and the index numbers of all the subsequent rows are incremented by one. For example, inserting a new row at index 2 shifts the existing row at index 2 to index 3, the previous index 3 to index 4, and so on.
5. If the **Save** button on the Web interfaces toolbar is surrounded by a red border (see figure below), save your settings to flash memory. If you don't save to flash, your configuration is discarded after the device restarts (without a save to flash) or powers off.

### Editing Table Rows

The following procedure describes how to modify (edit) the configuration of an existing table row. Remember that a gray-colored dot icon displayed next to a parameter's value (as shown in the example below), indicates that it was changed from its default value:

#### ➤ To edit a table row:

1. Select the row that you want to edit.
2. Click the **Edit** button, located on the table's toolbar; a dialog appears displaying the current configuration settings of the row.
3. Make your changes as desired, and then click **Apply**; the dialog box closes and your new settings are applied.
4. If the **Save** button is surrounded by a red border, you must save your settings to flash memory, otherwise they are discarded if the device restarts (without a save to flash) or powers off.

### Deleting Table Rows

The following procedure describes how to delete a row from a table.

#### ➤ To delete a table row:

1. Select the row that you want to delete.
2. Click the delete icon, located on the table's toolbar; a confirmation message box appears requesting you to confirm deletion, as shown in the example below:

3. Click **Yes, Delete**; the row is removed from the table and the total number of configured rows that is displayed next to the page title and page item in the Navigation tree is updated to reflect the deletion.

If the deleted row (e.g., a Proxy Set) was referenced in another table (e.g., IP Group), the reference is removed and replaced with an empty field. In addition, if the reference in the other table is for a mandatory parameter, the invalid ● icon is displayed where relevant. For example, if you delete a SIP Interface that you have assigned to a Proxy Set, the invalid icon appears alongside the **Proxy Sets** item in the Navigation tree as well as on the Proxy Sets page.

### Invalid Value Indications

The Web interface provides the following indications of invalid values when configuring table rows:

- **Parameters configured with invalid values:** An invalid value is a value that is not permissible for the parameter. This can include incorrect syntax (string, numeral, or character) or an out-of-range value. If you enter an invalid value and then click **Apply**, the field is surrounded by a colored border, as shown in the example below.

60000000

If you hover your mouse over the field, a pop-up message appears providing the valid values. If you enter a valid value, the colored border is removed from the field. If you leave the parameter at the invalid value and click **Apply**, the parameter reverts to its previous value.

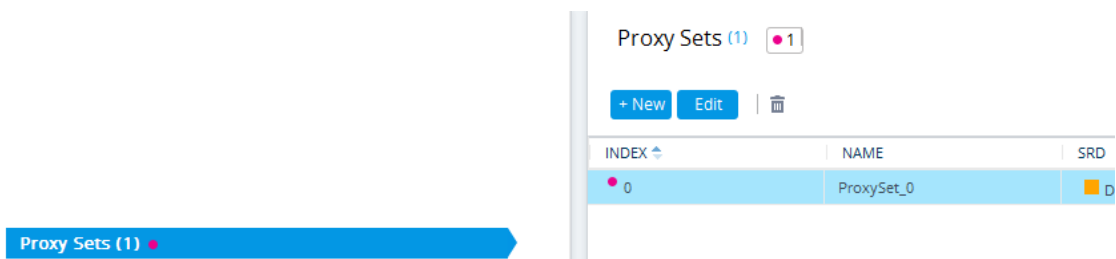

- **Mandatory parameters that reference rows of other configuration tables:**

- **Adding a row:** If you do not configure the parameter and you click **Apply**, an error message is displayed at the bottom of the dialog box. If you click **Cancel**, the dialog box closes and the row is not added to the table. For example, if you do not configure the 'SIP Interface' field (mandatory) for a Proxy Set (in the Proxy Sets table), the below message appears:

- **Editing a row:** If you modify the parameter so that it's no longer referencing a row of another table (i.e., blank value), when you close the dialog box, the **Invalid Line** icon appears in the following locations:
  - ◆ 'Index' column of the row.
  - ◆ Page title of the table. The total number of invalid rows in the table is also displayed with the icon.
  - ◆ Item in the Navigation tree that opens the table.

For example, if you do not configure the 'SIP Interface' field (mandatory) for Proxy Set #0, the **Invalid Line** icon is displayed for the Proxy Sets table, as shown below:

- **Parameters that reference rows of other configuration tables that are configured with invalid values:** If a row has a parameter that references a row of another table that has a parameter with an invalid value, the **Invalid Reference Line** icon is displayed in the following locations:

- 'Index' column of the row.
- Page title of the table. The total number of invalid rows in the table is also displayed with the icon.
- Item in the Navigation tree that opens the table.

For example, if you configure IP Group #0 (in the IP Groups table) with a parameter that references Proxy Set #0, which is configured with an invalid value, **Invalid Reference Line** icons are displayed for the IP Groups table, as shown below:

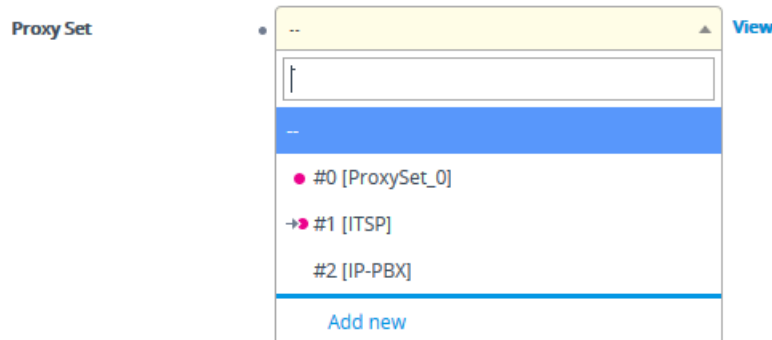

- **Invalid icon display in drop-down list items of parameters that reference rows of other tables:**

- If the row has an invalid line (see description above), the **Invalid Line** icon appears along side the item.

- If the row has an invalid reference line (see description above), the **Invalid Reference Line** icon appears along side it.

For example, when configuring an IP Group, the 'Proxy Set' parameter's drop-down list displays items: Proxy Set #0 with  indicating that it has an invalid parameter value, and Proxy Set #1 with  indicating that it has a parameter that is referenced to a row of another table that has an invalid value:

If you assign a non-mandatory parameter with a referenced row and then later delete the referenced row (in the table in which the row is configured), the parameter's value automatically changes to an empty field (i.e., no row assigned). Therefore, make sure that you are aware of this and if necessary, assign a different referenced row to the parameter. Only if the parameter is mandatory is the **Invalid Line** icon displayed for the table in which the parameter is configured.

### Viewing Table Rows

Tables display a certain number of rows per page. If you have configured more than this number, you can use the table's navigation bar to scroll through the table pages, as shown below and described in the subsequent table:

**Table 6-3: Table Navigation Bar Description**

Item	Description
1	Navigation buttons to view previous table rows:  <<Displays the previous table page  <Displays the first table page (i.e., page with at least the first index row)

Item	Description
2	Navigation buttons to view the next table rows:  >>Displays the next table page  >Displays the last table page (i.e., page with last index row)
3	Currently displayed table page. To open a specific table page, enter the page number and then press the Enter key.
4	Total number of table pages.

### Sorting Tables Rows

You can sort table rows by any column and in ascending order (e.g., 1, 2 and 3 / a, b, and c) or descending order (e.g., 3, 2, and 1 / c, b, and a). By default, most tables are sorted by the Index column and in ascending order.

#### ➤ To sort table rows by column:

1. Click the name of the column by which you want to sort the table rows; the up-down  arrows appear alongside the column name and the up button is displayed in a darker shade of color, indicating that the column is sorted in ascending order:

INDEX 
0
1
2
3
4

2. To sort the column in descending order, click the column name again; only the down arrow is displayed in a darker shade of color, indicating that the column is sorted in descending order:

INDEX 
4
3
2
1
0

### Changing Table Row Position

You can change the position (index) of rows in some tables. This is done by using the up-down   arrows located on the table's toolbar.

- You can only change a row's position when the table is sorted by the 'Index' column in ascending order; otherwise, the ↑ ↓ buttons are grayed out. For sorting table columns, see [Sorting Tables Rows](#) on the previous page.
- Changing row position is supported only by certain tables (e.g., IP-to-IP Routing table).

#### ➤ To change the position of a table row:

1. Click the 'Index' column header so that the rows are sorted in ascending order (e.g., 0, 1, 2, and so on).
2. Select the row that you want to move, and then do one of the following:
  - **To move row one or more indexes up:** Click the up ↑ arrow; the row moves one index up in the table (e.g., from Index #3 to #2) and the row that originally occupied the index is moved one index down (e.g., from Index #2 to #3). Continue clicking the arrow until the row has moved up to the desired position (index) in the table.
  - **To move row one or more indexes down:** Click the down ↓ arrow; the row moves one index down in the table (e.g., from Index #3 to #4) and the row that originally occupied the index is moved one index up (e.g., from Index #4 to #3). Continue clicking the arrow until the row has moved down to the desired position (index) in the table.

### Searching Values in Tables

Tables provide a search tool that allows you to search for parameter values.

Your search string can be partial or complete. The searched result displays only the table rows (indexes) in which the value appears. The number of rows in which the searched string appears is shown next to the table name. If the search is unsuccessful, no rows are displayed.

The following figure shows an example of searching the IP Groups table for IP Groups (rows) with parameter values containing the string "itsp". In this example, a match is found in the 'Name' parameter of two rows.

IP Groups **(2)**

+ New

X

INDEX	NAME	SRD	TYPE	SBC OPERATION MODE	PROXY SET	IP PROFILE	MEDIA REALM	SIP GROUP NAME	CLASSIFY BY PROXY SET	INBOUND MESSAGE MANIPULATION SET	OUTBOUND MESSAGE MANIPULATION SET
4	ITSP-A	DefaultSRD	Server	Not Configured	--	--	--		Enable	-1	-1
5	ITSP-B	DefaultSRD	Server	Not Configured	--	--	--		Enable	-1	-1

- The search string is case-insensitive.
- For searching parameters in the Web interface, see [Searching for Configuration Parameters](#) on page 41.

➤ **To search for a parameter value:**

1. In the search box located in the top-right side above the table, enter the value for which you want to search.
2. Click the magnifying-glass icon to run the search.
3. To quit the search tool, click the **x** icon located in the search box.

## Parameter Values Referencing Table Rows

Some parameters reference rows in configuration tables. These parameters can be global parameters or parameters in configuration tables that reference rows in a different configuration table.

For example, the IP Groups table contains the 'Proxy Set' parameter whose value is an assigned Proxy Set, configured in the Proxy Sets table. These parameter types provide a drop-down list for selecting the value and a **View** button, as shown in the example below:

You can assign a referenced-row using one of the following methods:

■ **Selecting a referenced-row from the drop-down list:**

- Scroll down to the desired item and click it.
- Search for the item by entering in the field the first few characters of the desired row, and then clicking it. The figure below shows an example of searched results for items (Proxy Sets) that begin with the letter "i":

■ **Selecting an existing referenced-row directly from the referenced-table:**

- a. Click **View**; the table (e.g., IP Groups table) and dialog box in which the button was clicked is minimized to the bottom-left corner of the Web interface and the referenced-table (e.g., Proxy Sets table) opens.
- b. Add a new row, if required; otherwise, skip this step.
- c. Select the desired row in the row-referenced table, and then click **Use selected row** located on the top-right of the table, as shown in the example below:

↓  
Use selected row

Proxy Sets (3)

+ New Edit [trash icon] Page 1 of 1 Show 10 records per page [search icon]

INDEX	NAME	SRD	GATEWAY IPv4 SIP INTERFACE	SBC IPv4 SIP INTERFACE	PROXY KEEP-ALIVE TIME [SEC]	REDUNDANCY MODE	PROXY HOT SWAP
0	ProxySet_0	DefaultSRD	--	SIPInterface_0	60		Disable
1	ITSP	DefaultSRD	--	ITSP	60		Disable
2	IP-PBX	DefaultSRD	--	IP-PBX	60		Disable

### ■ Adding a new referenced-row:

- a. From the drop-down list, select the **Add new** option; as shown in the example below:

The table (e.g., IP Groups table) and dialog box in which the **Add new** option was selected is minimized to the bottom-left corner of the Web interface and a dialog box appears for adding a new row in the referenced-table (e.g., Proxy Sets table).

- b. Configure the referenced-row and click **Apply**; the referenced-table (e.g., Proxy Sets table) closes and you are returned to the dialog box in which you selected the **Add new** option (e.g., IP Groups table), where the newly added row now appears selected.

You may want to access the referenced-table (e.g., Proxy Sets table) to simply view all its configured rows and their settings, without selecting one. To do this, click the **View** button. To return to the dialog box of the table (e.g., IP Groups table) in which you are making your configuration, click the arrow ↗ icon on the minimized dialog box to restore it to its previous size.

## Searching for Configuration Parameters

The Web interface provides a search tool that allows you to search for the following:

- Parameters - standalone parameters and parameters (column headings) in tables
- Tables (by title)
- Pages (by title)

Your search can be based on the Web interface parameter name, ini file parameter name, or CLI command name.

You can search using the full parameter name or a partial string. If you use a partial string, the results include all parameter names and descriptions that contain the string. For example, to search for the 'Secured Web Connection (HTTPS)' parameter, you can use any of the following search strings:

- Partial string: "http"
- Full Web parameter name: "Secured Web Connection (HTTPS)"
- Full ini file parameter name: "HTTPSOnly"
- Full CLI command name: "secured-connection"

When the device completes the search, it displays a list of found results based on the search query. Each possible result, when clicked, opens the page on which the parameter or value is located.

- The search string can include only alphanumeric characters, periods, and spaces.
- The search string is not case-sensitive.
- For searching manually typed values in tables (e.g., IP address or row name), see [Searching Values in Tables](#) on page 39.

➤ **To search for a parameter:**

1. In the search box, enter the search string, for example "https":

2. Click the search  icon; a Search Result window pops up, listing found parameters based on your search query. Searched results for standalone parameters are listed under the **Search by name** group; searched results for parameters in tables are listed under **Search by table**.

Each searched result displays the following:

- Navigation path (link) to the page on which the parameter appears.
- Parameter's Web interface name, where the searched string is displayed in **orange**.
- Parameter description, where the searched string is displayed in **orange**.

Search results for: https		
Search by name:		
Page	Parameter	Description
<a href="#">Administration-&gt;WEB &amp; CLI-&gt;Web Settings</a>	Secured Web Connection ( <b>HTTPS</b> )	Defines secure access (HTTP/S) to the device's Web and REST management interfaces
<a href="#">IP-Network-&gt;HTTP Proxy-&gt;HTTP Proxy Settings</a>	Secondary DNS Server IP	Defines the Secondary DNS server IP address for the HTTP proxy.
<a href="#">Troubleshoot-&gt;Call Detail Record-&gt;Call Detail Record Settings</a>		Defines the name of REST HTTP SERVER from HTTP Remote Services table
SEARCH BY TABLE		
Page	Parameter	Description
<a href="#">IP-Network-&gt;HTTP Proxy-&gt;HTTP Proxy Servers</a>	<b>HTTPS</b> Listening Port	<b>HTTPS</b> Listening Port
<a href="#">Administration-&gt;WEB &amp; CLI-&gt;Web Interfaces</a>	<b>HTTPS</b> Only	<b>HTTPS</b> only indication
<a href="#">Administration-&gt;WEB &amp; CLI-&gt;Web Interfaces</a>	<b>HTTPS</b> Port	Interface <b>HTTPS</b> Port
Close		

- Click the link of the navigation path corresponding to the required found parameter to open the page on which the parameter appears.

## Getting Help

The Web interface provides you with the following options for getting help:

- Tooltip:** When you hover your mouse over a parameter's field, a pop-up appears (tooltip) with a short description of the parameter, as shown in the following example:

- Technical documentation:** If you click the  icon on the toolbar, a drop-down list of document names appear (e.g., Release Notes, Installation Manual and User's Manual). Simply click the required document to view it on AudioCodes website. For private labeling (customizing Web interface), this icon is hidden from the toolbar. However, you can display it, as described in [Displaying Referenced Document List](#) on page 52.

## Logging Out the Web Interface

The following procedure describes how to log out of the device's Web interface.

### ➤ To log out of Web interface:

- On the menu bar, from the 'Admin' drop-down list, click **Log Out**:

A confirmation message box appears.

2. Click **Yes** to confirm; you are logged out the Web session and the Web Login window is displayed, enabling you to log in again if you want.

## Customizing the Web Interface

You can customize the following elements of the device's Web interface (GUI):

- Corporate logo (see [Corporate Logo](#) below)
- Device's (product) name (see [Customizing the Product Name](#) on page 48)
- Web browser tab label (see [Web Browser's Tab Title](#) on page 47)
- Web browser Favicon (see [Customizing the Browser Favicon](#) on page 50)
- Login welcome message (see [Creating a Login Welcome Message](#) on page 51)

- The product name also affects other management interfaces.
- In addition to Web-interface customization, you can also customize the following:
  - ✓ **SIP Messages:** User-Agent header (see the UserAgentDisplayInfo parameter), SDP "o" line (see the SIPSDPSessionOwner parameter), and Subject header (see the SIPSubject parameter).

## Corporate Logo

You can replace the default corporate logo image (i.e., AudioCodes logo) that is displayed in the Web interface. The logo appears in the following Web areas:

- **Web Login screen:**

#### ■ Menu bar:

You can replace the logo with one of the following:

- A different image (see [Replacing the Corporate Logo with an Image](#) below)
- Text (see [Replacing Corporate Logo with Text](#) on the next page)

### Replacing the Corporate Logo with an Image

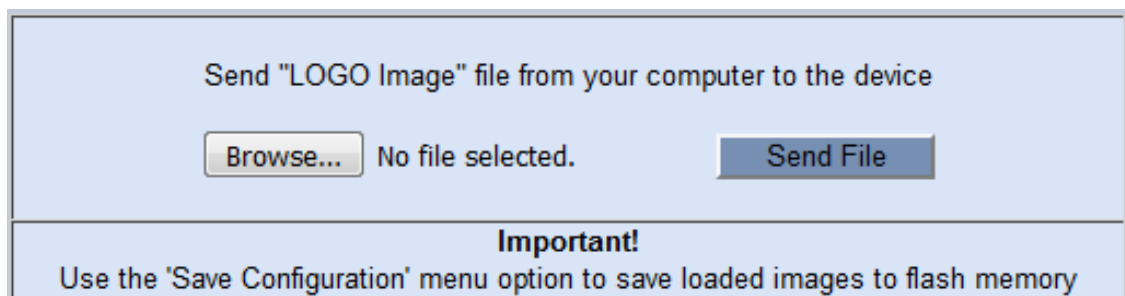

You can replace the default corporate logo with a different image.

- The logo image file type can be GIF, PNG, JPG, or JPEG.
- The logo image must have a fixed height of 24 pixels. The width can be up to 199 pixels (default is 145).
- The maximum size of the image file can be 64 Kbytes.

#### ➤ To replace the logo:

1. Save your new logo image file to a folder on the same PC that you are using to access the device's Web interface.
2. In your browser's URL address field, append the case-sensitive suffix `/AdminPage` to the device's IP address (e.g., `http://10.1.229.17/AdminPage`).
3. If you're not logged in already, log in with your credentials; the Admin page appears.
4. On the left pane, click **Logo/Favicon Load**; the right pane displays the following:

5. Use the **Browse** (or **Choose File**, depending on your browser) button to select your logo file, and then click **Send File**; the device uploads the file.
6. On the left pane, click **Back to Main** to exit the Admin page.
7. Restart the device with a save-to-flash for your settings to take effect.

### Replacing Corporate Logo with Text

You can replace the logo that is displayed on the Web interface's toolbar with text, as shown in the following example ("My Device"):

#### ➤ To replace Web interface logo with text:

1. Create an ini file that includes the following parameter settings:

```
UseWebLogo = 1
WebLogoText = <text to replace logo, for example, My Device>
```

2. Upload the ini file to the device as an incremental ini file, using the Auxiliary Files page (see [Uploading Auxiliary Files](#) on page 1347).
3. Restart the device with a save-to-flash for your settings to take effect.

Make sure that the [LogoFileName] parameter is not configured to any value. If [LogoFileName] is configured, it overrides [UseWebLogo] and an image will always be displayed.

### Replacing Text with Corporate Logo

If you have replaced the logo with text (as described in [Replacing Corporate Logo with Text](#) above), you can return the logo as described below.

#### ➤ To replace text with logo:

1. Create an ini file that includes the following parameter settings:

```
UseWebLogo = 0
```

2. Load the ini file as an incremental ini file, using the Auxiliary Files page (see [Uploading Auxiliary Files](#) on page 1347).
3. Restart the device with a save-to-flash for your settings to take effect.

## Web Browser's Tab Title

By default, the title (name) of the tab of the web browser that you use to access the device's Web interface displays "AudioCodes". However, you can customize this tab to display one of the following:

- device's IP address - see [Customizing Browser Tab to Display Device's IP Address](#) below
- User-defined text - see [Customizing Browser Tab to Display Text](#) below

### Customizing Browser Tab to Display Device's IP Address

You can customize the tab of the web browser that you use to access the device's Web interface to display the device's IP address.

You can customize the tab to display the device's IP address only if a logo image is used in the Web interface (see [Replacing the Corporate Logo with an Image](#) on page 45).

#### ➤ To display device's IP address on browser tab:

1. Create an ini file that includes the following parameter settings:

```
UseWebLogo = 1
WebLogoText =
```

If you have never configured the [WebLogoText] parameter, you can omit it from the ini file. If you have configured it, then set it to an empty value, as shown above.

2. Upload the ini file as an incremental ini file, using the Auxiliary Files page (see [Uploading Auxiliary Files](#) on page 1347).
3. Restart the device with a save-to-flash for your settings to take effect.

### Customizing Browser Tab to Display Text

You can customize the tab of the web browser that you use to access the device's Web interface to display any user-defined text.

- If you are using the default corporate logo image (AudioCodes) in the Web interface, you can only customize the tab to display "AudioCodes" (default) or the device's IP address (see [Customizing Browser Tab to Display Device's IP Address](#) on the previous page).
- You can customize the tab to display text other than "AudioCodes" only if you are using a non-AudioCodes logo image in the Web interface.
- If you have replaced the corporate logo image with text (see [Replacing Corporate Logo with Text](#) on page 46), the same text is used for the tab.

➤ **To customize browser tab with title text:**

1. Create an ini file that includes the following parameter settings:

- To replace the default text:

```
UseWebLogo = 1
WebLogoText = <your text, for example, Hello>
```

- To restore the tab title to default (i.e., "AudioCodes"):

```
UseWebLogo = 0
```

2. Upload the ini file as an incremental ini file, using the Auxiliary Files page (see [Uploading Auxiliary Files](#) on page 1347).
3. Restart the device with a save-to-flash for your settings to take effect.

## Customizing the Product Name

You can customize the device's product name. The name is displayed in various places in the management interfaces, as shown below using the example of the customized product name "Product":

■ **Web Login screen:**

A screenshot of the 'Web Login' form. The form is titled 'Web Login' and contains two input fields: 'Username' with the value 'Admin' and 'Password' which is empty. Below the password field is a checkbox labeled 'Remember Username' which is checked. A blue 'Log In' button is located to the right of the checkbox.

#### ■ Web tab bar:

#### ■ ini file "Board" field:

```
;Board: My Product
```

#### ■ CLI prompt:

```
My Product(config-voip)#
```

#### ➤ To customize device's product name:

1. Create a text file using a text editor (e.g., Notepad) with the following parameter settings:

```
UseProductName = 1  
UserProductName = <Your Product Name>
```

2. Save the file as a .ini file (e.g., productname.ini).
3. Upload the file to the device as an incremental ini file (see [Uploading Auxiliary Files](#) on page 1347).
4. On the toolbar, click the **Save** button to save your settings to flash memory.
5. Log out of the Web interface; the new product name is now applied.

## Customizing the Browser Favicon

You can replace the default favicon with your own personalized favicon.

Depending on the browser, the favicon is displayed in various areas. For example, it could be displayed in the URL address bar, on the page tab, or when bookmarked.

- The logo image file type can be ICO, GIF, or PNG.
- The maximum size of the image file can be 16 Kbytes.

### ➤ To customize the favicon:

1. Save your new favicon file in a folder on the same PC that you are using to access the device's Web interface.
2. In your browser's URL address field, append the case-sensitive suffix `"/AdminPage"` to the device's IP address (e.g., `http://10.1.229.17/AdminPage`).
3. Log in with your credentials; the Admin page appears.
4. On the left pane, click **Logo/Favicon Load**; the right pane displays the following:

5. Use the **Browse**(or **Choose File**, depending on your browser) button to select your favicon file.
6. Click **Send File**; the device uploads the image file.
7. On the left pane, click **Back to Main** to exit the Admin page.
8. Restart the device with a save-to-flash for your settings to take effect.

## Creating a Login Welcome Message

You can create a personalized welcome message, which is displayed on the Web Login page when you first browse to the device, as shown in the following example:

**Note**  
Welcome!  
This is My SBC  
\*\*\*\*\*

### Web Login

**Username**

**Password**

Remember Username ☒

### ➤ To create a login welcome message:

1. Use a text-based editor (e.g., Notepad) to create an ini file that includes **only** the [WelcomeMessage] table parameter. Each index row is a line in your message. Each message line must be enclosed by double quotation marks ("...") and end with a semicolon (;).

Example:

```
[WelcomeMessage]
FORMAT Index = Text;
WelcomeMessage 1 = "Welcome";
WelcomeMessage 2 = "This is My SBC";
WelcomeMessage 3 = "*****";
[WelcomeMessage]
```

2. Upload the file to the device as an incremental ini file (see [Uploading Auxiliary Files](#) on page 1347).
3. Save your configuration to flash.

Uploading an ini file through the Auxiliary Files page doesn't require a device restart.

➤ **To remove the welcome message:**

1. Download the device's configuration as an ini file (see [Downloading or Uploading ini File](#) on page 1386).
2. Open the file in a text-based editor.
3. Delete the [WelcomeMessage] table, and then save the file.
4. Upload the file to the device.

After the file is uploaded, the device restarts to apply your new configuration.

## Displaying Referenced Document List

By default, the question mark  icon is displayed on the Web interface's toolbar, and when clicked provides a drop-down list of documents that can be referenced.

If you change the Web interface's logo to a non-default logo, the  icon isn't displayed on the toolbar. However, you can make it re-appear, by adding a forward slash ("/") at the end of the following parameter's value:

```
ExternalDocumentsBaseURL = 'https://acredirect.azurewebsites.net/api/'
```

## Configuring Web Interfaces

The Web Interfaces table lets you configure up to 20 Web interfaces, which are used for accessing the device's Web and REST management interfaces. You can only access these management interfaces through the configured Web Interfaces.

A Web Interface is associated with an IP Interface in the IP Interfaces table. The IP Interface can be of any type (e.g., OAMP, Media, or Control). For each Web Interface, you can also configure secure HTTPS-based remote access, using TLS certificates (TLS Contexts).

Before deleting any Web Interface in the Web Interfaces table, make sure that you have configured **at least one** other Web Interface through which you can access the device's Web / REST management interface. If you delete all the Web Interfaces, you

will not be able to access these management interfaces.

- The Web Interfaces table is applicable only to the device's Web and REST management interfaces.
- The device provides a default Web Interface (Index #0), which is assigned the default IPv4 OAMP IP Interface ("O+M+C", Index 0).
- It's highly recommended to configure a hostname for accessing the device's Web interface, as described in [Configuring a Hostname for Device's Web Interface](#) on page 87. Accessing the device with a hostname helps to protect the device against HTTP Host header attacks and DNS rebinding attacks.

The following procedure describes how to configure Web interfaces through the Web interface. You can also configure it through ini file [WebInterfaces] or CLI (`configure system > web > web-if`).

➤ **To configure Web interfaces:**

1. Open the Web Interfaces table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Interfaces**).
2. Click **New**; the following dialog box is displayed:

Web Interfaces - x

GENERAL

Index	0
Interface Name	#0 [O+M+C] <span style="float: right;">▼ View</span>
HTTP Port	80
HTTPS Port	443
TLS Context Name	#0 [default] <span style="float: right;">▼ View</span>
Require Client Certificate	No ▼
HTTPS Only	Use global definition ▼

3. Configure a Web Interface according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 6-4: Web Interfaces Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
'Interface Name' network-source [InterfaceName]	<p>Assigns an IP Interface (IPv4 or IPv6) from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) through which the Web / REST management interfaces can be accessed. The IP Interface can be any Application Type (e.g., Media, Control, or OAMP).</p> <p>By default, the IPv4 OAMP interface is assigned.</p>
'HTTP Port' http-port [HTTPPort]	<p>Defines the device's HTTP port for remote management access.</p> <p>The valid range is 1 to 65535. The default is 80.</p>
'HTTPS Port' https-port [HTTPSPort]	<p>Defines the device's HTTPS port for secured remote management access.</p> <p>The valid range is 1 to 65535 (other restrictions may apply within this range). The default is 443.</p>
'TLS Context Name' tls-context-name [TLSContextName]	<p>Assigns a TLS Context, which is configured in the TLS Contexts table (see <a href="#">Configuring TLS Certificate Contexts</a> on page 227). A TLS Context provides secured TLS-based management access.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The parameter is applicable if you are using HTTPS for remote management access.</p>
'Require Client Certificate' require-client-certificate [HTTPSRequireClientCertificate]	<p>Enables the requirement of client certificates for HTTPS connection.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Client certificates are not required.</li> <li>■ [1] <b>Enable</b> = Enables the requirement of client certificates for HTTPS connection. This enables two-way authentication whereby both management client and server are authenticated using X.509 certificates.</li> </ul> <p>For more information on implementing client certificates, see <a href="#">Configuring Secured (HTTPS) Web and REST Access</a> on page 75.</p> <p><b>Note:</b> The parameter is applicable if you are using HTTPS for remote management access.</p>
'HTTPS Only'	Defines the protocol required for accessing the

Parameter	Description
https-only-val [HTTPOnly]	<p>device's management interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>HTTP and HTTPS</b> = The management interface can be accessed over a secured (HTTPS) and an unsecured (HTTP) connection.</li> <li>■ [1] <b>HTTPS Only</b> = The management interface can be accessed only over a secured (HTTPS) connection.</li> </ul>

## Configuring Local Management User Accounts

The Local Users table lets you configure up to 20 management user accounts for the device's management interfaces (Web interface, CLI, and REST API).

The table below lists the different types of user levels.

**Table 6-5: Management User Levels**

User Level	Numeric Representation in RADIUS	Privileges
<b>Security Administrator</b>	200	<p>This user level has the following privileges:</p> <ul style="list-style-type: none"> <li>■ Read-write to all Web pages.</li> <li>■ Read-write (access) to the CLI's Basic mode and Privileged User mode (&gt; enable).</li> <li>■ Access to all the device's folders (e.g., <i>/debug</i> and <i>/configuration</i>) through SFTP.</li> <li>■ Create all other user levels.</li> </ul> <p><b>Note:</b> At least one Security Administrator user must exist.</p>
<b>Administrator</b>	100	<p>This user level has the following privileges:</p> <ul style="list-style-type: none"> <li>■ Read-write to all Web pages, except security-related pages (including Local Users table) where this user has read-only privileges.</li> <li>■ Access to only the CLI's Basic User mode.</li> </ul>
<b>Monitor</b>	50	<p>This user level has the following privileges:</p> <ul style="list-style-type: none"> <li>■ Read-only to all Web pages, except security-related pages (including Local Users table and</li> </ul>

User Level	Numeric Representation in RADIUS	Privileges
		<p>Configuration Wizard) which are blocked to this user.</p> <ul style="list-style-type: none"> <li>■ Access to only the CLI's Basic User mode.</li> <li>■ Access blocked to the device's folders through SFTP.</li> </ul>

- Only **Security Administrator** users can configure users in the Local Users table.
- For the device's REST API user levels, refer to the document [REST API for SBC-Gateway-MSBR Devices](#).
- All users, regardless of user level, can change their login password (see [Changing Login Password](#) on page 68).
- You can change the read-write and read-only privileges per Web page for **Monitor**, **Administrator**, and **Security Administrator** user levels. For more information, see [Customizing Access Levels per Web Page](#) on page 83.
- If the LDAP/RADIUS response doesn't include an access level attribute for determining the user's management access level, the device assigns the access level according to the settings of the 'Default Access Level' parameter.

The device provides the following two default user accounts:

**Table 6-6: Default User Accounts**

User Level	Username (case-sensitive)	Password (case-sensitive)
<b>Security Administrator</b>	<b>Admin</b>	<b>Admin</b>
<b>Monitor</b>	<b>User</b>	<b>User</b>

- For security, it's recommended that you change the default username and password of the default users.
- To restore the device to the default users (with their default usernames and passwords), configure the [ResetWebPassword] parameter to [1]. All other configured accounts are deleted.
- If you want to use the same Local Users table configuration for another device, before uploading this device's configuration file (.ini) to the other device, you **must** edit the file so that the passwords are in plain text.
- If you modify any parameter in the Local Users table of an existing user or delete the user, and the user is currently logged into the device's management interface (i.e., active session), after clicking **Apply** the device immediately logs the user out of the management interface.
- If you delete a user who is currently in an active Web session, the user is immediately logged off the device.
- Web sessions capacity:
  - ✓ The device supports up to 10 concurrent Web interface sessions (regardless of which users are logged in). For example, if user "Sue" and user "Joe" are each currently running 5 sessions (i.e., a total of 10), no more Web sessions can be established with the device, by any user.
  - ✓ Up to five users can be concurrently logged in to the Web interface.
  - ✓ You can define the maximum number of concurrent Web interface (and REST) sessions allowed for a specific user, accessed from different management stations / computers (IP addresses) or different Web browsers. For more information, see the '[Web Session Limit](#)' parameter below.
- You can set the entire Web interface to read-only (regardless of Web user access levels), using the [DisableWebConfig] parameter (see [Management Parameters](#) on page 1701).
- You can configure additional Web user accounts using a RADIUS server (see [RADIUS-based User Login Authentication](#) on page 374).

The following procedure describes how to configure user accounts through the Web interface. You can also configure it through ini file [WebUsers] or CLI (`configure system > user`).

➤ **To configure management user accounts:**

1. Open the Local Users table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Local Users**).
2. Click **New**; the following dialog box is displayed:

3. Configure a user account according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 6-7: Local Users Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Username' user [Username]	<p>Defines a username for the user.</p> <p>The valid value is a string of up to 100 characters (without spaces):</p> <ul style="list-style-type: none"> <li>■ Alphanumeric characters (a-z, A-Z, and 0-9)</li> <li>■ Period "."</li> <li>■ Underscore "_"</li> <li>■ Hyphen "-"</li> <li>■ At "@"</li> </ul> <p><b>Note:</b> You can enforce username complexity. For more information, see <a href="#">Configuring Login Username and Password Complexity</a> on page 65.</p>
'Password' password [Password]	<p>Defines a password for the user.</p> <p>The valid value is a string of 8 to 100 ASCII characters, and can't contain the following:</p> <ul style="list-style-type: none"> <li>■ Wide characters</li> <li>■ Spaces</li> <li>■ Backslashes "\"</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can enforce password complexity (strong passwords). For more information, see <a href="#">Configuring Login Username and Password Complexity</a> on page 65.</li> <li>■ To enforce password history policy so that users can't reuse any of their four previous (old) passwords, see the <a href="#">[configure system &gt; web &gt; check-password-history</a> on page 1704] parameter.</li> <li>■ For security, the password is not displayed in the Web interface or ini file. In the Web interface, passwords are</li> </ul>

Parameter	Description
	<p>displayed as dots when you enter the password and then once applied, they are displayed as an asterisk (*) in the table. In the ini file, they are displayed as an encrypted string.</p> <ul style="list-style-type: none"> <li>■ To enforce obscured (encrypted) passwords when configuring the Local Users table through CLI, see the <a href="#">[configure system &gt; mgmt-auth &gt; obscure-password-mode on page 1715]</a> parameter.</li> <li>■ You can configure a list of weak passwords (in the Weak Passwords List table) and if the user's password also appears in this list, the device raises an SNMP alarm. For more information, see <a href="#">Detection of Weak Login Passwords on page 67</a>.</li> </ul>
'Confirm Password'	Retype the password that you configured in the 'Password' field (above).
'User Level' privilege [UserLevel]	<p>Defines the user's access level.</p> <ul style="list-style-type: none"> <li>■ <b>Monitor</b> = (Default) Read-only user. This user can only view Web pages and access to security-related pages is denied.</li> <li>■ <b>Administrator</b> = Read/write privileges for all pages except security-related pages including the Local Users table where this user has read-only privileges.</li> <li>■ <b>Security Administrator</b> = Full read/write privileges for all pages.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ At least one <b>Security Administrator</b> user must exist. You can't delete the last remaining <b>Security Administrator</b> user.</li> <li>■ Only <b>Security Administrator</b> users can add, edit, and delete <b>Administrator</b> and <b>Monitor</b> users.</li> </ul>
'SSH Public Key' public-key [SSHPublicKey]	<p>Defines a Secure Socket Shell (SSH) public key for RSA or ECDSA public-key authentication (PKI) of the remote user when logging into the device's CLI through SSH. Connection to the CLI is established only when a successful handshake with the user's private key occurs.</p> <p>The valid value is a string of up to 512 characters. By default, no value is defined.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For more information on SSH and for enabling SSH, see <a href="#">Configuring CLI over SSH using Public Key Authentication</a> on page 93.</li> <li>■ To configure whether SSH public keys are optional or mandatory, use the [SSHRequirePublicKey] parameter.</li> </ul>
'Confirm SSH Public Key'	Retype the SSH public key that you configured in the 'SSH Public Key' field (above).
'TLS Subject Name' tls-subject-name	<p>Defines the Subject Name of the TLS certificate used for the TLS connection with the user.</p> <p>If this value matches the Subject Name in the certificate in the incoming HTTPS request from the user, the device accepts the login request. If there is no match and the Subject Alternative Name (SAN) is marked "critical", the device blocks the request. If there is no match but the SAN isn't marked "critical", the device checks if the parameter's value matches the certificate's Common Name (CN) and allows login if there is a match.</p> <p>By default, no value is defined.</p> <p>For more information, see <a href="#">Configuring Secured (HTTPS) Web and REST Access</a> on page 75.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The TLS Subject Name must be unique (i.e., two users can't have the same value).</li> <li>■ If you configure this parameter, password configuration ('Password' parameter) is not mandatory.</li> </ul>
'Status' status [Status]	<p>Defines the status of the user.</p> <ul style="list-style-type: none"> <li>■ <b>New</b> = (Default) The user is required to change the password upon the next login. When the user logs in to the Web interface or CLI, the user is immediately prompted to change the current password (see the figure for the 'Password Age' parameter below).</li> <li>■ <b>Valid</b> = User can log in to the Web interface as normal.</li> <li>■ <b>Failed Login</b> = The state is automatically set for users that exceed a user-defined number of failed login attempts, set by the 'Deny Access on Fail Count' parameter (see <a href="#">Configuring Web Session Timeouts</a> on page 74). These users can log in only after a user-defined timeout configured by</li> </ul>

Parameter	Description
	<p>the 'Block Duration' parameter (see below) or if their status is changed (to <b>New</b> or <b>Valid</b>) by a <b>Security Administrator</b> user.</p> <ul style="list-style-type: none"> <li>■ <b>Inactivity</b> = The state is automatically set for users that have not accessed the Web interface for a user-defined number of days, configured by the 'User Inactivity Timer' parameter (see <a href="#">Configuring Web Session Timeouts</a> on page 74). These users can only log in to the Web interface if their status is changed (to <b>New</b> or <b>Valid</b>) by a <b>Security Administrator</b> user.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The <b>Inactivity</b> option is applicable only to <b>Administrator</b> and <b>Monitor</b> users; <b>Security Administrator</b> users can be inactive indefinitely.</li> <li>■ If there is only one Security Administrator user, you cannot configure it to <b>Inactivity</b>; at least one Security Administrator must be <b>Valid</b>.</li> <li>■ For security, it is recommended to configure the status of a newly added user to <b>New</b> in order to enforce password change.</li> <li>■ If you have configured LDAP- or RADIUS-based user authentication, users in the Local Users table whose 'Status' is <b>New</b> are blocked from logging into the device.</li> </ul>
<b>Security</b>	
'Password Age' password-age [PwAgeInterval]	<p>Defines the duration (in days) of the validity of the password. When the duration elapses (i.e., password expires) and you try to log in to the device, you're blocked from logging in and prompted to change the password (as shown below). Configure a new password, and then log in again but with the new password.</p>

Parameter	Description
	<div data-bbox="738 282 1291 772"> <p><b>Change Password</b></p> <p>You must change your password to continue</p> <p>Current Password</p> <input type="password"/> <p>New Password</p> <input type="password"/> <p>Confirm Password</p> <input type="password"/> <p>Cancel Change</p> </div> <p>The valid value is 0 to 10000, where 0 means that the password is always valid (unlimited). The default is 90.</p> <p><b>Note:</b> After logging in with your new password, save your settings by clicking the <b>Save</b> button on the Web interface's toolbar. If not, the next time you attempt to log in, you'll be prompted again to change the expired password.</p>
'Password Expiration Date'	<p>Read-only field that displays the date and time when your login password will expire.</p> <p><b>Note:</b> The field displays an expiration date only if you've configured the 'Password Age' field (above).</p>
'Password status'	<p>Read-only field that displays the status of your login password:</p> <ul style="list-style-type: none"> <li>■ [0] <b>Unlimited</b> = The password hasn't been configured with an expiry date ( see 'Password Age' field above).</li> <li>■ [1] <b>Valid</b> = The password is still valid (i.e., hasn't expired).</li> <li>■ [2] <b>Expired</b> = The password has expired (i.e., reached or exceeded expiration date).</li> </ul>
'Web Session Limit' session-limit [SessionLimit]	<p>Defines the maximum number of concurrent Web interface and REST sessions allowed for the specific user, from different management stations / computers (IP addresses) or different Web browsers.</p> <p>For example, if configured to 2, the user account can be logged into the device's Web interface (i.e., same username-password combination) from two different management stations (i.e., IP addresses), or from two different Web browsers (e.g., Google Chrome and Microsoft Edge) at the same time.</p>

Parameter	Description
	<p>Once the user logs in to the device, the session is active until the user logs off or until the session expires if the user is inactive for a user-defined duration (see the 'Web Session Timeout' parameter below).</p> <p>The valid value is 0 to 10. The default is 5. A value of 0 means that no sessions are allowed (see note below regarding REST).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter, you're automatically logged out of the Web session (and can log in again if configured to any value other than 0) after you click <b>Apply</b>.</li> <li>■ Closing the Web browser's window (by clicking the window's <b>x</b> button) doesn't end the session. Therefore, whenever you finish using the Web interface, it's recommended to log out of the Web interface to end your session.</li> <li>■ If the number of concurrently logged-in users is at maximum, the device allows an additional user to log in through REST.</li> </ul>
'CLI Session Limit' cli-session-limit [CliSessionLimit]	<p>Defines the maximum number of concurrent CLI sessions allowed for the specific user. For example, if configured to 2, the same user account can be logged into the device's CLI (i.e., same username-password combination) from two different management stations (i.e., IP addresses) at any one time. Once the user logs in, the session is active until the user logs off or until the session expires if the user is inactive for a user-defined duration (see the 'Web Session Timeout' parameter below).</p> <p>The valid value is -1, or 0 to 100. The default is -1, which means that the limit is according to the global parameters, 'Maximum Telnet Sessions' (TelnetMaxSessions) or 'Maximum SSH Sessions' (SSHMaxSessions).</p>
'Web Session Timeout' session-timeout [SessionTimeout]	<p>Defines the duration (in minutes) of inactivity of a logged-in user in the Web interface, after which the user is automatically logged off the Web session. In other words, the session expires when the user has not performed any operations (activities) in the Web interface for the configured timeout duration.</p> <p>The valid value is 0, or to 100000. A value of 0 means no timeout. The default value is according to the settings of the [WebSessionTimeout] global parameter (see <a href="#">Configuring Web</a></p>

Parameter	Description
	<a href="#">Session Timeouts</a> on page 74).
'Block Duration' block-duration [BlockTime]	<p>Defines the duration (in seconds) for which the user is blocked when the user exceeds the maximum number of allowed failed login attempts, configured by the global parameter, 'Deny Access On Fail Count' [DenyAccessOnFailCount] parameter (see <a href="#">Configuring Web Session Timeouts</a> on page 74).</p> <p>The valid value is 0 to 100000, where 0 means that the user can do as many login failures without getting blocked. The default is according to the settings of the global parameter, 'Deny Authentication Timer' [DenyAuthenticationTimer] parameter (see <a href="#">Configuring Web Session Timeouts</a> on page 74).</p> <p><b>Note:</b> The 'Deny Authentication Timer' parameter relates only to failed Web logins from specific IP addresses (management stations), which configures the interval (in seconds) that the user needs to wait before logging into the device from the same IP address after reaching the maximum number of failed login attempts.</p>

## Deleting All Users in Local Users Table

When using an external, third-party service (e.g., RADIUS, LDAP, or OAuth 2.0) to authenticate and authorize users attempting to log in to the device, you may want to increase security by ensuring that the device doesn't use its Local Users table to locally authenticate users. To do this, you can remove all from the local Users table.

### ➤ To delete all users in Local Users table:

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).
2. Select the 'Local Users Table can be Empty' check box:

Local Users Table can be Empty

3. Open the Local Users table (see [Configuring Local Management User Accounts](#) on page 55), and then delete all the users.

Only the **Security Administrator** can delete the last **Security Administrator** user.

## Configuring Login Username and Password Complexity

You can configure the device to enforce username or password complexity. When enforced, the device checks that the configured username or password meets the complexity requirements. If they don't, the device displays an error message indicating invalid configuration.

Username and password complexity is applicable to the following:

- Local users (see [Configuring Local Management User Accounts](#) on page 55)
- SNMP Community Strings (see [Configuring SNMP Community Strings](#) on page 109)
- SNMPv3 users (see [Configuring SNMPv3 Users](#) on page 116)

The device's implementation of username and password complexity depends on configuration:

### ■ Username:

- **'Enforce Username Complexity' is disabled:** The device enforces the default complexity requirements: Can contain up to 100 alphanumeric characters (without spaces), and can contain only the symbols ".", "\_", "-", and "@".
- **'Enforce Username Complexity' is enabled:** The device enforces complexity depending on the following configuration:
  - ◆ 'Username Complexity Check By Regex' is configured: The device enforces username complexity based on the configured regex.
  - ◆ 'Username Complexity Check By Regex' is empty: The device enforces the default username complexity requirements (see 'Enforce Username Complexity' is disabled).

### ■ Password:

- **'Enforce Password Complexity' is disabled:** The device doesn't enforce any password complexity and you can configure the password to whatever you want.
- **'Enforce Password Complexity' is enabled:** The device enforces password complexity depending on whether or not you've configured complexity using regex:
  - ◆ 'Password Complexity Check By Regex' is configured: The device enforces password complexity according to the configured regex.
  - ◆ 'Password Complexity Check By Regex' is empty: The device enforces the default password complexity requirements:
    - At least eight characters
    - At least two uppercase letters (A to Z)
    - At least two lowercase letters (a to z)
    - At least two numbers (0 to 9)
    - At least two symbols (non-alphanumeric characters, e.g., \$, #, %)
    - At least four new characters that weren't used in the previous password

- If you enable password complexity, you can also configure the minimum length (number of characters) of the password, using the [\[configure system > web > min-web-password-len](#) on page 1704] parameter.
- To enforce password history policy so that users can't reuse an old password (can't change password to any of the four previous passwords), see the [\[configure system > web > check-password-history](#) on page 1704] parameter.
- You can configure a list of weak passwords (in the Weak Passwords List table) and if the user's password appears in this list, the device raises an SNMP alarm. For more information, see [Detection of Weak Login Passwords](#) on the next page.
- For the device's CLI, password complexity applies to both Basic and Privileged command mode (> enable). In addition to the default complexity rules listed previously, password complexity for CLI also includes the following requirements:
  - ✓ The username and password must be different.
  - ✓ The username and password can't be the opposite of each other (e.g., "admin" and "nimda").

➤ **To configure username and password complexity:**

1. Open the Local Users Settings table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Local Users Settings**):

USERNAME COMPLEXITY	
Enforce Username Complexity	<input checked="" type="checkbox"/>
Username Complexity Check By Regex	<input type="text" value="^[A-Za-z0-9.\-_\@]{1,100}\$"/>

PASSWORD COMPLEXITY	
Enforce Password Complexity	<input checked="" type="checkbox"/>
Password Complexity Check By Regex	<input type="text"/>

2. To enforce username complexity by regex, do the following under the **Username Complexity** group:
  - a. Select the 'Enforce Username Complexity' check box (EnforceUsernameComplexity).
  - b. In the 'Username Complexity Check By Regex' field (UsernameComplexityCheckByRegex), type a regex for username complexity.
3. To enforce password complexity, do the following under the **Password Complexity** group:
  - a. Select the 'Enforce Password Complexity' check box (EnforcePasswordComplexity).
  - b. In the 'Password Complexity Check By Regex' field (PasswordComplexityCheckByRegex), either type a regex for password complexity or

leave this field empty to enforce the default password complexity policy (described above).

4. Click **Apply**.

## Detection of Weak Login Passwords

You can configure the device to detect if a management user in the Local Users table has been configured with a weak password. The device detects this by checking if the user's password also appears in the list of defined weak passwords in the Weak Passwords List table. If the device finds a matching entry in the Weak Passwords List table, it raises the SNMP alarm `acWeakPasswordAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.156), which indicates the user (username) for which the weak password was configured.

To configure this feature, you need to do the following:

1. Enable weak password detection - see [Enabling Detection of Weak Password](#) below
2. Configure a list of weak passwords - see [Configuring the Weak Passwords List](#) below

### Enabling Detection of Weak Password

The following procedure describes how to enable the weak password detection feature. Once you have enabled the feature, you can configure in the Weak Passwords List table (see [Configuring the Weak Passwords List](#) below) a list of passwords that you want the device to consider as weak.

#### ➤ To enable weak password detection:

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**).
2. Select the 'Check Weak Passwords' check box:

Check Weak Passwords ☒

3. Click **Apply**.

### Configuring the Weak Passwords List

The Weak Passwords List table lets you configure up to 150 passwords that you want the device to consider as weak. If a user's password in the Local Users table also appears in the Weak Passwords List table, the device raises the SNMP alarm `acWeakPasswordAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.156), indicating that a weak password was configured for the specific user (Username). The alarm is cleared if the user's password is reconfigured to a password that is not considered weak (i.e., not in the Weak Passwords List table), or if the user is deleted from the Local Users table (see [Configuring Local Management User Accounts](#) on page 55).

- Before you can use the device's weak password detection feature, you need to enable the feature (see [Enabling Detection of Weak Password](#) on the previous page.)
- By default, the Weak Passwords List table contains six weak passwords: "Admin", "mindA", "password", "Password", "123456", and "12345678". You can modify or delete these entries.

The following procedure describes how to configure the weak password list through the Web interface. You can also configure it through ini file [WeakPasswordsList] or CLI (`configure system > web > weak-passwords-list`).

➤ **To configure a list of weak passwords:**

1. Open the Weak Passwords List table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Weak Passwords List**).
2. Click **New**; the following dialog box is displayed:

3. Configure a weak password according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 6-8: Weak Passwords List Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Weak Password' weak-pass [WeakPassword]	Defines a weak password. The valid value is a string of up to 39 characters.

## Changing Login Password

Regardless of your user level (e.g., Monitor or Administrator), you can change your login password through the Change Password dialog box, accessed from the Web interface's top bar.

- Security Administrator users can also change passwords for themselves and for other user levels in the Local Users table (see [Configuring Local Management User Accounts](#) on page 55).
- For valid passwords, see the 'Password' parameter in the Local Users table.
- You can only change the password if the duration, configured by the 'Password Change Interval' parameter (Web Settings page - **Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**), has elapsed since the last password change.

➤ **To change the login password:**

1. On the top bar of the Web interface, click the username that is displayed for the currently logged-in user (e.g., "Admin"); a drop-down box appears:

2. Click **Change Password**; the following appears:

3. In the 'Current Password' field, enter your current login password.
4. In the 'New Password' field, enter your new password, and then in the 'Confirm Password' field, enter your new password again.
5. Click **Change**; you are logged off the Web session and prompted to log in again with your new password.

## Configuring Login Password Expiration Alarm

By default, the device sends the SNMP alarm `acExpiredPasswordAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.161) 14 days before your login password is about to expire. This reminds you to change your password (as described in [Changing Login Password](#) on page 68). The alarm is sent with minor severity level and is automatically cleared when you successfully change the password.

You can configure when you want the device to send the alarm before password expiration.

### ➤ To configure when password expiration alarm sent:

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**).
2. Under the **Security** group, in the 'Password Expired Alarm' field, type the number of days before password expiration when you want the device to send the alarm:

Password Expired Alarm [days]

A value of 0 disables this alarm from being sent.

3. Click **Apply**.

## User Login Authentication Methods

The device supports the following methods for the authentication (username-password combination) and authorization (privilege level) of users when logging into the device:

- Locally, using the device's Local Users table (see [Configuring Local Management User Accounts](#) on page 55)
- Externally, using any of the following protocols:
  - RADIUS-based authentication, using a third-party RADIUS server (see [RADIUS-based User Login Authentication](#) on page 374)
  - LDAP-based authentication, using a third-party LDAP server (see [LDAP-based Services](#) on page 378)
  - OAuth 2.0 based authentication, using Microsoft Azure Active Directory (see [OAuth-based User Login Authentication and Authorization](#) on page 417)

## Denying Access for Failed Login Attempts

You can configure the device to block users or management stations (IP addresses) from accessing the web interface if the user enters incorrect login credentials for a user-defined number of successive login attempts.

Only **Security Administrator** users can perform the configuration described in this section. For more information, see [Configuring Local Management User Accounts](#) on page 55.

➤ **To configure deny access upon failed login attempts:**

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**).
2. Under the **Security** group, configure the following parameters:

#### SECURITY

Deny Authentication Timer	<input type="text" value="60"/>
Blocking Duration Factor	<input type="text" value="1"/>
Valid time of Deny Access counting	<input type="text" value="60"/>
Deny Access On Fail Count (0 = No Deny)	<input type="text" value="3"/> 

- 'Deny Authentication Timer' [DenyAuthenticationTimer]: Define the duration (in seconds) for which login to the Web interface is denied from a specific IP address (management station) for **all** users, when the number of failed login attempts has exceeded the maximum. To configure the blocked duration **per user**, use the 'Block Duration' parameter in the Local Users table (see [Configuring Local Management User Accounts](#) on page 55).
- 'Blocking Duration Factor' [BlockDurationFactor]: Define the number to multiple the previous blocking time for blocking the IP address or the user upon the next failed login scenario.
- 'Value time of Deny Access counting' [DenyAccessCountingValidTime]: Defines the maximum time interval (in seconds) between failed login attempts to be included in the count of failed login attempts for denying access to the user.
- 'Deny Access On Fail Count' [DenyAccessOnFailCount]: Define the maximum number of failed login attempts, after which the requesting IP address (management station) for all users is blocked.

For a detailed description of the parameters mentioned above, see [Web Parameters](#) on page 1706.

3. Click **Apply**.

## Displaying Login Information upon Login

You can enable the device to display login information each time you log in to the device's Web interface. This information is displayed in the pop-up Login Information window, as shown in the example below. To close the window, click **Close**.

Login Information <span>x</span>	
Last Login Privilege	Security Administrator
Last Failed Login Date and Time	2025-03-18T03:17:02
Last Failed Login IP	10.11.2.2
Login Attempts Since Last Success	0
Last Successful Login Date and Time	2025-03-23T03:14:39
Last Success Login IP	10.11.2.2
Number Of Other Sessions	1

The window displays the following information:

Field	Description
'Last Login Privilege'	The user level (e.g., <b>Security Administrator</b> ) of the user that was last logged into the Web interface.
'Last Failed Login Date and Time'	The date and time of the most recent failed login attempt.
'Last Failed Login IP'	The IP address of the remote management (client) from which the last failed login attempt was made.
'Login Attempts Since Last Success'	The total number of failed login attempts since the last successful login.
'Last Successful Login Date and Time'	The date and time of the most recent successful login attempt.
'Last Success Login IP'	The IP address of the remote management (client) from which the last successful login was made.
'Number of Other Sessions'	The number of currently active web sessions for the same user (e.g., "John") with the same user level (e.g., <b>Security Administrator</b> ). A value of "0" indicates no other active web sessions. <b>Note:</b> If other active sessions exist, you can

Field	Description
	end them as described in <a href="#">Terminating Other Active Web Sessions of User</a> on the next page.

➤ **To enable display of user login information upon login:**

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**).
2. Select the 'Display Last Login Information' check box:

Display Last Login Information ☒

3. Click **Apply**.

## Viewing Currently Logged-In User Information

You can quick-and-easily view brief information about the currently logged-in user.

➤ **To view information of currently logged in user:**

- On the menu bar, click the displayed username (e.g., **Admin**); the following drop-down window appears:

The following information is displayed:

- Username of the currently logged-in user (e.g., "Admin").
- User level of the currently logged-in user (e.g., **Security Administrator**).
- Duration of the current Web session (since logging in).
- Number of other active Web sessions of the same user and with the same user level. To end other sessions, see [Terminating Other Active Web Sessions of User](#) on the next page.

The following buttons are also displayed:

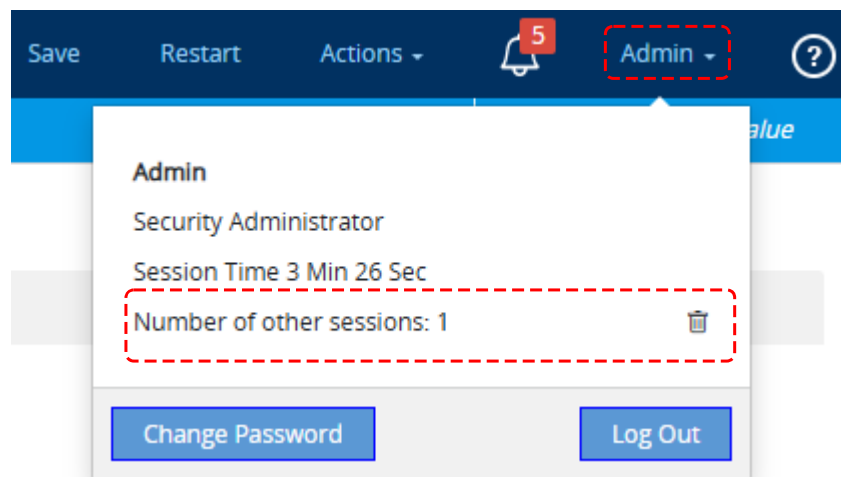

- **Change Password:** Allows you to change your login password (see [Changing Login Password](#) on page 68).
- **Log Out:** Logs you out of the Web session (see [Logging Out the Web Interface](#) on page 43).

## Terminating Other Active Web Sessions of User

You can end other established (active) Web sessions belonging to the same logged-in user (e.g., "Admin") and with the same user level (e.g., Administrator Security). These other sessions may be logged in from different computers or web browsers.

### ➤ To end other Web sessions of user:

1. On the menu bar, click the displayed username (e.g., **Admin**); the following drop-down window appears, displaying the number of other active sessions of the user in the 'Number Of Other Sessions' field (e.g., 1 other session):

2. Click the delete icon corresponding to the 'Number Of Other Sessions' field; the other session(s) are immediately terminated and logged out of the Web interface.

## Configuring Web Session Timeouts

You can configure the following timeouts for the device's Web interface:

- **Logged-in timeout:** The user is blocked from logging into the Web interface if the user has not logged in within a user-defined duration.
- **Session timeout:** The user is logged out of the Web interface if inactive for a user-defined duration.

Only **Security Administrator** users can perform the configuration described in this section.

➤ **To configure Web user sessions and access security:**

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**).
2. Under the **Session** group, configure the following parameters:

SESSION	
Password Change Interval (minutes)	<input type="text" value="1440"/>
User Inactivity Timeout (days)	<input type="text" value="90"/>
Session Timeout (minutes)	<input type="text" value="60"/>

- 'User Inactivity Timeout': If the user has not logged into the Web interface within this duration, the status of the user becomes inactive and the user can no longer access the Web interface. The user can only log in to the Web interface if its status is changed (to **New** or **Valid**) by a **Security Administrator** user.
- 'Session Timeout': Defines the duration (in minutes) of inactivity (i.e., no actions are performed in the Web interface) of a logged-in user, after which the Web session expires and the user is automatically logged out of the Web interface and needs to log in again to continue the session. You can also configure this timeout per user in the Local Users table (see [Configuring Local Management User Accounts](#) on page 55), which overrides this global setting.

3. Click **Apply**.

For a detailed description of the above parameters, see [Web Parameters](#) on page 1706.

## Configuring Secured (HTTPS) Web and REST Access

By default, the device allows remote management (client) to the device's Web and REST interfaces through both HTTP and HTTPS. However, you can enforce secure (HTTPS) access so that the device allows only HTTPS requests.

By default, servers using TLS provide one-way authentication. The client is certain that the identity of the server (i.e., device) is authentic.

When an organizational Public Key Infrastructure (PKI) is used, two-way authentication (mutual TLS authentication or mTLS) may be desired; both client and server (i.e., device) are authenticated using X.509 certificates. This is achieved by installing a client certificate on the client side (e.g., management computer, web browser, or REST-management tool) and uploading the Certification Authority's (CA) root certificate to the device's Trusted Root Certificates table (certificate root store). The Trusted Root Certificate file may contain more than one CA certificate (combined using a text editor).

The device's REST-based management interface supports mTLS that also conditions access based on the certificate's subject name—Subject Alternative Name (SAN) or Common Name

(CN). When a user attempts to connect to the REST interface, the device verifies whether the subject name in the client's certificate matches the 'TLS Subject Name' parameter value configured for any user in the Local Users table. If a match is found, the client is automatically authenticated, without needing to enter a username or password. The authenticated client is granted the user permission level associated with the corresponding user in the Local Users table.

When a user attempts to connect to the device's secured Web or REST interface:

- If the user has a client certificate from a CA that is listed in the device's Trusted Root Certificate store, the device accepts the connection and prompts the user for the login password.
- If both the client certificate and CA certificate are in the Trusted Root Certificate store, the user is not prompted for a password. This provides a single sign-on (SSO) experience; authentication is performed only using the X.509 digital signature.
- If the user's client certificate isn't from a listed CA or doesn't have a client certificate, the device rejects connection.

- For secure management through the device's default management network interface (i.e., **OAMP** Application Type in the IP Interfaces table), the device uses the default TLS Context (Index #0 and named "default"). However, for secure Web- and REST-based management using additional management interfaces configured in the Web Interfaces table (see [Configuring Web Interfaces](#) on page 52), you can use any TLS Context.
- The 'Secured Web Connection (HTTPS)' parameter (mentioned below) is applicable to both Web- and REST-based management.

You can enforce HTTPS access to the Web and REST interfaces through the default management IP interface (#0) by configuring either a global parameter or the Web Interfaces table. However, using the Web Interfaces table is recommended, as it provides greater flexibility. In addition to configuring the Web Interface for the default IP interface, the table allows you to create additional management interfaces and offers enhanced functionality.

➤ **To configure HTTPS for Web and REST using global parameter:**

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**), and then do the following.
2. From the 'Secured Web Connection (HTTPS)' drop-down list, select **HTTPS Only**:

Secured Web Connection (HTTPS) • HTTPS Only ▼

3. Click **Apply**.

The following procedure describes how to configure HTTPS and mTLS for accessing the Web and REST interfaces.

➤ **To configure HTTPS and mTLS for Web and REST:**

1. **(mTLS)** Add client TLS certificates to your third-party REST management tool or web browser. For examples, see the following sections:
  - [Adding Client Certificate to Web Browser Client](#) on page 81
  - [Adding TLS Certificates to REST Client](#) on page 80
2. Open the Web Interfaces table (see [Configuring Web Interfaces](#) on page 52), and then configure the default Web Interface which uses the default IP network interface (**#0**) or configure a new Web Interface:
  - a. From the 'TLS Context Name' drop-down list, select a TLS Context in the TLS Contexts table.
  - b. **(mTLS)** From the 'Require Client Certificates' drop-down list, select **Yes**.
  - c. From the 'HTTPS Only' drop-down list, select **HTTPS only**.
  - d. Click **Apply**.

**Web Interfaces**

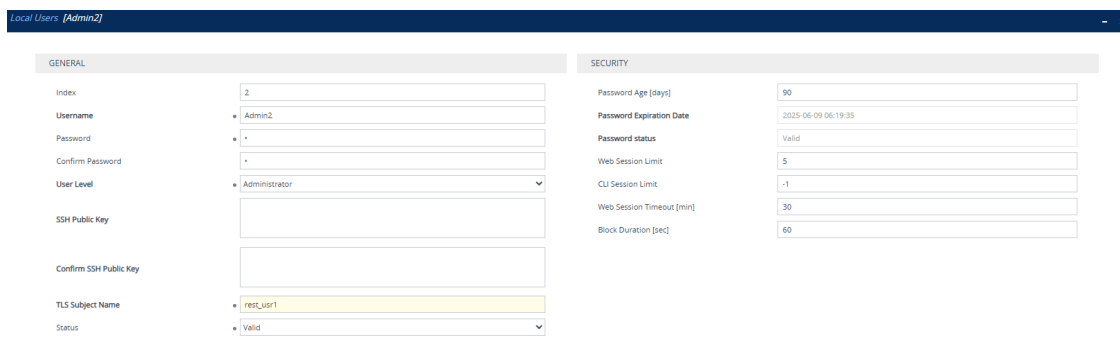

**GENERAL**

Index	<input type="text" value="0"/>
Name	<input type="text"/>
Interface Name	• <input type="text" value="#0 [O+M+C]"/> <a href="#">View</a>
HTTP Port	<input type="text" value="80"/>
HTTPS Port	<input type="text" value="443"/>
TLS Context Name	• <input type="text" value="#0 [default]"/>
Require Client Certificate	• <input type="text" value="Yes"/>
HTTPS Only	• <input type="text" value="HTTPS only"/>

3. **(mTLS)** Import the client's certificate file that was issued by the CA into the device's Trusted Root Certificates store:
  - a. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
  - b. Select the required TLS Context, and then click the **Trusted Root Certificates** link located below the table; the Trusted Root Certificates table appears.
  - c. Click **Import**, and then select the certificate file to import.
4. **(mTLS for REST)** To use the TLS subject name as a matching criteria between the client's certificate and a user in the Local Users table:

- a. Open the Local Users table (see [Configuring Local Management User Accounts](#) on page 55).
- b. For the required user, configure the 'TLS Subject Name' parameter with the Subject Alternative Name or Common Name of the client's certificate.
- c. Click **Apply**.

The example below shows the configured 'TLS Subject Name' as "rest\_usr1":

GENERAL		SECURITY	
Index	2	Password Age [days]	90
Username	Admin2	Password Expiration Date	2025-06-09 06:19:35
Password	*	Password status	Valid
Confirm Password	*	Web Session Limit	5
User Level	Administrator	CLI Session Limit	-1
SSH Public Key		Web Session Timeout [min]	30
Confirm SSH Public Key		Block Duration [sec]	60
TLS Subject Name	rest_usr1		
Status	Valid		

The TLS subject name can be found in the Common Name (CN) or Subject Alternative Name fields of the client's certificate. Below shows "rest\_usr1" in the Subject Alternative Name field:

- The value of the 'TLS Subject Name' parameter for each user in the Local Users table must be unique.
- If you configure the 'TLS Subject Name' parameter, password configuration for the user is not mandatory.

5. Restart the device with a save-to-flash for your settings to take effect.

- Installing a client certificate on your computer is beyond the scope of this document. For more information, refer to your operating system documentation and consult with your security administrator.
- You can also upload the root certificate using the device's Auto-Update mechanism (see the [HTTPSRootFileName] parameter).
- You can enable the device to verify if a peer's certificate has been revoked by an OCSP server per TLS Context (see [Configuring TLS Certificate Contexts](#) on page 227).

## Adding TLS Certificates to REST Client

The following procedure describes how to add a client certificate in Postman, the third-party REST tool. This is required when using Mutual TLS (mTLS) authentication with the device's REST API.

➤ **To add client certificate in Postman:**

1. Start your Postman application.
2. On the toolbar, click the grid icon, and then from the drop-down menu, choose **Settings**.
3. Select the **Certificates** tab.
4. Click **Add Certificates**, and then do the following:
  - a. In the 'Host' field, type the device's IP address (or hostname).
  - b. Select the **CRT file** and the **Key file** for your certificate.
  - c. Click **Add**.

The screenshot shows the 'Add certificate' dialog in Postman. On the left, a sidebar lists settings: General, Themes, Shortcuts, Data, Add-ons, Certificates (selected), Proxy, Update, and About. The main panel is titled 'Add certificate' and contains the following fields:

- Host (required):** A text field containing 'https://' followed by a port field containing '443'.
- CRT file:** A field containing 'certificate.crt' with a close button.
- KEY file:** A field containing 'certKey.key' with a close button.
- PFX file:** A field with a 'Select File' button.
- Passphrase:** An empty text field with a toggle icon.

At the bottom, there are 'Add' and 'Cancel' buttons, and a link that says 'Learn more about [working with certificates](#)'.

5. For your URL endpoint:
  - a. Make sure that the URL endpoint is "https" (not "http").
  - b. Click the **Authorization** tab, and then from the 'Auth Type' drop-down list, select **No Auth**.

Once you've add the trusted root certificate to the device, your REST requests through Postman are seamless, eliminating any need to provide username and password.

## Adding Client Certificate to Web Browser Client

The following procedure describes how to add a client certificate to your web browser (e.g., Google Chrome). This is required when using Mutual TLS (mTLS) authentication with the device's REST API or Web interface.

### ➤ To add client certificate to web browser (e.g., Google Chrome):

1. Open your Chrome web browser.
2. In the top-right corner, click the ellipsis button, and then choose **Settings**.
3. Select **Privacy and security**, and then click **Security**.
4. Under 'Advanced', select **Manage certificates**, and then click **Manage imported certificates from Windows**:

5. Click **Import**, and then use the wizard to import your .pfx certificate file.

Once you've add the trusted root certificate to the device, your REST requests through the web browser are seamless, **eliminating** the need to provide user credentials (username and password). However, upon initial connection, your browser may prompt you to select the new certificate that you imported into the browser:

## Enabling CSRF Protection

The device's embedded Web server provides support for cross-site request forgery (CSRF) protection. CSRF prevents malicious exploits of a website, whereby unauthorized commands are transmitted from a user that the website trusts (i.e., authenticated user). Whenever a user opens (i.e., GET method) one of the device's Web pages, the device automatically generates a CSRF "token" (unique number). When the user performs actions (i.e., POST method) on that page (e.g., configures parameters), the token is included to verify that the authenticated user is the one performing the actions.

To enable CSRF protection, use the ini file parameter [CSRFProtection] or CLI command `configure system > web > csrf-protection`.

## Customizing Access Levels per Web Page

The Customize Access Level table lets you configure up to 100 Customize Access Level rules. These rules assign read-write (view and configure) and read-only (view) privileges to Web interface pages based on management user levels (**Monitor**, **Administrator**, and **Security Administrator**).

The user level you assign for a page applies to that level and all higher levels. For example, if you grant read-write access for the RADIUS Servers page to the **Administrator** user level, the **Security Administrator** user level also inherits read-write access. You can restrict (block) access for a page by specifying a high user level for read-only access. For example, if you grant read-only access to the RADIUS Servers page to the **Administrator** user level, it means that **Monitor** users won't be able to access this page.

If you try to open a page for which you don't have access privileges because of your user level, the page displays the following message: "Your access level doesn't allow you to view this page".

- Customized Access Level rules override the default read-write and read-only privileges assigned to the user levels (see [Configuring Local Management User Accounts](#) on page 55).
- The highest user level is **Security Administrator** and the lowest is the **Monitor** user level.
- Read-only access level must be the same or lower than the read-write access level. For example:
  - ✓ Read-Write Access Level = **Security Administrator**
  - ✓ Read-Only Access Level = **Administrator**
- For parent-child tables, the access level of the child table must be the same or higher than the parent table. For example:
  - ✓ Parent table:
    - Read-Write Access Level = **Administrator**
    - Read-Only Access Level = **Administrator**
  - ✓ Child table:
    - Read-Write Access Level = **Security Administrator**
    - Read-Only Access Level = **Administrator**

The following table provides configuration examples to facilitate your understanding of assigning read-write and read-only privileges to user levels per Web page.

Index	Page Name	Read-Write Access Level	Read-Only Access Level	Description
0	RADIUS Servers	Monitor	Monitor	Assigns read-write (and read-only) privileges for the RADIUS Servers page to <b>Monitor</b> users. As this is the lowest user level, it means that all higher user levels (i.e., <b>Administrator</b> and <b>Security Administrator</b> ) also have read-write access.
1	Firewall	Security Administrator	Monitor	Assigns read-write privileges for the Firewall page to <b>Security Administrator</b> users. As this is the highest user level, only <b>Security Administrator</b> users have write privileges for this page. This rule also assigns read-only privileges to <b>Monitor</b> users, which means that all higher user levels (i.e., <b>Administrator</b> ) also have read-

Index	Page Name	Read-Write Access Level	Read-Only Access Level	Description
				only privileges.
2	SNMP Community Strings	Security Administrator	Administrator	Assigns read-write privileges for the SNMP Community Strings page to <b>Security Administrator</b> users. As this is the highest user level, only <b>Security Administrator</b> users have write privileges for this page. This rule also assigns read-only privileges to <b>Administrator</b> users, which means that <b>Monitor</b> users can't access this page.
3	TLS Contexts	Security Administrator	Security Administrator	Assigns read-write (and read-only) privileges for the TLS Contexts page to <b>Security Administrator</b> users. As this is the highest user level, no other user level can access (read) or configure (write) this page.

The following procedure describes how to configure customized access level rules through the Web interface. You can also configure it through ini file [WebPagesAccessLevel].

➤ **To customize access levels:**

1. Open the Customize Access Level table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Customize Access Level**).
2. Click **New**; the following dialog box is displayed:

3. Configure the rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 6-9: Customize Access Level Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Page Name' [PageNameFromTree]	Defines the Web page whose access level you want to customize. <b>Note:</b> For security reasons, some pages are not listed under this parameter and therefore, cannot be customized.
'Read-Write Access Level' [RWAccessLevel]	Defines the <b>minimum</b> user level to which you want to assign read-write access privileges for the selected Web page. <ul style="list-style-type: none"> <li>■ [50] <b>Monitor</b></li> <li>■ [100] <b>Administrator</b> (default)</li> <li>■ [200] <b>Security Administrator</b></li> </ul>
'Read-Only Access Level' [ROAccessLevel]	Defines the <b>minimum</b> user level to which you want to assign read-only access privileges for the selected Web page.

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [50] <b>Monitor</b> (default)</li> <li>■ [100] <b>Administrator</b></li> <li>■ [200] <b>Security Administrator</b></li> </ul> <p><b>Note:</b> The user level must be the same or lower than the user level you configured in the 'Read-Write Access Level' parameter. For example, you can't assign read-only privileges to the <b>Security Administrator</b> if you assigned read-write privileges to the <b>Administrator</b>.</p>

## Configuring a Hostname for Device's Web Interface

You can configure a hostname (FQDN) for the device's Web interface. This means that you can access the Web interface using the device's hostname (e.g., `http://mysbc.com`) instead of its IP address. You can also enforce (default) access only through the device's hostname, blocking any access attempts using its IP address.

If you configure a hostname, you also need to define it on a DNS server. When you try to access the Web interface with the hostname, a query is first sent to the DNS server to resolve the hostname into the device's IP address.

If you access the device's Web interface using its hostname, the toolbar displays the hostname (first 16 characters only) instead of the device type.

It's recommended to configure a hostname for accessing the device's Web interface because it helps protect the device against HTTP Host header attacks and DNS rebinding attacks.

### ➤ To configure a hostname for Web interface:

1. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**).
2. In the 'Web Server Name' field [WebHostname], type a hostname:

Web Server Name

• sbcols1.eastus.12345.com

3. To enforce access to the device's Web interface **only** through the hostname (not IP address), select the 'Enforce Web Host Name' check box:

Enforce Web Host Name

4. Click **Apply**.

Due to a known issue, the following OVOC features do **not** function when the 'Enforce Web Host Name' parameter is enabled:

- OVOC Single Sign-On (SSO)
- OVOC Performance Monitoring (PM)
- OVOC Service Availability

If you need to use any of these OVOC features, make sure that the 'Enforce Web Host Name' parameter is disabled.

- If you disable the 'Enforce Web Host Name' parameter, or you leave the 'Web Server Name' parameter empty (regardless of the 'Enforce Web Host Name' parameter's setting), the Web interface can be accessed through its hostname or IP address.
- If you're upgrading the device from version 7.4.500-2 (7.40A.500.775) or later to version 7.4.500-5 or later and have configured the 'Web Server Name' parameter and use the device's IP address to access the Web interface, access to the device through the IP address will be denied. If you want to retain such capability, disable the 'Enforce Web Host Name' parameter.
- When the device operates in High-Availability mode, the active and redundant units share the same hostname.
- To configure a hostname that is used for the CLI prompt name, SNMP interface's SysName object value, and communication with OVOC, see [Configuring a Hostname for the Device](#) on page 144.

## Configuring Management Access List

The Management Access List table lets you control access to the device's management interfaces (Web, REST API, SSH, and Telnet). You can define up to 50 rules, where each rule defines a management station (client) by IP address (IPv4 or IPv6) and the management interface that the client can access. You can select a specific management interface or you can select the **All** option to allow access to all management interfaces.

By default (i.e., Management Access List table is empty), any client (IP address) can access all the device's management interfaces. Once you configure access rules for a specific management interface, the device blocks all undefined clients to that specific management interface (rejects with an HTTP 403 Forbidden response).

- If you want to configure management access list rules, the **first** rule must allow access to the current management interface from the IP address of the computer from which you are currently logged into the device. If you don't configure this rule first, after you configure an access rule for any other IP address, the device immediately blocks your access.
- If you configure network firewall rules in the Firewall table (see [Configuring Firewall Rules](#) on page 253), you must configure a firewall rule that allows traffic from IP addresses that you configured in the Management Access List table.
- If you have configured management access list rules and you no longer want to restrict access to the management interfaces, you need to delete all the rules in the table. However, make sure that you delete the rule **last** that allows access from the computer (IP address) from which you are currently logged into the device; otherwise, access from your computer will be immediately denied.
- If you downgrade the device to a version earlier than 7.6, the access list is deleted.

The following procedure describes how to configure the Management Access List table through the Web interface. You can also configure it through ini file [WebAccessList] or CLI (configure system > management-access-list).

➤ **To restrict access to a management interface:**

1. Open the Management Access List table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Management Access List**).
2. Click **New**; the following dialog box is displayed:

3. Configure a management access list rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 6-10: Management Access List Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'IP Address' ip-	Defines the management station (client) as an IP address (IPv4 or IPv6) that is allowed to access the specified management interface (see the

Parameter	Description
address [IpAddress]	'Type' parameter below) . <b>Note:</b> <ul style="list-style-type: none"> <li>■ If you configure an IPv6 address, use the shortened address format and without square brackets (e.g., 2010:31::2:56).</li> <li>■ You can configure multiple rules with the same IP address as long as you configure each with a different management interface type.</li> </ul>
'Type' type [Type]	Defines the type of device's management interface that the client is allowed to access. <ul style="list-style-type: none"> <li>■ [0] <b>All</b> (default)</li> <li>■ [1] <b>Web</b></li> <li>■ [2] <b>REST</b></li> <li>■ [3] <b>SSH</b></li> <li>■ [4] <b>Telnet</b></li> </ul>

## Viewing Active Web Interface and CLI Users

You can view all users that are currently logged in to the device's Web interface and CLI.

### ➤ To view active users:

- Open the Active Users page (**Monitor** menu > **Monitor** tab > **Summary** folder > **Active Users**).

ACTIVE WEB USERS TABLE

Web Users

#	USERNAME	IP ADDRESS	LEVEL	MODE	STATUS	SESSION TIME
0	Admin	10.11.2.2	Security Administrator	WEB	Active	32 Min, 52 Sec

Items per page: 10 1 - 1 of 1 |< < 1 > >|

ACTIVE CLI USERS TABLE

CLI Users

#	USERNAME	IP ADDRESS
0	Admin	10.11.2.2

The Active Users table is described below:

Parameter	Description
<b>Active Web Users Table</b>	
'Username'	Displays the user's login username.
'IP Address'	Displays the IP address of the management station from where the user accessed the device's Web interface.
'Level'	Displays the user's privilege level (e.g., <b>Security Administrator</b> or <b>Monitor</b> ).
'Mode'	<p>Displays the method of how the user accessed the device's Web interface:</p> <ul style="list-style-type: none"> <li>■ "WEB" = Accessed directly through the Web Login page.</li> <li>■ "OSN" = Accessed from the OSN server.</li> <li>■ "CCE" = Accessed from Cloud Connector Edition (CCE).</li> <li>■ "OVOC" = Accessed from OVOC (Single-Sign On).</li> <li>■ "OAUTH" = Accessed through OAuth-based login authentication (Azure AD).</li> </ul>
'Status'	Displays the status of the user (always "Active").
'Session Time'	<p>Displays the time remaining until the user's session expires due to inactivity in the Web interface and is logged out of the Web interface. To obtain the time in minutes, divide the displayed time by three.</p> <p>The timer starts counting down whenever the user is inactive. As soon as the user becomes active, the timer resets to the full session inactivity time, configured by the 'Web Session Timeout' parameter in the Local Users table (see <a href="#">Configuring Local Management User Accounts</a> on page 55).</p>
<b>Active CLI Users Table</b>	
'Username'	Displays the user's login username.
'IP Address'	Displays the IP address of the management station from where the user accessed the device's CLI.

## 7 CLI-Based Management

This section provides an overview of the CLI-based management and provides configuration relating to CLI management.

- By default, CLI is disabled for security purposes.
- The CLI provides two access modes - Basic mode (basic commands) and Privileged mode (all commands). Access to these modes depends on management user level:
  - ✓ Monitor user level: Basic mode only
  - ✓ Administrator user level: Basic mode only
  - ✓ Security Administrator user level: Basic and Privileged modes
- For a description of the CLI commands, refer to the document *SBC-Gateway CLI Reference Guide* by clicking [here](#).

### Configuring Telnet for CLI

The device provides an embedded Telnet server, which allows you to access its CLI from a remote Telnet client using the Telnet application protocol. By default, the Telnet server is disabled.

If you enable secured Telnet connectivity, the device uses the TLS security protocol, whereby information is transmitted encrypted (instead of in clear text). For TLS, the device uses the TLS settings of the TLS Context at Index #0 ("default"). A special Telnet client is required on your PC to connect to the Telnet interface over the TLS connection, for example, C-Kermit for UNIX and Kermit-95 for Windows. For more information on TLS, see [TLS Certificates](#) on page 227.

For security, some organizations require the display of a proprietary notice upon starting a Telnet session. To configure such a message, see [Creating a Login Welcome Message](#) on page 51.

To assign IP interfaces for Telnet sessions, see [Configuring Telnet Interface](#) on page 98.

#### ➤ To configure Telnet:

1. Open the Administration Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Administration Settings**).
2. From the 'Enable Telnet Server' drop-down list, select **Enable Unsecured** or **Enable Secured** (i.e., TLS) to enable Telnet.

Enable Telnet Server

Enable Unsecured ▼

3. In the 'Idle Timeout' field, enter the duration of inactivity in the Telnet session after which the session is automatically terminated.

Telnet Server Idle Timeout [minutes] •

4. In the 'Default Terminal Window Height' field, enter the maximum number of output lines to display in the CLI terminal window.

Default terminal window height

5. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

For a detailed description of the Telnet parameters, see [Telnet and CLI Parameters](#) on page 1713.

## Configuring CLI over SSH using Public Key Authentication

When using a Secure Shell (SSH) connection for secure access to the device's CLI, the device uses the username-password method for authenticating users, by default. To increase security, you can use RSA or ECDSA public keys for user authentication instead of passwords. In this setup, when establishing an SSH connection, the device checks that the SSH private key of the client (user) matches the public key configured for the user on the device.

This section describes how to enable SSH for public key authentication (see [Enabling SSH for Public Key Authentication](#) below) and how to configure SSH public key authentication on the following operating systems:

- Windows using PuTTY (see [Configuring SSH Public Key Authentication on Windows](#) on the next page)
- Linux using OpenSSH (see [Configuring SSH Public Key Authentication on Linux](#) on page 97)

The device's embedded SSH server supports SHA-256 (rsa-sha2-256) and SHA-512 (rsa-sha2-512) signature algorithms for public-key client authentication that utilizes RSA keys:

- Server host key algorithms (refer to RFC 4253 Section 7.1)
- Algorithm for client authentication (refer to RFC 8303 Section 3.1, and RFC 8332 Section 3.2)

## Enabling SSH for Public Key Authentication

This section describes how to enable SSH public key authentication for accessing the device's CLI.

### ➤ To enable SSH for public key authentication:

1. Open the Administration Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Administration Settings**).
2. Select the 'Enable SSH Server' check box to enable SSH:

**Enable SSH Server**

3. Select the 'Public Key' check box to enforce SSH access with a username and SSH public key (not username and password):

**Public Key**

4. Configure the key algorithm string, cipher string, or MAC string:

**Kex Algorithms String**

- diffie-hellman-group1-sha1:diffie-hellma

**Ciphers String**

- aes128-ctr:aes128-cbc:aes256-ctr:aes256

**MACs String**

- hmac-sha1:hmac-sha2-256

5. Click **Apply**, and then save your settings to flash memory.

For a detailed description of the all SSH parameters, see [SSH Parameters](#) on page 1815.

To configure IP network interfaces for the SSH application, see [Configuring SSH Interfaces](#) on page 99.

## Configuring SSH Public Key Authentication on Windows

This section describes how to configure SSH public key authentication on Windows, using PuTTY.

The public key cannot be configured with wide characters.

### ➤ To configure SSH public key authentication on Windows using PuTTY:

1. Generate private-public keys using PuTTY:
  - a. Download the PuTTY application (free and open-source terminal emulator).
  - b. Start the PuTTYgen (PuTTY Key Generator) tool.
  - c. Under the **Parameters** group, do the following:
    - i. Select the **RSA** or **ECDSA** option.
    - ii. In the 'Number of bits in a generated key' field, enter the bit size.
  - d. Under the **Actions** group, do the following:
    - i. Click **Generate** and then follow the on-screen instructions to generate the public-private key pair.

- ii. Click **Save private key** to save the generated private key to a file (\*.ppk) on your PC.
- e. Under the **Key** group, copy the generated public key string to your clipboard, from after the first space to before the last space, for example:

**PuTTY Key Generator**

File Key Conversions Help

**Key**

Public key for pasting into OpenSSH authorized\_keys file:

```
ecdsa-sha2-nistp256
AAAAE2VjZHNhLXNoYTItbmlzdHAyNTYAAAAIbmlzdHAyNTYAAABBBNtQj8CXwEfh9EfPBeaQnFKc5fivuO6ZR
GUpOlxc3g7KkwM2EWLmvCazbhcP0BoHTFBey92gS7QPJRkzxiNiLo=ecdsa-key-20220711
```

Key fingerprint: ecdsa-sha2-nistp256 256 SHA256:nkOqsh/jCrU6snOJj9FBzPbUr1F4Pgxc87sXcYrJeQ

Key comment: ecdsa-key-20220711

Key passphrase:

Confirm passphrase:

**Actions**

Generate a public/private key pair Generate

Load an existing private key file Load

Save the generated key Save public key Save private key

**Parameters**

Type of key to generate:

☐ RSA ☐ DSA ☒ ECDSA ☐ EdDSA ☐ SSH-1 (RSA)

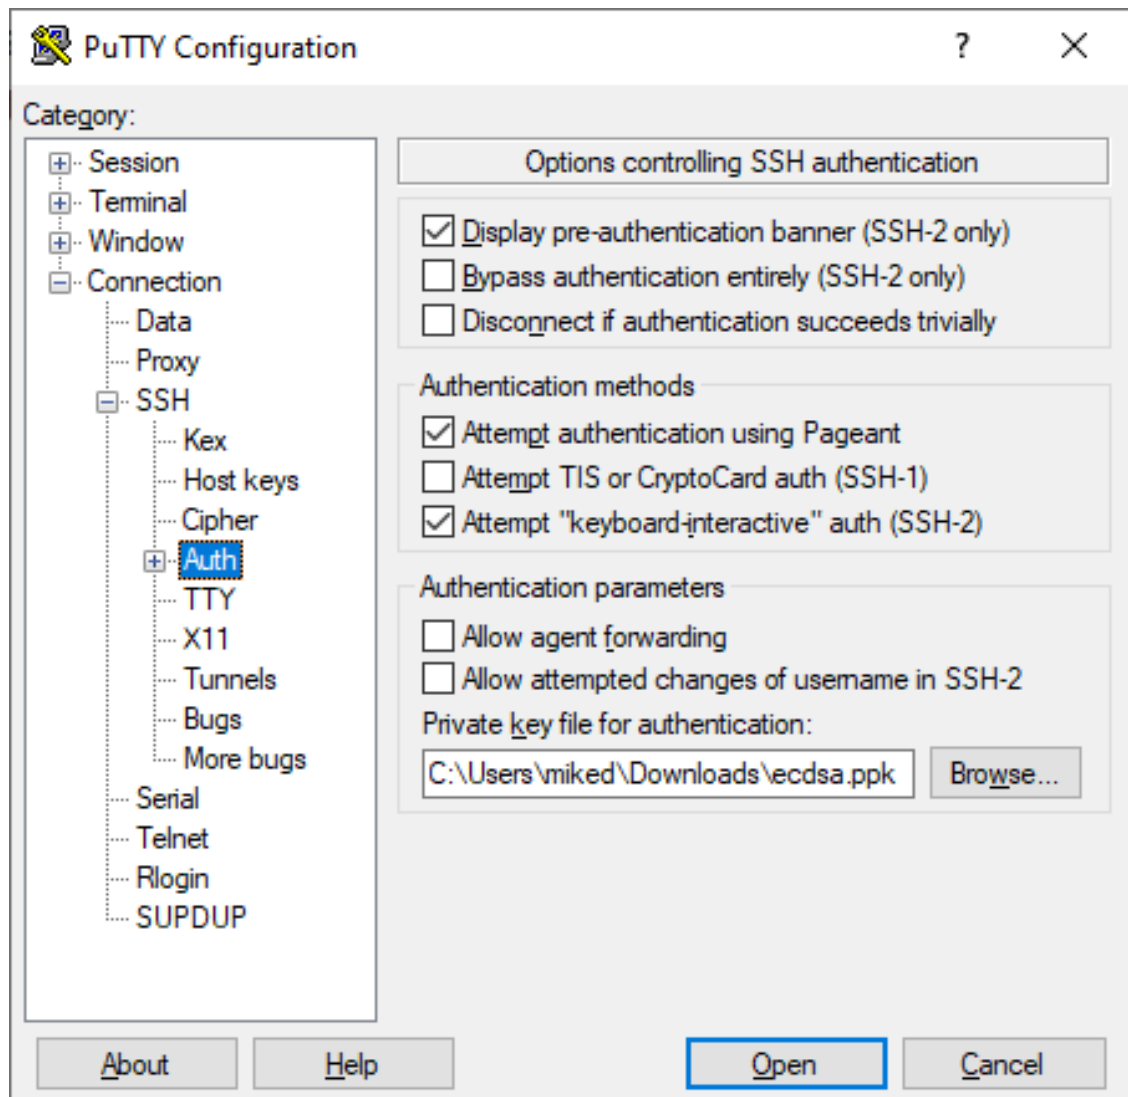

Curve to use for generating this key: nistp256

2. Configure the required user with the generated public key:
  - a. Open the Local Users table (see [Configuring Local Management User Accounts](#) on page 55).
  - b. Select the required user, and then click **Edit**.
  - c. In the 'SSH Public Key' field, paste the public key that you copied previously, as shown in the following example:

**Local Users**

GENERAL		SECURITY	
Index	0	Password Age (days)	0
Username	Admin	Web Session Limit	5
Password	*	CLI Session Limit	-1
User Level	Security Administrator	Web Session Timeout (min)	120
SSH Public Key	AAAAE2VjZHNhLXNoYTItbmlzdHAyNTYAAAAIbmlzdHAyNTYAAABBBNtQj8CXwEfh9EfPBeaQnFKc5fivuO6ZRGUpOlxc3g7KkwM2EWLmvCazbhcP0BoHTFBey92gS7QPJRkzxiNiLo=	Block Duration (sec)	60
Status	Valid		

- d. Click **Apply**, and then save your settings to flash memory. If you are editing the user that you are currently logged in as, then you are logged out of the Web interface after clicking **Apply** and need to log in again.
3. Establish an SSH connection with the device:
  - a. Start the PuTTY application.
  - b. In the navigation tree, drill down to **Connection > SSH > Auth**.
  - c. Under the **Authentication parameters** group, click **Browse** to select the private key file (\*.ppk) that you generated and then saved in Step 1:

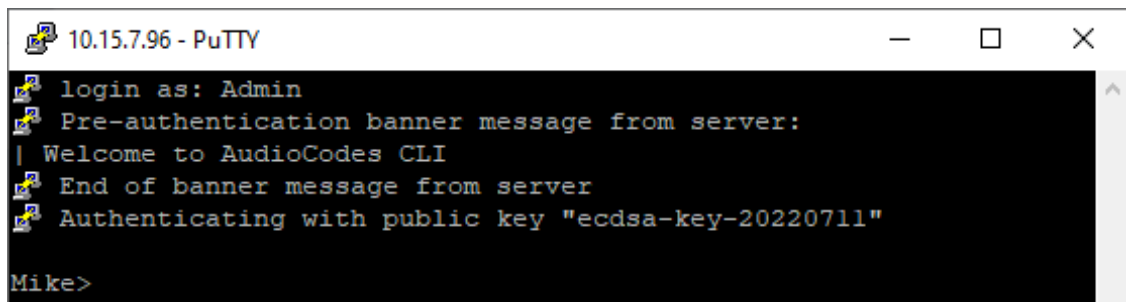

- d. In the navigation tree, click **Session**, and then establish an SSH connection with the device.

When defining the session in PuTTY, make sure that you don't select a saved session that is not associated with the \*.ppk key; otherwise, SSH with public key authentication will fail.

- e. Log in with your username only (e.g., "Admin"); public-private key negotiation occurs for user authentication and if successful, you are logged into the CLI, as shown in the following example:

```

10.15.7.96 - PuTTY
login as: Admin
Pre-authentication banner message from server:
| Welcome to AudioCodes CLI
End of banner message from server
Authenticating with public key "ecdsa-key-20220711"
Mike>

```

## Configuring SSH Public Key Authentication on Linux

This section describes how to configure SSH public key authentication on Linux, using OpenSSH.

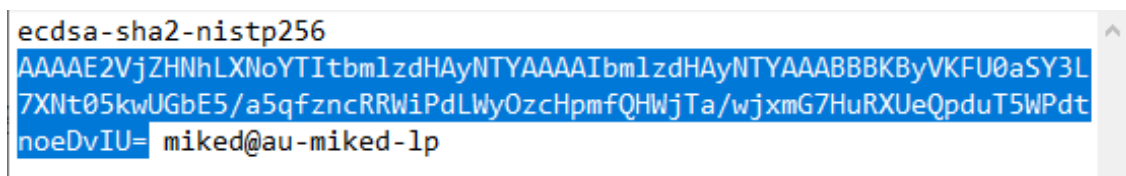

The public key cannot be configured with wide characters.

### ➤ To configure SSH public key authentication on Linux using OpenSSH 9.0:

1. Create a new key in the admin.key file and save the public portion to the admin.key.pub file, using the following command:

```
ssh-keygen -f admin.key -t [ecdsa|rsa]
```

2. Open the admin.key.pub file, and then copy the public key string to your clipboard from after the first space to before the last space, for example:

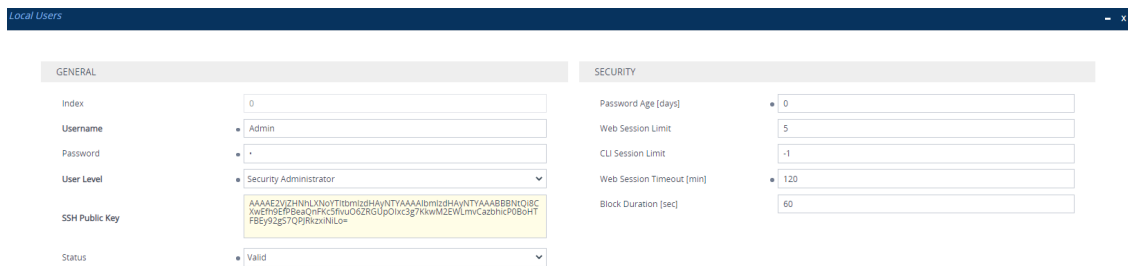

```

ecdsa-sha2-nistp256
AAAAE2VjZHNhLXNoYTItbmlzdHAyNTYAAAAIbmlzdHAyNTYAAABBBKByVKFU0aSY3L
7XNt05kwUGbE5/a5qfzncRRWiPdLWyOzcHpmfQHwJTa/wjxmG7HuRXUeQpduT5WPdt
noeDvIU= miked@au-miked-lp

```

3. Configure the required user with the generated public key:
  - a. Open the Web interface's Local Users table (see [Configuring Local Management User Accounts](#) on page 55).
  - b. Select the required user, and then click **Edit**.
  - c. In the 'SSH Public Key' field, paste the public key that you copied previously, as shown in the following example:

- d. Click **Apply**, and then save your settings to flash memory. If you are editing the user that you are currently logged in as, then you are logged out of the Web interface after clicking **Apply** and need to log in again.

4. Establish an SSH connection with the device, using the following command:

```
ssh -i admin.key <username>@<IP address>
```

For example:

```
ssh -i admin.key Admin@10.4.30.215
```

Key negotiation occurs for user authentication and if successful, you are logged into the CLI.

## Configuring Telnet Interface

The Telnet Interfaces table lets you configure up to 16 Telnet interfaces, which are used to access the device's CLI over Telnet.

The device provides a default Telnet Interface (Index 0), which is assigned the IP Interface for IPv4 OAMP ("O+M+C", Index 0).

The following procedure describes how to configure Telnet interfaces through the Web interface. You can also configure it through ini file [TelnetInterfaces] or CLI (`configure system > cli-settings > telnet-if`).

### ➤ To configure Telnet interfaces:

1. Open the Telnet Interfaces table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Telnet Interfaces**).
2. Click **New**; the following dialog box is displayed:

Telnet Interfaces - x

GENERAL

Index

1

Name

Interface Name

#1 [HA]
▼
View

Port

23

3. Configure the row according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 7-1: Telnet Interfaces Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 19 characters. <b>Note:</b> Configure each row with a unique name.
'Interface Name' interface-name [InterfaceName]	Assigns an IP Interface (IPv4 or IPv6) from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for communication with the embedded Telnet server. The IP Interface can be any Application Type (e.g., Media, Control, or OAMP). By default, the OAMP interface (Index 0 "O+M+C") is assigned. <b>Note:</b> The parameter is mandatory.
'Port' port [Port]	Defines the local port to use for Telnet application. The valid range is 1 to 65535. The default is 23. <b>Note:</b> The parameter is mandatory.

## Configuring SSH Interfaces

The SSH Interfaces table lets you configure up to 16 SSH interfaces, which are used to access the device's CLI over SSH.

The device provides a default SSH Interface (Index 0), which is assigned the IP Interface for IPv4 OAMP ("O+M+C", Index 0).

The following procedure describes how to configure SSH interfaces through the Web interface. You can also configure it through ini file [SshInterfaces] or CLI (`configure system > cli-settings > ssh-if`).

➤ **To configure SSH interfaces:**

1. Open the SSH Interfaces table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **SSH Interfaces**).
2. Click **New**; the following dialog box is displayed:

The screenshot shows a web-based configuration window titled "SSH Interfaces". It has a dark blue header bar with a close button and a maximize button. Below the header is a tab labeled "GENERAL". The form contains four fields: "Index" (text input with "1"), "Name" (text input, empty), "Interface Name" (dropdown menu showing "#1 [HA]" with a "View" link to its right), and "Port" (text input with "22").

3. Configure the row according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 7-2: SSH Interfaces Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 19 characters. <b>Note:</b> Configure each row with a unique name.
'Interface Name' interface-name [InterfaceName]	Assigns an IP Interface (IPv4 or IPv6) from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for communication with the SSH application. The IP Interface can be any Application Type (e.g., Media, Control, or OAMP). By default, the OAMP interface (Index 0 "O+M+C") is assigned. <b>Note:</b> The parameter is mandatory.
'Port' port [Port]	Defines the local port to use for the SSH application. The valid range is 1 to 65535. The default is 22. <b>Note:</b> The parameter is mandatory.

## Establishing a CLI Session

You can access the device's CLI using any of the following methods:

- **RS-232:** The device's CLI can be accessed through its RS-232 serial port, by connecting a VT100 terminal to it or using a terminal emulation program (e.g., HyperTerminal) with a PC. For connecting to the CLI through RS-232, see [Changing OAMP Address through CLI](#) on page 15.
- **Secure SHell (SSH):** The device's CLI can be accessed through its Ethernet interface by the SSH protocol using SSH client software. A popular and freeware SSH client software is PuTTY, which can be downloaded from <https://www.putty.org>.
- **Telnet:** The device's CLI can be accessed through its Ethernet interface by the Telnet protocol using Telnet client software.

The following procedure describes how to access the CLI through Telnet/SSH.

- The CLI login credentials are the same as all the device's other management interfaces (such as Web interface). The default username and password is "Admin" and "Admin" (case-sensitive), respectively. To configure login credentials and management user accounts, see [Configuring Local Management User Accounts](#) on page 55.
- After three consecutive failed login attempts because of incorrect credentials, the device ends the CLI session and you will need to re-establish it.

### ➤ To establish a CLI session through Telnet or SSH:

1. Connect the device to the network.
2. Establish a Telnet or SSH session using the device's OAMP IP address.
3. Log in to the session using the username and password assigned to the Admin user of the Web interface:
  - a. At the Username prompt, type the username, and then press Enter:

```
Username: Admin
```

- b. At the Password prompt, type the password, and then press Enter:

```
Password: Admin
```

- c. At the prompt, type the following, and then press Enter:

```
> enable
```

- d. At the prompt, type the password again, and then press Enter:

Password: Admin

## Configuring Maximum Telnet and SSH Sessions

You can configure the maximum number of concurrent Telnet and SSH sessions allowed by the device.

- Before changing the setting, make sure that not more than the number of sessions that you want to configure are currently active; otherwise, the new setting will not take effect.
- The device supports up to five concurrent Telnet and SSH sessions.

### ➤ To configure maximum number of concurrent Telnet and SSH sessions:

1. Open the Administration Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Administration Settings**).
2. In the 'Maximum Telnet Sessions' field, enter the maximum number of concurrent **Telnet** sessions:

Maximum Telnet Sessions •

3. In the 'Maximum SSH Sessions' field, enter the maximum number of concurrent **SSH** sessions:

Maximum SSH Sessions

4. Click **Apply**.

## Running Multiple Non-Interactive SSH Commands from Command Line

You can configure the device with multiple, non-interactive SSH (CLI) commands from a command-line connection, instead of using a terminal emulator program (e.g., PuTTY). Unlike terminal emulator programs, the command line has no user prompts and is similar to Unix SSH. This feature may be useful, for example, if you want to run a batch of SSH commands via automated connections.

As an SSH client, you can run the command-line connection tool (e.g., PuTTY Link or Plink) from a computer's command prompt. For computers running Windows, this can be done using the Command Prompt command-line app. When you enter a command, it's executed on the device instead of through a login shell.

You can enter multiple commands on the **single** command line, including standalone commands and command sequences. Separate each command with a semicolon (;).

The command-line syntax depends on the command-line connection tool that you are using to connect to the device. The following are examples using the Plink command-line connection tool:

- To display network interfaces and CPU status (i.e., `show` commands):

```
C:\projects\tftp>plink.exe -no-antispoof -ssh 10.4.30.11 -l Admin -pwd Admin  
"sh run ne int; sh sys util"
```

- To configure the syslog server's IP address:

```
C:\projects\tftp>plink.exe -no-antispoof -ssh 10.4.30.11 -l Admin -pwd Admin  
"conf tr; sys; syslog-ip 10.4.2.11; act"
```

- To configure commands that are located in two different CLI paths:

```
C:\projects\tftp>plink.exe -no-antispoof -ssh 10.4.30.11 -l Admin -pwd Admin  
"conf voip; sip-definition settings; 100-to-18x-timeout 100; exit; exit; show  
system utilization"
```

- This feature is applicable only to non-interactive commands.
- This feature is not supported for async commands (e.g., `ping`).
- You can enter up to 8,000 characters on the command line (input).
- When using the command line, no other SSH connections (sessions) can be established with the device.
- The device's Activity Log (see [Reporting Management User Activities](#) on page 1634) also logs the commands executed from the command line (which are indicated in syslog as "Activity Log: Executing multiple CLI commands").

## Viewing Current CLI and Web Sessions

You can view users that are currently logged in to the device's CLI and Web interface. For CLI, This applies to users logged in to the CLI through RS-232 (console), Telnet, or SSH. For each logged-in user, the following is displayed: the type of interface (console, Telnet, SSH, or Web), username, remote IP address from where the user logged in, and the duration (days and time) of the session. Each user is displayed with a unique index (session ID).

### ➤ To view currently logged-in CLI users:

1. Establish a CLI session with the device.
2. Run the following command:

```
# show users
[0]* ssh      Admin  10.11.2.2    0d00h17m55s
[0]  WEB      Admin  10.11.2.2    0d00h01m44s
```

The current session from which this show command was run is displayed with an asterisk (\*).

The device can display management sessions of up to 24 hours. After this time, the duration counter is reset.

## Terminating a User's CLI Session

You can terminate users that are currently logged in to the device's CLI. This applies to users logged in to the CLI through RS-232 (console), Telnet, or SSH.

### ➤ To terminate the CLI session of a specific CLI user:

1. Establish a CLI session with the device.
2. Run the following command:

```
# clear user <session ID>
```

Where *<session ID>* is a unique identification of each currently logged in user. You can view the session ID by running the **show users** command (see [Viewing Current CLI and Web Sessions](#) on the previous page).

The session in which the command is run cannot be terminated.

## Configuring CLI Command Aliases

The CLI Aliases table lets you configure up to 100 CLI Alias rules. A CLI command alias is a shortcut or abbreviation of a command. Instead of typing the command, you can type the alias name.

Aliases may be useful for commands that you frequently use. For example, if you often use the command `copy firmware from`, you can configure an alias called "CopyF" for it and then whenever you want to type the command, you can simply type `CopyF` instead.

To use an alias, you must access the relevant CLI command path where the command that it represents is located. Using the example above, to use the alias "CopyF" for the `copy firmware from` command, you must be at the root prompt.

The following procedure describes how to configure CLI command aliases through the Web interface. You can also configure it through ini file [CliAlias] or CLI (`configure system > cli-settings > cli-alias`).

➤ **To configure CLI command aliases:**

1. Open the CLI Aliases table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **CLI Aliases**).
2. Click **New**; the following dialog box appears:

The screenshot shows a web-based configuration window titled "CLI Aliases". It has a dark blue header bar with the title and window controls. Below the header is a light gray bar labeled "GENERAL". The main area contains three input fields: "Index" with the value "0", "Alias" (empty), and "Command" (empty).

3. Configure a CLI Alias rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 7-3: CLI Aliases Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Alias' alias-name [AliasName]	Defines the alias name for the CLI command. The valid value is a string of up to 255 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The alias name must be unique.</li> <li>■ The alias name is case-sensitive.</li> <li>■ The alias name cannot contain spaces.</li> </ul>
'Command' alias-command [AliasCommand]	Defines the CLI command (or command sequence) for which the alias represents. The valid value is a string of up to 500 characters.

## Configuring Maximum Number of Displayed CLI Output Lines

You can configure the maximum number of lines (height) displayed in the terminal window for the output of CLI commands (Telnet and SSH). The number of displayed lines can be from 0 to 65,535, or determined by re-sizing the terminal window by mouse-dragging the window's border.

➤ **To configure maximum number of displayed output lines:**

1. Establish a CLI session with the device.
2. Access the System menu:

```
# configure system
```

3. At the prompt, type the following command:

```
(config-system)# cli-terminal
```

4. At the prompt, type the following command:

```
<cli-terminal># window-height [0-65535]
```

If window-height is set to 0, the entire command output is displayed. In other words, even if the output extends beyond the visible terminal window length, the --MORE-- prompt is not displayed.

➤ **To configure number of displayed output lines by dragging terminal window:**

1. Establish a CLI session with the device.
2. Access the System menu:

```
# configure system
```

3. At the prompt, type the following command:

```
(config-system)# cli-terminal
```

4. At the prompt, type the following command:

```
<cli-terminal># window-height automatic
```

When this mode is configured, each time you change the height of the terminal window using your mouse (i.e., dragging one of the window's borders or corners), the number of displayed output command lines is changed accordingly.

## Idle CLI Session Timeout for RS-232 Connections

If you have established a CLI session (successfully logged in) with the device through an RS-232 serial interface and you don't perform any actions in the CLI session for five minutes, the device automatically logs you out the session. In such a scenario, you need to log in to the CLI again if you want to continue using the CLI. This idle session timeout is not configurable.

## 8 SNMP-Based Management

The device provides an embedded SNMP agent that lets you manage it using AudioCodes One Voice Operations Center (OVOC) or a third-party SNMP manager. The SNMP agent supports standard and proprietary Management Information Base (MIBs). All supported MIB files are supplied to customers as part of the release. The SNMP agent can send unsolicited SNMP trap events to the SNMP manager.

- The device supports SNMPv1, SNMPv2, and SNMPv3.
- SNMPv2 or SNMPv3 is required to query 64-bit counters because SNMPv1 doesn't support 64-bit counters (per RFC 2233). Therefore, to ensure that your SNMP Get requests (e.g., especially for performance monitoring parameters) are successful, it's recommended to use SNMPv2 or SNMPv3.
- For more information on SNMP trap alarms, refer to the [SBC-Gateway Series SNMP Alarm Reference Guide](#).
- For more information on OVOC, refer to the *OVOC User's Manual* (click [here](#)).

### Enabling or Disabling SNMP

By default, management of the device through SNMP is enabled.

#### ➤ To enable or disable SNMP:

1. Open the SNMP Settings page (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Settings**).
2. From the 'Disable SNMP' drop-down list (DisableSNMP parameter), select one of the following:
  - **Yes** to disable SNMP.
  - **No** to enable SNMP.

Disable SNMP

3. Click **Apply**.

If you want the device to be managed by the One Voice Operations Center (OVOC) tool, you must enable SNMP.

### Configuring SNMP Get / Set Port

By default, the device uses UDP port 161 for SNMP Get and Set request commands. You can change the port number (100 to 3999), as described below.

➤ **To configure the SNMP port:**

1. Open the SNMP Settings page (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Settings**).
2. In the 'SNMP Port' field (SNMPPort parameter), type the port number:

SNMP Port

161

3. Click **Apply**, and then restart the device with a burn-to-flash for your settings to take effect.

## Configuring SNMP Community Strings

SNMP community strings determine the access privileges (read-only and read-write) of SNMP clients with the device's SNMP agent for SNMPv1 and SNMPv2 users. You can configure up to 10 SNMP community strings. The device's SNMP agent accepts SNMP Get (read-only) and Set (read-write) requests only if the correct community string is used in the request.

- SNMP community strings are applicable only to SNMPv1 and SNMPv2c. SNMPv3 uses username-password authentication along with an encryption key (see [Configuring SNMPv3 Users](#) on page 116).
- If you configure SNMPv3 users (see [Configuring SNMPv3 Users](#) on page 116), the device automatically deletes all configured SNMP community strings in the SNMP Community Strings table. In addition, the device ignores all SNMP requests (Get and Set operations) from SNMPv2 users, sending the authenticationFailure SNMP trap.
- If you don't configure any community strings, the default community strings are "public" and "private".
- The read-only community strings must be different to the read-write community strings.
- You can enhance security by configuring Trusted Managers (see [Configuring SNMP Trusted Managers](#) on page 115). A Trusted Manager is an address from which the SNMP agent accepts Get and Set requests.

The following procedure describes how to configure SNMP Community Strings through the Web interface. You can also configure it through ini file [SNMPCommunityStrings] or CLI (configure system > snmp settings > community-strings).

➤ **To configure SNMP Community Strings:**

1. Open the SNMP Community Strings table (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Community Strings**).
2. Click **New**; the following dialog box appears:

3. Configure an SNMP community string according to the parameters described in the table below.
4. Click **Apply**, and then reset the device with a save-to-flash for your settings to take effect.

**Table 8-1: SNMP Community Strings Table Parameter Descriptions**

Parameter	Description
'Index' [SNMPCommunityStrings_Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [SNMPCommunityStrings_Name]	Defines a descriptive name for the SNMP community string. The valid value is a string of up to 31 characters.
'Password' password [SNMPCommunityStrings_Password]	Defines a password (string) for the SNMP community string. The valid value is a string of up to 30 characters that can include only the following: <ul style="list-style-type: none"> <li>■ Uppercase letters (A to Z)</li> <li>■ Lowercase letters (a to z)</li> <li>■ Numbers (0 to 9)</li> <li>■ Hyphen (-)</li> <li>■ Underline (_)</li> </ul> For example: "Public-comm_string1". <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter cannot be configured with wide characters.</li> <li>■ The password cannot contain spaces.</li> <li>■ To enforce the use of strong passwords (password complexity), configure the <a href="#">[EnforcePasswordComplexity]</a> on page 1703</li> </ul>

Parameter	Description
	parameter to [1]. <ul style="list-style-type: none"> <li>The read-only community strings must be different to the read-write community strings.</li> </ul>
'Group' group [SNMPCommunityStrings_Group]	Defines the access privilege of the SNMP community string. <ul style="list-style-type: none"> <li>[0] <b>Read-Only</b></li> <li>[1] <b>Read-Write</b> (default)</li> </ul>

## Configuring SNMP Trap Destinations

The SNMP Trap Destinations table lets you configure up to five SNMP Trap Managers for receiving traps sent by the device. Trap Managers are defined by IP address or FQDN (IPv4 and/or IPv6).

You can associate a trap destination with SNMPv2 users or a specific SNMPv3 users. Associating a trap destination with an SNMPv3 user sends encrypted and authenticated traps to the SNMPv3 destination. By default, traps are sent unencrypted using SNMPv2.

The following procedure describes how to configure SNMP trap destinations through the Web interface. You can also configure it through ini file [SNMPTrapDestinations] or CLI (`configure system > snmp settings > trap-destinations`).

### ➤ To configure SNMP trap destinations:

1. Open the SNMP Trap Destinations table (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Trap Destinations**).
2. Click **New**; the following dialog box appears:

The screenshot shows a configuration window titled "SNMP Trap Destinations". It has a "GENERAL" tab. The fields are as follows:

- Index:** 0
- Name:** (empty text field)
- Address:** 0.0.0.0
- Port:** 162
- SNMP Version:** SNMPv2 (dropdown menu)
- SNMPv3 User:** .. (dropdown menu with a "View" link)
- Enable:** Enable (dropdown menu)

3. Configure the SNMP Trap Manager according to the table below.

4. Click **Apply**.**Table 8-2: SNMP Trap Destinations Table Parameters Description**

Parameter	Description
'Index' [SNMPTrapDestinations_ Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [SNMPTrapDestinations_ Name]	Defines a descriptive name for the SNMP trap manager. The valid value is a string of up to 31 characters.
'Address' address [SNMPTrapDestinations_ Address]	<p>Defines the address of the remote host used as the SNMP trap manager where the device sends the traps. The valid value can be one of the following:</p> <ul style="list-style-type: none"> <li>■ IPv4 address in dotted-decimal notation (e.g., 108.10.1.255).</li> <li>■ IPv6 address in colon-separated hexadecimal (e.g., 3ffe:1900:4545:3:200:f8ff:fe21:67cf).</li> <li>■ Hostname or FQDN (e.g., mngr.corp.mycompany.com). The device sends traps to the DNS-resolved IP address.</li> </ul> <p>The default is 0.0.0.0 (i.e., not defined). <b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Depending on IP version (IPv4 or IPv6), the device uses the corresponding IP Interface (in the IP Interfaces table), assigned in <a href="#">Configuring SNMP Interfaces</a> on page 114.</li> <li>■ If you configure the address as an FQDN: <ul style="list-style-type: none"> <li>✓ The IP address version (IPv4 or IPv6) of the FQDN and IP Interface (in the IP Interfaces table) must be the same. For assigning IP Interfaces for SNMP, see <a href="#">Configuring SNMP Interfaces</a> on page 114.</li> <li>✓ To resolve the FQDN into an IP address, the device uses the DNS server configured in the IP Interfaces table of the corresponding IP Interface.</li> <li>✓ If the DNS response contains multiple DNS-resolved IP addresses, the device uses only the first IP address in the list.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>If you are using a WebSocket tunnel connection between the device and OVOC, configure the parameter to the IP address mentioned in <a href="#">Configuring WebSocket Tunnel with OVOC</a> on page 123</li> </ul>
'Port' port [SNMPTrapDestinations_ Port]	<p>Defines the port number of the remote SNMP trap manager. The device sends SNMP traps to this port. The valid value range is 100 to 4000. The default is 162.</p>
'SNMP Version' snmp-version [SNMPTrapDestinations_ Version]	<p>Defines the SNMP version of the SNMP trap manager (user).</p> <ul style="list-style-type: none"> <li>[2] <b>SNMPv2</b> = (Default) Defines the trap manager as an SNMPv2 user.</li> <li>[3] <b>SNMPv3</b> = Defines the trap manager as an SNMPv3 user.</li> </ul> <p><b>Note:</b> If you configure the parameter to <b>SNMPv3</b>, you need to select the user in the 'SNMPv3 User' parameter (below).</p>
'SNMPv3 User' snmpv3-user [SNMPTrapDestinations_ User]	<p>Assigns an SNMPv3 user from the SNMPv3 Users table (see <a href="#">Configuring SNMPv3 Users</a> on page 116) to this SNMP trap destination.</p> <p>By default, no user is assigned.</p> <p><b>Note:</b> The parameter is applicable only if you configured the 'SNMP Version' parameter (above) to <b>SNMPv3</b>.</p>
'Enable' enable [SNMPTrapDestinations_ Enable]	<p>Enables the SNMP trap manager to receive traps.</p> <ul style="list-style-type: none"> <li>[0] <b>Disable</b></li> <li>[1] <b>Enable</b> (default)</li> </ul>

## Configuring SNMP Community String for Traps

You can configure a unique password-like community string for SNMP traps. The device sends the traps with this community string.

The valid value is a string of up to 30 characters that can include only the following:

- Uppercase letters (A to Z)
- Lowercase letters (a to z)
- Numbers (0 to 9)
- Hyphen (-)

### ■ Underline ( \_ )

- The community string value cannot contain the following:
  - ✓ Wide characters
  - ✓ Spaces
- If you don't configure a trap community string, the default community string is "trapuser".

### ➤ To configure community string for traps:

1. Open the SNMP Settings page (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Settings**).
2. In the 'Trap Community String' field, type a community string:

Trap Community String

3. Click **Apply**.

## Enabling SNMP Traps for Web Activity

You can enable the device to send SNMP traps to notify of management users' activities in the Web interface. A trap is sent each time an activity is done by a user. To configure the types of Web activities that you want reported, see [Reporting Management User Activities](#) on page 1634.

### ➤ To enable traps to SNMP manager for Web activity:

1. Open the SNMP Settings page (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Settings**).
2. Select the 'Activity Trap' check box (EnableActivityTrap):

Activity Trap

3. Click **Apply**.

## Configuring SNMP Interfaces

You can assign IP Interfaces (configured in the IP Interfaces table - see [Configuring IP Network Interfaces](#) on page 159) to the device's SNMP application. You can assign an IPv4 IP Interface for SNMP over IPv4, and/or an IPv6 IP Interface for SNMP over IPv6. By default, the device uses the IPv4 OAMP IP Interface for SNMP.

➤ **To configure IP Interfaces for SNMP:**

1. Open the SNMP Settings page (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Settings**).
2. From the 'IPv4 Interface Name' drop-down list, select an IP Interface from the IP interfaces table for SNMP over IPv4.
3. From the 'IPv6 Interface Name' drop-down list, select an IP Interface from the IP interfaces table for SNMP over IPv6.

IPv4 Interface Name	<input type="text" value="O+M+C"/>
IPv6 Interface Name	<input type="text" value="IPv6-Interface"/>

4. Click **Apply**.

## Configuring SNMP Trusted Managers

The SNMP Trusted Managers table lets you configure up to five SNMP Trusted Managers. By default, the SNMP agent accepts SNMP Get and Set requests from any IP address as long as the correct community string is used in the request (see [Configuring SNMP Community Strings](#) on page 109). You can enhance security by configuring Trusted Managers, which is an IP address from which the device's SNMP agent accepts and processes SNMP requests. If no SNMP Trusted Manager is configured, any SNMP manager can access the device (as long as the community string is correct).

The following procedure describes how to configure SNMP Trusted Managers through the Web interface. You can also configure it through ini file [SNMPTrustedManagers] or CLI (configure system > snmp settings > trusted-manager).

➤ **To configure SNMP Trusted Managers:**

1. Open the SNMP Trusted Managers table (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMP Trusted Managers**).

SNMP Trusted Managers

GENERAL

Index	<input type="text" value="0"/>
Name	<input type="text"/>
IP Address	<input type="text" value="0.0.0.0"/>

2. Configure an SNMP Trusted Manager according to the table below.

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

**Table 8-3: SNMP Trusted Managers Table Parameter Descriptions**

Parameter	Description
'Index' [SNMPTrustedManagers_Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [SNMPTrustedManagers_TrustedManagerName]	Defines a descriptive name for the SNMP Trusted Manager. The valid value is a string of up to 31 characters.
'IP Address' ip-address [SNMPTrustedManagers_IpAddress]	Define the IP address of the SNMP Trusted Manager. The valid value is an IPv4 address in dotted-decimal notation. The default is 0.0.0.0.

## Configuring SNMPv3 Users

The SNMPv3 Users table lets you configure up to 10 SNMPv3 users for authentication and privacy.

- If you delete an SNMPv3 user that is associated with a trap destination (see [Configuring SNMP Trap Destinations](#) on page 111), the trap destination becomes disabled and the trap user reverts to default (i.e., SNMPv2).
- If you want to use the same SNMPv3 Users table configuration for another device, before uploading this device's configuration file (.ini) to the other device, you **must** edit the file so that the passwords ('Authentication Key' and 'Privacy Key' parameters) are in plain text.
- If you configure an SNMPv3 user(s), the device automatically deletes all configured SNMP community strings in the SNMP Community Strings table (see [Configuring SNMP Community Strings](#) on page 109). In addition, the device ignores all SNMP requests (Get and Set operations) from SNMPv2 users, sending the authenticationFailure SNMP trap.

The following procedure describes how to configure SNMPv3 users through the Web interface. You can also configure it through ini file [SNMPUsers] or CLI (`configure system > snmp settings > v3-users`).

### ➤ To configure an SNMPv3 user:

1. Open the SNMPv3 Users table (**Setup** menu > **Administration** tab > **SNMP** folder > **SNMPv3 Users**).
2. Click **New**; the following dialog box appears:

SNMPv3 Users - x

GENERAL

Index

d

User Name

Authentication Protocol

None ▼

Privacy Protocol

None ▼

Authentication Key

•

Confirm Authentication Key

Privacy Key

•

Confirm Privacy Key

Group

Read-Write ▼

3. Configure the SNMPv3 parameters according to the table below.

4. Click **Apply**.

**Table 8-4: SNMPv3 Users Table Parameters Description**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'User Name' username [Username]	Defines a name for the SNMPv3 user. <b>Note:</b> The name must be unique.
'Authentication Protocol' auth-protocol [AuthProtocol]	Defines the authentication protocol for the SNMPv3 user. <div style="margin-top: 10px;"> <div><input checked="" type="checkbox"/> [0] <b>None</b> (default)</div> <div><input checked="" type="checkbox"/> [1] <b>MD5</b></div> <div><input checked="" type="checkbox"/> [2] <b>SHA-1</b></div> <div><input checked="" type="checkbox"/> [3] <b>SHA-2-224</b></div> <div><input checked="" type="checkbox"/> [4] <b>SHA-2-256</b></div> <div><input checked="" type="checkbox"/> [5] <b>SHA-2-384</b></div> <div><input checked="" type="checkbox"/> [6] <b>SHA-2-512</b></div> </div>
'Privacy Protocol' priv-	Defines the privacy (encryption) protocol for the SNMPv3 user. <div style="margin-top: 10px;"> <div><input checked="" type="checkbox"/> [0] <b>None</b> (default)</div> </div>

Parameter	Description
protocol [PrivProtocol]	<ul style="list-style-type: none"> <li>■ [1] <b>DES</b></li> <li>■ [2] <b>3DES</b></li> <li>■ [3] <b>AES-128</b></li> <li>■ [4] <b>AES-192</b></li> <li>■ [5] <b>AES-256</b></li> </ul>
'Authentication Key' auth-key [AuthKey]	<p>Defines the authentication key (password). You can configure keys in the form of a text password or long hex string. Keys are always persisted as long hex strings and keys are localized. The value must be at least six characters (preferably 8 characters).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter cannot be configured with wide characters.</li> <li>■ To enforce the use of strong passwords (password complexity), configure the <a href="#">[[EnforcePasswordComplexity]</a> on page 1703] parameter to [1].</li> </ul>
'Confirm Authentication Key'	Retype the authentication key that you configured in the 'Authentication Key' field (above).
'Privacy Key' priv-key [PrivKey]	<p>Defines the privacy key (password). You can configure keys in the form of a text password or long hex string. Keys are always persisted as long hex strings and keys are localized.</p> <p><b>Note:</b> To enforce the use of strong passwords (password complexity), configure the <a href="#">[[EnforcePasswordComplexity]</a> on page 1703] parameter to [1].</p>
'Confirm Privacy Key'	Retype the privacy key that you configured in the 'Privacy Key' field (above).
'Group' group [Group]	<p>The group with which the SNMPv3 user is associated.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Read-Only</b></li> <li>■ [1] <b>Read-Write</b> (default)</li> <li>■ [2] <b>Trap</b></li> </ul> <p><b>Note:</b> All groups can be used to send traps.</p>

## Customizing SNMP Alarm Severity

The Alarms Customization table lets you configure up to 150 Alarm Customization rules. The table allows you to customize the severity levels of the device's SNMP trap alarms.

The table also allows you to disable (*suppress*) specific alarms all together, suppress an alarm with a specific severity level, or suppress a specific alarm sent from a specific entity (e.g., IP Group 2).

For example, by default, when an alarm cannot be entered in the Active Alarms table due to it being full, the device sends the acActiveAlarmTableOverflow alarm with major severity level. By using this table, you can customize this alarm and change the severity level to warning.

- When you add a rule to the table, it's immediately applied to all relevant active alarms in the Active Alarms table (see [Viewing Active Alarms](#) on page 1454).
- If you added a rule and it affected currently active alarms (i.e., changed their severity level) and you then later delete the rule, the customized severity level of these active alarms remain.
- If you have customized an alarm that has subsequently been raised by the device and you then delete the rule when the alarm is still active, the device doesn't send the alarm again for that instance. For example, assume that you customize the severity of the acBoardEthernetLinkAlarm alarm to **Warning** and the Ethernet cable is subsequently disconnected. If you then delete the rule while this condition still exists (i.e., cable still disconnected), the device doesn't re-send the acBoardEthernetLinkAlarm alarm (with the default severity level -- Major or Minor).
- If you configure multiple Alarm Customization rules for the **same** alarm, out of all these same rules the device applies only the rule that you configured first (i.e., listed highest in the table -- with lowest index) and ignores the others.
- After an HA switchover, all disabled (**Suppressed**) alarms are restored (not suppressed).

The following procedure describes how to customize alarm severity levels through the Web interface. You can also configure it through ini file [AlarmSeverity] or CLI (`configure system > snmp alarm-customization`).

### ➤ To customize SNMP alarm severity levels:

1. Open the Alarms Customization table (**Setup** menu > **Administration** tab > **SNMP** folder > **Alarm Customization**).

Alarms Customization [acACDThresholdAlarm] - x

GENERAL

Index	<input style="width: 80%;" type="text" value="q"/>
Name	<input style="width: 80%;" type="text" value="acACDThresholdAlarm"/>
Entity ID	<input style="width: 80%;" type="text"/>
Original Severity	<input style="width: 80%;" type="text" value="Default"/>
Customized Severity	<input style="width: 80%;" type="text" value="Indeterminate"/>

2. Configure a rule according to the parameters described in the table below.

3. Click **Apply**.

**Table 8-5: Alarms Customization Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines the SNMP alarm that you want to customize. <b>Note:</b> The CLI and ini file use the last digits of the alarm's OID as the name. For example, configure the parameter to "12" for the acActiveAlarmTableOverflow alarm (OID is 1.3.6.1.4.15003.9.10.1.21.2.0.12). For more information on alarm OIDs, refer to the document <a href="#">SBC-Gateway Series SNMP Alarm Reference Guide</a> .
'Entity ID' entity-id [EntityID]	Defines the specific entity (e.g., port number or IP Group index) for which the alarm was sent. The entity ID appears in the alarm source after the hash (#) symbol. For example, "2" in the Board#1/IPGroup#2 alarm indicates that the alarm was sent for IP Group index 2 in the IP Groups table.  The valid value can be a single number (e.g., 4), multiple numbers separated by commas (e.g., 4,5,8), or a number range (e.g., 4-8). The value can be a combination of single numbers and ranges (e.g., 4,5,6-20).  <b>Note:</b> If not configured, the rule applies to all alarms of the type specified using the 'Name' parameter (above), regardless of entity.
'Original Severity' alarm-original-severity [OriginalSeverity]	Defines the original severity level of the alarm, according to the MIB.  ■ [0] <b>Default</b> = (Default) All supported severity levels of

Parameter	Description
	<p>the alarm. If you select this option, the alarm and its severity depends on the settings of the 'Original Severity' parameter:</p> <ul style="list-style-type: none"> <li>✓ If configured to <b>Suppressed</b>, the device doesn't send the alarm at all.</li> <li>✓ If configured to any value other than <b>Suppressed</b>, the device always sends the alarm with the configured severity (regardless of condition).</li> </ul> <ul style="list-style-type: none"> <li>■ [1] <b>Indeterminate</b></li> <li>■ [2] <b>Warning</b></li> <li>■ [3] <b>Minor</b></li> <li>■ [4] <b>Major</b></li> <li>■ [5] <b>Critical</b></li> </ul>
<p>'Customized Severity' alarm-customized-severity [CustomizedSeverity]</p>	<p>Defines the new (customized) severity of the alarm. This severity replaces the alarm's original severity that you specified using the 'Original Severity' parameter. For example, if you want to change the severity of the acCertificateExpiryAlarm alarm from minor to major, then configure the 'Original Severity' parameter to <b>Minor</b> and the 'Customized Severity' parameter to <b>Major</b>.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Suppressed</b> = Disables (suppresses) the alarm or a specified severity, depending on the 'Original Severity' parameter:</li> <li>✓ To suppress an alarm: Configure the 'Original Severity' parameter to <b>Default</b>, or if the alarm has only one severity level, configure the 'Original Severity' parameter to this severity. For example, as the acBoardConfigurationError alarm is only sent with critical severity, configure the 'Original Severity' parameter to <b>Critical</b>.</li> <li>✓ To suppress the sending of a specific alarm severity: If the alarm has multiple severity levels (based on conditions), configure the 'Original Severity' parameter to the severity that you don't want the device to send. For example, if you don't want the device to send the acProxyConnectionLost alarm when its' severity is</li> </ul>

Parameter	Description
	<p>minor, configure the 'Original Severity' parameter to <b>Minor</b>.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Indeterminate</b> (default)</li> <li>■ [2] <b>Warning</b></li> <li>■ [3] <b>Minor</b></li> <li>■ [4] <b>Major</b></li> <li>■ [5] <b>Critical</b></li> </ul>

## Configuring SNMP for OVOC Connectivity

Connection between the device and OVOC is through SNMP. Once connected, the device can send SNMP traps to OVOC, and OVOC can perform various operations on the device such as maintenance actions, and fault and performance management.

- Make sure that the SNMP settings on the device and on OVOC are **identical**.
- OVOC uses the following default settings:
  - ✓ Trap port: **162**.
  - ✓ SNMPv2: **public** for the read-community string, **private** for read-write community string, and **trapuser** for the trap community string.
  - ✓ SNMPv3: **OVOCUser** for user name; **SHA-1** for authentication protocol; **AES-128** for privacy protocol; **123456789** for the 'Authentication Key' and 'Privacy Key' password.
- If the device is located behind NAT and you have added it to OVOC by serial number or by auto-detection, you also need to configure (through ini file) the device to send NAT keep-alive traps to the OVOC port to keep the NAT pinhole open for SNMP messages sent from OVOC to the device:
  - ✓ [SendKeepAliveTrap] = [1]
  - ✓ [KeepAliveTrapPort] = [161]
  - ✓ [NatBindingDefaultTimeout] = [30]
- When the device operates in High-Availability (HA) mode and it sends alarms to OVOC, the name of the device as configured by the 'HA Device Name' parameter is displayed at the beginning of the alarm description in OVOC, for example, "(SBCSITE01): Proxy lost. looking for another proxy". However, the name is not displayed for the alarms retrieved (from the device's Active Alarms table) when OVOC **initially** connects to the device.

### ➤ To configure SNMP for device-OVOC connectivity:

1. Make sure that SNMP is enabled (see [Enabling or Disabling SNMP](#) on page 108).
2. Configure the local SNMP port (for Get/Set commands) on the device to 161 (default), as described in [Configuring SNMP Get / Set Port](#) on page 108.

3. Configure an SNMPv2 or SNMPv3 user:
  - **For SNMPv2 user:**
    - i. Configure read-only and read-write community strings ([Configuring SNMP Community Strings](#) on page 109).
    - ii. Configure the community string for traps (see [Configuring SNMP Community String for Traps](#) on page 113).
  - **For SNMPv3 users:** Configure an SNMPv3 user (see [Configuring SNMPv3 Users](#) on page 116).
4. Configure the device to send its traps to OVOC acting as an SNMP Manager (see [Configuring SNMP Trap Destinations](#) on page 111).
5. If the device is located behind NAT and you have added the device to OVOC by its serial number or using auto-detection, you also need to configure (through ini file) the device to send NAT keep-alive traps to the OVOC port to keep the NAT pinhole open for SNMP messages sent from OVOC to the device:
  - a. Enable the sending of NAT keep-alive traps to OVOC, by configuring the [SendKeepAliveTrap] parameter to [1].
  - b. Define the OVOC port to where the device sends the NAT keep-alive traps, by using the [KeepAliveTrapPort] parameter.
  - c. Define the interval between each sent NAT keep-alive trap, by using the [NatBindingDefaultTimeout] parameter.
6. Restart the device with a save-to-flash for your settings to take effect.

## Configuring WebSocket Tunnel with OVOC

When OVOC is deployed in a public cloud environment (e.g., Amazon Web Services), it can manage devices that are located **behind NAT**, by implementing WebSocket tunneling (over HTTP/S). All communication and management traffic (e.g., HTTP-based file download, NTP, syslog, debug recording, and SNMP) between the device and OVOC flows through this WebSocket tunnel. In this tunneling application, the device is the WebSocket client and OVOC is the WebSocket server.

WebSocket tunneling has many advantages over the alternative method for connecting OVOC to the device when located behind NAT (refer to the document [One Voice Operations Center IOM Manual](#) for more information). WebSocket tunneling easily resolves NAT traversal problems and requires minimal amount of configuration (e.g., no need for port forwarding and no need for firewall settings to allow certain traffic).

The WebSocket tunnel connection between the device and OVOC is secure (HTTPS). When the device initiates a WebSocket tunnel connection, it verifies that the TLS certificate presented by OVOC is signed by one of the CAs in the trusted root store of its default TLS Context (ID #0). The device authenticates itself with OVOC using a username and password. These must be the same credentials as configured on OVOC.

By default, the device establishes the WebSocket connection through its default IPv4 OAMP IP interface, but if you want you can associate a different IP Interface. The device keeps the WebSocket tunnel connection open (i.e., persistent), allowing it to send and receive future management traffic through it. The connection only closes before the device (or OVOC) restarts.

- WebSocket tunneling with OVOC for that is Microsoft Azure, Amazon AWS, VMware, or Microsoft Hyper-V cloud platforms To check if other cloud platforms are supported, refer to the [OVOC documentation](#).
- If you configure the address of the WebSocket tunnel server (see the 'OVOC WebSocket Tunnel Server Address' parameter below) as a domain name, you also need to configure the address of the DNS server that you want to use for resolving the domain name into an IP address. This is configured in the IP Interfaces table for the associated IP Interface (see [Configuring IP Network Interfaces](#) on page 159).
- If you configure WebSocket tunneling with OVOC, the IP address **169.254.0.1** must not be configured for any IP Interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
- If you configure WebSocket tunneling with OVOC, the SBC Configuration Wizard (see [SBC Configuration Wizard](#) on page 1424) is not supported (and not available in the Web interface).
- To configure WebSocket tunneling on OVOC, refer to the document [One Voice Operations Center IOM Manual](#).

The following procedure describes how to configure WebSocket tunneling on the device through the Web interface. You can also configure it through CLI (`configure network > ovoc-tunnel-settings`).

➤ **To configure WebSocket tunneling with OVOC on the device:**

1. Configure an SNMP trap manager with IP address 169.254.0.1 (see [Configuring SNMP Trap Destinations](#) on page 111).

IP address 169.254.0.1 represents the OVOC server in the WebSocket tunnel overlay network.

2. For sending Quality of Experience (QoE) voice metric reports to OVOC, open the Quality of Experience Settings table (see [Reporting QoE to OVOC](#) on page 523), and then configure the 'Primary OVOC Address' parameter to IP address 169.254.0.1.
3. Obtain the OVOC server's default certificate (trusted root certificate) for Managed Devices, and then import (see [Importing Certificates into Trusted Root CA Certificate Store](#) on page 244) the certificate into the device's Trusted Root store of the default TLS Context (ID #0).
4. Open the Web Service Settings page (**Setup** menu > **IP Network** tab > **Web Services** folder > **Web Service Settings**), and then under the OVOC Tunnel group, configure the following parameters:

OVOC TUNNEL	
OVOC WebSocket Tunnel Server Address	<input type="text" value="0.0.0.0"/> ⚡
Interface Name	<input type="text" value="--"/> View ⚡
Path	• <input type="text" value="tun"/> ⚡
Username	• <input type="text" value="VPN"/> ⚡
Password	<input type="password" value="....."/> ⚡
Secured (HTTPS)	<input checked="" type="checkbox"/> ⚡
Verify Certificate	• <input type="checkbox"/> ⚡
Tunnel Connected	Not Configured
Tunnel IP Address	Not Applicable

- a. In the 'OVOC WebSocket Tunnel Server Address' field [WSTunServer], enter the IP address or hostname (FQDN) of the OVOC server. If you configure the parameter to a hostname, the device uses the DNS server configured in [Configuring a DNS Server for HTTP Services](#) on page 471 to resolve it into an IP address. If you use a hostname, the device checks that the hostname matches the certificate's Subject Name.
  - b. From the 'Interface Name' drop-down list [WSTunInterfaceName], select the device's IP Interface for the WebSocket tunnel. If not specified, the device uses the default OAMP IP Interface.
  - c. In the 'Path' [WSTunServerPath] field, enter "tun" (without quotation marks) to match the default OVOC configuration.
  - d. In the 'Username' [WSTunUsername] field, enter the WebSocket Tunnel username configured in OVOC. The default username is "VPN" (without quotation marks).
  - e. In the 'Password' [WSTunPassword] field, enter the WebSocket Tunnel password configured in OVOC. The default password is "123456" (without quotation marks).
  - f. Select the 'Secured (HTTPS)' check box [WSTunSecured] to enable secure (HTTPS) transport for the WebSocket tunnel connection.
  - g. Select the 'Verify Certificate' check box [WSTunVerifyPeer] to enable the device to verify the TLS certificate presented by OVOC during the establishment of the WebSocket tunnel connection.
5. Restart the device with a save-to-flash for your settings to take effect.

You can view the status of the WebSocket connection in the following read-only fields on the Web Service Settings page (see Step 4):

■ **'Tunnel Connected':** Displays the connection status of the WebSocket tunnel:

- "Not Configured"
- "Not Connected"

- "Connected"
- "Re-Connected"
- **'Tunnel IP Address':** Displays the IP address allocated to the device by OVOC through the WebSocket tunnel.

## 9 INI File-Based Management

You can configure the device through an ini file, which is a text-based file with an \*.ini file extension name, created using any standard text-based editor such as Notepad. Once you have created an ini file with all your configuration settings, you need to install (upload) it to the device to apply the configuration. For a list of the *ini* file parameters, see [Configuration Parameters Reference](#) on page 1701.

### INI File Format

There are two types of *ini* file parameters:

- Individual parameters - see [Configuring Individual ini File Parameters](#) below
- Table parameters - see [Configuring Table ini File Parameters](#) below

### Configuring Individual ini File Parameters

The syntax for configuring individual *ini* file parameters in the ini file is as follows:

- An optional, subsection name (or group name) enclosed in square brackets "[...]". This is used to conveniently group similar parameters by their functionality.
- Parameter name, followed by an equal "=" sign and then its value.
- Comments must be preceded by a semicolon ";".

```
[optional subsection name]
parameter name = value
parameter name = value
; this is a comment line
```

```
; for example:
[System Parameters]
SyslogServerIP = 10.13.2.69
EnableSyslog = 1
```

For general *ini* file formatting rules, see [Syntax Rules for the ini File](#) on page 129.

### Configuring Table ini File Parameters

Table ini file parameters allow you to configure tables, which include multiple parameters (*columns*) and row entries (*indices*). The table ini file parameter is composed of the following elements:

- **Table title:** The name of the table in square brackets, e.g., [MY\_TABLE\_NAME].

- **Format line:** Specifies the columns of the table (by their string names) that are to be configured.
  - The first word of the Format line must be "FORMAT", followed by the Index field name and then an equal "=" sign. After the equal sign, the names of the columns are listed.
  - Columns must be separated by a comma ",".
  - The Format line must only include columns that can be modified (i.e., parameters that are not specified as read-only). An exception is Index fields, which are mandatory.
  - The Format line must end with a semicolon ";".
- **Data line(s):** Contain the actual values of the columns (parameters). The values are interpreted according to the Format line.
  - The first word of the Data line must be the table's string name followed by the Index field.
  - Columns must be separated by a comma ",".
  - A Data line must end with a semicolon ";".
- **End-of-Table Mark:** Indicates the end of the table. The same string used for the table's title, preceded by a backslash "\", e.g., [\MY\_TABLE\_NAME].

The following displays an example of the structure of a table ini file parameter:

```
[Table_Title]
; This is the title of the table.
FORMAT Index = Column_Name1, Column_Name2, Column_Name3;
; This is the format line.
Index 0 = value1, value2, value3;
Index 1 = value1, value 2, value3;
; These are the data lines.
[\Table_Title]
; This is the end-of-the-table-mark.
```

- The table ini file parameter formatting rules are listed below:
- Indices (in both the Format and the Data lines) must appear in the same order. The Index field must never be omitted.
- The Format line can include a subset of the configurable fields in a table. In this case, all other fields are assigned with the pre-defined default values for each configured line.
- The order of the fields in the Format line isn't significant (as opposed to the Index fields). The fields in the Data lines are interpreted according to the order specified in the Format line.
- The order of the Data lines is insignificant.

- Data lines must match the Format line, i.e., it must contain exactly the same number of Indices and Data fields and must be in exactly the same order.
- A row in a table is identified by its table name and Index field. Each such row may appear only once in the *ini* file.
- Table dependencies: Certain tables may depend on other tables. For example, one table may include a field that specifies an entry in another table. This method is used to specify additional attributes of an entity, or to specify that a given entity is part of a larger entity. The tables must appear in the order of their dependency (i.e., if Table X is referred to by Table Y, Table X must appear in the *ini* file before Table Y).

The table below displays an example of a table ini file parameter:

```
[ SNMPUsers ]
FORMAT Index = Username, AuthProtocol, PrivProtocol, AuthKey, PrivKey,
Group;
SNMPUsers 0 = "John", 0, 0, "$1$rIE=", "$1$rIE=", 1;
SNMPUsers 1 = "Sue", 0, 0, "$1$rIE=", "$1$rIE=", 1;
[ \SNMPUsers ]
```

Don't include read-only parameters in table ini file parameters. This may cause an error when uploading the file to the device.

## Syntax Rules for the ini File

The *ini* file must adhere to the following formatting rules:

- The *ini* file name must not include hyphens "-" or spaces; if necessary, use an underscore "\_" instead.
- Lines beginning with a semi-colon ";" are ignored. These can be used for adding remarks in the *ini* file.
- A carriage return (i.e., Enter) must be done at the end of each line.
- The number of spaces before and after the equals sign "=" is irrelevant.
- Subsection names for grouping parameters are optional.
- If there is a syntax error in the parameter name, the value is ignored.
- Syntax errors in the parameter's value can cause unexpected errors (parameters may be set to the incorrect values).
- Parameter string values that denote file names (e.g., CallProgressTonesFileName) must be enclosed with inverted commas, e.g., CallProgressTonesFileName = 'cpt\_usa.dat'.
- The parameter name is not case-sensitive.
- The parameter value is not case-sensitive, except for coder names.

- The *ini* file must end with at least one carriage return.

## Methods for Configuring an ini File

There are different methods that you can use for configuring an ini file before you upload it to the device.

- Modifying the device's current ini file: This method is recommended if you mainly need to change the settings of parameters that you have previously configured.
  - a. Save the device's current configuration as an *ini* file on your computer, using the Web interface (see [Saving Configuration](#) on page 1332).
  - b. Open the file using a text file editor, and then modify the *ini* file as required.
  - c. Save and close the file.
  - d. Upload the file to the device.
- Creating a new ini file that includes only updated configuration:
  - a. Open a text file editor such as Notepad.
  - b. Add only the required parameters and their settings.
  - c. Save the file with the ini file extension name (e.g., myconfiguration.ini).
  - d. Upload the file to the device.

For uploading ini files to the device, see [Uploading an ini File to Device](#) below.

- If you save an ini file from the device and a table row is configured with invalid values, the ini file displays the row prefixed with an exclamation mark (!), for example:

!CpMediaRealm 1 = "ITSP", "Voice", "", 60210, 2, 6030, 0, "", "";

- To restore the device to default settings through the *ini* file, see [Restoring Factory Defaults](#) on page 1437.

## Uploading an ini File to Device

You can upload an *ini* file to the device using the following methods:

### ■ CLI:

- Configuration:
  - ◆ To apply the parameter settings of the file and restore parameters that are not included in the file to default settings:

```
# copy ini-file from <URL>
```

- ◆ To apply the parameter settings of the file and keep the current settings of parameters that are not included in the file:

```
# copy incremental-ini-file from <URL>
```

#### ■ Web interface:

- Auxiliary Files page (see [Uploading Auxiliary Files](#) on page 1347): The device updates its configuration according to the loaded ini file while preserving the remaining current configuration.
- Configuration File page (see [Downloading and Uploading Configuration Files](#) on page 1386): The device updates its configuration according to the loaded ini file and applies default values to parameters that were not included in the loaded ini file.

When you upload an ini file, its configuration settings are saved to the device's non-volatile memory (flash).

Before you upload an *ini* file, make sure that the file extension name is *\*.ini*.

## Secured Encoded ini File

The *ini* file contains sensitive information that is required for the functioning of the device. The file may be uploaded to the device using HTTP. These protocols are not secure and are vulnerable to potential hackers. To overcome this security threat, the AudioCodes DConvert utility allows you to binary-encode (encrypt) the *ini* file before uploading it to the device. For more information, refer to the [DConvert Utility User's Guide](#).

If you save an ini file from the device to a folder on your PC, an *ini* file that was uploaded to the device encoded is saved as a regular *ini* file (i.e., unencoded).

## INI Viewer and Editor Utility

AudioCodes INI Viewer & Editor utility simplifies viewing and editing of the device's downloaded Configuration file (\*.ini). You can download the utility from AudioCodes [website](#). Once installed, every time you download the Configuration file (see [Downloading or Uploading ini File](#) on page 1386), it's automatically opened by this utility.

For more information, refer to the *INI Viewer & Editor User's Guide*, by clicking [here](#).

## 10 REST-Based Management

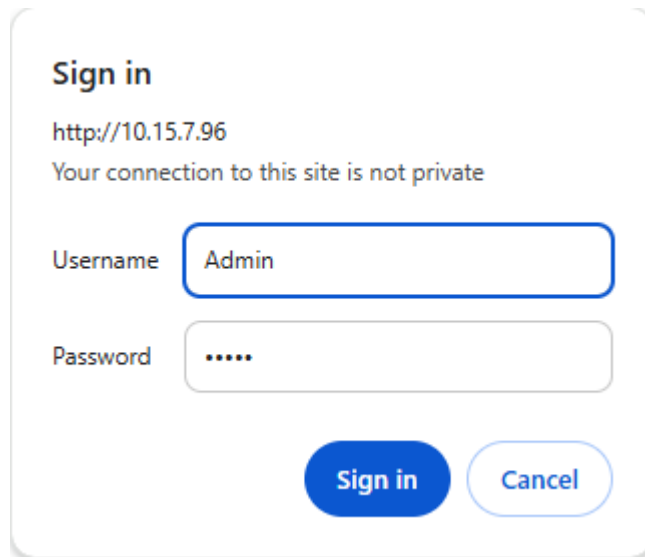

You can manage the device through the Representational State Transfer (REST) architecture. REST is a Web-based access service, allowing you to access the device's management interface over HTTP/S. Developers can use the device's REST API to integrate the device into their solution and allow administrators to perform management and configuration tasks through automation scripts. The REST API also displays performance monitoring counters.

The REST API relies on a simple pre-defined URL path (**<device's OAMP IP address>/api/v1**) through which device resources can be accessed. Each resource represents a specific device management element (e.g., file upload), state object (e.g., alarms), or maintenance action (e.g., restart). The REST API uses the standard HTTP/1.1 protocol. Standard HTTP methods (GET, PUT, POST and DELETE) are used to read the resource's state and to create, update, and delete the resources, respectively. Resource state is described in JSON format and included in the HTTP request or response bodies.

Basic authentication using your login username and password can be used to access the device's REST interface. However, for security, it's recommended to secure REST traffic using HTTPS. For more information, see [Configuring Secured \(HTTPS\) Web and REST Access](#) on page 75.

### ➤ To access device's REST API interface:

1. Use one of the following methods:
  - **Third-party REST API client (e.g., Postman):**
    - i. Configure the top-most endpoint or collection with device's base URL (e.g., `https://10.15.7.96/api/v1/`).
    - ii. Configure the required authorization (e.g., basic authentication, bearer token, or mTLS).
  - **Web browser:**
    - i. Start your web browser, and then in the URL field, enter the device's address followed by `"/api/v1"` (e.g., `10.15.7.96/api/v1`); you're prompted to log in with your username and password:

**Sign in**

http://10.15.7.96

Your connection to this site is not private

Username

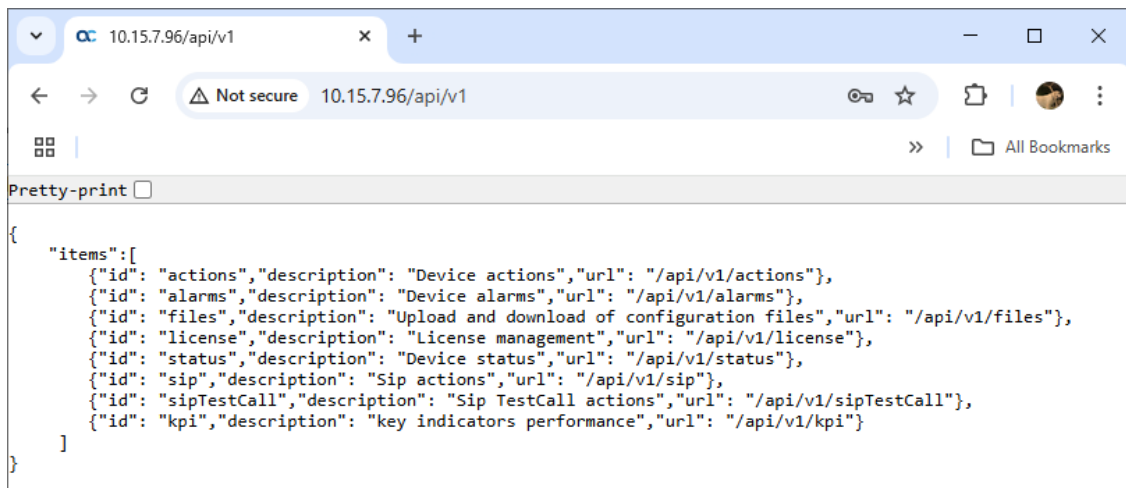

Password

**Sign in** Cancel

When using mTLS, you're not prompted for your credentials.

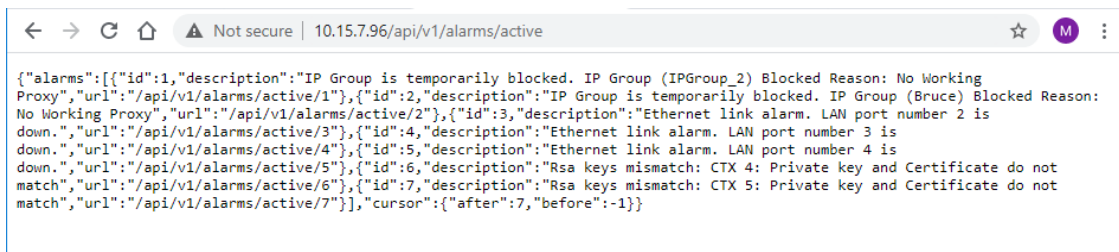

- a. Enter your credentials, and then click **Sign in**; the device's REST interface appears, showing the URL paths of the different resource items:

2. Access the required resource item using the shown URL. For example, to access the device's alarms resource, append `/alarms` to the URL (i.e. `10.15.7.96/api/v1/alarms`). Some items have sub-resources such as the alarms item. When you access the alarms item, the URLs to the active and history alarms resources are shown.

3. To access a sub-resource (e.g., active alarms) if exists, use the shown URL. For example, to access the active alarms resource, append `/active` to the URL (i.e. `10.15.7.96/api/v1/alarms/active`).

```
{
  "alarms": [
    {
      "id": 1,
      "description": "IP Group is temporarily blocked. IP Group (IPGroup_2) Blocked Reason: No Working Proxy",
      "url": "/api/v1/alarms/active/1"
    },
    {
      "id": 2,
      "description": "IP Group is temporarily blocked. IP Group (Bruce) Blocked Reason: No Working Proxy",
      "url": "/api/v1/alarms/active/2"
    },
    {
      "id": 3,
      "description": "Ethernet link alarm. LAN port number 2 is down.",
      "url": "/api/v1/alarms/active/3"
    },
    {
      "id": 4,
      "description": "Ethernet link alarm. LAN port number 3 is down.",
      "url": "/api/v1/alarms/active/4"
    },
    {
      "id": 5,
      "description": "Ethernet link alarm. LAN port number 4 is down.",
      "url": "/api/v1/alarms/active/5"
    },
    {
      "id": 6,
      "description": "Rsa keys mismatch: CTX 4: Private key and Certificate do not match",
      "url": "/api/v1/alarms/active/6"
    },
    {
      "id": 7,
      "description": "Rsa keys mismatch: CTX 5: Private key and Certificate do not match",
      "url": "/api/v1/alarms/active/7"
    }
  ],
  "cursor": {
    "after": 7,
    "before": -1
  }
}
```

- If you know the URL of the resource, instead of accessing each resource menu, you can access it directly using the full URL path (e.g., **/api/v1/alarms/active**).
- For more information on REST API, refer to the document [REST API for SBC-Gateway-MSBR Devices](#).

# Part III

## General System Settings

# 11 Date and Time

The device's internal clock (date and time) can be set using one of the following methods:

- Manually (see [Configuring Date and Time Manually](#) on the next page)
- Automatically synchronized using a third-party, remote Simple Network Time Protocol (SNTP) server (see [Synchronizing Date and Time through SNTP](#) on page 138)
- Automatically synchronized using the SIP Date header (see [Synchronizing Date and Time through SIP](#) on page 140)

For automatic synchronization, NTP takes highest preference, and then SIP Date header. For example, if you enable NTP, the device ignores the SIP Date header settings. If you do enable multiple synchronization methods, the device sends the SNMP alarm acClockConfigurationAlarm to notify you of this configuration scenario.

## Viewing Date and Time

You can view the date and time of the device and the method that it uses to obtain or synchronize its date and time.

### ➤ To view date and time:

1. Open the Time & Date page (**Setup** menu > **Administration** tab > **Time & Date**).
2. Under the Time group, the following read-only fields are displayed:

#### TIME

Local Time	18 Dec, 2022 11:41:46
UTC Time	18 Dec, 2022 10:41:46
Time Synchronization Source	Manual

- 'Local Time': Displays the date and time of the geographical location in which the device is deployed.
- 'UTC Time': Displays the UTC time (without offset time or daylight saving), or date and time automatically synchronized through NTP or SIP Date header.
- 'Time Synchronization Source': Indicates the method used by the device to obtain and synchronize its date and time:
  - ◆ "Manual": Date and time is configured manually (see [Configuring Date and Time Manually](#) on the next page).

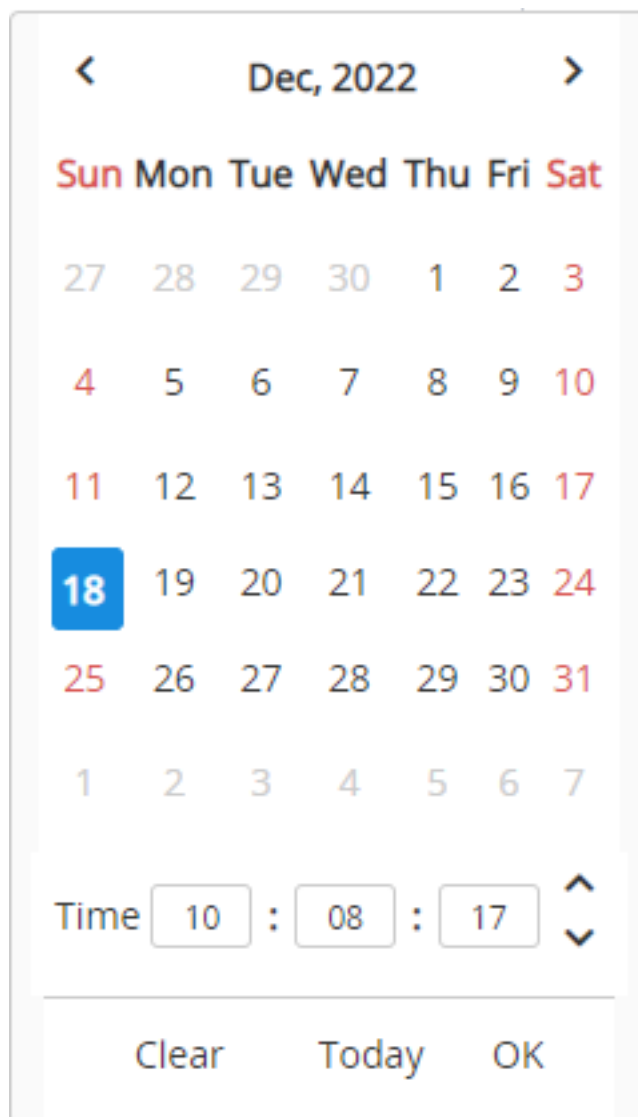

- ◆ "NTP": Date and time is automatically obtained and synchronized from an Simple Network Time Protocol (SNTP) server (see [Synchronizing Date and Time through SNTP](#) on the next page).
- ◆ "Date Header": Date and time is automatically obtained and synchronized from the SIP Date header (see [Synchronizing Date and Time through SIP](#) on page 140).

## Configuring Date and Time Manually

You can manually configure the date and time of the device instead of using an NTP server (as described in [Synchronizing Date and Time through SNTP](#) on the next page).

### ➤ To manually configure date and time through Web interface:

1. Open the Time & Date page (**Setup** menu > **Administration** tab > **Time & Date**).
2. Under the Set Time group, click **Set Local Time**; the following calendar and time dialog box appears:

A date and time selection dialog box. At the top, it shows navigation arrows, the month 'Dec, 2022', and another navigation arrow. Below is a calendar grid with days of the week (Sun, Mon, Tue, Wed, Thu, Fri, Sat) in red. The date '18' is highlighted in a blue box. Below the calendar is a 'Time' section with three input boxes containing '10', '08', and '17', separated by colons. To the right of the time boxes are up and down arrows. At the bottom are three buttons: 'Clear', 'Today', and 'OK'.

3. If you want the current date and time, click **Today**; otherwise, select a specific date and time (HH:MM:SS).
4. Click **OK**; the dialog box closes.
5. Click **Apply**; the date and time is displayed in the 'Local Time' read-only field under the Time group.

If you do a hardware restart, the date and time are returned to default values and therefore, you should update the date and time.

## Synchronizing Date and Time through SNTP

The device's Simple Network Time Protocol (SNTP) client functionality generates requests and reacts to the resulting responses using the NTP Version 3 protocol definitions (according to RFC 1305). Through these requests and responses, the device (acting as an NTP client), synchronizes its date and time to a time source within the network, thereby eliminating any potential issues

should the local clock "drift" during operation. The NTP client follows a simple process in managing system time: 1) the NTP client requests an NTP update, 2) receives an NTP response and then 3) updates the local clock based on an NTP server within the network. The client requests a time update from the user-defined NTP server (IP address or FQDN) at a user-defined update interval. Typically, the update interval is every 24 hours based on when the device was restarted.

You can also configure the device to authenticate and validate NTP messages received from the NTP server. Authentication is done using an authentication key with the MD5 cryptographic hash algorithm. If you enable this feature, the device ignores NTP messages received without authentication.

The following procedure describes how to configure SNTP through the Web interface. For detailed descriptions of the configuration parameters, see [Clock \(Date and Time\) Synchronization Parameters](#) on page 1759.

➤ **To configure SNTP through the Web interface:**

1. Open the Time & Date page (**Setup** menu > **Administration** tab > **Time & Date**), and then scroll down to the NTP Server group:

**NTP SERVER**

<b>Enable NTP</b>	<input checked="" type="checkbox"/>
NTP Interface	• #0 [O+M+C] <span style="float: right; color: #007bff; text-decoration: underline;">View</span>
<b>Primary NTP Server Address (IP or FQDN)</b>	<input type="text" value="0.0.0.0"/>
<b>Secondary NTP Server Address (IP or FQDN)</b>	<input type="text" value="0.0.0.0"/>
<b>NTP Update Interval</b>	Hours: <input type="text" value="24"/> Minutes: <input type="text" value="0"/>
NTP Authentication Key Identifier	<input type="text" value="0"/>
NTP Authentication Secret Key	<input type="password" value="....."/> 

2. Select the 'Enable NTP' check box to enable SNTP.
3. From the 'NTP Interface' drop-down list, select an IP Interface from the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159) that you want to use for NTP communication. By default, the IPv4 OAMP interface is assigned.
4. Configure the NTP server address:
  - In the 'Primary NTP Server Address' [NTPServerIP] field, configure the primary NTP server's address (IPv4 or IPv6, or FQDN).
  - (Optional) In the 'Secondary NTP Server Address' [NTPSecondaryServerIP] field, configure the address of the backup NTP server.
5. In the 'NTP Updated Interval' [NTPUpdateInterval] field, configure the periodic time to synchronize the date and time with the NTP server.

6. Configure NTP message authentication:
  - In the 'NTP Authentication Key Identifier' field, configure the NTP authentication key identifier.
  - In the 'NTP Authentication Secret Key' field, configure the secret authentication key shared between the device and the NTP server.
7. Click **Apply**.
8. Verify that the device has received the correct date and time from the NTP server. The date and time is displayed in the 'UTC Time' read-only field under the Time group (see [Viewing Date and Time](#) on page 136).

- The IP address version (IPv4 or IPv6) of the assigned IP Interface and the NTP server's address must be the same.
- If the device doesn't receive a response from the NTP server, it polls the NTP server for 10 minutes. If there is still no response after this duration, the device declares the NTP server as unavailable and sends the SNMP alarm acNTPServerStatusAlarm. The failed response could be due to incorrect configuration.
- Synchronization by NTP takes highest preference, then by SIP Date header, and only then by PTP. For example, if you enable NTP, the device ignores the SIP Date header and PTP settings. If you do enable multiple synchronization methods, the device sends the SNMP alarm acClockConfigurationAlarm to notify you of this configuration scenario.

## Synchronizing Date and Time through SIP

You can configure the device to synchronize its internal clock (date and time) with a remote SIP endpoint (according to RFC 3261). When enabled, the device obtains the date and time from the Date header in the incoming 200 OK message received in response to a REGISTER request sent by the device. This can be any REGISTER request sent for normal SIP traffic handling (i.e., it's not a specific REGISTER message that is sent to a specific SIP server or endpoint). An example of a SIP Date header with date and time is shown below:

Date: Sat, 12 Mar 2020 23:29:00 GMT

### ➤ To configure clock synchronization through SIP:

1. Open the Time & Date page (**Setup** menu > **Administration** tab > **Time & Date**), and then scroll down to the Date Header Time Sync group:

**DATE HEADER TIME SYNC**Synchronize Time from SIP Date Header • ☒Time Synchronization Interval [sec] 

2. Select the 'Synchronize Time from SIP Date Header' [DateHeaderTimeSync] check box to enable the feature.
3. In the 'Time Synchronization Interval' [DateHeaderTimeSyncInterval] field, enter the minimum time (in seconds) between synchronization updates. For example, if configured to 8640 (24 hours) and the device receives within this 24-hour interval a SIP response to a REGISTER with the Date header, it ignores the date. Only if it receives such a header after this interval does it update its clock according to the header, and then does the next update 24 hours later.
4. Click **Apply**. When the device receives a SIP response with the Date header, it updates its clock and the date and time is displayed in the 'UTC Time' read-only field under the Time group (see [Viewing Date and Time](#) on page 136).

- The device only uses the date and time in the SIP Date header if its value is year 2016 or later.
- If you have enabled clock synchronization using an NTP server (see [Synchronizing Date and Time through SNTP](#) on page 138) and using the SIP Date header, synchronization using the NTP server takes precedence (i.e., device ignores received Date headers). When both are enabled, the device sends the SNMP alarm acClockConfigurationAlarm.
- Once a week, the device stores the clock's date and time in its flash memory. If the device is restarted, its clock is set to this stored date and time, and updated once it receives a Date header in a SIP response to a sent REGISTER message.
- Synchronization by NTP takes highest preference, and then by SIP Date header. For example, if you enable NTP, the device ignores the SIP Date header settings. If you do enable multiple synchronization methods, the device sends the SNMP alarm acClockConfigurationAlarm to notify you of this configuration scenario.

## Configuring UTC Offset or Time Zone

You can configure the time zone in which the device is deployed. This is referred to as the Coordinated Universal Time (UTC) time offset and defines how many hours the device is from Greenwich Mean Time (GMT). For example, Germany Berlin is one hour ahead of GMT (UTC/GMT +1 hour) and therefore, you would configure the offset to "1". USA New York is five hours behind GMT (UTC/GMT offset -5 hours) and therefore, you would configure the offset as a minus value "-5".

➤ **To configure UTC time zone:**

1. Open the Time & Date page (**Setup** menu > **Administration** tab > **Time & Date**), and then scroll down to the Time Zone group:

**TIME ZONE**

UTC Offset      Hours:       Minutes:

2. In the 'UTC Offset' fields (NTPServerUTCOffset), configure the time offset in relation to the UTC. For example, if your region is GMT +1 (an hour ahead), enter "1" in the 'Hours' field.
3. Click **Apply**; the updated time is displayed in the 'UTC Time' read-only field under the Time group (see [Viewing Date and Time](#) on page 136).

## Configuring Daylight Saving Time

You can apply daylight saving time (DST) to the date and time of the device. DST defines a date range in the year (summer) where the time is brought forward so that people can experience more daylight. DST applies an offset of up to 60 minutes (default) to the local time. For example, Germany Berlin has DST from 30 March to 26 October, where the time is brought forward by an hour (e.g., 02:00 to 03:00 on 30 March). Therefore, you would configure the DST offset to 60 minutes (one hour).

➤ **To configure DST through the Web interface:**

1. Open the Time & Date page (**Setup** menu > **Administration** tab > **Time & Date**), and then scroll down to the Time Zone group:

**Daylight Saving Time**     

**DST Mode**     

**Start Time**         :

**End Time**         :

**Offset [min]**     

**Day of Month Start**          :

**Day of Month End**          :

**Daylight Saving Time**

**DST Mode**

**Start Time**

**End Time**

2. Select the 'Daylight Saving Time' (DayLightSavingTimeEnable) check box to enable daylight saving.
3. From the 'DST Mode' drop-down list, select the range type for configuring the start and end dates for DST:
  - **Day of year:** The range is configured by exact date (day number of month), for example, from March 30 to October 30. If 'DST Mode' is set to **Day of year**, in the 'Start Time' (DayLightSavingTimeStart) and 'End Time' (DayLightSavingTimeEnd) drop-down lists, configure the period for which DST is relevant.
  - **Day of month:** The range is configured by month and day type, for example, from the last Sunday of March to the last Sunday of October. If 'DST Mode' is set to **Day of month**, in the 'Start Time' and 'End Time' drop-down lists, configure the period for which DST is relevant.
4. In the 'Offset' (DayLightSavingTimeOffset) field, configure the DST offset in minutes.
5. If the current date falls within the DST period, verify that it has been successful applied to the device's current date and time. You can view the device's date and time in the 'UTC Time' read-only field under the Time group (see [Viewing Date and Time](#) on page 136).

## 12 Configuring a Hostname for the Device

You can configure a hostname (FQDN) for the device, which affects the following:

- **CLI:** The device's CLI (remotely using Telnet/SSH) can be accessed (logged in) using the hostname (instead of the OAMP IP address). The CLI prompt displays the hostname instead of the device type.
- **SNMP:** The device's SNMP interface's SysName object (under MIB-2) is set to the hostname.
- **OVOC:** TLS certificates used by the device for HTTPS-based communication with AudioCodes OVOC are issued with a hostname (instead of an IP address). For certificate signing requests (CSR) with a Certification Authority (CA), the hostname is used as the Common Name (CN or Subject Name) and Subject Alternative Name (SAN). For configuring CSRs, see [Assigning CSR-based Certificates to TLS Contexts](#) on page 234.

If you configure a hostname, you also need to define it on a DNS server so that when queried, the DNS server can resolve the hostname into the device's OAMP IP address.

➤ **To configure a hostname for the device:**

1. Open the Network Settings page (**Setup** menu > **IP Network** tab > **Advanced** folder > **Network Settings**).
2. In the 'Hostname' field [Hostname], enter the hostname.

Hostname

• Site44

3. Click **Apply**.

- To configure a hostname for accessing the device's Web interface, see [Configuring a Hostname for Device's Web Interface](#) on page 87.
- For HA systems, the device-pair share the same hostname.

# Part IV

## General VoIP Configuration

## 13 Network

This section describes network-related configuration.

### Building and Viewing your Network Topology

The Network view lets you easily build and view your voice network topology entities, including IP network interfaces, Ethernet Devices (VLANs), Ethernet Groups, and physical Ethernet ports. The Network view graphically displays these entities and the associations between them, giving you a better understanding of your network topology and configuration. You can use the Network view as an alternative to configuring the entities in their respective Web pages or you can use it in combination.

#### ➤ To access the Network view:

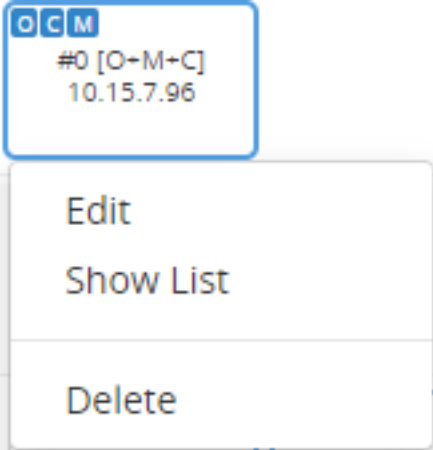

- Click the Network View home  icon (**Setup** menu > **IP Network** tab > **Network View**).

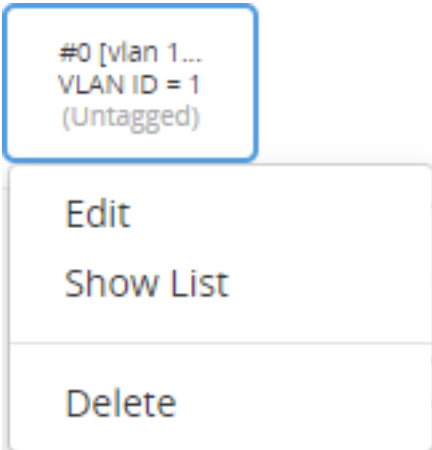

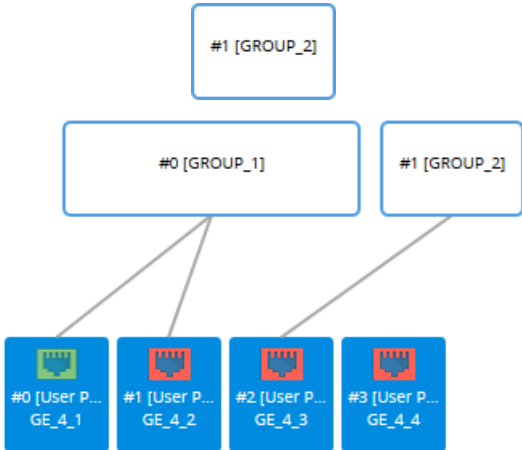

The areas of the Network view are shown in the example below and described in the subsequent table.

The figure above is used only as an example; your device may show different Ethernet Groups and Ethernet ports.

**Table 13-1: Description of Network View**

Item	Description
1	<p>Displays IP Interfaces that you configured in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159). IP Interfaces appear as icons, showing the application type ("OCM" for OAMP, "C" for Control, and "M" for Media), row index number, name, and IP address, for example:</p>  <ul style="list-style-type: none"> <li>■ <b>Edit:</b> Opens a dialog box in the IP Interfaces table to modify the IP Interface.</li> <li>■ <b>Show List:</b> Opens the IP Interfaces table, allowing you to configure IP Interfaces.</li> <li>■ <b>Delete:</b> Opens the IP Interfaces table where you are prompted to confirm deletion of the IP Interface.</li> </ul> <p><b>To add an IP Interface:</b></p> <ol style="list-style-type: none"> <li>1. Click  <b>Add IP Interface</b>; the IP Interfaces table opens with a new dialog box for adding an IP Interface to the next available index row.</li> <li>2. Configure the IP Interface as desired, and then click <b>Apply</b>; the IP Interfaces table closes and you are returned to the Network View, displaying the newly added IP Interface.</li> </ol>
2	<p>Displays configured Ethernet Devices (see <a href="#">Configuring Underlying Ethernet Devices</a> on page 156). The Ethernet Device appears as an icon, displaying the row index number, name, VLAN ID and if its tagged or untagged. If you click the icon, a drop-down menu appears, listing commands:</p>

Item	Description
	<div data-bbox="692 277 1126 725">  </div> <ul style="list-style-type: none"> <li>■ <b>Edit:</b> Opens a dialog box in the Ethernet Devices table to modify the Ethernet Device.</li> <li>■ <b>Show List:</b> Opens the Ethernet Devices table, allowing you to configure all Ethernet Devices.</li> <li>■ <b>Delete:</b> Opens the Ethernet Devices table where you are prompted to confirm deletion of the Ethernet Device.</li> </ul> <p><b>To add an Ethernet Device:</b></p> <ol style="list-style-type: none"> <li>1. Click  <b>Add VLAN</b>; the Ethernet Devices table opens with a new dialog box for adding an Ethernet Device to the next available index row.</li> <li>2. Configure the Ethernet Devices as desired, and then click <b>Apply</b>; the Ethernet Devices table closes and you are returned to the Network View, displaying the newly added Ethernet Device.</li> </ol>
3	<p>Displays configured Ethernet Groups (see <a href="#">Configuring Ethernet Port Groups</a> on page 152). The Ethernet Groups appear as icons, displaying the row index number, and name. Ethernet ports associated with Ethernet Groups are indicated by lines connecting between them, as shown in the example below:</p> <div data-bbox="647 1525 1171 1973">  </div>

Item	Description
	<p><b>To edit an Ethernet Group:</b></p> <ol style="list-style-type: none"> <li>1. Click the Ethernet Group icon, and then from the drop-down menu, choose <b>Edit</b>; the Ethernet Groups table opens with a dialog box for editing the Ethernet Group.</li> <li>2. Configure the Ethernet Group as desired, and then click <b>Apply</b>; the Ethernet Groups table closes and you are returned to the Network View.</li> </ol> <p>To open the Ethernet Groups table, click any Ethernet Group icon, and then from the drop-down menu, choose <b>Show List</b>. You can then view and edit all the Ethernet Groups in the table.</p>
4	<p>Configures and displays the device's Ethernet ports.</p> <p><b>To configure an Ethernet port:</b></p> <ol style="list-style-type: none"> <li>1. Click the required port icon, and then from the drop-down menu, choose <b>Edit</b>; the Physical Ports table opens with a dialog box for editing the Ethernet port.</li> <li>2. Configure the Ethernet Port as desired, and then click <b>Apply</b>; the Physical Ports table closes and you are returned to the Network View.</li> </ol> <p>For more information on configuring Ethernet ports, see <a href="#">Configuring Underlying Ethernet Devices</a> on page 156.</p> <p>The Ethernet ports appear as icons, displaying the row index number, description, and port string number, as shown in the example below:</p> <div data-bbox="858 1234 963 1350" data-label="Image"> </div> <p>The connectivity status of the port is indicated by the color of the icon:</p> <ul style="list-style-type: none"> <li>■  Green: Network connectivity exists through port (port connected to network).</li> <li>■  Red: No network connectivity through port (e.g., cable disconnected).</li> </ul> <p>To refresh the status indication, click the <b>Refresh Network View</b> button (described below in Item #5).</p> <p>To open the Physical Ports table, click any port icon, and then from the drop-down menu, choose <b>View List</b>. You can then view and edit all the ports in the table.</p>
5	<p>If you keep the Network view page open for a long time, you may want to click the <b>Refresh Network View</b> button to refresh the connectivity status display of the Ethernet ports.</p>

## Configuring Physical Ethernet Ports

The Physical Ports table lets you configure the device's Ethernet ports. This includes configuring port speed and duplex mode (half or full), and a brief description of the port. The table also displays the status of the port as well as the port group (*Ethernet Group*) to which the port belongs. For more information on Ethernet Groups, see [Configuring Ethernet Port Groups](#) on page 152.

The names of the ports displayed in the device's management tools (e.g., Web interface) are different to the labels of the physical ports on the chassis. The figure below shows the mapping between the two:

Figure 13-1: Ethernet Port String Names

You can also view the mapping of the ports, using the following CLI command:

```
# show network physical-port
```

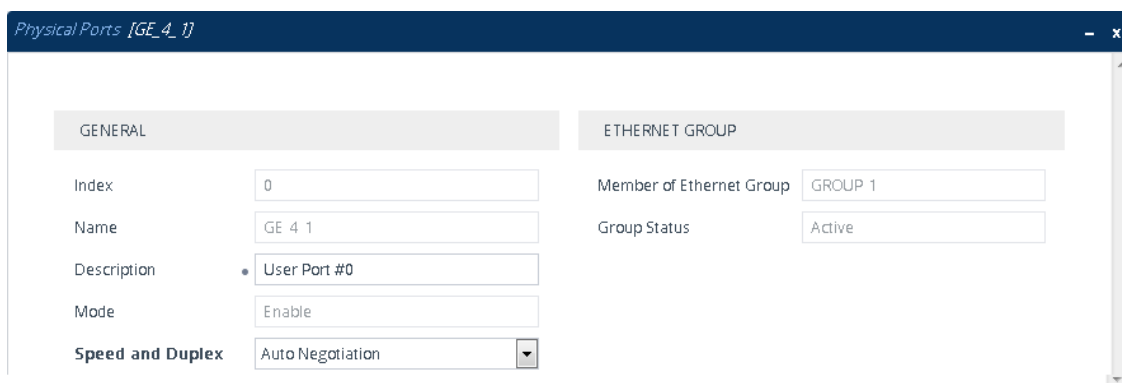

- All LAN ports have the same MAC address, which is the MAC address of the device.
- Each Ethernet Group must have a unique VLAN ID in scenarios where the ports of multiple Ethernet Groups are connected to the same switch.

The following procedure describes how to configure Ethernet ports through the Web interface. You can also configure it through ini file [PhysicalPortsTable] or CLI (`configure network > physical-port`).

### ➤ To configure the physical Ethernet ports:

1. Open the Physical Ports table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **Physical Ports**).
2. Select a port that you want to configure, and then click **Edit**; the following dialog box appears:

**Physical Ports [GE\_4\_1]**

GENERAL		ETHERNET GROUP	
Index	0	Member of Ethernet Group	GROUP 1
Name	GE 4 1	Group Status	Active
Description	User Port #0		
Mode	Enable		
Speed and Duplex	Auto Negotiation		

3. Configure the port according to the parameters described in the table below.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

**Table 13-2: Physical Ports Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index'	(Read-only) Displays the index number for the table row.
'Name' port [Port]	(Read-only) Displays the Ethernet port number. See the figure in the beginning of this section for the mapping between the GUI port number and the physical port on the chassis.
'Description' port- description [PortDescription]	Defines a description of the port. By default, the value is "User Port #<row index>". <b>Note:</b> Configure each row with a unique name.
'Mode' mode [Mode]	(Read-only) Displays the mode of the port. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b> (default)</li> </ul>
'Speed and Duplex' speed-duplex [SpeedDuplex]	Defines the speed and duplex mode of the port. <ul style="list-style-type: none"> <li>■ [0] <b>10BaseT Half Duplex</b></li> <li>■ [1] <b>10BaseT Full Duplex</b></li> <li>■ [2] <b>100BaseT Half Duplex</b></li> <li>■ [3] <b>100BaseT Full Duplex</b></li> <li>■ [4] <b>Auto Negotiation</b> (default)</li> <li>■ [6] <b>1000BaseT Half Duplex</b></li> <li>■ [7] <b>1000BaseT Full Duplex</b></li> </ul>

Parameter	Description
<b>Ethernet Group</b>	
'Member of Ethernet Group' group-member [GroupMember]	(Read-only) Displays the Ethernet Group to which the port belongs. To assign the port to a different Ethernet Group, see <a href="#">Configuring Ethernet Port Groups</a> below.
'Group Status' group-status [GroupStatus]	(Read-only) Displays the status of the port: <ul style="list-style-type: none"> <li>■ "Active": Active port. When the Ethernet Group includes two ports and their transmit / receive mode is configured to <b>REDUN_2RX_1TX</b> or <b>REDUN_2RX_2TX</b>, both ports show "Active".</li> <li>■ "Redundant": Standby (redundant) port.</li> </ul>

## Configuring Ethernet Port Groups

The Ethernet Groups table lets you configure Ethernet Groups. An Ethernet Group represents a physical Ethernet port(s) on the device. You can assign an Ethernet Group with one, two, or no ports (*members*). When two ports are assigned to an Ethernet Group, 1+1 Ethernet port redundancy can be implemented in your network. In such a configuration, one port can be active while the other standby or both ports can be active, depending on the ports' transmit (Tx) and receive (Rx) settings. This provides port redundancy within the Ethernet Group, whereby if a port is disconnected the device switches over to the other port in the Ethernet Group. If you configure an Ethernet Group with only one port, the Ethernet Group operates as a single port (no redundancy).

The Ethernet Groups table lets you configure the transmit (Tx) and receive (Rx) settings of the Ethernet ports per Ethernet Group. The Tx/Rx setting is applicable only to Ethernet Groups that contain two ports. This setting determines if both ports or only one of the ports can receive and transmit traffic.

The maximum number of Ethernet Groups that you can configure is the same as the number of Ethernet ports provided by the device. Thus, the device supports up to 12 Ethernet Groups. You can assign one or two ports to an Ethernet Group. By default, each Ethernet Group is assigned twoports (Ethernet Group 2 which is assigned only port 0/3); the other Ethernet Groups are empty. For default port assignment to Ethernet Groups, see [Configuring Physical Ethernet Ports](#) on page 150.

You can assign Ethernet ports to IP network interfaces. This is done by first configuring an Ethernet Device with the required Ethernet Group containing the port or ports (see [Configuring Ethernet Port Groups](#)). Then by assigning the Ethernet Device to the IP network interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159). This enables physical separation of network interfaces, providing a higher level of segregation of sub-networks. Equipment connected to different physical ports is not accessible to one another; the only

connection between them can be established by cross connecting them with media streams (VoIP calls).

The port names (strings) displayed in the Ethernet Groups table represent the physical ports on the device. For the mapping of these strings to the physical ports, see [Configuring Physical Ethernet Ports](#) on page 150.

- If you want to assign a port to a different Ethernet Group, you must first remove the port from its current Ethernet Group. To remove the port, configure the 'Member' field so that no port is selected or select a different port.
- As all ports have the same MAC address, you must connect each port to a different Layer-2 switch.
- When implementing 1+1 Ethernet port redundancy, each port in the Ethernet Group (port pair) must be connected to a different switch (but in the same subnet).

The following procedure describes how to configure Ethernet Groups through the Web interface. You can also configure it through ini file [EtherGroupTable] or CLI (`configure network > ether-group`).

#### ➤ To configure Ethernet Groups:

1. Open the Ethernet Groups table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **Ethernet Groups**).
2. Select the Ethernet Group that you want to configure, and then click **Edit**; the following dialog box appears:

Ethernet Groups [GROUP\_1] - x

GENERAL	
Index	0
Name	GROUP_1
Mode	REDUN_1RX_1TX
Member 1	#0 [GE_4_1] <a href="#">View</a>
Member 2	#1 [GE_4_2] <a href="#">View</a>
Active Port	GE_4_1

3. Configure the Ethernet Group according to the parameters described in the table below.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

**Table 13-3: Ethernet Groups Table Parameter Descriptions**

Parameter	Description
'Index'	(Read-only) Displays the index number for the table row.

Parameter	Description
'Name' group [EtherGroupTable_Group]	(Read-only) Displays the Ethernet Group number.
'Mode' mode [EtherGroupTable_Mode]	<p>Defines the mode of operation of the ports in the Ethernet Group. This applies only to Ethernet Groups containing two ports.</p> <ul style="list-style-type: none"> <li>■ [0] <b>NONE</b> = Select this option to remove all ports from the Ethernet Group.</li> <li>■ [1] <b>SINGLE</b> = Select this option if the Ethernet Group contains only one port.</li> <li>■ [2] <b>REDUN_1RX_1TX</b> = (Default) At any given time, only one of the ports in the Ethernet Group transmits and receives packets. If a link exists on both ports, the active one is either the first to have a link up or the lower-numbered port if both have the same link up from start.</li> <li>■ [3] <b>REDUN_2RX_1TX</b> = Both ports in the Ethernet Group can receive packets, but only one port can transmit. The transmitting port is determined arbitrarily by the device. If the selected port fails at a later stage, a switchover to the redundant port is done, which begins to transmit and receive.</li> <li>■ [4] <b>REDUN_2RX_2TX</b> = Both ports in the Ethernet Group can receive and transmit packets. This option is applicable only to the Maintenance interface when the device operates in High-Availability (HA) mode. For more information, see <a href="#">Network Topology Types and Rx/Tx Ethernet Port Group Settings</a> on page 1308.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When configured to <b>REDUN_2RX_1TX</b> or <b>REDUN_2RX_2TX</b>, you can configure an Ethernet Group with the following port members only: <ul style="list-style-type: none"> <li>✓ (GX-800C Mediant 800C Only) <b>4-port model:</b> Any two ports of GE_4_1, GE_4_2, GE_4_3 or GE_4_4. However, if the device includes OSN7, OSN8, or OSN9, then GE_4_4 can't be used as a port member.</li> <li>✓ <b>8-port model:</b></li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>Any two ports of GE_4_1, GE_4_2, or GE_4_3 (<b>not</b> GE_4_4)</li> <li>Any two ports of GE_4_5, GE_4_6, GE_4_7, or GE_4_8</li> </ul> <p>✓ <b>12-port model:</b></p> <ul style="list-style-type: none"> <li>Any two ports of GE_4_1, GE_4_2, or GE_4_3 (<b>not</b> GE_4_4)</li> <li>Any two ports of FE_5_1, FE_5_2, FE_5_3, FE_5_4, FE_5_5, FE_5_6, FE_5_7, or FE_5_8</li> </ul> <p>■ When implementing High Availability:</p> <ul style="list-style-type: none"> <li>✓ It's recommended to use <b>REDUN_2RX_1TX</b> for the Maintenance interface.</li> <li>✓ When the Ethernet cables are connected back-to-back between the two devices, don't use <b>REDUN_1RX_1TX</b> for the Maintenance interface. This is because both sides may choose different ports, resulting in disconnected traffic.</li> </ul> <p>For more information on Ethernet Group settings for HA, see <a href="#">Network Topology Types and Rx/Tx Ethernet Port Group Settings</a> on page 1308.</p>
'Member 1' member1 [EtherGroupTable_ Member1]	<p>Assigns the first port to the Ethernet Group. To assign no port, set this field to <b>NONE</b>.</p> <p><b>Note:</b> Before you can re-assign a port to a different Ethernet Group, you must first remove the port from its current Ethernet Group. To remove the port, either set this field to <b>NONE</b> or to a different port.</p>
'Member 2' member2 [EtherGroupTable_ Member2]	<p>Assigns the second port to the Ethernet Group. To assign no port, set this field to <b>NONE</b>.</p> <p><b>Note:</b> Before you can re-assign a port to a different Ethernet Group, you must first remove the port from its current Ethernet Group. To remove the port, either set this field to <b>NONE</b> or to a different port.</p>
'Active Port'	<p>(Read-only) Displays the currently active port of the Ethernet Group.</p> <p>If the 'Mode' is <b>SINGLE</b> or <b>REDUN_1RX_1TX</b>, the field displays the name of the active port. If the 'Mode' is <b>REDUN_2RX_1TX</b></p>

Parameter	Description
	or <b>REDUN_2RX_2TX</b> , the field displays "Both". If there are no port members in the Ethernet Group, the field displays "None".

## Configuring Underlying Ethernet Devices

The Ethernet Devices table lets you configure up to 16 *Ethernet Devices*. An Ethernet Device represents a Layer-2 bridging device and is assigned a VLAN ID and an Ethernet Group (Ethernet port group). Multiple Ethernet Devices can be associated with the same Ethernet Group. The Ethernet Device (VLAN) can be configured with a VLAN tagging policy, which determines whether the Ethernet Device accepts tagged or untagged packets received on the Ethernet port associated with the Ethernet Device.

Once configured, assign the Ethernet Device to an IP network interface in the IP Interfaces table ('Underlying Device' field) and/or with a static route in the Static Routes table ('Ethernet Output Device' field). You can assign the same Ethernet Device to multiple IP network interfaces and thereby, implement multi-homing (multiple addresses on the same interface/VLAN).

By default, the device provides a pre-configured Ethernet Device at Index 0 with the following settings:

- Name: "vlan 1"
- VLAN ID: 1
- Ethernet Group: GROUP 1
- Tagging Policy: Untagged
- MTU: 1500

The pre-configured Ethernet Device is associated with the default IP network interface (ie., OAMP) in the IP Interfaces table. The Untagged policy of the pre-configured Ethernet Device enables you to connect to the device using the default OAMP interface.

You can view configured Ethernet Devices that have been successfully applied to the device (saved to flash) in the Ethernet Device Status table. This page is accessed by clicking the **Ethernet Device Status Table** button located at the bottom of the Ethernet Devices table. The Ethernet Device Status table can also be accessed from the Navigation tree (see [Viewing Ethernet Device Status](#) on page 1502).

You cannot delete an Ethernet Device that is associated with an IP network interface (in the IP Interfaces table). You can only delete it after you've disassociated it from the IP network interface.

The following procedure describes how to configure Ethernet Devices through the Web interface. You can also configure it through ini file [DeviceTable] or CLI (`configure network > network-dev`).

➤ **To configure an Ethernet Device:**

1. Open the Ethernet Devices table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **Ethernet Devices**).
2. Click **New**; the following dialog box appears:

3. Configure an Ethernet Device according to the parameters described in the table below.
4. Click **Apply**.

**Table 13-4: Ethernet Devices Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [DeviceName]	Defines a name for the Ethernet Device. The name is used to associate the Ethernet Device with an IP network interface in the IP Interfaces table ('Underlying Device' field - see <a href="#">Configuring IP Network Interfaces</a> on page 159) and/or with a static route in the Static Routes table ('Ethernet Output Device' field - see <a href="#">Configuring Static IP Routes</a> on page 176).
'VLAN ID' vlan-id [VlanID]	Defines a VLAN ID for the Ethernet Device. The valid value is 1 to 3999. The default is 1. <b>Note:</b> Each Ethernet Device must be configured with a unique VLAN ID.

Parameter	Description
'Underlying Interface' underlying-if [UnderlyingInterface]	<p>Assigns an Ethernet Group to the Ethernet Device. To configure Ethernet Groups, see <a href="#">Configuring Ethernet Port Groups</a> on page 152.</p> <p><b>Note:</b> The parameter is mandatory.</p>
'Tagging' tagging [Tagging]	<p>Defines VLAN tagging for the Ethernet Device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Untagged</b> = (Default for pre-configured Ethernet Device) The Ethernet Device accepts untagged packets and packets with the same VLAN ID as the Ethernet Device. Incoming untagged packets are assigned the VLAN ID of the Ethernet Device. The Ethernet Device sends these VLAN packets untagged (i.e., removes the VLAN ID).</li> <li>■ [1] <b>Tagged</b> = (Default for new Ethernet Devices) The Ethernet Device accepts packets that have the same VLAN ID as the Ethernet Device and sends packets with this VLAN ID. For all Ethernet Devices that are associated with the same Ethernet Group (see 'Underlying Interface' parameter above) and configured to <b>Tagged</b>, incoming untagged packets received on this Ethernet Group are discarded.</li> </ul> <p><b>Note:</b> Only one Ethernet Device can be configured as Untagged per associated Ethernet Group. In other words, if multiple Ethernet Devices are associated with the same Ethernet Group, only one of these Ethernet Devices can be configured to <b>Untagged</b>; all the others must be configured to <b>Tagged</b>.</p>
'MTU' mtu [MTU]	<p>Defines the Maximum Transmission Unit (MTU) in bytes per VLAN (Ethernet Device).</p> <p>The valid value is 68 to 1,500. The default is 1,500.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ MTU is not applicable to SBC Direct Media traffic and to debug recording traffic.</li> <li>■ If your first Ethernet Device is configured with an untagged VLAN, its MTU value is the maximum MTU that can be configured for all other Ethernet Devices that are associated with the same Ethernet Group. In other words, if you configure additional Ethernet Devices (tagged VLANs) that are associated with the same Ethernet Group, their MTUs must be equal to or less than the MTU of the first Ethernet Device (untagged VLAN). For example, if the untagged VLAN is configured with MTU of 100 bytes, you can configure a tagged VLAN with an MTU value of either 100 bytes or less.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If your first Ethernet Device is configured with a tagged VLAN and you later configure an additional Ethernet Device with an untagged VLAN that is associated with the same Ethernet Group, the MTU of the untagged VLAN must be equal to or greater than the highest MTU value configured out of all the Ethernet Devices (VLANs) associated with the Ethernet Group. For example, if VLAN 1 is configured with the highest MTU (100 bytes) out of all your VLANs, you can configure an untagged VLAN with an MTU value of either 100 bytes or greater.</li> </ul>

## Configuring IP Network Interfaces

The IP Interfaces table lets you configure up to 16 IP Interfaces.

The device is shipped with a default IP Interface (Index #0 and named "O+M+C") that has an IPv4 address (see [Default IP Address](#) on page 13). This default IP Interface can be used for all types of traffic (*Application Types*) - Operations, Administration, Maintenance and Provisioning (OAMP), *Media* (RTP or voice) and *Control* (SIP signaling).

- The default IPv4 OAMP IP Interface is **used by default by many of the device's features**. For example, management access (Web, REST, CLI over Telnet, CLI over SSH, and SNMP) uses the default IP Interface. In addition, if you don't specify an IP Interface for features (e.g., syslog), the device uses the default IP Interface.

Some features (e.g., WebSocket tunneling and OVOC-managed licensing such as Floating License) don't allow you to specify an IP Interface and always use the default IP Interface. In addition, the device uses the default IP Interface for DNS if the IP Interface that you have associated with a feature is not configured with a DNS server (see the 'Primary DNS' parameter in this section for more information).

Therefore, it's recommended **not** to delete the default IPv4 OAMP interface. If removal is necessary (e.g., for an all-IPv6 deployment), make sure that you've assigned valid IP Interfaces to all required features.

- If you're using WebSocket tunneling for any of the device's features, the IP address **169.254.0.1** must not be configured for any IP Interface in the IP Interfaces table. WebSocket tunneling is used, for example, for OVOC (see [Configuring WebSocket Tunnel with OVOC](#) on page 123) or WebRTC (see [Configuring WebRTC](#) on page 1274).

You can configure IP Interfaces for specific traffic (*Application Type*):

- **OAMP:** The default IP Interface is used for accessing the device's management interfaces - Web, CLI (Telnet and SSH), REST, and SNMP. However, you can configure different IP

Interfaces for management interfaces (with any Application Type) and then assign them to the relevant management interface:

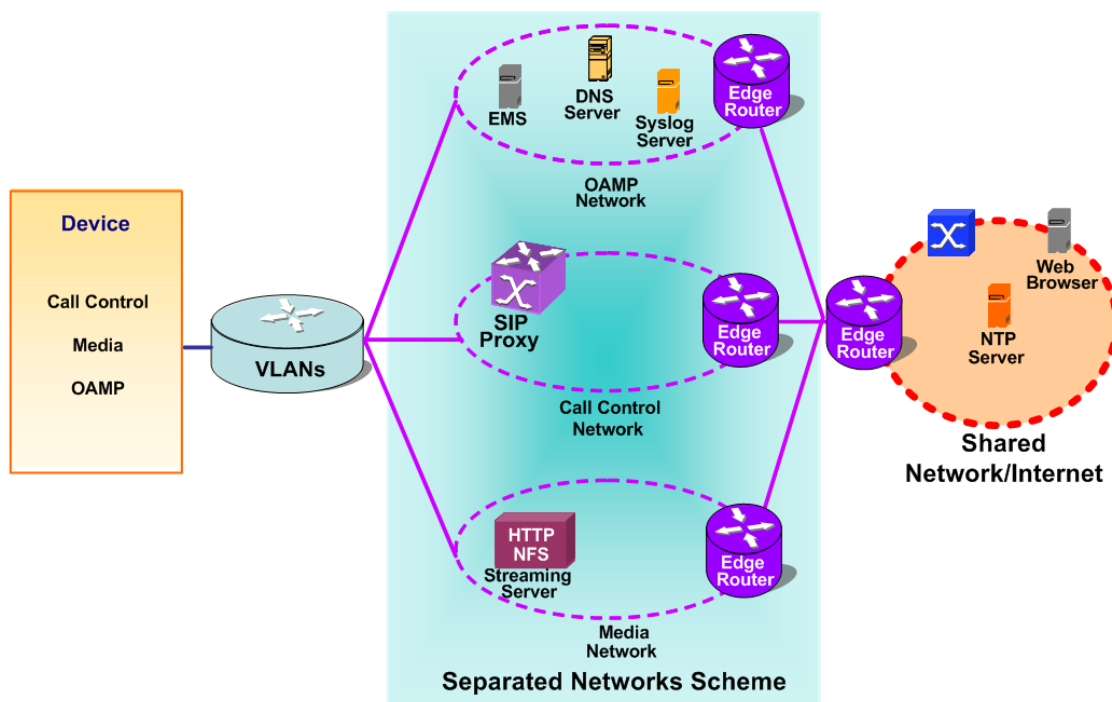

- For Web- and REST-based management, use the Web Interfaces table (see [Configuring Web Interfaces](#) on page 52).
- For Telnet-based management, use the Telnet Interfaces table (see [Configuring Telnet Interface](#) on page 98).
- For SSH-based management, use the SSH Interfaces table (see [Configuring SSH Interfaces](#) on page 99).
- For SNMP-based management, see [Configuring SNMP Interfaces](#) on page 114.

- You can configure IP Interfaces for management interfaces with any Application Type (OAMP, Media, Control, or any combination). However, at least one OAMP IP Interface must be configured in the IP Interfaces table.
- By default, the Web Interfaces, Telnet Interfaces, and SSH Interfaces tables all provide a pre-configured interface that is associated with the default IP Interface (IPV4 OAMP).

- **Media:** This Application Type is used for media (RTP or voice) traffic.
- **Control:** This Application Type is used for SIP signaling traffic (messaging).
- **MAINTENANCE:** This Application Type is used for HA maintenance traffic when the device operates in High-Availability (HA) mode.

You can configure the device with a single IP Interface (default) for all Application Types. Alternatively, you can configure multiple logical, IP Interfaces for these applications. You may need to logically separate network segments for these applications for administration and security. This can be achieved by employing Layer-2 VLANs and Layer-3 subnets. The figure below illustrates a typical network architecture where the device is configured with three IP Interfaces, each representing the OAMP, Control, and Media applications. The device is connected to a VLAN-aware switch for directing traffic from and to the device to the three separated Layer-3 broadcast domains according to VLAN tags (middle pane).

Prior to configuring your IP Interfaces, please adhere to the following guidelines:

- **At least one** OAMP interface must be configured (IPv4 or IPv6).
- Up to **two** OAMP interfaces can be configured, each with a different IP version (IPv4 or IPv6).
- OAMP interfaces can be combined with Media and Control type interfaces.
- At least one Media interface **must** be configured (IPv4 or IPv6). The Media interface can be combined with OAMP and/or Control type interfaces.
- At least one Control interface **must** be configured (IPv4 or IPv6). The Control interface can be combined with OAMP and/or Media type interfaces.
- Multiple Control and Media interfaces can be configured and they can have overlapping IP addresses and subnets.
- The prefix length replaces the dotted-decimal subnet mask presentation and **must** have a value of 0-31 for IPv4 addresses, and a value of 64 for IPv6 addresses.
- IP Interface types (OAMP, Media, and Control) can be combined:
  - Example 1:
    - ◆ One combined OAMP-Media-Control interface with an IPv4 address.
    - ◆ One combined OAMP-Media-Control interface with an IPv6 address.
  - Example 2:
    - ◆ One OAMP interface with an IPv4 address.
    - ◆ One or more Control interfaces with IPv4 addresses.
    - ◆ One or more Media interfaces with IPv4 addresses.

- Example 3:
  - ◆ One OAMP interface with an IPv4 address.
  - ◆ One combined Media-Control interface with an IPv4 address.
  - ◆ One combined Media-Control interface with an IPv6 address.
- Multiple IP Interfaces that are assigned to the same Ethernet Device can't be configured with different Default Gateways. If you need to use a different Default Gateway for one of the subnets defined on this Ethernet Device to reach a specific network (and not a default destination route), configure a Static Route rule.
- The address of the Default Gateway **must** be in the same subnet as the associated IP Interface. Additional static routing rules can be configured in the Static Routes table.
- The IP Interface name **must** be configured (mandatory) and must be unique for each interface.
- Each IP Interface must be assigned an Ethernet Device. You can assign the same Ethernet Device to multiple IP Interfaces. However, for IP Interfaces that are assigned the same Ethernet Device (VLAN), only one of the IP Interfaces can be configured for dynamic IPv6 addressing.

The following procedure describes how to configure IP network interfaces through the Web interface. You can also configure it through ini file [InterfaceTable] or CLI (`configure network > interface network-if`).

#### ➤ To configure IP Interfaces:

1. Open the IP Interfaces table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **IP Interfaces**).
2. Click **New**; the following dialog box appears:

GENERAL		IP ADDRESS	
Index	2	Interface Mode	IPv4 Manual
Name		IP Address	0.0.0.0
Application Type	OAMP + Media + Control	Prefix Length	16
Ethernet Device	--	Default Gateway	0.0.0.0

DNS	
Primary DNS	0.0.0.0
Secondary DNS	0.0.0.0
Overwrite Dynamic DNS Servers	Disable

3. Configure the IP network interface according to the parameters described in the table below.
4. Click **Apply**.
5. On the toolbar, click **Save** to save your settings to flash memory.

- If you change the address of the OAMP interface through which you are currently connected to the device and then click **Apply**, connectivity with the device is lost. You then need to re-access the device with the new OAMP address, and then click the **Save** button on the toolbar for the new address to take effect.
- If you edit or delete an IP Interface, current calls using the interface are immediately terminated.
- If you delete an IP Interface, rows configured in other tables (e.g., Media Realms table) that are associated with the deleted IP Interface, lose their association with the IP Interface ('Interface Name' field displays "None") and the rows become invalid.
- The SBC Configuration Wizard isn't supported and isn't available in the Web interface (see [SBC Configuration Wizard](#) on page 1424) if you configure any IPv6 interfaces in the IP Interfaces table.
- To view currently active IP Interfaces, click the **IP Interface Status Table** link located at the bottom of the table. For more information, see [Viewing Active IP Interfaces](#) on page 1502.
- Upon device start up, the IP Interfaces table is parsed and passes a comprehensive validation test. If any errors occur during this validation phase, the device sends an error message to the syslog server and falls back to a "safe mode", using a single interface without VLANs. It's recommended that you view the syslog messages that the device sends at startup to see if any errors occurred.
- Complementing the IP Interfaces table is the Static Routes table, which lets you configure static routing rules for non-local hosts/subnets. For more information, see [Configuring Static IP Routes](#) on page 176.

Table 13-5: IP Interfaces Table Parameters Description

Parameter	Description
<b>General</b>	
'Index' network-if [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [InterfaceName]	Defines a name for the interface. The valid value is a string of up to 16 characters. The default (if no name is configured) is "Interface_n", where <i>n</i> is the row index number. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
'Application Type'	Defines the type of application (traffic) for which you

Parameter	Description
application-type [ApplicationTypes]	<p>want to use the IP Interface (see note below).</p> <ul style="list-style-type: none"> <li>■ [0] <b>OAMP</b> = This IP Interface type is the device's Operations, Administration, Maintenance and Provisioning (OAMP) management interface, which is used for device management through Web, CLI (Telnet and SSH), SNMP, and REST. The device is shipped with a default OAMP (and Media and Control) interface which has an IPv4 address (see <a href="#">Default IP Address</a> on page 13). By default, this IPv4 OAMP interface is also used for various device applications such as syslog and debugging (but you can configure the device to use different IP Interfaces for these applications).</li> <li>■ [1] <b>Media</b> = This IP Interface type is typically used for media (i.e., RTP streams of voice).</li> <li>■ [2] <b>Control</b> = This IP Interface is typically used for the SIP call control application.</li> <li>■ [3] <b>OAMP + Media</b> = Combined OAMP and Media applications.</li> <li>■ [4] <b>OAMP + Control</b> = Combined OAMP and Call Control applications.</li> <li>■ [5] <b>Media + Control</b> = Combined Media and Call Control applications.</li> <li>■ [6] <b>OAMP + Media + Control</b> = Combined All application types are allowed on the interface.</li> <li>■ [99] <b>MAINTENANCE</b> = This IP Interface is used when the device is in High-Availability (HA) mode and is for HA maintenance traffic. This IP Interface represents one of the LAN interfaces or Ethernet Groups on each device in the HA system, used for the Ethernet connectivity between the two devices. For more information on HA and the Maintenance interface, see on page 1301.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure up to <b>two</b> OAMP interfaces (dedicated or combined with Media and/or Control), but each must have a different IP</li> </ul>

Parameter	Description
	<p>version (IPv4 or IPv6). At least one OAMP interface must exist in the IP Interfaces table.</p> <ul style="list-style-type: none"> <li>■ If you edit or delete the MAINTENANCE interface (for HA mode), you must restart the device for your changes to take effect.</li> </ul>
'Ethernet Device' underlying-dev [UnderlyingDevice]	<p>Assigns an Ethernet Device (see <a href="#">Configuring Underlying Ethernet Devices</a> on page 156) to the IP interface.</p> <p>An Ethernet Device is a Layer-2 bridging device, which is a VLAN that is associated with a physical Ethernet port (Ethernet Group). This is useful for setting trusted and untrusted networks on different physical Ethernet ports. You can assign the same Ethernet Device to multiple IP Interfaces, providing multi-homing IP configuration (i.e., multiple IP addresses on the same interface / VLAN).</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ For IP Interfaces that are assigned the same Ethernet Device (VLAN), only one of the IP Interfaces can be configured for dynamic IPv6 addressing (i.e., 'Interface Mode' parameter below configured to <b>IPv6 Stateless</b> or <b>IPv6 DHCP</b>).</li> <li>■ For IP Interfaces that are assigned the same Ethernet Device (VLAN), only one of the IP Interfaces can be configured for dynamic IPv4 addressing (i.e., 'Interface Mode' parameter below configured to <b>IPv4 DHCP</b>).</li> </ul>
<b>IP Address</b>	
'Interface Mode' mode [InterfaceMode]	<p>Defines the method to configure the IP address of the IP Interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>IPv6 Stateless</b> = This option dynamically acquires an IPv6 address for the IP Interface, using the IPv6 Stateless Address Autoconfiguration (SLAAC) method. This auto-</li> </ul>

Parameter	Description
	<p>configures the IP Interface with an IPv6 address without the need for the device to manage a DHCP server. The device generates the IPv6 address using local and non-local information. The non-local information is the prefix advertised by routers, which forms the first 64-bit segment (network part) of the 128-bit address. The local information is generated by the device using an algorithm based on the device's MAC address, which forms the second 64-bit segment (client ID). The device ensures that a unique IPv6 address is generated for the IP Interface. This option can also be used to acquire the addresses for the DNS servers through DHCP (see 'Primary DNS' and 'Secondary DNS' parameters below), and the address for the Default Gateway through Router Advertisement (RA) messages (see 'Default Gateway' parameter below).</p> <ul style="list-style-type: none"> <li>■ [3] <b>IPv6 Manual Prefix</b> = This option is used if you want to manually configure an IPv6 prefix (higher 64 bits) while the interface ID (the lower 64 bits) is derived from the device's MAC address.</li> <li>■ [4] <b>IPv6 Manual</b> = This option is used if you want to manually configure an IPv6 address (128 bits).</li> <li>■ [10] <b>IPv4 Manual</b> = (Default) This option is used if you want to manually configure an IPv4 address (32 bits).</li> <li>■ [13] <b>IPv6 DHCP</b> = This option dynamically acquires an IPv6 address for the IP Interface, using the Stateful (DHCPv6) Autoconfiguration method. The device acts as a DHCP client to obtain the IPv6 address(es) from an external DHCP server. The device sends a DHCP request once you have configured the IP Interface and upon every device restart. The DHCP server can also provide the addresses for the DNS servers (see 'Primary DNS' and 'Secondary DNS' parameters below) and the address for the Default Gateway (see 'Default Gateway' parameter below). Based on the DHCP lease</li> </ul>

Parameter	Description
	<p>time, the device renews its lease over the IP address(es) with the DHCP server.</p> <ul style="list-style-type: none"> <li>■ [11] <b>IPv4 DHCP</b> = This option dynamically acquires an IPv4 address for the IP Interface. The device acts as a DHCP client to obtain the IPv4 address from an external DHCP server. The device sends a DHCP request once you have configured the IP Interface and upon every device restart. The DHCP server can also provide the addresses for the DNS servers (see 'Primary DNS' and 'Secondary DNS' parameters below) and the address for the Default Gateway (see 'Default Gateway' parameter below). Based on the DHCP lease time, the device renews its lease over the IP address(es) with the DHCP server.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>IPv6 Stateless</b>, <b>IPv6 DHCP</b>, or <b>IPv4 DHCP</b>, the following parameters become read-only: 'IP Address', 'Prefix Length', 'Default Gateway', 'Primary DNS', and 'Secondary DNS'.</li> <li>■ Dynamic IPv6 addressing (i.e., <b>IPv6 Stateless</b>, <b>IPv6 DHCP</b>, and <b>IPv4 DHCP</b>) is not supported in High-Availability (HA) mode.</li> </ul>
<p>'IP Address'</p> <p><code>ip-address</code></p> <p>[IPAddress]</p>	<p>Defines an IP address.</p> <p>The valid value is an IPv4 address (in dotted-decimal notation) or an IPv6 address (see RFC 4291). By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the 'Interface Mode' parameter (see above) to <b>IPv6 Manual Prefix</b>, <b>IPv6 Manual</b>, or <b>IPv4 Manual</b>, the 'IP Address' parameter is mandatory.</li> <li>■ For IPv6, instead of configuring a static address using this parameter, you can use dynamic IPv6 addressing (stateless or stateful) to autoconfigure the IP Interface with an IPv6 address (and optionally, with DNS addresses and the Default Gateway address). Therefore, if you</li> </ul>

Parameter	Description
	<p>configure the 'Interface Mode' parameter (see above) to <b>IPv6 Stateless</b> or <b>IPv6 DHCP</b>, the 'IP Address' parameter is read-only and automatically populated with the dynamic IPv6 address after you apply your IP Interface settings.</p> <ul style="list-style-type: none"> <li>■ For IPv4, instead of configuring a static address using this parameter, you can use DHCP to autoconfigure the IP Interface with an IPv4 address (and optionally, with DNS addresses and the Default Gateway address). Therefore, if you configure the 'Interface Mode' parameter (see above) to <b>IPv4 DHCP</b>, the 'IP Address' parameter is read-only and automatically populated with the dynamic IPv4 address after you apply your IP Interface settings.</li> </ul>
<p>'Prefix Length' prefix-length [PrefixLength]</p>	<p>Defines the prefix length of the related IP address. This is a Classless Inter-Domain Routing (CIDR)-style representation of a dotted-decimal subnet notation. The CIDR-style representation uses a suffix indicating the number of bits which are set in the dotted-decimal format. For example, 192.168.0.0/16 is synonymous with 192.168.0.0 and subnet 255.255.0.0. This CIDR lists the number of '1' bits in the subnet mask (i.e., replaces the standard dotted-decimal representation of the subnet mask for IPv4 interfaces). For example, a subnet mask of 255.0.0.0 is represented by a prefix length of 8 (i.e., 11111111 00000000 00000000 00000000) and a subnet mask of 255.255.255.252 is represented by a prefix length of 30 (i.e., 11111111 11111111 11111111 11111100).</p> <p>The prefix length is a Classless Inter-Domain Routing (CIDR) style presentation of a dotted-decimal subnet notation. The CIDR-style presentation is the latest method for interpretation of IP addresses. Specifically, instead of using eight-bit address blocks, it uses the variable-length subnet masking technique to allow allocation on arbitrary-length prefixes.</p> <p>The valid value of the prefix length depends on the IP address version:</p> <ul style="list-style-type: none"> <li>■ <b>IPv4:</b> 0 to 31</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ <b>IPv6:</b> Depends on the settings of the 'Interface Mode' parameter (above): <ul style="list-style-type: none"> <li>✓ <b>IPv6 Manual Prefix:</b> 64</li> <li>✓ <b>IPv6 Manual:</b> Up to 126</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For IPv6, instead of configuring a static prefix length using this parameter, you can use dynamic IPv6 addressing (stateless or stateful) to autoconfigure the IP Interface with an IPv6 address and prefix (and optionally, with DNS addresses and the Default Gateway address). Therefore, if you configure the 'Interface Mode' parameter (see above) to <b>IPv6 Stateless</b> or <b>IPv6 DHCP</b>, the 'Prefix Length' parameter is read-only and automatically populated with the dynamic IPv6 address after you apply your IP Interface settings.</li> <li>■ For IPv4, instead of configuring a static address using this parameter, you can use DHCP to autoconfigure the IP Interface with an IPv4 address and prefix (and optionally, with DNS addresses and the Default Gateway address). Therefore, if you configure the 'Interface Mode' parameter (see above) to <b>IPv4 DHCP</b>, the 'Prefix Length' parameter is read-only and automatically populated with the dynamic IPv4 address after you apply your IP Interface settings.</li> </ul>
'Default Gateway' gateway [Gateway]	<p>Defines the IP address of the Default Gateway for the IP Interface. When the device sends traffic from this IP Interface to an unknown destination (i.e., not in the same subnet and not defined for any static routing rule), it forwards the traffic to this Default Gateway.</p> <p>By default, no value is defined.</p> <p>When configuring a prefix length value of 31 (for IPv4 point-to-point connections), configure the peer IP address as the Default Gateway IP address.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For IPv6, instead of configuring a static address using this parameter, you can use dynamic IPv6 addressing (stateless or stateful) to autoconfigure the IP Interface with a Default Gateway IPv6 address. Therefore, if you configure the 'Interface Mode' parameter (see above) to <b>IPv6 Stateless</b> or <b>IPv6 DHCP</b>, the 'Default Gateway' parameter becomes read-only. However, it's not populated with the obtained IPv6 address. To view the obtained Default Gateway address, use the CLI command <code>show network route</code> or view it in the Static Routes Status table (see <a href="#">Viewing Static Routes Status</a> on page 1503).</li> <li>■ For IPv4, instead of configuring a static address using this parameter, you can use DHCP to autoconfigure the IP Interface with a Default Gateway IPv4 address. Therefore, if you configure the 'Interface Mode' parameter (see above) to <b>IPv4 DHCP</b>, the 'Default Gateway' parameter becomes read-only. However, it's not populated with the obtained IPv4 address. To view the obtained Default Gateway address, use the CLI command <code>show network route</code> or view it in the Static Routes Status table (see <a href="#">Viewing Static Routes Status</a> on page 1503).</li> </ul>
<b>DNS</b>	
'Primary DNS' <code>primary-dns</code> [PrimaryDNSServerIPAddress]	<p>Defines the primary DNS server's IP address (IPv4 or IPv6), which is used for translating (resolving) domain names (FQDNs) into IP addresses for applications that are associated with the IP Interface.</p> <p>By default, no IP address is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For IPv6, instead of configuring a static DNS address using this parameter, you can use dynamic IPv6 addressing (stateless or stateful) to obtain the address through DHCP. Parameter	Description
	'Interface Mode' parameter configured to <b>IPv4 DHCP</b> ) or dynamic IPv6 addressing (i.e., 'Interface Mode' parameter configured to <b>IPv6 Stateless</b> or <b>IPv6 DHCP</b> ).

## Networking Configuration Examples

Examples of IP network interface configuration are listed below:

### ■ Single IP network interface for all applications:

The IP Interfaces table is configured with a single interface for OAMP, Media and Control:

Index	Name	Application Type	Ethernet Device	Interface Mode	IP Address	Prefix Length	Default Gateway
0	myInterface	OAMP + Media + Control	1	IPv4 Manual	192.168.0.2	16	192.168.0.1

Two routes are configured in the **Static Routes table** for directing traffic for subnet 201.201.0.0/16 to 192.168.11.10, and all traffic for subnet 202.202.0.0/16 to 192.168.11.1:

Index	Destination	Prefix Length	Gateway
0	201.201.0.0	16	192.168.11.10
1	202.202.0.0	16	192.168.11.1

The NTP applications remain with their default application types.

### ■ Multiple interfaces, one per application type:

The IP Interfaces table is configured with three interfaces, each for a different application type (one for OAMP, one for Call Control, and one for RTP Media), and each with a different VLAN ID and default gateway:

Index	Name	Application Type	Ethernet Device	Interface Mode	IP Address	Prefix Length	Default Gateway
0	ManagementIF	OAMP	1	IPv4 Manual	192.168.0.2	16	192.168.0.1

Index	Name	Application Type	Ethernet Device	Interface Mode	IP Address	Prefix Length	Default Gateway
1	myControlIF	Control	200	IPv4 Manual	200.200.85.14	24	200.200.85.1
2	myMediaIF	Media	211	IPv4 Manual	211.211.85.14	24	211.211.85.1

A routing rule in the Static Routes table is required to allow remote management from a host in 176.85.49.0/24:

Index	Destination	Prefix Length	Gateway
0	176.85.49.0	24	192.168.11.1

All other parameters are set to their respective default values. The NTP application remains with its default application types.

#### ■ Multiple interfaces with combined application types:

- A single interface for OAMP.
- Interfaces for Call Control and Media applications, where two of them are IPv4 interfaces and one is an IPv6 interface.

The IP Interfaces table is configured as follows:

Index	Name	Application Type	Ethernet Device	Interface Mode	IP Address	Prefix Length	Default Gateway
0	Mgmt	OAMP	1	IPv4 Manual	192.168.0.2	16	192.168.0.1
1	MediaCtrl1	Media + Control	201	IPv4 Manual	200.200.85.14	24	200.200.85.1
2	MediaCtrl2	Media + Control	202	IPv4 Manual	200.200.86.14	24	200.200.86.1
3	V6CtrlMedia2	Media + Control	202	IPv6 Manual	2000::1:200:200:86:14	64	::

Index	Name	Application Type	Ethernet Device	Interface Mode	IP Address	Prefix Length	Default Gateway
				I			

1. A routing rule in the Static Routes table is required to allow remote management from a host in 176.85.49.0/24:

Index	Destination	Prefix Length	Gateway
0	176.85.49.0	24	192.168.0.10

The NTP application is configured (through the ini file) to serve as OAMP applications:

```
EnableNTPasOAM = 1
```

Configure Layer-2 QoS mapping in the QoS Mapping table. Packets sent with the configured DiffServ get the configured VLAN priority:

Index	Differentiated Services	VLAN Priority
0	46	6
1	40	6
2	26	4
3	10	2

Configure Layer-3 QoS in the QoS Settings table:

- 'Media Premium QoS' - the default DiffServ value is 46
- 'Control Premium QoS' - the default DiffServ value is 24
- 'Gold QoS' - the default DiffServ value is 26
- 'Bronze QoS' - the default DiffServ value is 10

#### ■ IP Network Interfaces and Multiple Default Gateways:

This example includes a different Default Gateway per IP network interface. The Default Gateway of the OAMP interface is 192.168.0.1 and of the Media and Control is 200.200.85.1. The configuration in the IP Interfaces table is shown below:

Index	Name	Application Type	Ethernet Device	Interface Mode	IP Address	Prefix Length	Default Gateway
0	Mgmt	OAMP	100	IPv4 Manual	192.168.0.2	16	192.168.0.1
1	CntrlMedia	Media & Control	200	IPv4 Manual	200.200.85.14	24	200.200.85.1

Configuring the following static routing rules in the Static Routes table enables OAMP applications to access peers on subnet 17.17.0.0 through the Default Gateway 192.168.10.1 and Media + Control applications to access peers on subnet 171.79.39.0 through Default Gateway 200.200.85.10 (which is not the default gateway of the interface).

Index	Destination	Prefix Length	Ethernet Output Device	Gateway
0	17.17.0.0	16	100	192.168.10.1
1	171.79.39.0	24	200	200.200.85.10

## Configuring Static IP Routes

The Static Routes table lets you configure up to 30 static IP routing rules. Static routes let you communicate with LAN networks that are not located behind the Default Gateway that is specified for an IP network interface in the IP Interfaces table, from which the packets are sent. Before sending an IP packet, the device searches the Static Routes table for an entry that matches the requested destination host/network. If an entry is found, the device sends the packet to the gateway that is configured for the static route. If no explicit entry is found, the packet is sent to the Default Gateway as configured for the IP interface in the IP Interfaces table.

You can view the status of configured static routes in the IP Routing Status table. This table can be accessed by clicking the **Static Routes Status Table** link located at the bottom of the Static Routes table (see [Viewing Static Routes Status](#) on page 1503).

The following procedure describes how to configure static routes through the Web interface. You can also configure it through ini file [StaticRouteTable] or CLI (`configure network > static`).

### ➤ To configure static IP routes:

1. Open the Static Routes table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **Static Routes**).
2. Click **New**; the following dialog box appears:

Static Routes - x

GENERAL

Index	<input type="text" value="4"/>
Destination	<input type="text" value="0.0.0.0"/>
Prefix Length	<input type="text" value="16"/>
Ethernet Output Device	<div style="border: 1px solid #ccc; padding: 2px; display: flex; align-items: center;"> <span style="flex-grow: 1;">--</span> <span style="font-size: 0.8em;">▼</span> </div> <a href="#" style="color: #002060; font-size: 0.8em; margin-left: 5px;">View</a>
Gateway	<input type="text" value="0.0.0.0"/>
Description	<input type="text"/>

3. Configure a static route according to the parameters described in the table below. The address of the host/network you want to reach is determined by an AND operation that is applied to the fields 'Destination' and 'Prefix Length'. For example, to reach network 10.8.x.x, enter "10.8.0.0" in the 'Destination' field and "16" in the 'Prefix Length'. As a result of the AND operation, the value of the last two octets in the 'Destination' field are ignored. To reach a specific host, enter its IP address in the 'Destination' field and "32" in the 'Prefix Length' field.
4. Click **Apply**, and then save your settings to flash memory.

- You can only delete Static Route rules that are inactive.
- You can configure only one Static Route rule with the same 'Destination' and 'Ethernet Output Device'.

**Table 13-6: Static Routes Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. The valid value is 0 to 29. <b>Note:</b> Each row must be configured with a unique index.
'Destination' destination [Destination]	Defines the IP address of the destination host/network. The destination can be a single host or a whole subnet, depending on the prefix length configured for this routing rule.
'Prefix Length' prefix-length [PrefixLength]	Defines the Classless Inter-Domain Routing (CIDR)-style representation of a dotted-decimal subnet notation of the destination host/network. The CIDR-style representation uses a suffix indicating the number of bits that are set in the dotted-decimal format. For example, the value 16 represents subnet 255.255.0.0

Parameter	Description
	<p>The valid value depends on the IP address version:</p> <ul style="list-style-type: none"> <li>■ IPv4: 0 to 32</li> <li>■ IPv6: 0 to 128</li> </ul>
'Ethernet Output Device' device-name [DeviceName]	<p>Associates an IP network interface through which the static route's Gateway is reached. The association is done by assigning the parameter the same Ethernet Device that is assigned to the IP network interface in the IP Interfaces table ('Ethernet Device' parameter). To configure IP network interface, see <a href="#">Configuring IP Network Interfaces</a> on page 159. To configure Ethernet Devices, see <a href="#">Configuring Underlying Ethernet Devices</a> on page 156.</p>
'Gateway' gateway [Gateway]	<p>Defines the IP address of the Gateway (next hop) used for traffic destined to the subnet/host configured in the 'Destination' and 'Prefix Length' parameters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The Gateway's address must be in the same subnet as the IP address of the network interface that is associated with the static route (using the 'Ethernet Output Device' parameter - see above).</li> <li>■ The IP network interface associated with the static route must be of the same IP address family (IPv4 or IPv6).</li> </ul>
'Description' description [Description]	<p>Defines a name for the rule.</p> <p>The valid value is a string of up to 20 characters.</p>

## Configuration Example of Static IP Routes

An example of the use for static routes is shown in the figure below. In the example, the device needs to communicate with a softswitch at IP address 10.1.1.10. However, the IP network interface from which packets destined for 10.1.1.10 is sent, is configured to send the packets to a Default Gateway at 10.15.0.1. Therefore, the packets do not reach the softswitch. To resolve

this problem, a static route is configured to specify the correct gateway (10.15.7.22) in order to reach the softswitch.

Note the following configuration:

- The static route is configured with a subnet mask of 24 (255.255.255.0), enabling the device to use the static route to send all packets destined for 10.1.1.x to this gateway and therefore, to the network in which the softswitch resides.
- The static route in the Static Routes table must be associated with the IP network interface in the IP Interfaces table. This is done by configuring the 'Ethernet Output Device' field in the Static Routes table to the same value as configured in the 'Ethernet Device' field in the IP Interfaces table.
- The static route's Gateway address in the Static Routes table is in the same subnet as the IP address of the IP network interface in the IP Interfaces table.

#### No Static Route:

The device sends packets to 10.15.0.1, which is the Default Gateway defined for this IP network interface in the IP Interfaces table. Therefore, the device will not succeed in reaching the softswitch.

INDEX	NAME	APPLICATION TYPE	INTERFACE MODE	IP ADDRESS	PREFIX LENGTH	DEFAULT GATEWAY	PRIMARY DNS	SECONDARY DNS	ETHERNET DEVICE
0	O+M+C	OAMP + Media	IPv4 Manual	10.15.7.95	16	10.15.0.1	0.0.0.0	0.0.0.0	vlan 1

#### Static Route Configured:

A static route with the correct gateway is needed for routing to the softswitch. The device communicates with the softswitch (10.1.1.0/24) using the gateway 10.15.7.22. Note that the device first searches for a matching route in the Static Routes table. If not found, it uses the default gateway defined in the IP Interfaces table.

INDEX	DESTINATION	PREFIX LENGTH	ETHERNET OUTPUT DEVICE	GATEWAY	DESCRIPTION
0	10.1.1.0	24	vlan 1	10.15.7.22	Softswitch

## Troubleshooting the Static Routes Table

When adding a new static route to the Static Routes table, the added rule passes a validation test. If errors are found, the static route is rejected and not added to the table. Failed static route validations may result in limited connectivity (or no connectivity) to the destinations specified in the incorrect static route. For any error found in the Static Routes table or failure to configure a static route, the device sends a notification message to the syslog server reporting the problem.

Common static routing configuration errors may include the following:

- The IP address specified in the 'Gateway' field is unreachable from the IP network interface associated with the static route.
- The same destination has been configured in two different static routing rules.
- More than 30 static routes have been configured.

If a static route is required to access OAMP applications (for remote management, for example) and the route is not configured correctly, the route is not added and the device is not accessible remotely. To restore connectivity, the device must be accessed locally from the OAMP subnet and the required routes be configured.

## Network Address Translation Support

Network Address Translation (NAT) is a mechanism that maps internal IP addresses (and ports) used within a private network to global IP addresses and vice versa, providing transparent routing to end hosts. The primary advantages of NAT include (1) reduction in the number of global IP addresses required in a private network (global IP addresses are only used to connect to the Internet) and (2) better network security by hiding the internal architecture.

The design of SIP creates a problem for VoIP traffic to pass through NAT. SIP uses IP addresses and port numbers in its message body. However, the NAT server is unable to modify the SIP messages and thus, can't change local addresses to global addresses.

This section discusses the device's solutions for overcoming NAT traversal issues.

### Device Located behind NAT

Two different streams of traffic traverse through NAT - signaling and media. A device located behind NAT that initiates a signaling path has problems receiving incoming signaling responses, as they are blocked by the NAT server. Therefore, the initiating device must inform the receiving device where to send the media. To resolve this NAT problem, the device provides the following solutions (listed in priority of the method used):

- (Gateway Application Only) If configured, uses the single Static NAT IP address for all interfaces - see [Configuring a Static NAT IP Address for All Interfaces](#) on the next page
- NAT Translation table, which configures NAT per IP network interface - see [Configuring NAT per IP Interface](#) on the next page.

If NAT is not configured, the device sends the packet according to its IP address configured in the IP Interfaces table.

The figure below illustrates the NAT problem faced by SIP networks when the device is located behind a NAT:

### Configuring a Static NAT IP Address for All Interfaces

You can configure a global (public) IP address of the router to enable static NAT between the device and the Internet for all network interfaces. The device replaces the source IP address for media of all outgoing SIP messages sent on any of its network interfaces to this public IP address.

The following procedure describes how to configure a static NAT address through the Web interface. You can also configure it through ini file [StaticNATIP] or CLI (`configure voip > sip-definition settings > nat-ip-addr`).

#### ➤ To configure a single static NAT IP address:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**).
2. In the 'NAT IP Address' field, enter the NAT IP address in dotted-decimal notation.

**Figure 13-2: Configuring Static NAT IP Address**

**NAT IP Address**

3. Click **Apply**.

The feature is applicable only to the Gateway application.

### Configuring NAT per IP Interface

The NAT Translation table lets you configure up to 32 network address translation (NAT) rules for translating source IP addresses into NAT IP addresses (*global - public*) when the device is located behind NAT.

The device's NAT traversal mechanism replaces the source IP address of SIP messages sent from a specific IP Interface (Control or Media) in the IP Interfaces table to a public IP address. This allows, for example, the separation of VoIP traffic between different ITSPs and topology hiding of internal IP addresses from the “public” network. Each IP Interface (configured in the IP Interfaces table) can be associated with a NAT rule, translating the source IP address and port of the outgoing packet into the NAT address (IP address and port range).

The following procedure describes how to configure NAT translation rules through the Web interface. You can also configure it through ini file [NATTranslation] or CLI (`configure network > nat-translation`).

➤ **To configure NAT translation rules:**

1. Open the NAT Translation table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **NAT Translation**).
2. Click **New**; the following dialog box appears:

3. Configure a NAT translation rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 13-7: NAT Translation Table Parameter Descriptions**

Parameter	Description
<b>Source</b>	
'Index' index [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Source Interface' src-interface-name [SrcIPInterfaceName]	Assigns an IP Interface (configured in the IP Interfaces table) to the rule. Outgoing packets sent from the specified network interface are NAT'ed. By default, no value is defined. To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.

Parameter	Description
'Source Start Port' src-start-port [SourceStartPort]	Defines the optional starting port range (0-65535) of the IP interface, used as matching criteria for the NAT rule. If not configured, the match is done on the entire port range. Only IP addresses and ports of matched source ports will be replaced.
'Source End Port' src-end-port [SourceEndPort]	Defines the optional ending port range (0-65535) of the IP interface, used as matching criteria for the NAT rule. If not configured, the match is done on the entire port range. Only IP addresses and ports of matched source ports will be replaced.
Target	
'Target IP Address' target-ip-address [TargetIPAddress]	Defines the global (public) IP address. The device adds the address in the outgoing packet to the SIP Via header, Contact header, 'o=' SDP field, and 'c=' SDP field.
'Target Start Port' target-start-port [TargetStartPort]	Defines the optional starting port range (0-65535) of the global address. If not configured, the ports are not replaced. Matching source ports are replaced with the target ports. This address is set in the SIP Via and Contact headers and in the 'o=' and 'c=' SDP fields.
'Target End Port' target-end-port [TargetEndPort]	Defines the optional ending port range (0-65535) of the global address. If not configured, the ports are not replaced. Matching source ports are replaced with the target ports. This address is set in the SIP Via and Contact headers and in the 'o=' and 'c=' SDP fields.

## SIP User Agent Located behind NAT

This section describes configuration for scenarios where the device sends signaling and media packets to a remote SIP user agent (UA) that is located behind NAT.

### Enabling SIP NAT Detection when UA Located behind NAT

By default, the device resolves NAT issues for SIP signaling, using its NAT Detection mechanism. The NAT Detection mechanism checks whether the endpoint is located behind NAT by comparing the source IP address of the incoming UDP/TCP packet (in which the SIP message is received) with the IP address in the SIP Contact header. If the packet's source IP address is a public address and the Contact header's IP address is a local address, the device considers the endpoint as located behind NAT. In this case, the device sends the SIP messages to the

endpoint using the packet's source IP address. Otherwise (or if you have disabled the NAT Detection mechanism), the device sends the SIP messages according to the SIP standard (RFC 3261), where requests within the SIP dialog are sent using the IP address in the Contact header and responses to INVITEs are sent using the IP address in the Via header.

If necessary, you can also configure the device to always consider incoming SIP INVITE messages as sent from endpoints that are located behind NAT. When this is enabled, the device sends responses to the INVITE (to the endpoint) using the source IP address of the packet (INVITE) initially received from the endpoint. This is useful in scenarios where the endpoint is located behind a NAT firewall and the device (for whatever reason) is unable to identify NAT using its regular NAT Detection mechanism. This feature is enabled per specific calls using the 'Always Use Source Address' parameter in the IP Groups table (see [Configuring IP Groups](#) on page 591). If this feature is disabled, the device's NAT detection is according to the settings of the global parameter, 'SIP NAT Detection' parameter (see below procedure).

➤ **To enable NAT Detection feature (global):**

1. Open the Transport Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Transport Settings**).
2. Select the 'SIP NAT Detection' check box (SIPNatDetection):

SIP NAT Detection ☒

3. Click **Apply**.

### **Media (RTP/RTCP/T.38)**

When a remote UA initiates a call and is not located behind a NAT server, the device sends the media (RTP, RTCP, and T.38) packets to the remote UA using the IP address:port (UDP) indicated in the SDP body of the SIP message received from the UA. However, if the UA is located behind NAT, the device sends the RTP with the IP address of the UA (i.e., private IP address) as the destination instead of that of the NAT server. Thus, the RTP will not reach the UA. To resolve this NAT traversal problem, the device offers the following features:

- First Incoming Packet Mechanism - see [First Incoming Packet Mechanism](#) on the next page
- RTP No-Op packets according to the avt-rtp-noop draft - see [No-Op Packets](#) on the next page

The figure below illustrates a typical network architecture where the remote UA is located behind NAT:

### First Incoming Packet Mechanism

In scenarios where the remote user agent (UA) resides behind a NAT server, it's possible that the device, if not configured for NAT traversal, will send the media (RTP, RTCP and T.38) streams to an invalid IP address and UDP port. In other words, it will send the media to the private IP address:port of the UA and not the public address (of the NAT server) and therefore, the media will not reach the UA. When the UA is located behind NAT, although the UA sends its private IP address:port in the original SIP message (INVITE), the device receives the media packets with a source address of a public IP address:port (i.e., allocated by the NAT server). Therefore, to ensure that the media reaches the UA, the device must send it to the public address.

The device identifies whether the UA is located behind NAT by comparing the source IP address of the first received media packet with the IP address and UDP port of the first received SIP message (INVITE) when the SIP session was started. This is done for each media type--RTP, RTCP and T.38--and therefore, they can have different destination IP addresses and UDP ports than one another.

The device supports various NAT traversal methods, which you can configure using the 'NAT Traversal' (NATMode) parameter. For more information on the different options provided by this parameter, see [NAT and STUN Parameters](#) on page 1754.

#### ➤ To enable NAT resolution using the First Incoming Packet mechanism:

1. Open the Media Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Settings**).
2. From the 'NAT Traversal' drop-down list (NATMode), select the required NAT option.

**NAT Traversal**

• **NAT by Signaling Restricted** ▼

3. Click **Apply**.

### No-Op Packets

The device can send No-Op packets to verify Real-Time Transport Protocol (RTP) and T.38 connectivity, and to keep NAT bindings and Firewall pinholes open. The No-Op packets can be sent in RTP and T.38 formats:

- **RTP No-Op:** The RTP No-Op support complies with IETF Internet-Draft draft-wing-avt-rtp-noop-03 ("A No-Op Payload Format for RTP"). The IETF document defines a No-Op payload format for RTP. The draft defines the RTP payload type as dynamic. You can configure the payload type as described in the following procedure (default is 120).
- **T.38 No-Op:** T.38 No-Op packets are sent only while a T.38 session is activated. Sent packets are a duplication of the previously sent frame (including duplication of the sequence number).

➤ **To configure the No-Op packet feature:**

1. Enable the feature, using the [NoOpEnable] parameter. You can also enable this feature per IP Profile (for SBC calls only), using the 'Generate No-Op Packets' parameter (see [Configuring IP Profiles](#) on page 674).
2. Configure the interval between each No-Op packet sent by the device during the silence period (i.e., no RTP or T.38 traffic), using the [NoOpInterval] parameter.
3. For RTP No-Op packets, configure the payload type of the No-Op packets, using the [RTPNoOpPayloadType] parameter.

The receipt of No-Op packets is always supported.

### Fax Transmission behind NAT

The device supports transmission from fax machines (connected to the device) located inside (behind) NAT. Generally, the firewall blocks T.38 (and other) packets received from the WAN, unless the device behind the NAT sends at least one IP packet from the LAN to the WAN through the firewall. If the firewall blocks T.38 packets sent from the termination IP fax, the fax fails. To overcome this problem, the device sends No-Op ("no-signal") packets to open a pinhole in the NAT for the answering fax machine. The originating fax doesn't wait for an answer, but immediately starts sending T.38 packets to the terminating fax machine upon receipt of a re-INVITE with T.38 only in the SDP, or T.38 and audio media in the SDP. This feature is configured using the [T38FaxSessionImmediateStart] parameter. The No-Op packet feature is enabled using the [NoOpEnable] and [NoOpInterval] parameters.

### Implementing ICE for Media Sessions

The device supports Interactive Connectivity Establishment (ICE) for SBC calls. ICE is a methodology for NAT traversal, enabling VoIP interoperability across networks to work better across NATs and firewalls. It employs Session Traversal Utilities for NAT (STUN) and Traversal Using Relays around NAT (TURN) protocols to provide a peer with a public IP address and port that can be used to connect to a remote peer. Therefore, for some applications such as when the device operates in Microsoft Teams Direct Routing (media bypass) environments, ICE is required.

ICE is applicable only to the SBC application.

For clients behind NATs and/or firewalls to send media (RTP) between one another, they need to discover each others IP address and port as seen by the "outside" world. If both peers are in different private networks behind a NAT, the peers must coordinate to determine the best communication path between them.

ICE first tries to make a connection using the client's private local address. If that fails (which it will for clients behind NAT), ICE obtains an external (public) address using a STUN server. If that fails, traffic is routed through a TURN relay server (which has a public address).

These addresses:ports (local, STUN, TURN and any other network address) of the client are termed "candidates". Each client sends its' candidates to the other in the SDP body of the SIP message (e.g., INVITE). Peers then perform connectivity checks per candidate of the other peer, using STUN binding requests sent on the RTP and RTCP ports. ICE tries each candidate and selects the one that works (i.e., media can flow between the clients).

The following figure provides a simple illustration of ICE:

The device supports ICE-Lite and ICE-Full (or ICE Full):

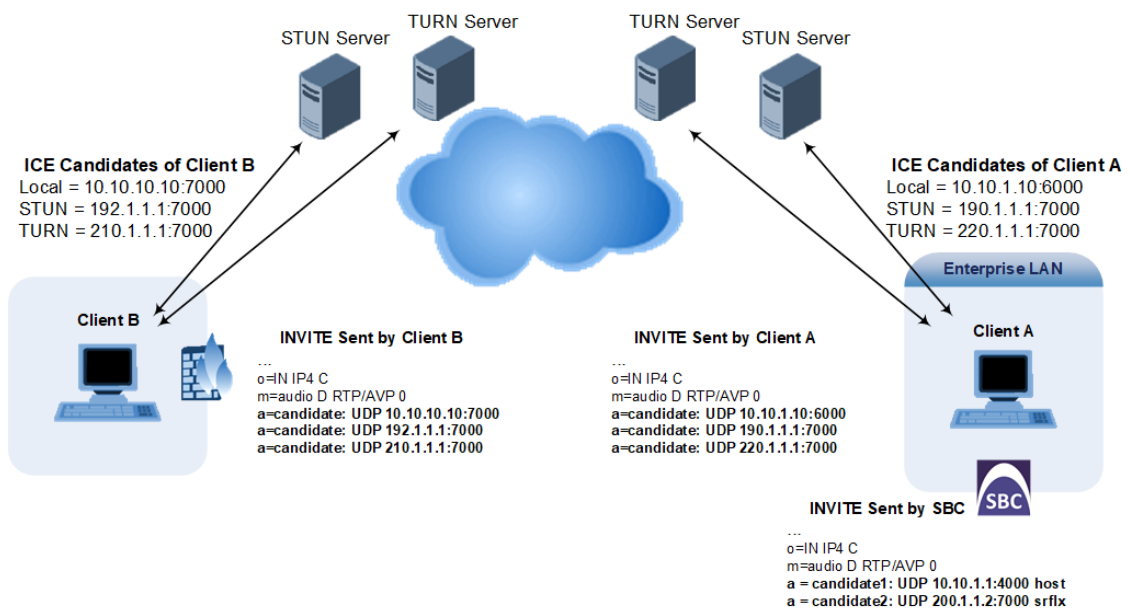

- **ICE-Lite:** When configured for ICE-Lite, the device doesn't initiate the ICE process. Instead, it supports remote endpoints that initiate ICE to discover their workable public IP address with the device. Therefore, the device supports the receipt of STUN binding requests for connectivity checks of ICE candidates and responds with STUN responses. Note that in the response to the INVITE message received from the remote endpoint, the device sends only a single candidate for its' IP address. This is the IP address of the device that the client uses.

The following figure shows an example of using ICE-Lite when the device communicates with a WebRTC client:

- **ICE-Full:** When configured for ICE-Full, the device can play the role as ICE controlled or ICE controlling. The device initiates STUN negotiation for all candidate pairs. The device sends the candidates with its local IP address, and a public IP address if configured in the NAT Translation table (see [Configuring NAT per IP Interface](#) on page 181). The device sends keep-alive messages to keep NAT bindings open for media sessions using ICE-Full.

The following figure shows an example of using ICE-Full, whereby the SBC device sends two candidates, one with its local IP address and one with its public IP address, according to its NAT Translation table.

To support ICE, the device's leg interfacing with the ICE-enabled client (SIP entity) must be enabled for ICE. This is done by using the IP Profile parameter 'ICE Mode' (see [Configuring IP Profiles](#) on page 674), which can be configured to **Lite** or **Full**.

As the ICE technique has been defined by the WebRTC standard as mandatory for communication with the WebRTC client, ICE support by the device is important for deployments implementing WebRTC. For more information on WebRTC, see [WebRTC](#) on page 1269. Once a WebRTC session (WebSocket) is established for SIP signaling between the device and the WebRTC client, the client's IP address needs to be discovered by the SBC device using the ICE technique.

## Media Latching for Robust Receipt of Media Streams

The device's Robust Media feature (or media latching) filters out unwanted media (RTP, RTCP, SRTP, SRTCP, and T.38) streams that are sent to the same port number of the device. Media ports may receive additional multiple unwanted media streams (from multiple sources of traffic) as result of traces of previous calls, call control errors, or deliberate malicious attacks (e.g., Denial of Service). When the device receives more than one media stream on the same port, the Robust Media mechanism detects the valid media stream and ignores the rest. Thus, this can prevent an established call been stolen by a malicious attacker on the media stream.

For the involved voice channel, the device latches on to the first stream of the first received packet. All packets (of any media type) received from the same IP address and SSRC are accepted (for T.38 packets, the device considers only the IP address). If the channel receives subsequent packets from a non-latched source, the device can either ignore this new stream and remain latched to the first original stream (IP address:port) or it can latch on to this new stream. The media latch mode is configured using the InboundMediaLatchMode parameter. If this mode is configured to latch on to new streams, you also need to configure the following:

- Minimum number of continuous media packets that need to be received from a different source(s) before the channel can latch onto this new incoming stream.
- Period (msec) during which if no packets are received from the current stream, the channel latches onto the next packet received from any other stream.

Depending on media latch mode, if the device has latched on to a new stream and a packet from the original (first latched onto) IP address:port is received at any time, the device latches on to this original stream.

Latching on to a new T.38 stream is reported in CDR using the CDR fields, LatchedT38Ip (new IP address) and LatchedT38Port (new port). In addition, the SIP PUBLISH message updates the latched RTP SSRC, for example:

RemoteAddr: IP=10.33.2.55 Port=4000 SSRC=0x66d510ec

### ➤ To configure media latching:

1. Open the Media Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Settings**), and then from the 'Inbound Media Latch Mode' drop-down list (InboundMediaLatchMode), configure the media latch mode:

Inbound Media Latch Mode

Dynamic ▼

2. If you configure Step 1 to **Dynamic** or **Dynamic-Strict**:

- Configure the minimum number of continuous media (RTP, RTCP, SRTP, and SRTCP) packets that need to be received by the channel before it can latch onto this new incoming stream:
  - ◆ 'New RTP Stream Packets'
  - ◆ 'New RTCP Stream Packets'
  - ◆ 'New SRTP Stream Packets'
  - ◆ 'New SRTCP Stream Packets'
- Configure a period (msec) after which if no packets are received from the current media session, the channel can re-latch onto another stream:
  - ◆ 'Timeout To Relatch RTP'
  - ◆ 'Timeout To Relatch SRTP'
  - ◆ 'Timeout To Relatch Silence'
  - ◆ 'Timeout To Relatch RTCP'
  - ◆ 'Fax Relay Rx/Tx Timeout'

#### ROBUSTNESS

New RTP Stream Packets	3
New RTCP Stream Packets	3
New SRTP Stream Packets	3
New SRTCP Stream Packets	3
Timeout To Relatch RTP (msec)	200
Timeout To Relatch SRTP (msec)	200
Timeout To Relatch Silence (msec)	10000
Timeout To Relatch RTCP (msec)	10000

3. Click **Apply**, and then save your settings to flash memory.

## Configuring Static ARP Table

The Static ARP table lets you configure up to 30 static Address Resolution Protocol (ARP) entries for mapping IP addresses to Media Access Control (MAC) addresses. Instead of dynamically mapping the Layer-3 address to a Layer-2 address, the device uses this table for mapping between these addresses.

- This table is for both IPv4 and IPv6 addresses. Neighbor Discovery Protocol (NDP) is the IPv6 equivalent of ARP.
- To view the device's cached and static ARP entries, use the CLI command `show network arp`. The command's output displays static ARP mappings as "permanent" and dynamic ARP mappings as "reachable".

The following procedure describes how to configure the ARP table through the Web interface. You can also configure it through ini file [StaticArp] or CLI (`configure network > static-arp-table`).

➤ **To configure static ARP table:**

1. Open the Static ARP table (**Setup** menu > **IP Network** tab > **Core Entities** folder > **Static ARP**).
2. Click **New**; the following dialog box appears:

3. Configure a static ARP entry according to the parameters described in the table below.
4. Click **Apply**.

**Table 13-8: Static ARP Table Parameter Descriptions**

Parameter	Description
'Index'	Defines an index number for the table row. <b>Note:</b> Each row must be configured with a unique index.
'Destination Address' <code>dest-addr</code> [DestAddress]	Defines the IP address of the destination host or network. By default, no value is defined. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ The IP address must be in the same subnet as the specified 'Ethernet Device' (below).</li> </ul>
'MAC Address' <code>mac-addr</code> [MacAddr]	Defines the MAC address that is mapped to the IP address specified in the 'Destination Address' parameter. The valid value is in hexadecimal bytes in the format

Parameter	Description
	nn:nn:nn:nn:nn:nn (e.g., 00:90:8f:12:13:df). By default, no value is defined. <b>Note:</b> The parameter is mandatory.
'Ethernet Device' eth-dev [EthDev]	Assigns an Ethernet Device from the Ethernet Devices table (see <a href="#">Configuring Underlying Ethernet Devices</a> on page 156), which is a VLAN associated with a specific IP interface in the IP Interfaces table. The ARP mapping rule is for packets that the device sends through this Ethernet Device to the specified destination address.

## Configuring Quality of Service

This section describes how to configure Layer-2 and Layer-3 Quality of Service (QoS).

### Configuring Class-of-Service QoS

The QoS Settings page lets you configure Layer-3 Class-of-Service Quality of Service (QoS). This configures Differentiated Services (DiffServ) values for each CoS. DiffServ is an architecture providing different types or levels of service for IP traffic. DiffServ (according to RFC 2474), prioritizes certain traffic types based on priority, accomplishing a higher-level QoS at the expense of other traffic types. By prioritizing packets, DiffServ routers can minimize transmission delays for time-sensitive packets such as VoIP packets.

You can assign DiffServ to the following class of services (CoS):

- Media Premium: RTP packets sent to the LAN
- Control Premium: Control protocol (SIP) packets sent to the LAN
- Gold: HTTP streaming packets sent to the LAN
- Bronze: OAMP packets sent to the LAN

The mapping of an application to its CoS and traffic type is shown in the table below:

**Table 13-9: Traffic/Network Types and Priority**

Application	Traffic / Network Types	Class-of-Service (Priority)
Debugging interface	Management	Bronze
Telnet	Management	Bronze
Web server (HTTP)	Management	Bronze
SNMP GET/SET	Management	Bronze

Application	Traffic / Network Types	Class-of-Service (Priority)
Web server (HTTPS)	Management	Bronze
RTP traffic	Media	Media Premium
RTCP traffic	Media	Media Premium
T.38 traffic	Media	Media Premium
SIP	Control	Control Premium
SIP over TLS (SIPS)	Control	Control Premium
Syslog	Management	Bronze
SNMP Traps	Management	Bronze
DNS client	Varies according to DNS settings: <ul style="list-style-type: none"> <li>■ OAMP</li> <li>■ Control</li> </ul>	Depends on traffic type: <ul style="list-style-type: none"> <li>■ Control: Control Premium</li> <li>■ Management: Bronze</li> </ul>
NTP	Varies according to the interface type associated with NTP (see Assigning NTP Services to Application Types): <ul style="list-style-type: none"> <li>■ OAMP</li> <li>■ Control</li> </ul>	Depends on traffic type: <ul style="list-style-type: none"> <li>■ Control: Control Premium</li> <li>■ Management: Bronze</li> </ul>

➤ **To configure DiffServ (Layer-3 QoS) values per CoS:**

1. Open the QoS Settings page (**Setup** menu > **IP Network** tab > **Quality** folder > **QoS Settings**).
2. Click **New**; the following dialog box appears:

GENERAL	
Media Premium QoS	<input type="text" value="46"/>
Control Premium QoS	<input type="text" value="40"/>
Gold QoS	<input type="text" value="26"/>
Bronze QoS	<input type="text" value="10"/>

- Configure DiffServ values per CoS according to the parameters described in the table below.
- Click **Apply**, and then save your settings to flash memory.

Table 13-10:QoS Settings Parameter Descriptions

Parameter	Description
'Media Premium QoS' media-qos [PremiumServiceClassMediaDiffServ]	Defines the DiffServ value for Premium Media CoS content. The valid range is 0 to 63. The default is 46. <b>Note:</b> You can also configure the parameter per IP Profile ('RTP IP DiffServ' parameter) or Tel Profile ('RTP IP DiffServ' parameter).
'Control Premium QoS' control-qos [PremiumServiceClassControlDiffServ]	Defines the DiffServ value for Premium Control CoS content (Call Control applications). The valid range is 0 to 63. The default is 24. <b>Note:</b> You can also configure the parameter per IP Profile ('Signaling DiffServ' parameter) or Tel Profile ('Signaling DiffServ' parameter).
'Gold QoS' gold-qos [GoldServiceClassDiffServ]	Defines the DiffServ value for Gold CoS content (streaming applications). The valid range is 0 to 63. The default is 26.
'Bronze QoS' bronze-qos [BronzeServiceClassDiffServ]	Defines the DiffServ value for Bronze CoS content (OAMP applications). The valid range is 0 to 63. The default is 10.

## Configuring DiffServ-to-VLAN Priority Mapping

The QoS Mapping table lets you configure up to 64 DiffServ-to-VLAN priority mapping for Layer 3 and Layer-2 Quality of Service (QoS). For each packet sent to the LAN, the VLAN Priority of the packet is set according to the DiffServ value in the IP header of the packet. Layer-2 802.1Q frames have a 2-byte field called Tag Control Information. The three most significant bits of this 2-byte field represents the Class of Service (CoS) value. Layer-2 QoS is represented by this CoS

value which is from 0 to 7 (thus 8 values). Layer-2 QoS parameters define the values for the 3 priority bits in the VLAN tag according to the value of the DiffServ field in the packet IP header (according to the IEEE 802.1p standard). Differentiated Services (DiffServ) is an architecture providing different types or levels of service for IP traffic. DiffServ (according to RFC 2474), prioritizes certain traffic types based on priority, accomplishing a higher-level QoS at the expense of other traffic types. By prioritizing packets, DiffServ routers can minimize transmission delays for time-sensitive packets such as VoIP packets.

The following procedure describes how to configure DiffServ-to-VLAN priority mapping through the Web interface. You can also configure it through ini file [DiffServToVlanPriority] or CLI (configure network > qos vlan-mapping).

➤ **To configure DiffServ-to-VLAN priority mapping:**

1. Open the QoS Mapping table (**Setup** menu > **IP Network** tab > **Quality** folder > **QoS Mapping**).
2. Click **New**; the following dialog box appears:

3. Configure a DiffServ-to-VLAN priority mapping rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 13-11:QoS Mapping Table Parameter Descriptions**

Parameter	Description
'Index'	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Differentiated Services' diff-serv [DiffServToVlanPriority_DiffServ]	Defines a DiffServ value. The valid value is 0 to 63. The default is 0.
'VLAN Priority' vlan-priority	Defines the VLAN priority level. The valid value is 0 to 7. The default is 0.

Parameter	Description
[DiffServToVlanPriority_VlanPriority]	

## Configuring ICMP Message Handling

Internet Control Message Protocol (ICMP) is one of the core protocols of the Internet Protocol suite. It's used by network devices such as routers to send error messages indicating, for example, that a requested service is unavailable.

You can configure the device to handle ICMP messages as follows:

- Send and receive ICMP Redirect messages.
- Send ICMP Destination Unreachable messages. The device sends this message in response to a packet that cannot be delivered to its destination for reasons other than congestion. The device sends these messages upon any of the following:
  - Address unreachable
  - Port unreachable

This feature is applicable to IPv4 and IPv6 addressing schemes.

### ➤ To configure ICMP message handling:

1. Open the Network Settings page (**Setup** menu > **IP Network** tab > **Advanced** folder > **Network Settings**).
2. Under the ICMP group, do the following:
  - To enable sending and receipt of ICMP Redirect messages, configure the 'Send and Received ICMP Redirect Messages' [DisableICMPRedirects] parameter to **Yes**.
  - To enable sending of ICMP Destination Unreachable messages, configure the 'Don't Send ICMP Unreachable Messages' [DisableICMPUnreachable] parameter to **No**.

ICMP	
Send and Receive ICMP Redirect Messages	<div><div></div>Yes</div>
Don't Send ICMP Unreachable Messages	<div>No</div>

3. Click **Apply**.

## DNS

If you are using fully qualified domain names (FQDN) instead of IP addresses for some of your device configuration, the domain names need to be resolved into IP addresses by Domain Name System servers. The device provides various ways to do this:

- External, third-party DNS servers:
  - DNS servers configured in the IP Interfaces table for the associated IP network interface (see [Configuring IP Network Interfaces](#) on page 159)
  - Default DNS servers (see [Configuring Default DNS Servers](#) on the next page)
- Device's embedded DNS (and SRV) server:
  - Internal DNS table (see [Configuring the Internal DNS Table](#) on page 199)
  - Internal SRV table ([Configuring the Internal SRV Table](#) on page 201)

### Default DNS Fallback Sequence

The device has a default DNS fallback sequence which is used if you don't configure customized DNS fallback policies in the DNS Fallback Policy table (see [Configuring DNS Fallback Policy](#) on page 203).

The device's default DNS fallback sequence for choosing which DNS server to query for DNS resolution depends on traffic type (IPv4 or IPv6) and is as follows:

- **IPv4 traffic:**
  - a. (Call Routing Only) The device checks the Internal DNS table or Internal SRV table for a matching FQDN and queries the corresponding DNS server (see [Configuring the Internal DNS Table](#) on page 199). If no matching FQDN is found, the device proceeds to the next DNS fallback priority (below).
  - b. The device queries the DNS server of the associated IP Interface configured in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
  - c. If no DNS server is configured for the associated IP Interface (or DNS failure occurs), the device queries the DNS server of the default IPv4 OAMP ("O+M+C") IP Interface.
  - d. If no DNS server is configured for the default OAMP IP Interface (or DNS failure occurs), the device queries the default IPv4 DNS servers (see [Configuring Default DNS Servers](#) on the next page).
- **IPv6 traffic:**
  - a. The device queries the DNS server of the associated IP Interface configured in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
  - b. If no DNS server is configured for the associated IP Interface (or DNS failure occurs), the device queries the DNS server of the default IPv6 OAMP ("O+M+C\_6") IP Interface.

- c. If no DNS server is configured for the default IPv6 OAMP IP Interface (or DNS failure occurs), the device queries the DNS server of the default IPv4 OAMP ("O+M+C") IP Interface.
- d. If no DNS server is configured for the default IPv4 OAMP IP Interface, the device queries the default IPv6 DNS servers (see [Configuring Default DNS Servers](#) below).
- e. If there are no default IPv6 DNS servers, the device queries the default IPv4 DNS servers (see [Configuring Default DNS Servers](#) below).

The device uses the default DNS servers only for specific applications, for example, SBC Configuration Wizard, CLI `ping` command, and Automatic Update. The device doesn't use the default DNS servers for call routing.

## Configuring Default DNS Servers

The device provides default DNS server addresses for IPv4 and IPv6 networks. Each IP address scheme (IPv4 and IPv6) has a primary and a secondary default DNS server. The default DNS servers ensure that applications (for example, Automatic Update feature or pinging a destination) which may need DNS lookups, run seamlessly if you haven't configured any DNS servers in the Internal DNS table and IP Interfaces table. In other words, the device uses the default DNS server as the last resort. For more information on when the device uses these default DNS servers for its default DNS fallback sequence, see [Default DNS Fallback Sequence](#) on the previous page.

The default IP addresses, which you can modify as described later in this section, of these default DNS servers are listed in the following table:

IP Addressing Scheme	Default Primary DNS Server	Default Secondary DNS Server
IPv4	8.8.8.8	8.8.4.4
IPv6	2001:4860:4860::8888	2001:4860:4860::8844

The device uses the default DNS servers only for specific applications, for example, SBC Configuration Wizard, CLI `ping` command, and Automatic Update feature. The device doesn't use the default DNS servers for call routing.

You can modify the IP addresses of the default DNS servers, as described below.

### ➤ To modify default DNS server addresses:

1. Open the DNS Settings page (**Setup** menu > **IP Network** tab > **DNS** folder > **DNS Settings**).

Default Primary DNS Server IP	8.8.8.8
Default Secondary DNS Server IP	8.8.4.4
Default Primary DNS Server IPv6	2001:4860:4860::8888
Default Secondary DNS Server IPv6	2001:4860:4860::8844

**2. For IPv4 DNS servers:**

- a. In the 'Default Primary DNS Server IP' field, configure the IPv4 address of the default primary DNS server.
- b. In the 'Default Secondary DNS Server IP' field, configure the IPv4 address of the default secondary DNS server.

**3. For IPv6 DNS servers:**

- a. In the 'Default Primary DNS Server IPv6' field, configure the IPv6 address of the default primary DNS server.
- b. In the 'Default Secondary DNS Server IPv6' field, configure the IPv6 address of the default secondary DNS server.

**4. Click **Apply**.**

## Configuring the Internal DNS Table

The Internal DNS table, similar to a DNS resolution can translate up to 20 host (domain) names into IP addresses. This functionality can be used when a domain name (FQDN) is configured as an IP destination in a routing rule. For the Gateway application, this is typically used for alternative Tel-to-IP call routing. Up to three different IP addresses can be assigned to the same host name.

The device attempts to resolve a domain name into an IP address in the following order:

1. The device first checks the Internal DNS table for a matching domain name and if found, resolves the domain name into the corresponding IP address(es).
2. If no matching domain name exists in the Internal DNS table, the device performs a DNS query with an external third-party DNS server whose address is configured for the associated IP network interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
3. If the associated IP interface is not configured with a DNS server or DNS resolution fails, DNS fallback is according to a configured DNS Fallback Policy (see [Configuring DNS Fallback Policy](#) on page 203) or the device's default DNS fallback sequence (see [Default DNS Fallback Sequence](#) on page 197) if you haven't configured a DNS Fallback Policy.

The device uses the Internal DNS table only for call routing, for example:

- Call routing according to a SIP Request-URI that contains a hostname.
- Call routing by destination address that is configured as a hostname.
- Call routing by ENUM and the result of the ENUM query is a hostname.
- DNS resolution of proxy servers in a Proxy Set that are configured with an FQDN.
- Registering a user agent whose REGISTER message has a Contact header that is a hostname.

The following procedure describes how to configure the DNS table through the Web interface. You can also configure it through ini file [DNS2IP] or CLI (`configure network > dns dns-to-ip`).

➤ **To configure the device's DNS table:**

1. Open the Internal DNS table (**Setup** menu > **IP Network** tab > **DNS** folder > **Internal DNS**).
2. Click **New**; the following dialog box appears:

3. Configure a DNS rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 13-12: Internal DNS Table Parameter Description**

Parameter	Description
'Index'	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Domain Name' domain-name [Dns2Ip_	Defines the host name to be translated. The valid value is a string of up to 31 characters.

Parameter	Description
DomainName]	
'First IP Address' first-ip-address [Dns2Ip_ FirstIpAddress]	Defines the first IP address (in dotted-decimal format notation) to which the host name is translated. The IP address can be configured as an IPv4 and/or IPv6 address.
'Second IP Address' second-ip-address [Dns2Ip_ SecondIpAddress]	Defines the second IP address (in dotted-decimal format notation) to which the host name is translated.
'Third IP Address' third-ip-address [Dns2Ip_ ThirdIpAddress]	Defines the third IP address (in dotted-decimal format notation) to which the host name is translated.

## Configuring the Internal SRV Table

The Internal SRV table lets you configure up to 10 SRV rows. The table is used to resolve hostnames into DNS A-Records. You can assign three different A-Records per hostname, where each A-Record includes the hostname, priority, weight, and port.

The device attempts to resolve a domain name into an IP address in the following order:

1. The device first checks the Internal SRV table for a matching domain name and if found, resolves the domain name into the corresponding IP address(es).
2. If no matching domain name exists in the Internal SRV table, the device performs a DNS query with an external third-party DNS server whose address is configured for the associated IP network interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
3. If the associated IP interface is not configured with a DNS server or DNS resolution fails, DNS fallback is according to a configured DNS Fallback Policy (see [Configuring DNS Fallback Policy](#) on page 203), or the device's default DNS fallback sequence (see [Default DNS Fallback Sequence](#) on page 197) if you haven't configured a DNS Fallback Policy.

The following procedure describes how to configure the Internal SRV table through the Web interface. You can also configure it through ini file [SRV2IP] or CLI (`configure network > dns srv2ip`).

➤ **To configure the device's SRV table:**

1. Open the Internal SRV table (**Setup** menu > **IP Network** tab > **DNS** folder > **Internal SRV**).
2. Click **New**; the following dialog box appears:

The screenshot shows the 'Internal SRV' configuration window. It is divided into four main sections for configuring different entries in the SRV table:

- GENERAL:** Contains fields for 'Index' (set to 0), 'Domain Name' (empty), and 'Transport Type' (set to UDP via a dropdown menu).
- 1ST ENTRY:** Contains fields for 'DNS Name 1', 'Priority 1' (0), 'Weight 1' (0), and 'Port 1' (0).
- 2ND ENTRY:** Contains fields for 'DNS Name 2', 'Priority 2' (0), 'Weight 2' (0), and 'Port 2' (0).
- 3RD ENTRY:** Contains fields for 'DNS Name 3', 'Priority 3' (0), 'Weight 3' (0), and 'Port 3' (0).

3. Configure an SRV rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 13-13: Internal SRV Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index'	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Domain Name' domain-name [Srv2Ip_ InternalDomain]	Defines the hostname to be translated. The valid value is a string of up to 31 characters. By default, no value is defined.
'Transport Type' transport- type [Srv2Ip_ TransportType]	Defines the transport type. <ul style="list-style-type: none"> <li>■ [0] <b>UDP</b> (default)</li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS</b></li> </ul>

Parameter	Description
1st/2nd/3rd Entry	
'DNS Name (1-3)' dns-name- 1   2   3 [Srv2Ip_Dns1/2/3]	Defines the first, second or third DNS A-Record to which the hostname is translated.  By default, no value is defined.
'Priority (1-3)' priority- 1   2   3 [Srv2Ip_ Priority1/2/3]	Defines the priority of the target host. A lower value means that it is more preferred.  By default, no value is defined.
'Weight (1-3)' weight-1   2   3 [Srv2Ip_ Weight1/2/3]	Defines a relative weight for records with the same priority.  By default, no value is defined.
'Port (1-3)' port-1   2   3 [Srv2Ip_Port1/2/3]	Defines the TCP or UDP port on which the service is to be found.  By default, no value is defined.

## Configuring DNS Fallback Policy

The DNS Fallback Policy table lets you configure up to two DNS fallback policies, each for a different traffic type - IPv4 and IPv6. The policy defines a DNS fallback sequence (priority), specifying which DNS server to use if a DNS server fails (unreachable). This table allows you to fully customize the DNS fallback sequence.

Each DNS Fallback policy allows you to prioritize (*rule*) the sequence ("chain") of DNS fallback between the following DNS servers:

- DNS server configured for the OAM IPv4 interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
- DNS server configured for the OAM IPv6 interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
- Device's Default IPv4 DNS servers, configured in [Configuring Default DNS Servers](#) on page 198.
- Device's Default IPv6 DNS servers, configured in [Configuring Default DNS Servers](#) on page 198.

- If you don't configure the DNS Fallback Policy table for a specific traffic type, the device's default DNS fallback sequence is applied, as described in [Default DNS Fallback Sequence](#) on page 197.
- Currently, the DNS fallback Policy can't be configured per IP Interface. It only uses the IPv4 and IPv6 OAM interfaces.
- If the device is restored to factory defaults, the DNS Fallback Policy table doesn't return to default, but maintains its current configuration.
- 

The following procedure describes how to configure DNS fallback policies through the Web interface. You can also configure it through ini file [DnsFallbackPolicy] or CLI (`configure network > dns-fallback-policy`).

➤ **To configure a DNS fallback policy:**

1. Open the DNS Fallback Policy table (**Setup** menu > **IP Network** tab > **DNS** folder > **DNS Fallback Policy**).
2. Select either the IPv4 or IPv6 pre-configured row, depending on the traffic type for which you want to configure a DNS Fallback policy, and then click **Edit**; the following dialog box appears (e.g., for IPv4 traffic):

3. Configure a DNS Fallback policy according to the parameters described in the table below.
4. Click **Apply**.

**Table 13-14:DNS Fallback Policy Table Parameter Description**

Parameter	Description
'Index'	(Read-only) Index number of the table row. <b>Note:</b> The table supports only two rows (index 0 and 1), each with a different IP version—one for IPv4 and one for IPv6.

Parameter	Description
'Type' type [Type]	<p>Defines the type of traffic (IP version) for which you want to apply the DNS Fallback policy.</p> <ul style="list-style-type: none"> <li>■ [0] <b>IPv4</b> (Default)</li> <li>■ [1] <b>IPv6</b></li> </ul> <p><b>Note:</b> The table supports only two rows, each with a different IP version—one for IPv4 and one for IPv6.</p>
'Rule1' rule1 [Rule1]	<p>Defines the first DNS fallback rule.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> (Default)</li> <li>■ [1] <b>OAM Interface IPv4</b></li> <li>■ [2] <b>OAM Interface IPv6</b></li> <li>■ [3] <b>Global DNS IPv4</b></li> <li>■ [4] <b>Global DNS IPv6</b></li> </ul> <p><b>Note:</b> The value <b>None</b> can appear in multiple rules, but the other values can only appear in one rule. For example, configuring both 'Rule1' and 'Rule2' to <b>Global DNS IPv4</b> is not allowed.</p>
'Rule2' rule2 [Rule2]	<p>Defines the second DNS fallback rule if rule 1 fails (or configured to <b>None</b>).</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> (Default)</li> <li>■ [1] <b>OAM Interface IPv4</b></li> <li>■ [2] <b>OAM Interface IPv6</b></li> <li>■ [3] <b>Global DNS IPv4</b></li> <li>■ [4] <b>Global DNS IPv6</b></li> </ul> <p><b>Note:</b> The value <b>None</b> can appear in multiple rules, but the other values can only appear in one rule. For example, configuring both 'Rule1' and 'Rule2' to <b>Global DNS IPv4</b> is not allowed.</p>
'Rule3' rule3 [Rule3]	<p>Defines the third DNS fallback rule if rule 2 fails (or configured to <b>None</b>).</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> (Default)</li> <li>■ [1] <b>OAM Interface IPv4</b></li> <li>■ [2] <b>OAM Interface IPv6</b></li> <li>■ [3] <b>Global DNS IPv4</b></li> <li>■ [4] <b>Global DNS IPv6</b></li> </ul> <p><b>Note:</b> The value <b>None</b> can appear in multiple rules, but the other values</p>

Parameter	Description
	can only appear in one rule. For example, configuring both 'Rule1' and 'Rule2' to <b>Global DNS IPv4</b> is not allowed.
'Rule4' rule4 [Rule4]	<p>Defines the fourth DNS fallback rule if rule 3 fails (or configured to <b>None</b>).</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> (Default)</li> <li>■ [1] <b>OAM Interface IPv4</b></li> <li>■ [2] <b>OAM Interface IPv6</b></li> <li>■ [3] <b>Global DNS IPv4</b></li> <li>■ [4] <b>Global DNS IPv6</b></li> </ul> <p><b>Note:</b> The value <b>None</b> can appear in multiple rules, but the other values can only appear in one rule. For example, configuring both 'Rule1' and 'Rule2' to <b>Global DNS IPv4</b> is not allowed.</p>

## Open Solution Network (OSN) Server

This section describes various networking settings for the OSN server.

- The OSN is a customer-ordered item.
- For information on cabling the OSN, refer to the device's *Hardware Installation Manual*.

## Configuring Native VLAN for OSN Server

You can configure a VLAN ID associated with any application type (Media, Control, or OAMP) to access the Open Solution Network (OSN) server through the device's internal port switch. By default, access to the OSN is from the OAMP interface VLAN ID 1. Configuring a Native VLAN is useful, for example, to separate traffic within the device - between the OSN (i.e., application traffic) and voice traffic.

This feature is applicable only if you connect to the OSN through one of the device's VoIP LAN ports (on the front panel). If you are connecting to the OSN through the OSN's Gigabit Ethernet port (on the rear panel), this feature is not applicable.

### ➤ To configure a Native VLAN for the OSN:

1. Open the Network Settings page (**Setup** menu > **IP Network** tab > **Advanced** folder > **Network Settings**).
2. Scroll down to the OSN group:

OSN

OSN Native VLAN ID

0

3. In the 'OSN Native VLAN ID' field, configure the VLAN ID, and then click **Apply**.

When configured to 0 (default), the OSN uses the OAMP VLAN ID. When set to any other value, it specifies a VLAN configured in the Ethernet Devices table (see [Configuring Underlying Ethernet Devices](#) on page 156), which is assigned to a Media and/or Control application in the IP Interfaces table.

## Disabling Internal Switch Port for OSN

You can enable or disable (block) the Ethernet port of the device's internal switch which interfaces with the OSN server. If the port is not blocked, you can optionally access the OSN server through any Ethernet port on the device's front panel (instead of through the OSN module's Ethernet ports located on the rear panel). If you block the port, then you can access the OSN server **only** through the Ethernet ports on the OSN module.

You can also view the status of the port (Up or Down), by running the following CLI command:

```
# show network interface osn
```

### ➤ To enable / disable the internal switch's Ethernet port interfacing with OSN:

1. Open the Network Settings page (**Setup** menu > **IP Network** tab > **Advanced** folder > **Network Settings**).
2. From the 'Block OSN Port' drop-down list, select **Yes** (to block) or **No**:

Block OSN Port

• Yes ▼

3. Click **Apply**.

## IP Multicasting

The device supports IP Multicasting level 1, according to RFC 2236 (i.e., IGMP version 2) for RTP channels. The device is capable of transmitting and receiving multicast packets.

## 14 Security

This section describes the VoIP security-related configuration.

### Overview of GDPR

AudioCodes is committed to supporting the European Union's (EU) General Data Protection Regulation (GDPR), by protecting and respecting personal data processed by the device.

To help you comply with GDPR, the device provides a tool as well as parameters that delete or mask (hide) personally identifiable information (PII), as described in this section:

- [Masking PII from Syslog Files using PII Log Scrubber Tool](#) below
- [Masking PII in CDRs](#) on the next page
- [Masking Digits in Syslog Messages](#) on page 211
- [Deleting Locally Stored CDRs](#) on page 212

### Masking PII from Syslog Files using PII Log Scrubber Tool

You can use the AudioCodes PII Log Scrubber tool (Python script) to remove (mask) all personally identifiable information (PII) from syslog files created by the device. You can run the tool on any laptop, PC, or server that has Python 3 installed.

A summary of the PII that the tool scrubs (masks) is listed below. For a full list, refer to the *history.txt* file that is downloaded with the tool (see procedure below).

- IP addresses
- SIP URIs - hostnames, numbers, and display names
- urn:uuid
- Hostnames in Host header
- Usernames in Authentication header
- MAC addresses
- Registration logs - AOR, URI, user-part, XML elements phoneNumber / extension / alias
- tel: URIs
- Gateway logs - caller and callee numbers, collected digits, and dialed digits

The tool replaces IP addresses with "0.0.0.0", user parts with "USER", host parts with "HOST", authentication usernames with "USERNAME", numbers with "NUM", AORs with "VALUE", and MACs with "MAC". An example of a scrubbed syslog file is shown below with some of these masks (scrubbed data highlighted in yellow):

```
08:47:51.97 local3.notice [S=2850846] [SID=f124e3:49:83278] (N
1 0.0.0.0 1062346) ---- Outgoing SIP Message to 0.0.0.0:61694
```

```

E, SUBSCRIBE,NOTIFY,PRACK,UPDATE,REFER"
Expires: 60
Content-Length: 0
[Time:09-05@08:47:51.214]

```

➤ **To remove PII using PII Log Scrubber:**

1. Make sure that you have Python 3 installed on your computer. For instructions on installing Python, got to <https://www.python.org/downloads>.
2. Download the PII Log Scrubber tool from <https://tools.audiocodes.com/install>.
3. Locate the PII Log Scrubber tool in the same folder in which the syslog file that you want to mask is located, and then run the Python script from the command line:

```
<Directory and folder> python log_scrub.py <syslog filename> <new masked
syslog filename>
```

## Masking PII in CDRs

For GDPR compliance, you can configure the device to mask personally identifiable information (PII) in CDRs that are created by the device. This includes CDRs that the device displays in the Web interface and CLI, as well as CDRs that it sends to syslog, REST, RADIUS, Local Storage, or OVOC (depending on configuration).

Depending on configuration, the PII that the device masks includes telephone numbers, URI user parts, display names, IP addresses, hostnames, and URI host parts.

The device masks PII in all CDR fields, except the following (based on destination):

- **OVOC:** SrcIP, DestIP, SigSrcIP, SigDstIP, SigRmtIP, OldDestIP, and NewRemIP.
- **Non-OVOC:** SourceIP, DestIP, IngressCallSourceIP, EgressCallDestIP, EgressLocalRtpIP, EgressRemoteRtpIP, IngressLocalRtpIP, IngressRemoteRtpIP, RemoteRtpIP, LocalRtpIP, LatchedRtpIP, and LatchedT38IP.

➤ **To mask PII in CDRs:**

1. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
2. From the 'Mask PII in CDRs' drop-down list, select one of the following:
  - **Disable:** No PII masking is done in management interfaces (Web and CLI), syslog, REST, Local Storage, and RADIUS.
  - **Mark PII in Web or CLI:** The device masks (by a single asterisk \* symbol) private information (caller and callee) in the Web interface's SBC CDR History table (see [Viewing CDR History of SBC and Test Calls](#) on page 1495) and Gateway CDR History table (see [Viewing Gateway CDR History](#) on page 1493), and CLI (e.g., `show voip calls`). For example, the device masks the URI "name@domain.com" as "\*".
  - **Mask PII in Detailed Records:** The device masks (by multiple asterisks \*) private information in CDRs. This applies to all destinations to where the device sends these records (i.e., syslog, REST, Local Storage, and RADIUS), except ARM and OVOC. This option also affects PII in the Web interface's SBC CDR History table and Gateway CDR History table, and CLI (e.g., `show voip calls`). For URIs, only the user part is masked when this option is selected.

Mask PII in CDRs

• Mask PII in Web or CLI ▼

If you enable the 'Mask URI Host Part in CDRs' parameter (see below), the device also masks IP addresses, hostnames, and URI host parts.

3. If you configure the above parameter to **Mask PII in Detailed Records**, you can configure which characters in the masked element (e.g., phone number) to mask:
  - a. In the 'Number of Unmasked Characters in PII' field, enter the number of characters to show. The rest of the characters are masked. To mask all characters, configure the parameter to "0".
  - b. In the 'Location in PII of Unmasked Characters' field, define from where in the PII element to show (not mask):

- ◆ **Last Characters:** The device shows the number of characters specified by the 'Number of Unmasked Characters in PII' parameter (above) starting from the end of the PII element. For example, if the original number is 97216789 and the 'Number of Unmasked Characters in PII' parameter is configured to "4", the device masks the number as "\*\*\*\*6789".
- ◆ **First Characters:** The device shows the number of characters specified by the 'Number of Unmasked Characters in PII' parameter (above) starting from the beginning of the PII element. For example, if the original number is 97216789 and the 'Number of Unmasked Characters in PII' parameter is configured to "4", the device masks the number as "9721\*\*\*\*".

Number of Unmasked Characters in PII

4

Location in PII of Unmasked Characters

Last Characters

4. Select the 'Mask PII in CDRs for OVOC' check box to mask (with asterisks) phone numbers, URI user part, and display names that appear in CDRs that the device sends to OVOC:

Mask PII in CDRs for OVOC

If you enable the 'Mask URI Host Part in CDRs' parameter, the device also masks IP addresses and hostnames in CDRs sent to OVOC.

5. Select the 'Mask URI Host Part in CDRs' check box to mask (with asterisks) the host part of URIs (including IP addresses) in CDRs that the device sends to Web, CLI, syslog, REST, RADIUS, and Local Storage (depending on the 'Mask PII in CDRs' parameter - see Step 2), or to OVOC if the 'Mask PII in CDRs for OVOC' parameter is enabled (see Step 4):

Mask URI Host Part in CDRs

The parameter is applicable only if you enable the 'Mask PII in CDRs' or 'Mask PII in CDRs for OVOC' parameters for the targets (i.e., this is an additional modifier of PII masking for these targets).

6. Click **Apply**.

## Masking Digits in Syslog Messages

You can mask digits (typically, in-band DTMF) that are sent as events and detected by the device, including SIP messages (INFO and NOTIFY) in syslog and Debug Recording (message body) generated by the device.

➤ **To mask digits:**

1. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
2. Select the 'Mask Digits' check box:

Mask Digits ☒

3. Click **Apply**.

## Deleting Locally Stored CDRs

If you have enabled local storage of CDRs (see [Storing CDRs Locally on the Device](#) on page 1516), you can delete them from storage at any time through the device's CLI:

- To delete all stored CDR files:

```
# clear storage-history cdr-storage-history all
```

- To delete all unused stored CDR files:

```
# clear storage-history cdr-storage-history unused
```

## Concealing Configured Passwords

For security, the device offers you various methods to conceal configured passwords:

- Password obfuscation using an encryption key - see [Password Obfuscation in CLI Script and ini Files](#) below
- Obscured passwords in CLI - see [Enabling or Disabling Password Obscured for CLI](#) on page 217

### Password Obfuscation in CLI Script and ini Files

You can enhance security by obfuscating passwords in the downloaded ini and CLI Script files. Password encryption is achieved using the AES-256 algorithm with a 16-bit random CFB initialization vector (IV) cipher mode, using an encryption key. This method offers robust protection of sensitive data.

Obscured passwords are displayed in the following syntax:

- **ini File:**

Syntax: `$2$<obfuscated password>`

Example:

```
WSTunPassword = $2$8EGYm+FG+JJT/p8ZOytU64upIPMKcw==
```

#### ■ CLI Script File:

Syntax: *<obscured password>== encrypted*

Example:

```
password B55osyLT1t7+oorwkaNB3bxEX4BI8g== encrypted
```

To configure an encryption key for password obfuscation, see [Configuring Password Obfuscation](#) below. To disable password obfuscation (by clearing encryption key), see [Disabling Password Obfuscation](#) on page 216

- If you need to downgrade the device to an earlier version that doesn't support password obfuscation, you must **clear** the encryption key (see [Disabling Password Obfuscation](#) on page 216).
- The encryption key remains unaffected even when the device is restored to factory defaults.
- If you configure password obfuscation by encryption key as described in this section, the device automatically disables the CLI password obscured feature (see [Enabling or Disabling Password Obscured for CLI](#) on page 217).

### Configuring Password Obfuscation

For password obfuscation, you need to configure the encryption key. You can manually define the encryption key or you can trigger the device to automatically generate a key.

If you want to manually configure the key, it must be exactly **32** characters long and can contain a combination of the following characters:

- Lowercase and uppercase letters (a-z and A-Z)
- Numbers (0-9)
- Special characters: !, #, \$, %, &, (, ), \*, +, ,, -, ., /, <, =, >, ?, @, [, ], ^, \_ ` {, }, ~

#### ➤ To configure encryption key for password obfuscation:

##### ■ Web interface:

- a. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Settings**).
- b. Scroll down the page to the **Encryption Key** group:

**ENCRYPTION KEY**

Encryption Key	<input type="text"/>
Generate Encryption Key	<button>Generate Encryption Key</button>
Clear Encryption Key	<button>Clear Encryption Key</button>

- c. Configure the encryption key, using one of the following methods:

- ◆ **Manually:** In the 'Encryption Key' field, enter your encryption key.
- ◆ **Automatically Generated by Device:** Click the **Generate Encryption Key** button; a message is displayed at the bottom of the page indicating that the key was successfully generated and copied to your clipboard. In addition, the key is partially displayed in the 'Encryption Key' field, showing the first four characters followed by three asterisks (\*), for example, "F/sZ\*\*\*". For future use, you can paste the key from your clipboard to a safe location.

■ **CLI:**

- **Manually:** `configure network > security-settings > encryption-key assign <your key>`
- **Automatically Generated by Device:** `configure network > security-settings > encryption-key generate`

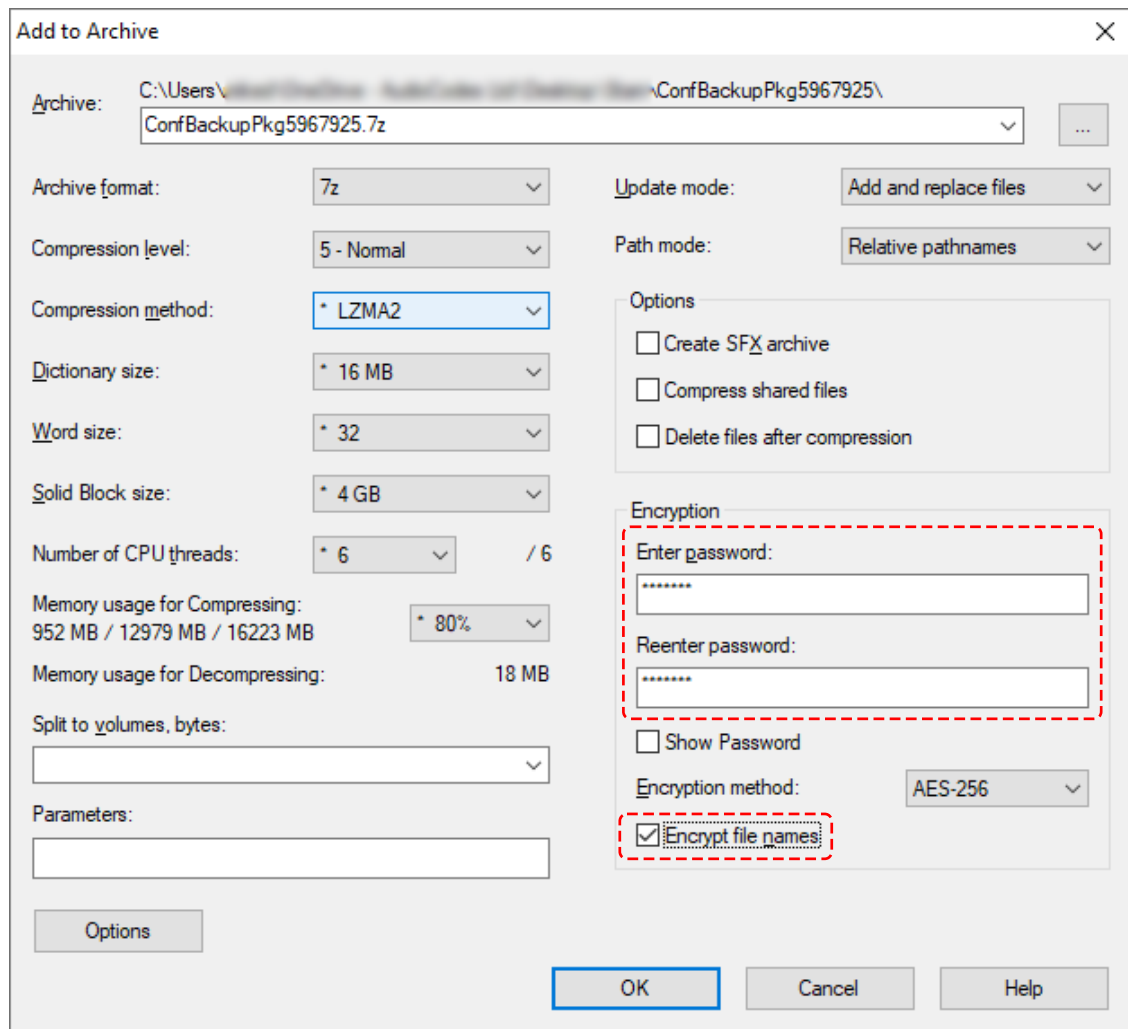

### ■ Configuration Package File (manually):

- a. Download the Configuration Package file as password-protected (see [Downloading or Uploading Configuration Package File](#) on page 1389).
- b. Unzip the downloaded file (you'll be prompted for the password).
- c. Open the unzipped file folder, and then create a file with the name "encryption.key" using any text editor (e.g., Notepad).
- d. Add an encryption key to the *encryption.key* file, and then save the file. The following shows an example of an unzipped Configuration Package file with a created encryption file:

- e. Compress all the files in the unzipped folder into a 7-Zip archive file:
  - i. Select all the files in the unzipped folder, right-click, and then from the drop-down menu, choose **7-Zip > Add to archive**; the Add to Archive dialog box appears.
  - ii. In the 'Enter password' and 'Reenter password' fields, enter the password that you used to encrypt the downloaded Configuration Package file, and then select the 'Encrypt file names' check box:

- iii. Click **OK**; the Configuration Package file is compressed into a 7-Zip archive file.
- f. Upload the zipped Configuration Package file to the device (you'll be prompted for the password used to encrypt it). For more information, see [Downloading or Uploading Configuration Package File](#) on page 1389.

### Disabling Password Obfuscation

If you want to disable password obfuscation, you need to delete (clear) the encryption key. You can do this using various methods.

#### ➤ To clear (disable) password obfuscation:

##### ■ Web interface:

- a. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Settings**).
- b. Scroll down the page to the **Encryption Key** group:

ENCRYPTION KEY	
Encryption Key	<input type="text"/>
Generate Encryption Key	<button>Generate Encryption Key</button>
Clear Encryption Key	<button>Clear Encryption Key</button>

- c. Click the **Clear Encryption Key** button.

■ **CLI:** `configure network > security-settings > encryption-key clear`

■ **Configuration Package File:**

- a. Download the encrypted Configuration Package file and unzip it (see [Downloading or Uploading Configuration Package File](#) on page 1389).
- b. Open the encryption.key file, delete the key, and then save the empty file.
- c. Compress all the files in the unzipped folder into a 7-Zip archive file, and then upload it to the device encrypted.

## Enabling or Disabling Password Obscured for CLI

You can enable the device to display passwords encrypted (obscured) instead of in plain text for the following CLI areas:

- Output of the `show running-config` CLI command.
- Downloaded CLI Script file.

When passwords are displayed in the obscured mode, the string "obscured" is displayed after the encrypted password, as shown in the following example:

```
password tIWWhYONjw== obscured
```

➤ **To enable or disable password obscured for CLI:**

```
(config-system)# cli-settings
(cli-settings)# password-obscurity on|off
```

- The password obscured feature is enabled by default.
- If you configure password obfuscation by encryption key (see [Password Obfuscation in CLI Script and ini Files](#) on page 212), the password obscured feature is automatically disabled.

## Default Password Obscured in Ini File

By default, the device displays passwords obscured (encrypted) instead of in plain text in the downloaded ini file. Passwords are displayed encoded in the ini file using the following format:

*\$1\$<obscured password>*

For example:

```
WSTunPassword = $1$tIWWhYONjw==
```

- When you upload an ini file to the device containing obscured passwords, the passwords are parsed and applied to the device.
- The View and Text modes in the INI Viewer & Editor utility display passwords in plain text in parenthesis, as shown in the following example:

```
WSTunPassword = $1$tIWWhYONjw== (123456)
```

## Approved FIPS 140-3 Operation Modes

This section describes the approved FIPS 140-3 operation modes.

### Security Rules

The following security guidelines must be adhered to in order to maintain the approved mode of operation:

- Telnet must be disabled.
- HTTPS must always be used instead of HTTP.
- A TLS session must be enabled for SIP.
- SNMPv3 keys must be entered in hexadecimal (password derivation must not be used).
- Keys must only be imported through a dedicated physical link or a secure tunnel.
- Configured passwords must contain at least eight characters.
- The configured RADIUS secret must contain at least eight characters.
- The module must be configured to restrict the number of failed authentication attempts to three per minute.
- MD5, HMAC MD5, and 3DES are not to be used, unless mandated by an Acceptable Key Establishment Protocol.
- TLS Context configuration:
  - Ciphers of Server/Client should be configured not to use specific ciphers, as follows:  
DEFAULT:!RC4:!aNULL:!eNULL:!AECDH:!ADH:!CAMELLIA:!ARIA128:!SEED:!kRSA:!3DES.
  - TLS1.3 Cipher of Server/Client should not use TLS\_HACHA20\_POLY1305\_SHA256.

- Key Exchange Groups should not use X25519 and X448 group.
  - DH Key size should be 2048.
  - PKEY file should not be encrypted with a passphrase.
  - PKEY file of PKCS12 format should not be used.
- Only the following algorithms are allowed:
- KexAlgorithms = "diffie-hellman-group-exchange-sha256:diffie-hellman-group14-sha1"
  - Ciphers = "aes128-ctr:aes128-cbc:aes256-ctr:aes256-cbc"
  - MAC = "hmac-sha1:hmac-sha2-256"

## User Roles

The Crypto Officer (CO) role as defined by FIPS is allowed for all types of configuration (including security settings). The equivalent user levels on the device are:

■ **Security Administrator**

- **Administrator** (Administrator user level requires an additional password to enter privileged commands and settings)

SNMPv3 access is also defined as CO access.

The User role, as defined by FIPS, can only view configuration. The equivalent user level on the device for User role is "Monitor" user level.

## FIPS Cryptographic Algorithms

This section lists the approved and non-approved algorithms for FIPS.

### Approved Algorithms

In FIPS mode, the cryptographic device supports the following approved algorithms:

- [Cryptographic Library](#)
- [Cryptographic Accelerator Module](#)
- [KDF](#)
- [Cryptographic Accelerator KDF](#)
- [Entropy Library](#)

### Non-Approved Applications in FIPS mode

User should not save information on external USB storage.

## Enabling FIPS Mode

This section provides step-by-step instructions on how to configure the device for FIPS 140 Approved mode.

### Prerequisites

Prior to configuring the device for FIPS, perform the steps described in this section.

### Obtaining PKI Files

Obtain from your organization's public key infrastructure (PKI) administrator three files per context:

- RSA private key file of 2048/3072/4096 bit, encoded in plaintext Base64 format or ECDSA private key files of 256/384/521 bit encoded in plaintext Base64 format. In this document, the name given to this file is `dev_pkey.pem`.
- X509 certificate file, encoded in plaintext Base64 format, containing the matching RSA/ECDSA public key. In this document, the name given to this file is `dev_cert.pem`.
- X509 certificate file, encoded in plaintext Base64 format, containing trusted chain(s) of certificates to be trusted by the device. In this document, the name given to this file is `root.pem`.

It is assumed that these certificates have been configured appropriately in the user's web browsers and that the environment has been secured.

### Initial Device Setup

If the device is in factory-default state, perform the following initial steps; otherwise, skip to [Change the Default Admin Password](#) below.

#### ➤ To perform initial device setup:

1. Connect to the device's management interface.
2. Change the device's default OAMP address (see [Configuring OAMP Interface](#) on page 14).

### Enabling HA Mode

If the target system needs to operate as a High Availability (HA) system, then complete configuration of the system as an HA system (see [Overview of High Availability Mode](#) on page 1302).

### Change the Default Admin Password

The default Administrator login username and password should be changed for security. The password should be at least 8 characters, containing at least two characters from each of the following four groups:

- Uppercase
- Lowercase
- Digits
- Special characters

For changing the password, see [Changing Login Password](#) on page 68.

By default, the module allows only three failed authentication attempts per minute, which ensures that the probability of multiple random authentication attempts being successful is less than 1/100,000.

### Upgrading Device Software to FIPS-Enabled Version

Before configuring the system to operate in FIPS mode, you need to upgrade it to a software version (.cmp file) that supports FIPS and includes the FIPS signature (2048-bit / SHA-256 digital signature).

If the current version doesn't include the FIPS signature, after moving to the FIPS mode, the device will fail to load and returns to the non-FIPS mode. The device performs authentication on the .cmp image file upon every restart. If authentication fails, the device performs zeroization and disables the FIPS mode.

### Initial FIPS Mode Settings

After configuring the OAMP IP address, the following changes must be done through the device's Web interface or CLI to comply with FIPS requirements.

### Setting Modes of Operations

The following table lists the relevant configuration parameters and the values permitted for FIPS mode.

**Table 14-1: Configuration Parameters and Values for FIPS Mode**

INI File Parameter	Permitted Value	Comment
[EnforcePasswordComplexity]	1	Enforces device validation that passwords are composed of at least two characters from each of the four groups (uppercase, lowercase, digits and special characters). This also means that passwords must be at least eight characters in size.
[HTTPSOnly]	1	Enforces only HTTPS connectivity with the device's management interface

INI File Parameter	Permitted Value	Comment
		(Web and REST API).
[TelnetServerEnable]	0	Enables SSH access to the device's CLI on port 22 (default). Telnet access must be blocked.
[HASecuredConnectivityMode]	1	When the device is configured to operate as an HA system (1+1), the Maintenance link must be configured to be secured.

➤ **To apply these parameter settings to the device:**

1. Create a text file (using any text-based tool such as Notepad) with the configuration settings, as shown below:

```
; Setting Password Complexity
EnforcePasswordComplexity = 1

; Secured WEB/REST access
HTTPSOnly = 1

; Allow only secured CLI access (SSH)
TelnetServerEnable = 0

; Set Maintenance Interface to be secured (for HA systems only)
HASecuredConnectivityMode = 1
```

2. Save the file as an .ini file (e.g., device.ini).
3. Upload the file to the device through the Web interface (see [Downloading or Uploading ini File](#) on page 1386).

Once the file is uploaded, the device restarts and is accessible only through HTTPS / SSH.

### Configuring NTP Server and UTC Offset

To ensure that certification is validated correctly, it is essential to configure an NTP server (see [Date and Time](#) on page 136).

### Enabling FIPS Mode

When you first enable the FIPS mode, the device automatically performs *zeroization*, which eventually causes a restart. Zeroization completely wipes out all sensitive content stored on the

device (but retains configuration):

- Security secrets (e.g., private keys for SSH and TLS)
- Debug and Core dump files

When operating in FIPS mode, the device removes all secret keys from generated syslog and debug recording messages. It also performs many internal security tests during runtime. As soon as any one of these tests fail, connection to the device is lost and the device automatically performs zeroization, disables FIPS mode, and then restarts.

- After the device performs zeroization, it automatically generates new secrets (private key) for the self-signed certificate. You can then use this certificate to connect to the device over HTTPS, if needed.
- If the device is operating in FIPS mode and you disable FIPS, the device automatically performs zeroization and then restarts.

➤ **To enable FIPS mode:**

■ **Web Interface:**

- a. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Setting**).
- b. Click the **Enable FIPS** button:

A message appears warning you that a device restart, and private key zeroization, and debug file deletion will occur.

- c. Confirm to enable FIPS mode.

■ **CLI (privileged mode):**

```
# fips on
```

After enabling the FIPS mode, the device performs zeroization and then restarts. When the restart is completed, verify that FIPS mode is enabled:

■ **Web Interface:**

- a. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Setting**).
- b. The text next to the button that enables and disables FIPS (**Enable FIPS** or **Disable FIPS**) indicates the FIPS mode:

- ◆ 'FIPS Mode is Enabled'
- ◆ 'FIPS Mode is Disabled'

■ **CLI:**

```
show system security status
```

### Updating the TLS Contexts

Once FIPS is enabled, all previous TLS Contexts and keys are zeroized, and should be updated with the organization's files, as described previously in [Prerequisites](#) on page 220.

➤ **To update TLS Contexts:**

1. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227), select the TLS Context, and then click the **Change Certificate** link (located below the table).
2. Under the **Upload Certificate Files From Your Computer** group, click the **Load Device Certificate File** button, and then upload the file *dev\_cert.pem* as the device's server/client self-certificate.
3. Click the **Load Private Key File** button, and then upload the file *dev\_pkey.pem* as the device's private key.
4. Navigate back to the the TLS Contexts table, and then click the **Change Certificate** link (located below the table).
5. Click **Import** to upload the file *root.pem* as the trusted root certificate.
6. Click the **Restart** button to save configuration to flash memory.

### Ongoing FIPS Settings

This section describes ongoing FIPS settings.

### Configuring SIP Entities

Perform the following for each SIP Interface, Proxy Set, or IP Profile:

- **SIP Interfaces:** To enforce only SIP over TLS, configure only the TLS port and change all other SIP ports (UDP, TCP and SCTP) to 0.
- **Proxy Sets:** When adding a Proxy Address for a Proxy Set, select **TLS** for the required transport type.
- **IP Profiles:** When adding an IP Profile, configure the 'SBC Media Security Mode' parameter to **SRTP**.

### Adding Management Interfaces

If you add management interfaces (Web, Telnet, or SSH), configure them to use **only** HTTPS. For example, to add Web interfaces, see [Configuring Web Interfaces](#) on page 52.

### Adding HTTP Proxy Servers

When adding HTTP Proxy Servers (see [Configuring HTTP Proxy Servers](#) on page 472), do the following:

- Configure the 'HTTPS Listening Port' field only (i.e. leave the 'HTTP Listening Port' field empty).
- Configure the 'TLS Context' field to the required TLS Context.
- Configure the 'Verify Client Certificate' field to **Yes**.

### Secured Quality of Experience Reports

If you are using OVOC to monitor SIP messages (SIP Ladder or SIP call flow), open the Quality of Experience Settings table (see [Reporting QoE to OVOC](#) on page 523), and then for each entry, enforce secured transport to OVOC:

- Configure the 'Use TLS' field to **Enable**.
- Configure the 'TLS Context' field to the required TLS context.

### Adding RADIUS Servers

If you're configuring RADIUS servers (see [Configuring RADIUS Servers](#) on page 369), the shared secret size must contain at least 8 characters. However, at least 16 characters are recommended.

### Adding SNMP Users

If SNMP is not being used, you should disable it (see [Enabling or Disabling SNMP](#) on page 108).

If you're using SNMP, SNMPv3 must be enforced by adding at least one SNMPv3 user (see [Configuring SNMP Community Strings](#) on page 109). When adding SNMPv3 users, configure the following:

- Configure the 'Authentication Protocol' field to **SHA-1**.
- Configure the 'Privacy Protocol' field to **AES-128**.
- Configure the 'Authentication Key' and 'Privacy Key' fields with values containing at least two characters from each of the four groups (uppercase, lowercase, digits and special characters). In other words, a minimum of eight characters in size.

## Create Default Snapshot

After you have completed FIPS configuration, it is recommended to create at least one snapshot and set it as default (see Rescue Options using System Snapshots). If you don't create a snapshot, the default snapshot remains non-FIPS and if the system ever returns to the default non-FIPS snapshot, all TLS Contexts will be zeroized before.

## Replacing a Faulty Device in HA System

When replacing a faulty device in a High-Availability (HA) system, the new (second) device should first be configured in an isolated network to be the same as the first device. For step-by-step instructions, refer to the User's Manual (see [Step 2: Configure the Second Device](#) on page 1311).

Before connecting the Maintenance interface of the new (second) device to the network, make sure that the [HASecuredConnectivityMode] ini file parameter is enabled (i.e., set to 1) on both devices.

## FIPS-Related CLI Commands

The device's CLI commands for FIPS include the following:

**Table 14-2: FIPS-Related CLI Commands**

CLI Command	Description
<code>clear security-files</code>	<p>Performs zeroization, which does the following chronologically listed actions:</p> <ol style="list-style-type: none"><li>1. Wipes all secrets.</li><li>2. Wipes the core dump file.</li><li>3. Wipes all snapshots.</li><li>4. Restarts the device .</li></ol> <p>Manually triggering zeroization can be useful, for example, when taking the device out of deployment for service (Return of Merchandise or RMA).</p>
<code>fips on</code>	<p>Enables the FIPS Mode, and does the following:</p> <ol style="list-style-type: none"><li>1. Sets the FIPS mode to "enabled".</li><li>2. Triggers zeroization.</li></ol> <p>After the device restarts, it runs in FIPS mode until it is manually disabled or until a security-test fails (which also causes zeroization of the device).</p>
<code>fips off</code>	<p>Disables the FIPS Mode, and does the following:</p>

CLI Command	Description
	<ol style="list-style-type: none"> <li>1. Sets the FIPS mode to "disabled".</li> <li>2. Triggers zeroization.</li> </ol>
<code>show system security status</code>	Displays the FIPS mode status (enable or disable).

When running in FIPS mode, the device performs the following:

- All boot and runtime security tests (as required by FIPS).
- Prevents the display of any secrets in system logs and captures.
- Allows only algorithms approved by FIPS (see [Approved Algorithms](#) on page 219), with exceptions as described in [Non-Approved Applications in FIPS mode](#) on page 219.

## TLS Certificates

The TLS Contexts table lets you configure X.509 certificates which are used for secure management of the device, secure SIP transactions, and other security applications.

- The device is shipped with an active, default TLS setup (TLS Context ID 0, named "default"). Therefore, configure certificates only if required.
- Since X.509 certificates have an expiration date and time, you must configure the device to use Network Time Protocol (NTP) to obtain the current date and time from an NTP server. Without the correct date and time, client certificates cannot work. To configure NTP, see [Synchronizing Date and Time through SNTP](#) on page 138.
- Only **Base64 (PEM)** encoded X.509 certificates can be loaded to the device.
- Modifying TLS Contexts doesn't require a device restart and therefore is not service affecting.

## Configuring TLS Certificate Contexts

The TLS Contexts table lets you configure up to 12 TLS Contexts. A TLS Context defines Transport Layer Security (TLS) settings (e.g., TLS certificates). The TLS protocol provides confidentiality, integrity, and authenticity between two communicating applications over TCP/IP.

You can use TLS for the following:

- To secure device management communication, for example, HTTPS-based Web sessions, Telnet sessions and SSH sessions.
- To secure SIP signaling connections, referred to as SIP Secure (SIPS) or SIP over TLS.

- To secure various other network applications supported by the device, for example, communication with a remote LDAP server used for LDAP-based user management authentication and authorization.

The device is shipped with a default TLS Context (Index #0 and named "default"), which includes a self-generated random private key and a self-signed server certificate. The Common Name (CN or subject name) of the default certificate is "ACL\_nnnnnnn", where *nnnnnnn* denotes the serial number of the device.

- The default TLS Context cannot be deleted.
- For secure management through the default management network interface (i.e., **OAMP** Application Type in the IP Interfaces table), the device uses the default TLS Context. However, for secure Web and REST access using the additional management interfaces configured in the Web Interfaces table (see [Configuring Web Interfaces](#) on page 52), you can use any TLS Context.
- If a TLS Context for an existing TLS connection is changed during the call by the user agent, the device ends the connection.
- For more information on secured management, see [Configuring Secured \(HTTPS\) Web and REST Access](#) on page 75.

You can configure each TLS Context with the following TLS settings:

- TLS version (TLS 1.0, TLS 1.1, TLS 1.2, and TLS 1.3).
- DTLS version (DTLS 1.0 and DTLS 1.2).
- TLS cipher suites for server and client roles (per OpenSSL syntax).
- Diffie-Hellman (DH) key size used by the device if it acts as a TLS server and DH is used for key exchange.
- Online Certificate Status Protocol (OCSP). Some Public-Key Infrastructures (PKI) can revoke a certificate after it has been issued. You can configure the device to check if a peer's certificate has been revoked, using OCSP. When OCSP is enabled, the device queries the OCSP server for revocation information whenever a peer certificate is received (TLS client mode, or TLS server mode with mutual authentication).

- The device doesn't query OCSP for its own certificate.
- Some PKIs do not support OCSP, but generate Certificate Revocation Lists (CRLs). For such scenarios, set up an OCSP server such as OCSPD.

- Private key - externally created and then uploaded to device.
- Different levels of security strength (key size) per TLS certificate.
- X.509 certificates - self-signed certificates or signed as a result of a certificate signing request (CSR).
- Trusted root certificate authority (CA) store (for validating certificates).

- When creating a TLS Context, you should create a certificate as described in [Creating Self-Signed Certificates for TLS Contexts](#) on page 243, and then check that the certificate is "Ok" as described in [Viewing Certificate Information](#) on page 239.
- For secure SIP messaging (SIP Secure or SIPS) using TLS, see [TLS for SIP Clients](#) on page 251 (two-way authentication) and [Configuring TLS for Secured SIP](#) on page 250.
- To map an SNI (hostname in 'server\_name' extension of "client hello" message) to a TLS Context, see [Configuring SNI-to-TLS Mapping](#) on page 248.
- To configure the device to periodically check the validation date of installed TLS server certificates of TLS Contexts, see [Configuring TLS Server Certificate Expiry Check](#) on page 247.

The following procedure describes how to configure a TLS Context through the Web interface. You can also configure it through ini file [TLSContexts] or CLI (`configure network > tls`).

➤ **To configure a TLS Context:**

1. Open the TLS Contexts table (**Setup** menu > **IP Network** tab > **Security** folder > **TLS Contexts**).
2. Click **New** to add a new TLS Context or **Edit** to modify the default TLS Context at Index 0; the following dialog box appears:

3. Configure the TLS Context according to the parameters described in the table below.
4. Click **Apply**.

**Table 14-3: TLS Contexts Parameter Descriptions**

Parameter	Description
General	
'Index' tls [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <p>■ Each row must be configured with a unique index.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>Index 0 ("default") is the default TLS Context.</li> </ul>
'Name' name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 31 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter value cannot contain a forward slash (/).</li> <li>The default TLS Context (Index 0) is named "default".</li> </ul>
'TLS Version' tls-version [TLSVersion]	<p>Defines the supported TLS protocol version. Clients attempting to communicate with the device using a different TLS version are rejected.</p> <ul style="list-style-type: none"> <li>[0] <b>Any TLS1.x</b> = TLSv1.0, TLSv1.1, TLSv1.2, and TLSv1.3 are supported.</li> <li>[1] <b>TLSv1.0</b> = Only TLS 1.0.</li> <li>[2] <b>TLSv1.1</b> = Only TLS 1.1.</li> <li>[3] <b>TLSv1.0 and TLSv1.1</b> = Only TLS 1.0 and TLS 1.1.</li> <li>[4] <b>TLSv1.2</b> = Only TLS 1.2.</li> <li>[6] <b>TLSv1.1 and TLSv1.2</b> = Only TLS 1.1 and TLS 1.2.</li> <li>[7] <b>TLSv1.0 TLSv1.1 and TLSv1.2</b> = Only TLS 1.0, TLS 1.1, and TLS 1.2.</li> <li>[8] <b>TLSv1.3</b> = Only TLS 1.3.</li> <li>[12] <b>TLSv1.2 and TLSv1.3</b> = (Default) Only TLS 1.2 and TLS 1.3.</li> <li>[14] <b>TLSv1.1 TLSv1.2 and TLSv1.3</b> = Only TLS 1.1, TLS 1.2, and TLS 1.3.</li> <li>[15] <b>TLSv1.0 TLSv1.1 TLSv1.2 and TLSv1.3</b> = Only TLS 1.0, TLS 1.1, TLS 1.2, and TLS 1.3.</li> </ul>
'DTLS Version' [DTLSVersion]	<p>Defines the Datagram Transport Layer Security (DTLS) version, which is used to negotiate keys for WebRTC calls.</p> <ul style="list-style-type: none"> <li>[0] <b>DTLSv1.0 and DTLSv1.2</b> (default)</li> <li>[1] <b>DTLSv1.0</b></li> <li>[2] <b>DTLSv1.2</b></li> </ul>

Parameter	Description
	<p>For more information on WebRTC, see <a href="#">WebRTC</a> on page 1269.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Cipher Server' <code>ciphers-server</code> [ServerCipherString]	<p>Defines the supported cipher suite for the TLS server (in OpenSSL cipher list format) when the TLS version is 1.2 or earlier.</p> <p>For possible values and additional details, visit the <a href="#">OpenSSL website</a>. The default is "DEFAULT".</p> <p><b>Note:</b> The parameter is applicable only to TLS 1.2 and earlier.</p>
'Cipher Client' <code>ciphers-client</code> [ClientCipherString]	<p>Defines the supported cipher suite for TLS clients when the TLS version is 1.2 or earlier.</p> <p>For possible values and additional details, visit the <a href="#">OpenSSL website</a>. The default is "DEFAULT".</p> <p><b>Note:</b> The parameter is applicable only to TLS 1.2 and earlier.</p>
'Cipher Server TLS1.3' <code>ciphers-server-tls13</code> [ServerCipherTLS13String]	<p>Defines the supported cipher suite for the TLS 1.3 server (in OpenSSL cipher list format).</p> <p>For possible values and additional details, visit the <a href="#">OpenSSL website</a>. The default is "TLS_AES_256_GCM_SHA384:TLS_CHACHA20_POLY1305_SHA256:TLS_AES_128_GCM_SHA256".</p> <p><b>Note:</b> The parameter is applicable only to TLS 1.3.</p>
'Cipher Client TLS1.3' <code>ciphers-client-tls13</code> [ClientCipherTLS13String]	<p>Defines the supported cipher suite for TLS 1.3 clients.</p> <p>For possible values and additional details, visit the <a href="#">OpenSSL website</a>. The default is "TLS_AES_256_GCM_SHA384:TLS_CHACHA20_POLY1305_SHA256:TLS_AES_128_GCM_SHA256".</p> <p><b>Note:</b> The parameter is applicable only to TLS 1.3.</p>
'Key Exchange Groups' <code>key-exchange-groups</code> [KeyExchangeGroups]	<p>Defines the groups that are supported for key exchange, ordered from most preferred to least preferred.</p> <p>The valid value is any combination of the following strings:</p> <ul style="list-style-type: none"> <li>■ X25519</li> <li>■ P-256</li> <li>■ P-384</li> </ul>

Parameter	Description
	<p>■ X448</p> <p>The default is "X25519:P-256:P-384:X448" (without quotation marks).</p> <p>When configuring the parameter with multiple values, separate each with a colon. In addition, the order of the values determines the group preference. For example, the value "P-384:P-256:X25519" (without quotation marks) gives preference to P-384. The TLS client uses the first configured value (e.g., P-384) as its group trial, while the TLS server uses the whole list to try and match the client's trial.</p> <p><b>Note:</b> The parameter is applicable to all TLS versions.</p>
'Strict Certificate Extension Validation' require-strict-cert [RequireStrictCert]	<p>Enables the validation of the extensions (keyUsage and extendedKeyUsage) of peer certificates. The validation ensures that the signing CA is authorized to sign certificates and that the end-entity certificate is authorized to negotiate a secure TLS connection.</p> <p>■ [0] <b>Disable</b> (default)</p> <p>■ [1] <b>Enable</b></p>
'DH Key Size' dh-key-size [DHKeySize]	<p>Defines the Diffie-Hellman (DH) key size (in bits). DH is an algorithm used mainly for exchanging cryptography keys used in symmetric encryption algorithms such as AES.</p> <p>■ [1024] <b>1024 - Not Recommended</b></p> <p>■ [2048] <b>2048</b> (default)</p> <p><b>Note:</b> 1024-bit key size is not recommended.</p>
'TLS Renegotiation' tls-renegotiation [TlsRenegotiation]	<p>Enables TLS renegotiations (handshakes) initiated by the client (peer) with the device.</p> <p>■ [0] <b>Disable</b> = The device blocks client-initiated TLS renegotiations and allows only one TLS handshake process. This is useful, for example, for preventing Denial-of-Service (DoS) attacks on the device caused by multiple TLS renegotiations per second by an attacker.</p> <p>■ [1] <b>Enable</b> (default)</p>
'Use default CA Bundle' trusted-root default-ca-bundle	<p>Enables the use of the default list of trusted root certificate authorities (CAs).</p>

Parameter	Description
[UseDefaultCABundle]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>To view the default list of CAs, see <a href="#">Viewing Default Certificate Authorities</a> on page 247.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can only use the default CAs for TLS Context IDs 0 through 4.</li> <li>■ This feature is applicable only to Mediant 800C.</li> </ul>
OCSP	
'OCSP Server' ocsp-server [OcspEnable]	<p>Enables certificate checking using Online Certificate Status Protocol (OCSP).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul>
'OCSP Interface' ocsp-interface [OcspInterface]	<p>Assigns an IP Interface for communication with the OCSP server.</p> <p>By default, the OAMP interface is assigned (Index 0 "O+M+C").</p> <p>To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p><b>Note:</b> The addresses of the IP Interface and the OCSP servers (see 'Primary OCSP Server' and 'Secondary OCSP Server' parameters below) must be of the same IP version (IPv4 or IPv6).</p>
'Primary OCSP Server' ocsp-server-primary [OcspServerPrimary]	<p>Defines the address (IPv4 or IPv6, or FQDN) of the primary OCSP server.</p> <p>The default is 0.0.0.0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The address configured for the 'Primary OCSP Server' parameter and the optional 'Secondary OCSP Server' parameter must be of the same IP version (IPv4 or IPv6).</li> <li>■ An FQDN address is supported only by TLS Contexts that are used for SIP connections. If you configure the parameter with an FQDN and the TLS Context is used for non-SIP connections, the certificate is not checked</li> </ul>

Parameter	Description
	by the OCSP server.
'Secondary OCSP Server' ocsp-server-secondary [OcspServerSecondary]	<p>Defines the address (IPv4 or IPv6, or FQDN) of the secondary OCSP server (optional). The default is 0.0.0.0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The address configured for the 'Primary OCSP Server' parameter and the 'Secondary OCSP Server' parameter must be of the same IP version (IPv4 or IPv6).</li> <li>■ An FQDN address is supported only by TLS Contexts that are used for SIP connections. If you configure the parameter with an FQDN and the TLS Context is used for non-SIP connections, the certificate is not checked by the OCSP server.</li> </ul>
'OCSP Port' ocsp-port [OcspServerPort]	<p>Defines the OCSP server's TCP port number. The default port is 2560.</p>
'OCSP Default Response' ocsp-default-response [OcspDefaultResponse]	<p>Defines if the device allows or rejects peer certificates if it cannot connect to the OCSP server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Reject</b> (default)</li> <li>■ [1] <b>Allow</b></li> </ul>

## Assigning CSR-based Certificates to TLS Contexts

You can request a digitally signed certificate from a Certification Authority (CA) for a TLS Context. This process is referred to as a certificate signing request (CSR) and is required if your organization employs a Public Key Infrastructure (PKI) system. The CSR contains information identifying the device such as a Distinguished Name (DN) or subject alternative names in the case of an X.509 certificate.

### ➤ To assign a CSR-based certificate to a TLS Context:

1. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
2. Select the required TLS Context, and then click the **Change Certificate** link located below the table; the Change Certificates page appears.
3. Under the **Certificate Signing Request/ Generate Self-Signed Certificate Request** group, fill in the following fields **according to your security provider's instructions**:

**CERTIFICATE SIGNING REQUEST / GENERATE SELF-SIGNED CERTIFICATE REQUEST**

Common Name [CN]	<input style="width: 90%;" type="text"/>	
Organizational Unit [OU]	<input style="width: 90%;" type="text"/>	
Company name [O]	<input style="width: 90%;" type="text"/>	
Locality or city name [L]	<input style="width: 90%;" type="text"/>	
State [ST]	<input style="width: 90%;" type="text"/>	
Country code [C]	<input style="width: 90%;" type="text"/>	
1st Subject Alternative Name [SAN]	EMAIL ▼	<input style="width: 80%;" type="text"/>
2nd Subject Alternative Name [SAN]	EMAIL ▼	<input style="width: 80%;" type="text"/>
3rd Subject Alternative Name [SAN]	EMAIL ▼	<input style="width: 80%;" type="text"/>
4th Subject Alternative Name [SAN]	EMAIL ▼	<input style="width: 80%;" type="text"/>
5th Subject Alternative Name [SAN]	EMAIL ▼	<input style="width: 80%;" type="text"/>
Subject Key Identifier	<input style="width: 90%;" type="text"/>	
Key Usage	<input style="width: 70%;" type="text"/>	Critical <input type="checkbox"/>
Extended Key Usage	<input style="width: 70%;" type="text"/>	Critical <input type="checkbox"/>
Signature Algorithm	SHA-256 ▼	
Authority Information Access	<input style="width: 90%;" type="text"/>	

- a. Distinguished Name (DN) fields (uniquely identifies the device):
  - ◆ In the 'Common Name [CN]' field, enter the common name. If you leave this field empty, the device generates the CSR with the default CN "CN=ACL\_<device's 6-digit serial number>".
  - ◆ In the 'Organizational Unit [OU]' field, enter the section of the organization.
  - ◆ In the 'Company name [O]' field, enter the legal name of your organization.
  - ◆ In the 'Locality or city name [L]' field, enter the city where your organization is located.
  - ◆ In the 'State [ST]' field, enter the state or province where your organization is located.
  - ◆ In the 'Country code [C]' field, enter the two-letter ISO abbreviation for your country.
- b. If you want to generate a CSR for SAN (with multiple subject alternate names), then from the 'Subject Alternative Name [SAN]' drop-down list, select the type of SAN (e-mail address, DNS hostname, URI, or IP address), and then enter the relevant value. You can configure multiple SAN names, using the 1st to 5th 'Subject Alternative Name [SAN]' fields.
- c. From the 'Subject Key Identifier' drop-down list, configure the subject key identifier (SKI) X.509 field:
  - ◆ User-defined hex value (max. 128 characters), without "0x, for example, "00D06F00D4D06746"

- ◆ **hash-SHA1** (sets SKI to 160 bits of SHA-1 digest on public key)
  - ◆ **hash-SHA1-60lsb** (sets SKI to 0100 followed by least significant 60 bits of SHA-1 digest on public key)
- d. From the 'Key Usage' drop-down list, select the key usage X.509 field values:
- ◆ **Digital Signature** (Certificate can be used to apply a digital signature)
  - ◆ **Non Repudiation** (Certificate can be used to sign data as above, but the certificate's public key may be used to provide non-repudiation services, preventing the signing entity from falsely denying some action)
  - ◆ **Key Encipherment** (Certificate may be used by the subject to encrypt a symmetric key which is then transferred to the target, decrypted, and subsequently used to encrypt and decrypt data sent between the two entities)
  - ◆ **Data Encipherment** (Certificate can be used by the subject to encrypt and decrypt actual application data)
  - ◆ **Key Agreement** (Certificate's subject can use a key agreement protocol such as Diffie-Hellman to establish a symmetric key with a target that may then be used to encrypt and decrypt data sent between the two entities)
  - ◆ **Key Certificate Sign** (Certificate's subject can use public key for verifying Digital Signature on Public Key certificates)
  - ◆ **Certificate Revocation List Sign** (Certificate's subject can use public key for verifying signatures on Certificate Revocation List lists, e.g., CRLs)
  - ◆ **Encipher Only** (Certificate's subject can use public key only for enciphering data while performing Key agreement)
  - ◆ **Decipher Only** (Certificate's subject can use public key only for deciphering data while performing Key agreement)

You can define the key as critical (mandatory), by selecting the 'Critical' check box.

- e. From the 'Extended Key Usage' drop-down list, select the extended key usage X.509 field values:
- ◆ **Server Authentication**
  - ◆ **Client Authentication**

You can define the key as critical (mandatory), by selecting the 'Critical' check box.

- f. From the 'Signature Algorithm' drop-down list, select the hash function algorithm (**SHA-256** or **SHA-512**) with which to sign the certificate.
- g. In the 'Authority Information Access - OCSP URI' field, configure the Authority Information Access (AIA) extension field with the URL of the server where the client can check the validity of the device's certificate during the TLS handshake. For example, the AIA extension can contain one of the following:

- ◆ CA Issuers URL to the issuing CA's certificate, allowing clients to download and validate the full certificate chain. This can be used if the client doesn't have the intermediate or root CA certificate in its trusted store.
  - ◆ OCSP Responder URL, allowing the client to verify if the certificate is still valid or has been revoked.
4. Click the **Create CSR** button; a textual certificate signing request is displayed below the button:

Create CSR

After creating the CSR, copy the text below (including the BEGIN/END lines) and send it to your Certification Authority for signing.

```
-----BEGIN CERTIFICATE REQUEST-----
MIICVjCCAT4CAQAwADCCASIwDQYJKoZIhvcNAQEBBQADggEPADCCAQoCggEBAKS6

-----END CERTIFICATE REQUEST-----
```

5. Click the  icon to copy the CSR text to your clipboard. The CSR text is copied from the "BEGIN CERTIFICATE REQUEST" line to the "END CERTIFICATE REQUEST" line.
6. Send the copied CSR text to your security provider (CA) to sign this request.
7. When the CA sends you a server certificate, save the certificate to a file (e.g., cert.txt). Make sure that the file is a plain-text file containing the "BEGIN CERTIFICATE" header.
8. Scroll down to the **Upload Certificates Files From Your Computer** group, and then select and upload the cert.txt file, by clicking **Load Device Certificate File**:

Send Device Certificate file from your computer to the device.  
The file must be in textual PEM format.

Load Device Certificate File

9. Wait for the certificate to successfully upload to the device.
10. Save configuration.
11. Verify that the private key is correct:
  - a. Open the TLS Contexts table, and then select the TLS Context.
  - b. Click the **Certificate Information** link located below the table.
  - c. Make sure that the 'Status' field displays "OK"; otherwise, consult with your security administrator:

**PRIVATE KEY**

Key size: 2048 bits

Status: OK

- The certificate replacement process can be repeated whenever necessary (e.g., when the new certificate expires).
- You can also upload the certificate through the device's Automatic Provisioning mechanism, using the [HTTPSCertFileName] parameter.

**TLS Context Parameters Relevancy per Application**

The following table shows the parameters of the TLS Context table that are used when establishing a TLS connection per SBC application.

Application	TLS Contexts Table Parameter								
	'TLS Version'	'Cipher Server'	'Cipher Client'	'Cipher Server TLS1.3'	'Cipher Client TLS1.3'	'Key Exchange Groups'	'Strict Certificate Extension Validation'	'DH key Size'	'TLS Renegotiation'

## Viewing Certificate Information

You can view information of TLS certificates installed on the device per TLS Context.

### ➤ To view certificate information:

1. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
2. Select a TLS Context, and then click the **Certificate Information** link located below the table; the Certificate Information page appears, showing certificate information, as shown in the following example (cropped for convenience):

CERTIFICATE	PRIVATE KEY
Certificate: Data: Version: 1 (0x0) Serial Number: 0 (0x0) Signature Algorithm: sha256WithRSAEncryption Issuer: CN=ACL_5967925 Validity Not Before: Aug 13 12:23:58 2020 GMT Not After : Aug 8 12:23:58 2040 GMT Subject: CN=ACL_5967925 Subject Public Key Info: Public Key Algorithm: rsaEncryption RSA Public-Key: (2048 bit) Modulus: 00:a4:ba:8a:91:9b:67:da:5e:f3:4f:0b:6b:89:80: a5:6b:a8:95:93:cb:29:ae:a6:18:1e:45:70:ad:c0: 53:67:3e:76:87:ca:02:4a:86:ca:6a:51:a7:a3:88:	Key size: 2048 bits Status: OK

## Assigning Externally Created Private Keys to TLS Contexts

You can assign externally created private keys to TLS Contexts.

### ➤ To assign an externally created private key to a TLS Context:

1. Obtain a private key in either textual PEM (PKCS #7) or PFX (PKCS #12) format (typically provided by your security administrator). The file may be encrypted with a short pass-phrase.
2. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
3. Select the required TLS Context, and then click the **Change Certificate** link located below the table; the Change Certificates page appears.
4. Scroll down to the **Upload Certificate Files From Your Computer** group.
  - a. (Optional) In the 'Private key pass-phrase' field, enter the password (passphrase) of the encrypted private key file. If there is no passphrase, leave the field blank.

Private key pass-phrase (optional)

- The passphrase can contain up to 32 characters, but can't contain wide characters.
- The default passphrase is "audc".

- b. Select and upload the private key file (mentioned in Step 1), by clicking **Load Private Key File**:

Send **Private Key** file from your computer to the device.  
The file must be in either PEM or PFX (PKCS#12) format.

**Note:** Replacing the private key is not recommended but if it's done, it should be over a physically-secure network link.

Load Private Key File

- c. If your security administrator has provided you with a device certificate file, select and upload it by clicking **Load Device Certificate File**:

Send **Device Certificate** file from your computer to the device.  
The file must be in textual PEM format.

**Load Device Certificate File**

The loaded private key file must match the loaded device certificate file.

5. After the files have successfully loaded to the device, save the configuration.
6. Verify that the private key is correct:
  - a. Open the TLS Contexts table.
  - b. Select the required TLS Context index row, and then click the **Certificate Information** link located below the table.
  - c. Make sure that the 'Status' field displays "OK"; otherwise (i.e., displays "Does not match certificate"), contact your security administrator:

#### PRIVATE KEY

Key size: 2048 bits

Status: OK

### Generating Private Keys for TLS Contexts

You can configure the device to generate private keys for TLS Contexts. You can generate the private keys for certificate signing requests (CSR) or self-signed certificates. You can choose to generate the keys in different formats - RSA or Elliptic Curve Digital Signature Algorithm (ECDSA) encryption algorithm.

#### ➤ To generate private keys for TLS Contexts:

1. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
2. Select the required TLS Context index row, and then click the **Change Certificates** link located below the table; the Change Certificates page appears.
3. Scroll down to the **Generate New Private Key** group:

**GENERATE NEW PRIVATE KEY**

Private Key Format

RSA

Private Key Size

2048

Important: generation of private key is a lengthy operation during which the device service may be affected.

**Generate Private Key**

4. From the 'Private Key Format' drop-down list, select the encryption algorithm for the private key:
  - **RSA**
  - **ECDSA**
5. From the 'Private Key Size' drop-down list, select the size of the private key (in bits):
  - **RSA:**
    - ◆ **2048** (default)
  - **ECDSA:**
    - ◆ **256**
    - ◆ **384**
    - ◆ **521**
6. Click **Generate Private Key**; the following confirmation message appears:

**Generate Private-Key** x

Warning: Generating a Private-Key will overwrite the currently installed private key. Are you sure you want to generate a new key?

No

**Yes**

7. Click **Yes** to confirm key generation; the device starts generating a new private key (may take a few minutes):

**Generate Private-Key**

Generating Private-Key..... this might take a while.

When the key is successfully generated, the following message appears (e.g., for 2048-bit key):

### Generate Private-Key

A new 2048-bits Private-Key was generated for Context-ID: 0  
Please save the configuration.

OK

8. Click **OK** to close the message box.
9. Continue with certificate configuration by creating a CSR or generating a new self-signed certificate.
10. On the toolbar, click the **Save** button to save your configuration to flash memory.

## Creating Self-Signed Certificates for TLS Contexts

You can assign a certificate that is digitally signed by the device itself to a TLS Context (i.e., self-signed certificate). In other words, the device acts as a CA. The Issuer (e.g., "Issuer: CN=ACL\_5967925") and Subject (e.g., " Subject: CN=ACL\_5967925") fields of the self-signed certificate have the same value.

- The device is shipped with a default TLS Context (Index 0 and named "default"), which includes a self-generated random private key and a self-signed server certificate. The Common Name (CN or subject name) of the default certificate is "ACL\_#####", where ##### denotes the serial number of the device.
- Creating a self-signed certificate is traffic affecting.

### ➤ To create and assign a self-signed certificate to a TLS Context:

1. Make sure that you have a unique DNS name for the device (e.g., dns\_name.corp.customer.com). The name is used to access the device and therefore, must be listed in the server certificate.
2. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
3. Select the required TLS Context index row, and then click the **Change Certificate** link located below the table; the Change Certificates page appears.
4. Under the **Certificate Signing Request / Generate Self-Signed Certificate Request** group, in the 'Common Name [CN]' field, enter the fully-qualified DNS name (FQDN) as the certificate subject. Alternatively (or in addition), if you want to generate a self-signed SAN certificate (with multiple subject alternate names), then from the 'Subject Alternative Name [SAN]' drop-down list, select the type of SAN (**EMAIL**, **DNS**, **URI**, or **IP**), and then enter the corresponding value. You can configure multiple SANs, using the 1st to 5th 'Subject Alternative Name [SAN]' fields.

For a description of additional (optional) parameters that you can configure such as 'Subject Key Identifier', 'Key Usage', and 'Extended Key Usage', see [Assigning CSR-based Certificates to TLS Contexts](#) on page 234. (The parameters under this group are applicable to both self-signed and CSR certificates.)

5. Click **Generate Self-Signed Certificate**; the following confirmation message appears:

**Generate Self-Signed Certificate** x

Warning: Generating a self-signed key will overwrite the currently installed certificate. Are you sure you want to generate a new self-signed certificate?

---

No **Yes**

 The self-signed certificate overwrites the currently installed certificate for the specific TLS Context.

**A new self-signed certificate was generated** x

TLS Context ID: 3  
Subject name:  
To complete the certificate replacement process, close this current browser session and then open a new session.

---

**Close**

7. Click **Close**, and then quit your current web browser session and open a new browser session with the device.
8. Save the configuration.

## Importing Certificates into Trusted Root CA Certificate Store

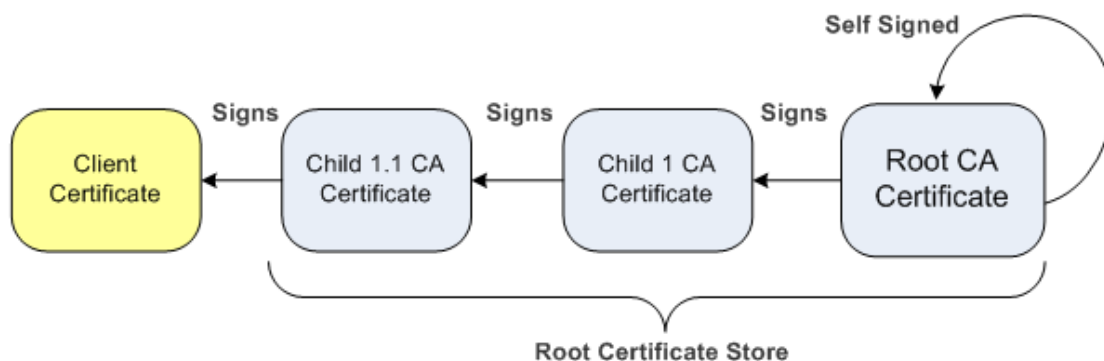

The device provides its own Trusted Root Certificate Authority (CA) Certificate store. This lets you manage certificate trust. Depending on certificate size, you can import up to approximately 150 certificates into the Trusted Root CA Certificate per TLS Context.

Instead of importing CA certificates into the Trusted Root CA Certificate store for a TLS Context, you can enable the TLS Context to use the device's default list of CAs. To do this, configure the 'Use default CA Bundle' parameter to **Enable** in the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227). To view the default CAs, see [Viewing Default Certificate Authorities](#) on page 247.

- For TLS Contexts that you have enabled the use of the device's default CAs:
  - ✓ The default CAs are not listed in the Trusted Root CA Certificate store of these TLS Contexts (even though they are used).
  - ✓ You can only enable the use of the default CAs for TLS Context IDs 0 through 4.
  - ✓ In addition to using the default CAs, you can import other CAs into the Trusted Root CA Certificate store. In this setup, the device uses both the default CAs and the ones that you have imported.
- Only **Security Administrator** users can import certificates.

The Trusted Root CA Certificate store can also be used for certificate chains. A certificate chain is a sequence of certificates where each certificate in the chain is signed by the subsequent certificate. The last certificate in the list of certificates is the Root CA certificate, which is self-signed. The purpose of a certificate chain is to establish a chain of trust from a child certificate to the trusted root CA certificate. The CA vouches for the identity of the child certificate by signing it. A client certificate is considered trusted if one of the CA certificates up the certificate chain is found in the server certificate directory. For the device to trust a whole chain of certificates per TLS Context, you need to import them into the device's Trusted Root CA Certificate, as described below.

You can also import multiple TLS root certificates in bulk from a single file. Each certificate in the file must be Base64 encoded (PEM). When copying-and-pasting the certificates into the file, each Base64 ASCII encoded certificate string must be enclosed between "**-----BEGIN CERTIFICATE-----**" and "**-----END CERTIFICATE-----**".

- You can import only Base64 (PEM) encoded X.509 certificates into the Trusted Root CA Certificate store.
- When importing certificates into the trusted root CA store through CLI, make sure you add a blank line containing a period (.) after the 'END CERTIFICATE' line, as shown in the following example:

```
M500(tls-5)*# trusted-root import
Enter data below. Type a period (.) on an empty line to finish.

-----BEGIN CERTIFICATE-----
MIID...5Njc5
MjU...DDAtB
Q0...6ipGb
Z9...3WxXS
JM...7LDBD
7wI...jlngX
3NI...dMqaI
IcI...sR8PH
fpI...pdNw1
tu...nXUEm
5c...8LEWD
N2...vfZNN
+m...Fol0b
gW...TlgLq
FFKsqw==
-----END CERTIFICATE-----
.
```

➤ **To import certificates into Trusted Root CA Certificate store:**

1. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).
2. Select the required TLS Context, and then click the **Trusted Root Certificates** link located below the table; the Trusted Certificates table appears.
3. Click the **Import** button, and then select the certificate file.
4. Click **OK**; the certificate is imported into the Trusted Root CA Certificate store:

⊕ **TLS Context [#0] > Trusted Root Certificates**

View			
Page 1 of 14 View 1 - 10 of 138			
<div> <span>Import</span> <span>Export</span> <span>Remove</span> </div>			
INDEX	SUBJECT	ISSUER	EXPIRES
0	AAA Certificate Services	AAA Certificate Services	12/31/2028

In addition to the **Import** button, the Trusted Root CA Certificate store provides the following buttons:

- **Remove:** Deletes the selected certificate.
- **Export:** Downloads the selected certificate to your computer.

## Viewing Default Certificate Authorities

The device provides a default list of trusted root certificate authorities (CA), which you can view on the Default CA Bundle page, as described in this section. These default CAs are used only for TLS Contexts whose 'Use default CA Bundle' parameter you have configured to **Enable** in the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227).

- This feature is applicable only to Mediant 800C.
- The list of CAs is aligned with [Mozilla CA Certificate Program's list](#) (January 1, 2024).

### ➤ To view default CAs:

1. Open the Default CA Bundle page (**Setup** menu > **IP Network** tab > **Security** folder > **Default CA Bundle**). A partial screenshot is shown below:

[Export All](#)

Page 1 of 15 View 1 - 10 of 146			
INDEX	SUBJECT	ISSUER	EXPIRES
0	AAA Certificate Services	AAA Certificate Services	12/31/2028
1	AC RAIZ FNMT-RCM SERVIDORES SEG	AC RAIZ FNMT-RCM SERVIDORES SEG	12/20/2043

    Issuer: C=GB, ST=Greater Manchester, L=Salford, O=Comodo CA Limited, CN=AAA Certificate Services
    Validity
      Not Before: Jan  1 00:00:00 2004 GMT
      Not After : Dec 31 23:59:59 2028 GMT
    Subject: C=GB, ST=Greater Manchester, L=Salford, O=Comodo CA Limited, CN=AAA Certificate Services
    Subject Public Key Info:
      Public Key Algorithm: rsaEncryption
  
```

2. To view detailed information of a CA, select the CA; the detailed information is displayed below the table (as shown above).
3. To download all the CAs to a file on your computer, click **Export All**.

## Configuring TLS Server Certificate Expiry Check

You can configure the device to periodically check the validation date of installed TLS server certificates of TLS Contexts (configured in [Configuring TLS Certificate Contexts](#) on page 227). You can also configure the device to send an SNMP alarm (acCertificateExpiryAlarm) at a user-

defined number of days before the installed TLS server certificate is to expire. The alarm indicates the TLS Context to which the certificate belongs.

- When a TLS certificate expires, services using the certificate may be discontinued (depending on the remote side's security configuration). Therefore, best practice is to replace (renew) the certificate as soon as possible with a valid certificate.
- This feature applies to all TLS Contexts.

➤ **To configure TLS certificate expiry checks and notification:**

1. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Settings**).
2. In the 'TLS Expiry Check Start' field, enter the number of days before the installed TLS server certificate is to expire when the device sends an SNMP trap event to notify of this.
3. In the 'TLS Expiry Check Period' field, enter the periodical interval (in days) for checking the TLS server certificate expiry date. By default, the device checks the certificate every 7 days.

### TLS GENERAL

TLS Expiry Check Start (days)

TLS Expiry Check Period (days)

4. Click **Apply**.

## Configuring SNI-to-TLS Mapping

The SNI-to-TLS Context Mapping table lets you configure up to 12 rules for mapping the 'server\_name' (Server Name Indication or SNI) received in the (extended) "client hello" message, to a specific TLS Context configured on the device (see [Configuring TLS Certificate Contexts](#) on page 227).

TLS doesn't provide a mechanism for a client to tell a server (i.e., the device) the name of the server it is contacting. It may be desirable for clients to provide this information to facilitate secure connections, for example, to servers that host multiple virtual servers at a single underlying IP network address. To provide any of the server names (hostnames or domain names), clients may include an extension of type called 'server\_name' in the (extended) "client hello" message during the TLS handshake. The SNI-to-TLS Context Mapping table lets you map this 'server\_name' to a specific TLS Context, configured in the TLS Contexts table. In this way, each hostname can have its own TLS certificate (TLS Context), which the device sends to the client in the "server hello" message.

When a match is found between the 'server\_name' extension in the "client hello" message and a row in the SNI-to-TLS Context Mapping table, the TLS connection is established using the TLS certificate (i.e., certificate and key) of the mapped TLS Context. However, the TLS connection continues using the configuration settings (e.g., TLS version, ciphers, and key exchange groups) of the TLS Context that was originally used to establish the connection. Any modification to the mapped TLS Context or the original TLS Context triggers an online update of the TLS connection according to the TLS Contexts modifications.

It's recommended to configure the mapped TLS Context and the TLS Context that is used to initially establish the connection with the **same parameter settings**, but **different certificates**.

The following procedure describes how to configure SNI-to-TLS Context mapping rules through the Web interface. You can also configure it through ini file [SNI2TLSTMapping] or CLI (configure network > sni-to-tls-mapping).

➤ **To configure SNI-to-TLS Context mapping rules:**

1. Open the SNI-to-TLS Context Mapping table (**Setup** menu > **IP Network** tab > **Security** folder > **SNI-to-TLS Context**).
2. Click **New**; the following dialog box appears:

1. Configure an SNI-to-TLS Context mapping rule according to the parameters described in the table below.
2. Click **Apply**, and then save your settings to flash memory.

**Table 14-4: SNI-to-TLS Context Mapping Rules Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table record.
'Host Name' host-name [HostName]	Defines the 'server_name' in the "client hello" message. The valid value is a string of up to 255 characters (case-insensitive).
'TLS Context'	Assigns a TLS Context, listed in the TLS Contexts table, to this rule. If the

Parameter	Description
tls-context [TLSContext]	incoming "client hello" message includes a 'server_name' extension type whose value is the same as configured in the 'Host Name' parameter (above), then the device uses this TLS Context. By default, no TLS Context is assigned.

## Configuring TLS for Secured SIP

The device uses TLS over TCP to encrypt and optionally, authenticate SIP messages. This is referred to as SIP Secure (SIPS). SIPS uses the X.509 certificate exchange process. For configuring TLS (TLS Context), see [TLS Certificates](#) on page 227.

To use a TLS Context for SIPS, you need to assign it to a Proxy Set or SIP Interface (or both) that is associated with the IP Group for which you want to employ TLS. When the device establishes a TLS connection (handshake) with a SIP user agent (UA), the TLS Context is determined as follows:

### ■ Incoming calls:

- a. Proxy Set: If the incoming call is successfully classified to an IP Group based on Proxy Set (i.e., IP address of calling party) and the Proxy Set is configured for TLS ('Transport Type' parameter is set to **TLS**), the TLS Context assigned to the Proxy Set is used. To configure Proxy Sets, see [Configuring Proxy Sets](#) on page 632.
- b. SIP Interface: If the Proxy Set is either not configured for TLS (i.e., the 'Transport Type' parameter is set to **UDP**) or not assigned a TLS Context, and/or classification to a Proxy Set fails, the device uses the TLS Context assigned to the SIP Interface used for the call. To configure SIP Interfaces, see [Configuring SIP Interfaces](#) on page 570.
- c. Default TLS Context (Index #0): If the SIP Interface is not assigned a TLS Context or no SIP Interface is used for the call, the device uses the default TLS Context.

### ■ Outgoing calls:

- a. Proxy Set: If the outgoing call is sent to an IP Group associated with a Proxy Set that is assigned a TLS Context and the Proxy Set is configured for TLS (i.e., 'Transport Type' parameter is set to **TLS**), the TLS Context is used. If the 'Transport Type' parameter is set to **UDP**, the device uses UDP to communicate with the proxy and no TLS Context is used.
- b. SIP Interface: If the Proxy Set is not assigned a TLS Context, the device uses the TLS Context assigned to the SIP Interface used for the call.
- c. Default TLS Context (Index #0): If the SIP Interface is not assigned a TLS Context or no SIP Interface is used for the call, the device uses the default TLS Context.

- When a TLS connection with the device is initiated by a SIP client, the device also responds using TLS, regardless of whether or not TLS was configured.
- The device regulates the number of new concurrent TLS connections that can be established per second. This protects the device from flooding (avalanches) of new TLS connections which may be caused from TLS-based malicious attacks or distributed denial-of-service (DDoS) attacks.
- To configure two-way (mutual) TLS authentication, see [TLS for SIP Clients](#) below.

#### ➤ To configure SIPS:

1. Configure a TLS Context (see [Configuring TLS Certificate Contexts](#) on page 227).
2. Assign the TLS Context to a Proxy Set or SIP Interface (see [Configuring Proxy Sets](#) on page 632 and [Configuring SIP Interfaces](#) on page 570, respectively).
3. Configure the SIP Interface with a TLS port number.
4. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Settings**), and then configure the following SIPS parameters:
  - a. Select the 'TLS Mutual Authentication' check box [SIPSRequireClientCertificate]:

TLS Mutual Authentication ☒

- b. Configure the other parameters as desired. For a description of the TLS parameters, see [TLS Parameters](#) on page 1811.
  - c. Click **Apply**.
5. By default, the device initiates a TLS connection only for the next network hop. To enable TLS all the way to the destination (**over multiple hops**):
    - a. Open the Transport Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Transport Settings**).
    - b. Select the 'SIPS' check box [EnableSIPS]:

SIPS ☒

- c. Click **Apply**.

## Configuring Mutual TLS Authentication

This section describes how to configure mutual (two-way) TLS authentication.

### TLS for SIP Clients

When Secure SIP (SIPS) is implemented using TLS, it is sometimes required to use two-way (mutual) authentication between the device and a SIP user agent (client). When the device acts

as the TLS server in a specific connection, the device demands the authentication of the SIP client's certificate. Both the device and the client use certificates from a CA to authenticate each other, sending their X.509 certificates to one another during the TLS handshake. Once the sender is verified, the receiver sends its' certificate to the sender for verification. SIP signaling starts when authentication of both sides completes successfully.

TLS mutual authentication can be configured for all calls (globally), or for specific calls by enabling mutual authentication for the associated SIP Interface. The TLS Context associated with the SIP Interface or Proxy Set belonging to these calls are used.

➤ **To configure mutual TLS authentication for SIP messaging:**

**1. Enable two-way authentication:**

- **Globally (for all calls):**

- i. Open the Security Settings page (**Setup** menu > **IP Network** tab > **Security** folder > **Security Settings**).
- ii. Select the 'TLS Mutual Authentication' check box [SIPSRequireClientCertificate]:

TLS Mutual Authentication • ☒

- **For specific SIP Interface:**

- i. Open the SIP Interfaces table (see [Configuring SIP Interfaces](#) on page 570).
- ii. Configure the 'TLS Mutual Authentication' parameter to **Enable**.

**2. Configure a TLS Context with the following certificates:**

- Import the certificate of the CA that signed the certificate of the SIP client into the Trusted Certificates table (certificate root store) so that the device can authenticate the client (see [Importing Certificates into Trusted Root CA Certificate Store](#) on page 244).
- Make sure that the TLS certificate is signed by a CA that the SIP client trusts so that the client can authenticate the device.

### **TLS for Remote Device Management**

For a description of secured device management by mutual TLS authentication, see [Configuring Secured \(HTTPS\) Web and REST Access](#) on page 75.

### **Reliable (TCP/TLS) Connections**

For the maximum number of concurrent TLS connections supported by the device, refer to the [Release Notes](#).

Reliable connection reuse depends on the [EnableTCPConnectionReuse] parameter. For incoming connections, reuse also depends on SIP message characteristics (presence of Via header's 'alias' parameter in initial request) and the [FakeTCPalias] parameter.

Persistent connections are determined by the [ReliableConnectionPersistentMode] parameter. However, if the destination is a Proxy server (configured in the Proxy Sets table), the connection is always persistent, regardless of the parameter's settings.

The device releases unnecessary persistent TLS connections to prevent them from accumulating and reaching the device's maximum number of supported TLS connections. If the number of incoming TLS connections exceeds 80% of the maximum, the device closes incoming TLS connections that aren't in use and that are kept open only because they are persistent. Similarly, the device releases reliable (TCP/TLS) connections that aren't in use (i.e., no active SIP dialogs and not associated with a registered user) and are kept open only because they are persistent, when exceeding 80% of the maximum number of supported reliable connections.

The device sends the SNMP alarm `acTLSSocketsLimitAlarm` (OID 1.3.6.1.4.1.5003.9.10.1.21.2.0.159) when the number of incoming TLS connections exceeds 95% of the maximum TLS connections supported by the device.

## Configuring Firewall Rules

The Firewall table lets you configure up to 50 firewall rules, which define network traffic filtering rules (*access list*) for incoming (ingress) traffic. The access list offers the following firewall possibilities:

- Blocking traffic from known malicious sources
- Allowing traffic only from known "friendly" sources, while blocking all other traffic
- Mixing allowed and blocked network sources
- Limiting traffic to a user-defined rate (blocking the excess)
- Limiting traffic to specific protocols and specific port ranges on the device

For each packet received on the IP network interface, the device searches the table from top to bottom until the first matching rule is found. The matched rule can permit (*allow*) or deny (*block*) the packet. Once a rule in the table is located, subsequent rules further down the table are ignored. If the end of the table is reached without a match, the packet is accepted.

- Only **Security Administrator** users can configure firewall rules.
- The rules configured by the Firewall table apply to a very low-level network layer and overrides all other security-related configuration. Thus, if you have configured higher-level security features (e.g., on the Application level), you must also configure firewall rules to permit this necessary traffic. For example, if you have configured IP addresses to access the device's Web and Telnet management interfaces in the Management Access List table (see [Configuring Management Access List](#) on page 88), you must configure a firewall rule that permits traffic from these IP addresses.
- The device supports dynamic firewall pinholes for media (RTP/RTCP) traffic negotiated in the SDP offer-answer of SIP calls. The pinhole allows the device to ignore its firewall and accept the traffic on the negotiated port. The device automatically closes the pinhole once the call terminates. Therefore, it is unnecessary to configure specific firewall rules to allow traffic through specific ports. For example, if you have configured a firewall rule to block all media traffic in the port range 6000 to 7000 and a call is negotiated to use the local port 6010, the device automatically opens port 6010 to allow the call.
- Setting the 'Prefix Length' field to **0** means that the rule applies to **all** packets, regardless of the defined IP address in the 'Source IP' field. Thus, it is highly recommended to set the parameter to a value other than 0.
- It is recommended to add a rule at the end of your table that blocks all traffic and to add firewall rules above it that allow required traffic (with bandwidth limitations). To block all traffic, use the following firewall rule:
  - ✓ Source IP: 0.0.0.0
  - ✓ Prefix Length: 0 (i.e., rule matches all IP addresses)
  - ✓ Start Port - End Port: 0-65535
  - ✓ Protocol: **Any**
  - ✓ Action Upon Match: **Block**
- The Firewall table supports up to 500 IP addresses (manually configured IP addresses or DNS-resolved IP addresses).
- If the device needs to communicate with AudioCodes OVOC, you must also add rules to allow incoming traffic from OVOC. For more information, see [Configuring Firewall Rules to Allow Incoming OVOC Traffic](#) on page 261.

The following procedure describes how to configure firewall rules through the Web interface. You can also configure it through ini file [AccessList] or CLI (`configure network > access-list`).

➤ **To configure a firewall rule:**

1. Open the Firewall table (**Setup** menu > **IP Network** tab > **Security** folder > **Firewall**).
2. On the table's toolbar, click **New** to add the row at the next available index number, or select a row before which you want to add the row and then click **Insert**; the following dialog box appears:

The screenshot shows the Firewall configuration window with two tabs: MATCH and ACTION. The MATCH tab is active, displaying various parameters for rule matching. The ACTION tab is also visible, showing options for action upon match and statistics.

MATCH		ACTION	
Index	0	Action Upon Match	Allow
Description		Packet Size	0
Source IP	0.0.0.0	Byte Rate	0
DNS Query Type	A	Byte Burst	0
Source Port	0		
Prefix Length	0		
Start Port	0		
End Port	65535		
Protocol	Any		
Use Specific Interface	Disable		
Interface Name	--		

STATISTICS

Match Count

3. Configure a firewall rule according to the parameters described in the table below.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

Table 14-5: Firewall Table Parameter Descriptions

Parameter	Description
<b>Match</b>	
'Index'	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Description' description [AccessList_Description]	Defines an arbitrary name to easily identify the row.
'Source IP' source-ip [AccessList_Source_IP]	Defines the IP address (or DNS name) or a specific host name of the source network from where the device receives the incoming packet. The default is 0.0.0.0.
'DNS Query Type' dns-query-type [AccessList_DnsQueryType]	Defines the DNS query (request) type used by the device to query the DNS server to resolve the domain name into an IP address(es). This is applicable only if you have configured the 'Source IP' parameter with an FQDN. <ul style="list-style-type: none"> <li>■ [1] <b>A</b> = (Default) The device performs an A-record DNS query, which is resolved into an IPv4 address(es).</li> <li>■ [2] <b>AAAA</b> = The device performs an AAAA-record DNS query, which is resolved into an IPv6 address(es).</li> <li>■ [3] <b>CNAME A</b> = The device performs a canonical name A-record query, which is resolved into an IPv4 address (es). A CNAME query is followed by an A-record address query and the resultant IP address is used.</li> <li>■ [4] <b>CNAME AAAA</b> = The device performs a canonical name query, which is resolved into an IPv6 address</li> </ul>

Parameter	Description
	<p>(es). A CNAME query is followed by an AAAA-record address query and the resultant IP address is used.</p> <ul style="list-style-type: none"> <li>■ [5] <b>SRV A</b> = The device performs an SRV A-record query, which is resolved into an IPv4 address(es). An SRV query is followed by an A-record address query and the resultant IP address is used. The firewall rule is active only if all the hostnames received from the SRV query were successfully resolved.</li> <li>■ [6] <b>SRV AAAA</b> = The device performs an SRV AAAA-record query, which is resolved into an IPv6 address(es). An SRV query is followed by an AAAA-record address query and the resultant IP address is used. The firewall rule is active only if all the hostnames received from the SRV query were successfully resolved.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For DNS resolutions, you also need to configure a DNS server: <ul style="list-style-type: none"> <li>✓ Third-party (external) DNS server: If you select an IP Interface for the firewall rule (see the 'Interface Name' parameter below), the device uses the DNS server configured for the IP Interface.</li> <li>✓ Device's integrated DNS server: You can configure domain name to IP address mapping in the device's Internal DNS table (see <a href="#">Configuring the Internal DNS Table</a> on page 199) and Internal SRV table (see <a href="#">Configuring the Internal SRV Table</a> on page 201).</li> </ul> </li> <li>■ The device performs DNS resolution periodically (i.e., resolved addresses are not persistent).</li> <li>■ You can do an nslookup to query the DNS server to obtain domain name or IP address mapping, using the CLI command <code>nslookup</code>.</li> </ul>
'Source Port' <code>src-port</code> <code>[AccessList_Source_Port]</code>	<p>Defines the source UDP/TCP ports of the remote host from where the device receives the incoming packet. The valid range is 0 to 65535. The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When set to 0, this field is ignored and any source port</li> </ul>

Parameter	Description
	<p>matches the rule.</p> <ul style="list-style-type: none"> <li>■ The source ports used for outgoing TCP and TLS connections are not configurable and are dynamically determined by the device in the range of 32,768-61,000.</li> </ul>
'Prefix Length' prefixLen [AccessList_PrefixLen]	<p>Defines the IP network mask (prefix length) of the IP address configured in the 'Source IP' parameter (above).</p> <ul style="list-style-type: none"> <li>■ IPv4: 0-32. For example: <ul style="list-style-type: none"> <li>✓ A value of 8 corresponds to IPv4 subnet class A (network mask of 255.0.0.0).</li> <li>✓ A value of 16 corresponds to IPv4 subnet class B (network mask of 255.255.0.0).</li> <li>✓ A value of 24 corresponds to IPv4 subnet class C (network mask of 255.255.255.0).</li> <li>✓ A value of 32 represents a single host (i.e., the specific IPv4 address configured in the 'Source IP' parameter).</li> </ul> </li> <li>■ IPv6: 0-128. For example: <ul style="list-style-type: none"> <li>✓ A value of 64 corresponds to subnet xxxx:xxxx:xxxx:xxxx::.</li> <li>✓ A value of 128 represents a single host (i.e., the specific IPv6 address configured in the 'Source IP' parameter).</li> </ul> </li> </ul> <p>The default is 32. A value of 0 means that the rule applies to all packets.</p> <p>The IP address of the sender of the incoming packet is trimmed in accordance with the prefix length (in bits) and then compared to the parameter 'Source IP'.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ A value of 0 applies to <b>all</b> packets, regardless of the configured IP address (in the 'Source IP' parameter). Therefore, you <b>must</b> configure the parameter to a value other than 0.</li> <li>■ The parameter is mandatory.</li> </ul>
'Start Port'	Defines the first UDP/TCP port in the range of ports on

Parameter	Description
<code>start-port</code> [AccessList_Start_Port]	<p>the device on which the incoming packet is received. From the perspective of the remote IP entity, this is the destination port. To configure the last port in the range, see the 'End Port' parameter (below).</p> <p>The valid range is 0 to 65535. The default is 0.</p> <p><b>Note:</b> When the protocol type isn't TCP or UDP, the entire range must be provided.</p>
'End Port' <code>end-port</code> [AccessList_End_Port]	<p>Defines the last UDP/TCP port in the range of ports on the device on which the incoming packet is received. From the perspective of the remote IP entity, this is the destination port. To configure the first port in the range, see the 'Start Port' parameter (above).</p> <p>The valid range is 0 to 65535. The default is 65535.</p> <p><b>Note:</b> When the protocol type isn't TCP or UDP, the entire range must be provided.</p>
'Protocol' <code>protocol</code> [AccessList_Protocol]	<p>Defines the protocol type (e.g., <b>UDP</b>, <b>TCP</b>, <b>ICMP</b>, <b>ESP</b> or <b>Any</b>) or the IANA protocol number in the range of 0 (Any) to 255.</p> <p>The default is <b>Any</b>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter also accepts the string value "HTTP", which implies selection of the TCP or UDP protocols and the appropriate port numbers as defined on the device.</li> <li>■ To specify SIP ports, configure rules with the UDP and TCP protocols for the required SIP Interfaces.</li> </ul>
'Use Specific Interface' <code>use-specific-interface</code> [AccessList_Use_Specific_Interface]	<p>Defines if you want to apply the rule to all IP interfaces or only a specific IP interface, configured in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159). In other words, the rule applies to packets that are received from the configured IP address ('Source IP' parameter) and received on this IP interface(s).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = The rule applies to all IP Interfaces.</li> <li>■ [1] <b>Enable</b> = (Default) The rule applies to a specific IP Interface only, which you assign using the 'Interface Name' parameter (below).</li> </ul>
'Interface Name'	Assigns an IP Interface (see <a href="#">Configuring IP Network</a>

Parameter	Description
network-interface-name [AccessList_Interface_x]	<p><a href="#">Interfaces</a> on page 159) to the rule.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'Use Specific Interface' parameter (above) to <b>Enable</b>.</p>
Action	
'Action Upon Match' allow-type [AccessList_Allow_Type]	<p>Defines the firewall action if the rule is matched.</p> <ul style="list-style-type: none"> <li>■ <b>Allow</b> = (Default) Permits the packets.</li> <li>■ <b>Block</b> = Rejects the packets</li> </ul>
'Packet Size' packet-size [AccessList_Packet_Size]	<p>Defines the maximum allowed packet size.</p> <p>The valid range is 0 to 65535. The default is 0.</p> <p><b>Note:</b> When filtering fragmented IP packets, this parameter relates to overall (re-assembled) packet size (and not to the size of each fragment).</p>
'Byte Rate' byte-rate [AccessList_Byte_Rate]	<p>Defines the expected traffic rate (bytes per second). This is the allowed bandwidth for the specified protocol.</p> <p>The default is 0.</p> <p>In addition to this parameter, the 'Burst Bytes' parameter provides additional allowance such that momentary bursts of data may utilize more than the configured byte rate, without being interrupted.</p> <p>For example, if 'Byte Rate' is configured to 40000 and 'Burst Bytes' to 50000, then this implies the following: the allowed bandwidth is 40000 bytes/sec with extra allowance of 50000 bytes. If, for example, the actual traffic rate is 45000 bytes/sec, this allowance would be consumed within 10 seconds, after which all traffic exceeding the allocated 40000 bytes/sec is dropped. If the actual traffic rate then slowed to 30000 bytes/sec, the allowance would be replenished within 5 seconds.</p>
'Burst Bytes' byte-burst [AccessList_Byte_Burst]	<p>Defines the tolerance of traffic rate limit (number of bytes).</p> <p>The default is 0.</p>
Statistics	
'Match Count' [AccessList_MatchCount]	<p>(Read-only) Displays the number of packets accepted or rejected by the rule.</p>

The table below provides an example of configured firewall rules:

**Table 14-6: Configuration Example of Firewall Rules**

Parameter	Firewall Rule				
	1	2	3	4	5
'Source IP'	12.194.231.76	12.194.230.7	0.0.0.0	192.0.0.0	0.0.0.0
'Prefix Length'	16	16	0	8	0
'Start Port and End Port'	0-65535	0-65535	0-65535	0-65535	0-65535
'Protocol'	Any	Any	icmp	Any	Any
'Use Specific Interface'	<b>Enable</b>	<b>Enable</b>	<b>Disable</b>	<b>Enable</b>	<b>Disable</b>
'Interface Name'	WAN	WAN	None	Voice-Lan	None
'Byte Rate'	0	0	40000	40000	0
'Burst Bytes'	0	0	50000	50000	0
'Action Upon Match'	<b>Allow</b>	<b>Allow</b>	<b>Allow</b>	<b>Allow</b>	<b>Block</b>

The firewall rules in the above configuration example do the following:

- **Rules 1 and 2:** Typical firewall rules that allow packets ONLY from specified IP addresses (e.g., proxy servers). Note that the prefix length is configured.
- **Rule 3:** A more "advanced" firewall rule - bandwidth rule for ICMP, which allows a maximum bandwidth of 40,000 bytes/sec with an additional allowance of 50,000 bytes. If, for example, the actual traffic rate is 45,000 bytes/sec, then this allowance would be consumed within 10 seconds, after which all traffic exceeding the allocated 40,000 bytes/sec is dropped. If the actual traffic rate then slowed to 30,000 bytes/sec, the allowance would be replenished within 5 seconds.
- **Rule 4:** Allows traffic from the LAN voice interface and limits bandwidth.
- **Rule 5:** Blocks all other traffic.

## Configuring Firewall Rules to Allow Incoming OVOC Traffic

If the device needs to communicate with AudioCodes OVOC, and you have configured at least one rule in the device's Firewall table, you also need to add firewall rules that permit (allow) incoming traffic from OVOC.

These OVOC-related firewall rules are required only if you have configured other firewall rules in the Firewall table. If you haven't configured any rules, the device allows all incoming traffic (including from OVOC) by default and the below firewall configuration is not required.

**Table 14-7: Firewall Rules to Allow Traffic from OVOC**

Index	Source IP	Source Port	Prefix Length	Start Port	End Port	Protocol	Use Specific Interface	Interface Name	Action Upon Match	Packet Size	Byte Rate	Byte Burst
0	Various rules for basic traffic.											
...												
N												
N+1 (SNMP)	<OVOC IP address>	1161	32	161	161	udp	Enable	OAM_IF	Allow	0	0	0
N+2 (NTP)	<OVOC IP address>	123	32	0	0	udp	Enable	<interface configured for NTP>	Allow	0	0	0
N+3 (HTTP)	<OVOC IP address>	80	32	0	0	tcp	Enable	<interface configured for file transfer>	Allow	0	0	0

Index	Source IP	Source Port	Prefix Length	Start Port	End Port	Protocol	Use Specific Interface	Interface Name	Action Upon Match	Packet Size	Byte Rate	Byte Burst
N+4 (HTTPS)	<OVOC IP address>	443	32	0	0	tcp	Enable	<interface configured for file transfer>	Allow	0	0	0
N+5 (QoE)	<OVOC IP address>	5000	32	0	0	tcp	Enable	<interface configured for QoE>	Allow	0	0	0
N+6 (QoE-secured)	<OVOC IP address>	5001	32	0	0	tcp	Enable	<interface configured for QoE>	Allow	0	0	0
N+7 (default - drop)	0.0.0.0	0	0	0	65535	Any	Disable	--	Block	0	0	0

## Intrusion Detection System

The device's Intrusion Detection System (IDS) feature detects malicious attacks on the device and reacts accordingly. A remote host is considered malicious if it reaches or exceeds a user-defined threshold (counter) of specified malicious attack types.

If malicious activity is detected, the device can do the following:

- Block remote hosts (IP addresses / ports) considered by the device as malicious. The device automatically blocks the malicious source for a user-defined period, after which it is

removed from the IDS Active Blocked List (see [Viewing IDS Active Blocked List](#) on page 1504).

- Send SNMP traps to notify of malicious activity and/or whether an attacker has been added to or removed from the IDS blocked list. For more information, see [Viewing IDS Alarms](#) on page 272.

IDS is an important feature as it ensures legitimate calls are not being adversely affected by attacks, and prevents Theft of Service and unauthorized access.

There are many types of malicious attacks, the most common being:

- **Denial of service:** This can be Denial of Service (DoS) where an attacker wishing to prevent a server from functioning correctly directs a large amount of requests – sometimes meaningless and sometimes legitimate, or it can be Distributed Denial of Service (DDoS) where the attacker controls a large group of systems to coordinate a large scale DoS attack against a system:
  - Message payload tampering: Attacker may inject harmful content into a message, e.g., by entering meaningless or wrong information, with the goal of exploiting a buffer overflow at the target. Such messages can be used to probe for vulnerabilities at the target.
  - Message flow tampering: This is a special case of DoS attacks. These attacks disturb the ongoing communication between users. An attacker can then target the connection by injecting fake signaling messages into the communication channel (such as CANCEL messages).
  - Message Flooding: The most common DoS attack is where an attacker sends a huge amount of messages (e.g., INVITEs) to a target. The goal is to overwhelm the target's processing capabilities, thereby rendering the target inoperable.
- **SPAM over Internet Telephony (SPIT):** VoIP spam is unwanted, automatically dialed, pre-recorded phone calls using VoIP. It is similar to e-mail spam.
- **Theft of Service (ToS):** Service theft can be exemplified by phreaking, which is a type of hacking that steals service (i.e., free calls) from a service provider, or uses a service while passing the cost to another person.

The IDS configuration is based on IDS Policies, where each policy can be configured with a set of IDS rules. Each rule defines a type of malicious attack to detect and the number of attacks during an interval (threshold) before an SNMP trap is sent. Each policy is then applied to a target under attack (SIP Interface) and/or source of attack (Proxy Set and/or subnet address).

## Enabling IDS

By default, IDS is disabled. You can enable it, as described below.

➤ **To enable IDS:**

1. Open the IDS General Settings page (**Setup** menu > **Signaling & Media** tab > **Intrusion Detection** folder > **IDS General Settings**).
2. Select the 'Intrusion Detection System (IDS)' check box:

Intrusion Detection System (IDS) ☒

3. Click **Apply**.

## Configuring IDS Policies

An IDS Policy is configured using two tables with "parent-child" type relationship:

- **IDS Policies table ("parent"):** Defines a name and provides a description for the IDS Policy. You can configure up to 20 IDS Policies.
- **IDS Rules table ("child"):** Defines the actual rules for the IDS Policy. Each IDS Policy can be configured with up to 20 rules.

A maximum of 100 IDS rules can be configured (regardless of how many rules are assigned to each policy).

For your convenience, the device provides default IDS Policies which you can use in your deployment if they meet your requirements:

- "DEFAULT\_FEU" - typically suited for far-end users in the WAN.
- "DEFAULT\_PROXY" - typically suited for proxy servers.
- "DEFAULT\_GLOBAL" - with global thresholds.

The following table shows the IDS rules per default IDS Policy:

Default IDS Policies and Rules	Default Values		
	'Threshold Scope'	'Threshold Window'	'Minor-Alarm Threshold'
<b>DEFAULT_FEU</b>			
Connection abuse	IP	30	5
Malformed message	IP	30	15
Authentication failure	IP	600	20
Dialog establish failure	IP	300	30

Default IDS Policies and Rules	Default Values		
	'Threshold Scope'	'Threshold Window'	'Minor-Alarm Threshold'
Abnormal flow	IP	30	15
<b>DEFAULT_PROXY</b>			
Connection abuse	IP	3	5
Malformed message	IP	3	50
Authentication failure	IP	5	30
Dialog establish failure	IP	3	50
Abnormal flow	IP	3	50
<b>DEFAULT_GLOBAL</b>			
Connection abuse	Global	3	15
Malformed message	Global	3	50
Authentication failure	Global	5	30
Dialog establish failure	Global	3	50
Abnormal flow	Global	3	50

- You can edit and delete the default IDS Policies.
- If the IDS Policies table is empty (i.e., you have deleted all IDS Policies) and you want to restore the default IDS Policies, disable and then enable the IDS feature (see [Enabling IDS](#) on page 263).

The following procedure describes how to configure IDS Policies through the Web interface. You can also configure it through ini file or CLI:

- IDS Policy table: IDSPolicy (ini file) or `configure voip > ids policy` (CLI)
- IDS Rules table: IDSRule (ini file) or `configure voip > ids rule` (CLI)

#### ➤ To configure an IDS Policy:

1. Open the IDS Policies table (**Setup** menu > **Signaling & Media** tab > **Intrusion Detection** folder > **IDS Policies**); the table displays the pre-configured IDS policies:

INDEX ↕	NAME	DESCRIPTION
0	DOS	dos-attacks
1	DEFAULT_FEU	Default policy for FEU
2	DEFAULT_PROXY	Default policy for proxies
3	DEFAULT_GLOBAL	Default policy for global scope

- Click **New**; the following dialog box appears:

The dialog box titled "IDS Policies" has a "GENERAL" tab. It contains three input fields:

- Index:** A text box containing the value "4".
- Name:** An empty text box.
- Description:** An empty text box.

- Configure an IDS Policy name according to the parameters described in the table below.
- Click **Apply**.

**Table 14-8: IDS Policies Table Parameter Descriptions**

Parameter	Description
'Index' policy [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' rule [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>The parameter value can't contain a forward slash (/).</li> <li>The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Description' description [Description]	Defines a brief description for the IDS Policy. The valid value is a string of up to 100 characters.

- In the IDS Policies table, select the required IDS Policy row, and then click the **IDS Rule** link located below the table; the IDS Rule table opens.
- Click **New**; the following dialog box appears:

The screenshot shows the 'IDS Rule' configuration window. It has three main sections: GENERAL, ALARMS, and DENY. In the GENERAL section, 'Index' is 1, 'Reason' is 'Malformed message', 'Threshold Scope' is 'IP', and 'Threshold Window' is 30. In the ALARMS section, 'Minor-Alarm Threshold' is 15, 'Major-Alarm Threshold' is 20, and 'Critical-Alarm Threshold' is 25. In the DENY section, 'Deny Threshold' is 25 and 'Deny Period' is 60.

GENERAL		ALARMS	
Index	1	Minor-Alarm Threshold	15
Reason	Malformed message	Major-Alarm Threshold	20
Threshold Scope	IP	Critical-Alarm Threshold	25
Threshold Window	30		

DENY	
Deny Threshold	25
Deny Period	60

The figure above shows a configuration example: If 15 malformed SIP messages ('Reason') are received within a period of 30 seconds ('Threshold Window'), a minor alarm is sent ('Minor-Alarm Threshold'). Every 30 seconds, the rule's counters are cleared ('Threshold Window'). If more than 25 malformed SIP messages are received within this period, the device blocks for 60 seconds the remote IP host ('Deny Threshold') from where the messages were received.

7. Configure an IDS Rule according to the parameters described in the table below.
8. Click **Apply**, and then save your settings to flash memory.

**Table 14-9: IDS Rule Table Parameter Descriptions**

Parameter	Description
General	
'Index' rule-id [IDSRule_RuleID]	Defines an index number for the new table record.
'Reason' reason [IDSRule_Reason]	<p>Defines the type of intrusion attack (malicious event).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Any</b> = All events listed below are considered as attacks and are counted together.</li> <li>■ [1] <b>Connection abuse</b> = (Default) Connection failures, which includes the following: <ul style="list-style-type: none"> <li>✓ Incoming TLS authentication (handshake) failure</li> <li>✓ Incoming WebSocket connection establishment failure</li> </ul> </li> <li>■ [2] <b>Malformed message</b> = Malformed SIP messages, which includes the following:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Message exceeds a user-defined maximum message length (50K)</li> <li>✓ Any SIP parser error</li> <li>✓ Message Policy match (see <a href="#">Configuring SIP Message Policy Rules</a> on page 867)</li> <li>✓ Basic headers not present</li> <li>✓ Content length header not present (for TCP)</li> <li>✓ Header overflow</li> <li>■ [3] <b>Authentication failure</b> = SIP authentication failure, which includes the following: <ul style="list-style-type: none"> <li>✓ Local authentication ("Bad digest" errors)</li> <li>✓ Remote authentication (SIP 401/407 is sent if original message includes authentication)</li> </ul> </li> <li>■ [4] <b>Dialog establish failure</b> = SIP dialog establishment (e.g., INVITE) failure, which includes the following: <ul style="list-style-type: none"> <li>✓ Classification failure (see <a href="#">Configuring Classification Rules</a> on page 1171).</li> <li>✓ Call Admission Control (CAC) threshold exceeded (see <a href="#">Configuring Call Admission Control</a> on page 1164)</li> <li>✓ Routing failure (i.e., no routing rule was matched)</li> <li>✓ Local reject by device (prior to SIP 180 response): REGISTER not allowed due to IP Group's 'Registration Mode' parameter, or SIP requests rejected based on a registered users policy (configured by the SRD parameter 'User Security Mode' or SIP Interface parameter 'User Security Mode').</li> <li>✓ No user found when routing to a User-type IP Group (similar to a SIP 404)</li> <li>✓ Remote rejects (prior to SIP 18x response). To specify SIP response codes to exclude from the IDS count, see <a href="#">Configuring SIP Response Codes to Exclude from IDS</a>.</li> <li>✓ Malicious signature pattern detected (see <a href="#">Configuring Malicious Signatures</a> on page 1247)</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [5] <b>Abnormal flow</b> = SIP call flow that is abnormal, which includes the following: <ul style="list-style-type: none"> <li>✓ Requests and responses without a matching transaction user (except ACK requests)</li> <li>✓ Requests and responses without a matching transaction (except ACK requests)</li> </ul> </li> </ul>
'Threshold Scope' threshold-scope [IDSRule_ThresholdScope]	<p>Defines the source of the attacker to consider in the device's detection count.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Global</b> = All attacks regardless of source are counted together during the threshold window.</li> <li>■ [2] <b>IP</b> = Attacks from each specific IP address are counted separately during the threshold window.</li> <li>■ [3] <b>IP+Port</b> = Attacks from each specific IP address:port are counted separately during the threshold window. This option is useful for NAT servers, where numerous remote machines use the same IP address but different ports. However, it is not recommended to use this option as it may degrade detection capabilities.</li> </ul>
'Threshold Window' threshold-window [IDSRule_ThresholdWindow]	<p>Defines the threshold interval (in seconds) during which the device counts the attacks to check if a threshold is crossed. The counter is automatically reset at the end of the interval. The valid range is 1 to 1,000,000. The default is 1.</p>
Alarms	
'Minor-Alarm Threshold' minor-alm-thr [IDSRule_MinorAlarmThreshold]	<p>Defines the threshold that if crossed a minor severity alarm is sent.</p> <p>The valid range is 1 to 1,000,000. A value of 0 or -1 means not defined.</p>
'Major-Alarm Threshold' major-alm-thr [IDSRule_MajorAlarmThreshold]	<p>Defines the threshold that if crossed a major severity alarm is sent.</p> <p>The valid range is 1 to 1,000,000. A value of 0 or -1 means not defined.</p>
'Critical-Alarm Threshold' critical-alm-thr [IDSRule_CriticalAlarmThreshold]	<p>Defines the threshold that if crossed a critical severity alarm is sent.</p> <p>The valid range is 1 to 1,000,000. A value of 0 or -1 means not defined.</p>

Parameter	Description
Deny	
'Deny Threshold' deny-thr [IDSRule_DenyThreshold]	<p>Defines the threshold that if crossed, the device blocks the remote host (attacker).</p> <p>The default is -1 (i.e., not configured).</p> <p>To view the IDS blocked list, see <a href="#">Viewing IDS Active Blocked List</a> on page 1504.</p> <p><b>Note:</b> The parameter is applicable only if the 'Threshold Scope' parameter is set to <b>IP</b> or <b>IP+Port</b>.</p>
'Deny Period' deny-period [IDSRule_DenyPeriod]	<p>Defines the duration (in sec) to keep the attacker on the blocked list, if configured using the 'Deny Threshold' parameter.</p> <p>The valid range is 0 to 1,000,000. The default is -1 (i.e., not configured).</p> <p>To view the IDS blocked list, see <a href="#">Viewing IDS Active Blocked List</a> on page 1504.</p> <p><b>Note:</b> The parameter is applicable only if the 'Threshold Scope' parameter is set to <b>IP</b> or <b>IP+Port</b>.</p>

## Assigning IDS Policies

The IDS Matches table lets you implement your configured IDS Policies. You do this by assigning IDS Policies to any, or a combination of the following configuration entities:

- **SIP Interface:** For detection of malicious attacks on specific SIP Interface(s). To configure SIP Interfaces, see [Configuring SIP Interfaces](#) on page 570.
- **Proxy Sets:** For detection of malicious attacks from specified Proxy Set(s). To configure Proxy Sets, see [Configuring Proxy Sets](#) on page 632.
- **Subnet addresses:** For detection of malicious attacks from specified subnet addresses.

You can configure up to 20 IDS Policy-Matching rules.

The following procedure describes how to configure the IDS Match table through the Web interface. You can also configure it through ini file [IDSMatch] or CLI (`configure voip > ids match`).

### ➤ To configure an IDS Policy-Matching rule:

1. Open the IDS Matches table (**Setup** menu > **Signaling & Media** tab > **Intrusion Detection** folder > **IDS Matches**).
2. Click **New**; the following dialog box appears:

The screenshot shows the 'IDS Matches' configuration window. The 'GENERAL' tab is selected. The configuration parameters are as follows:

Parameter	Value
Index	1
SIP Interface IDs	1-2
Proxy Set IDs	
Subnet	!10.1.0.0/16 & !10.2.2.2
Policy	#3 [SIP Trunk] <a href="#">View</a>

The figure above shows a configuration example where the IDS Policy "SIP Trunk" is applied to SIP Interfaces 1 and 2, and to all source IP addresses outside of subnet 10.1.0.0/16 and IP address 10.2.2.2.

3. Configure a rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 14-10:IDS Matches Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table record.
'SIP Interface IDs' sip-interface [SIPInterface]	<p>Assigns a SIP Interface(s) to the IDS Policy. This indicates the SIP Interfaces that are being attacked.</p> <p>The valid value is the ID of the SIP Interface. The following syntax is supported:</p> <ul style="list-style-type: none"> <li>■ A comma-separated list of SIP Interface IDs (e.g., 1,3,4)</li> <li>■ A hyphen (-) indicates a range of SIP Interfaces (e.g., 3,4-7 means IDs 3, and 4 through 7)</li> <li>■ A prefix of an exclamation mark (!) means negation of the set (e.g., !3,4-7 means all indexes excluding 3, and excluding 4 through 7)</li> </ul>
'Proxy Set IDs' proxy-set [ProxySet]	<p>Assigns a Proxy Set(s) to the IDS Policy. This indicates the Proxy Sets from where the attacks are coming from. The following syntax is supported:</p> <ul style="list-style-type: none"> <li>■ A comma-separated list of Proxy Set IDs (e.g., 1,3,4)</li> <li>■ A hyphen (-) indicates a range of Proxy Sets (e.g., 3,4-7 means IDs 3, and 4 through 7)</li> <li>■ A prefix of an exclamation mark (!) means negation of the set (e.g., !3,4-7 means all indexes excluding 3, and excluding 4 through 7)</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Only the IP address of the Proxy Set is considered (not port).</li> <li>If a Proxy Set has multiple IP addresses, the device considers the Proxy Set as one entity and includes all its IP addresses in the same IDS count.</li> </ul>
'Subnet' subnet [Subnet]	<p>Defines the subnet to which the IDS Policy is assigned. This indicates the subnets from where the attacks are coming from. The following syntax can be used:</p> <ul style="list-style-type: none"> <li>Basic syntax is a subnet in CIDR notation (e.g., 10.1.0.0/16 means all sources with IP address in the range 10.1.0.0–10.1.255.255)</li> <li>An IP address can be specified without the prefix length to refer to the specific IP address.</li> <li>Each subnet can be negated by prefixing it with (!), which means all IP addresses outside that subnet.</li> <li>Multiple subnets can be specified by separating them with "&amp;" (and) or " " (or) operations (without quotation marks), for example: <ul style="list-style-type: none"> <li>✓ 10.1.0.0/16   10.2.2.2: includes subnet 10.1.0.0/16 and IP address 10.2.2.2.</li> <li>✓ !10.1.0.0/16 &amp; !10.2.2.2: includes all addresses except those of subnet 10.1.0.0/16 and IP address 10.2.2.2. Note that the exclamation mark (!) appears before each subnet.</li> <li>✓ 10.1.0.0/16 &amp; !10.1.1.1: includes subnet 10.1.0.0/16, except IP address 10.1.1.1.</li> </ul> </li> </ul>
'Policy' policy [Policy]	<p>Assigns an IDS Policy (configured in <a href="#">Configuring IDS Policies</a> on page 264).</p>

## Viewing IDS Alarms

The device sends the following SNMP traps for the IDS feature:

- Traps that notify the detection of malicious attacks:

- **acIDSPolicyAlarm:** The device sends this alarm whenever a threshold of a specific IDS Policy rule is crossed. The trap displays the crossed severity threshold (Minor or Major), IDS Policy and IDS Rule, and the IDS Policy-Match index.
- **acIDSThresholdCrossNotification:** The device sends this event for each scope (IP address) that crosses the threshold. In addition to the crossed severity threshold (Minor or Major) of the IDS Policy-Match index, this event shows the IP address (or IP address:port) of the malicious attacker.

If the severity level is raised, the alarm of the former severity is cleared and the device sends a new alarm with the new severity. The alarm is cleared after a user-defined timeout during which no thresholds have been crossed.

➤ **To configure IDS alarm cleared timeout:**

1. Open the IDS General Settings page (**Setup** menu > **Signaling & Media** tab > **Intrusion Detection** folder > **IDS General Settings**).
2. From the 'IDS Alarm Clear Period' field (IDSAlarmClearPeriod), enter the timeout (in seconds) after which the alarm is cleared if no IDS thresholds have been crossed during the timeout.

IDS Alarm Clear Period [sec]

3. Click **Apply**.

This "quiet" timeout period must be at least twice the 'Threshold Window' value (configured in [Configuring IDS Policies](#) on page 264). For example, if you configure 'IDS Alarm Clear Period' to 20 sec and 'Threshold Window' to 15 sec, the 'IDS Alarm Clear Period' parameter is ignored and the alarm is cleared only after 30 seconds (2 x 15 sec).

The figure below displays an example of IDS alarms in the Active Alarms table ([Viewing Active Alarms](#) on page 1454). In this example, a Minor threshold alarm is cleared and replaced by a Major threshold alarm:

17	Minor	Board#1/IDSMATCH#2/IDSRULE#0	Policy 2 (Proxy): minor threshold (5) of signaling-msg cross in ip scope	24.10.2012, 9:48:53
18	cleared	Board#1/IDSMATCH#2/IDSRULE#0	Alarm cleared: Policy 2 (Proxy): minor threshold (5) of signaling-msg cross in ip scope	24.10.2012, 9:48:53
19	Major	Board#1/IDSMATCH#2/IDSRULE#0	Policy 2 (Proxy): major threshold (10) of signaling-msg cross in ip scope	24.10.2012, 9:48:53

- **acIDSBlacklistNotification** event: The device sends this event whenever an attacker (remote host at IP address and/or port) is added to or removed from the blocked list. To view the IDS blocked list, see [Viewing IDS Active Blocked List](#) on page 1504.

You can also view IDS alarms through CLI:

- To view all active IDS alarms:

```
# show voip ids active-alarm all
```

- To view all IP addresses that have crossed the threshold for an active IDS alarm:

```
# show voip ids active-alarm match <IDS Match Policy ID> rule <IDS Rule ID>
```

The IP address is displayed only if the 'Threshold Scope' parameter is set to IP or IP+Port; otherwise, only the alarm is displayed.

The device also sends IDS notifications and alarms in syslog messages to a syslog server. This occurs only if you have configured syslog (see [Enabling Syslog](#) on page 1622). An example of a syslog message with IDS alarms and notifications is shown below:

```
[S=92159] [SID:438286865] ( lgr_ids)(97420 ) IDS Event: reason=establish-fail,event=14003(establish-classify-fail),ip=10.13.45.200:5060(SII),transport=udp
[S=92160] [SID:438286865] ( lgr_ids)(97421 ) IDS Counter (0,19995): IDSMatch#0/IDSRule#0,policy=3(TEST),reason=establish-fail,scope=ip,scope-val=10.13.45.200(SII),value=6
[S=92161] [SID:438286865] ( lgr_ids)(97422 ) ?? [WARNING] IDS Rule (0): Threshold cross. IDSMatch#0/IDSRule#0,policy=3(TEST),value=6,severity=2(major)
[S=92162] [SID:438286865] ( lgr_ids)(97423 ) ?? [WARNING] IDS Rule (0): Threshold cross. IDSMatch#0/IDSRule#0,policy=3(TEST),value=6,severity=4(blacklist)
[S=92163] [SID:438286865] ( lgr_ids)(97424 ) ?? [WARNING] IDS Blacklist: Added IP 10.13.45.200(NI:0) to blacklist
[S=92164] [SID:438286865] ( lgr_psbdrif)(97425 ) SNMP EVENT: IDS_BLACKLIST_NOTIFY "Added IP 10.13.45.200(NI:0) to blacklist"
[S=92165] RAISE-ALARM:acIDSBlacklistNotification; Textual Description: Added IP 10.13.45.200(NI:0) to blacklist; Severity:indeterminate; Source; Unique ID:30;
[S=92166] [SID:438286865] ( lgr_psbdrif)(97426 ) InsertBoardEvent- event ADD BLACKLIST EV inserted channel -100
```

The table below lists the syslog text messages per malicious event:

**Table 14-11:Types of Malicious Events and Syslog Text String**

Reason	
Description	Syslog String
<b>Connection Abuse</b>	
TLS authentication failure	abuse-tls-auth-fail
WebSocket establishment failure	abuse-websocket-fail
<b>Malformed Messages</b>	
Message exceeds a user-defined maximum message length (50K)	malformed-invalid-msg-len
Any SIP parser error	malformed-parse-error
Message policy match	malformed-message-policy
Basic headers not present	malformed-miss-header
Content length header not present (for TCP)	malformed-miss-content-len
Header overflow	malformed-header-overflow
<b>Authentication Failure</b>	
Local authentication ("Bad digest" errors)	auth-establish-fail
Remote authentication (SIP 401/407 is sent if original message includes authentication)	auth-reject-response

Reason	
Description	Syslog String
<b>Dialog Establishment Failure</b>	
Classification failure	establish-classify-fail
Routing failure (no matched routing rule)	establish-route-fail
Other local rejects (prior to SIP 180 response)	establish-local-reject
Remote rejects (prior to SIP 180 response)	establish-remote-reject
Malicious signature pattern detected	establish-malicious-signature-db-reject
CAC threshold exceeded	establish-cac-reject
<b>Abnormal Flow</b>	
Requests and responses without a matching transaction user (except ACK requests)	flow-no-match-tu
Requests and responses without a matching transaction (except ACK requests)	flow-no-match-transaction

## Configuring SIP Response Codes to Exclude from IDS

You can specify SIP response codes (reject reasons) that you want the IDS mechanism to ignore in its' count as reasons for SIP-dialog establishment failures.

### ➤ To configure SIP responses to exclude from IDS:

1. Open the IDS General Settings page (**Setup** menu > **Signaling & Media** tab > **Intrusion Detection** folder > **IDS General Settings**).
2. In the 'Excluded Response Codes' field, enter the SIP response codes that you want ignored by IDS.

**Figure 14-1: Configuring SIP Response Codes to Exclude from IDS**

**Excluded Response Codes**

408,422,423,480,48

3. Click **Apply**.

- The parameter applies only to rejected responses received from the upstream server; not rejected responses generated by the device (except for 404).
- The response codes 401 and 407 are considered authentication failures and thus, are not applicable to this parameter.

## Configuring SIP Header Value Encryption

For enhanced security, you can configure the device to encrypt the value of a specific SIP header. Encryption is done using the AES-256 key encryption algorithm.

This feature is typically used between two AudioCodes devices, where one encrypts the SIP header value before sending the SIP message, while the other decrypts the value when it receives the SIP message.

This feature is intended for SIP headers that are not used by the device for classification or routing. For example, you may want to encrypt the value of a proprietary SIP header called "P-Access-Network-Info" that may contain sensitive information.

### ➤ To configure SIP header value encryption:

1. Configure the AES-256 encryption key:
  - a. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
  - b. In the 'AES-256 Encryption Key' parameter, enter the encryption key:

#### SIP HEADERS ENCRYPTION

AES-256 Encryption Key

- The key must be 32 characters.
- Configure both devices with the same key.

2. Configure a Message Manipulation rule to specify the SIP header to encrypt:
  - a. Open the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856).
  - b. Click **New**, and then configure the rule as follows:
    - ◆ 'Name': Assign a name.
    - ◆ 'Manipulation Set ID': Configure an ID.

- ◆ 'Message Type': Configure the type of SIP message (e.g., **Invite**).
- ◆ 'Action Subject': Configure the SIP header whose value you want to encrypt (e.g., **P-Access-Network-Info**).
- ◆ 'Action Type': Select **Modify**.
- ◆ 'Action Value': Use the **Funct.Encrypt** option to encrypt the SIP header (e.g., **Funct.Encrypt(P-Access-Network-Info)**).

On the device that decrypts the SIP header value, configure the 'Action Value' parameter to **Funct.Decrypt(P-Access-Network-Info)** for the relevant Message Manipulation rule.

3. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then assign the Manipulation Set ID (configured in the previous step) to the relevant IP Group.

## 15 Media

This section describes media-related configuration.

### Voice Settings

The section describes various voice-related configuration such as voice volume, silence suppression, and DTMF transport type. For a detailed description of these parameters, see [Configuration Parameters Reference](#) on page 1701.

### Configuring Voice Gain (Volume) Control

The device allows you to configure the level of the received (input gain) Tel-to-IP or IP-to-IP signal and the level of the transmitted (output gain) IP-to-Tel or IP-to-IP signal. The gain can be set between -32 and 31 decibels (dB).

➤ **To configure gain control through the Web interface:**

1. Open the Voice Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Voice Settings**).

Voice Volume (-32 to 31 dB)

Input Gain (-32 to 31 dB)

2. Configure the following parameters:
  - 'Voice Volume' (*VoiceVolume*): Defines the voice gain control (in decibels) of the transmitted signal.
  - 'Input Gain' (*InputGain*): Defines the PCM input gain control (in decibels) of the received signal.
3. Click **Apply**.

### Configuring Echo Cancellation

The device supports adaptive linear (line) echo cancellation according to G.168-2002. Echo cancellation is a mechanism that removes echo from the voice channel. Echoes are reflections of the transmitted signal.

In this line echo, echoes are generated when two-wire telephone circuits (carrying both transmitted and received signals on the same wire pair) are converted to a four-wire circuit. Echoes are reflections of the transmitted signal, which result from impedance mismatch in the hybrid (bi-directional 2-wire to 4-wire converting device).

An estimated echo signal is built by feeding the decoder output signal to an RLS-like adaptive filter, which adapts itself to the characteristics of the echo path. The 'estimated echo signal' (the output of this filter) is then subtracted from the input signal (which is the sum of the

desired input signal and the undesired echo) to provide a clean signal. To suppress the remaining residual echo, a Non Linear Processor (NLP) is used, as well as a double-talk (two people speak at the same time) detector that prevents false adaptation during near-end speech.

The device also supports acoustic echo cancellation for SBC calls. These echoes are composed of undesirable acoustical reflections (non-linear) of the received signal (i.e., from the speaker) which find their way from multiple reflections such as walls and windows into the transmitted signal (i.e., microphone). Therefore, the party at the far end hears his / her echo. The device removes these echoes and sends only the near-end's desired speech signal to the network (i.e., to the far-end party). The echo is composed of a linear part and a nonlinear part. However, in the Acoustic Echo Canceled, a substantial part of the echo is non-linear echo. To support this feature, the Forced Transcoding feature must be enabled so that the device uses DSPs.

The following procedure describes how to configure echo cancellation through the Web interface:

➤ **To configure echo cancellation:**

**1. Configure line echo cancellation:**

- a. Open the Voice Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Voice Settings**), and then select the 'Echo Canceller' check box (EnableEchoCanceller):

**Echo Canceller** ☒

**2. Enable acoustic echo cancellation for SBC calls:**

- a. Open the Voice Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Voice Settings**), and then configure the following:
  - ◆ From the 'Echo Canceller Type' drop-down list (EchoCancellerType), select the echo canceller type
  - ◆ Select the 'Network Echo Suppressor Enable' check box (AcousticEchoSuppressorSupport) to enable the network Acoustic Echo Suppressor.
  - ◆ In the 'Attenuation Intensity' field (AcousticEchoSuppAttenuationIntensity), enter the acoustic echo suppressor signals identified as echo attenuation intensity
  - ◆ In the 'Max ERL Threshold' field (AcousticEchoSuppMaxERLThreshold), enter the acoustic echo suppressor maximum ratio between signal level and returned echo from the phone
  - ◆ In the 'Min Reference Delay' field (AcousticEchoSuppMinRefDelayx10ms) enter the acoustic echo suppressor minimum reference delay
  - ◆ In the 'Max Reference Delay' field (AcousticEchoSuppMaxRefDelayx10ms), enter the acoustic echo suppressor maximum reference delay

### NETWORK ECHO SUPPRESSOR

Network Echo Suppressor Enable	<input checked="" type="checkbox"/>
Attenuation Intensity	<input type="text" value="0"/>
Max ERL Threshold - DB	<input type="text" value="0"/>
Min Reference Delay x10 msec	<input type="text" value="0"/>
Max Reference Delay x10 msec	<input type="text" value="40"/>

- b. Open the IP Profiles table, and then configure the 'Echo Canceller' parameter to **Acoustic** (see [Configuring IP Profiles](#) on page 674).
- c. Enable the Forced Transcoding feature (using the [TranscodingMode] parameter) to allow the device to use DSP channels, which are required for acoustic echo cancellation.

The following additional echo cancellation parameters are configurable only through *ini* file:

- *ECHybridLoss* - defines the four-wire to two-wire worst-case Hybrid loss
- *ECNLPMODE* - defines the echo cancellation Non-Linear Processing (NLP) mode
- *EchoCancellerAggressiveNLP* - enables Aggressive NLP at the first 0.5 second of the call

## Fax and Modem Capabilities

This section describes the device's fax and modem capabilities and corresponding configuration. Fax and modem configuration is done on the Fax/Modem/CID Settings page.

- Unless otherwise specified, parameters mentioned in this section are available on this page. For a detailed description of these fax and modem parameters, see [Configuration Parameters Reference](#) on page 1701.
- Some SIP parameters override these fax and modem parameters. For example, the [IsFaxUsed] parameter and V.152 parameters in Section [V.152 Support](#) on page 295.

### ➤ To access the fax and modem parameters:

- Open the Fax/Modem/CID Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Fax/Modem/CID Settings**).

GENERAL		FAX RELAY	
Fax Transport Mode	T.38 Relay	Fax Relay Redundancy Depth	0
T.38 Version	T.38 version 0	Fax Relay Enhanced Redundancy Depth	4
Caller ID Transport Type	Mute	Fax Relay ECM Enable	Enable
Caller ID Type	Standard Bellcore	Fax Relay Max Rate (bps)	14400bps
V.21 Modem Transport Type	Disable	Fax Relay Rx/Tx Timeout (sec)	10
V.22 Modem Transport Type	Enable Bypass		
V.23 Modem Transport Type	Enable Bypass		
V.32 Modem Transport Type	Enable Bypass		
V.34 Modem Transport Type	Enable Bypass		
Fax CNG Mode	Doesn't send T.38 re-INV		
CNG Detector Mode	Disable		

FAX/MODEM BYPASS	
Fax/Modem Bypass Coder Type	G711Alaw_64
Fax/Modem Bypass Packing Factor	1
Fax Bypass Output Gain	0
Modem Bypass Output Gain	0

## Fax and Modem Operating Modes

The device supports two modes of operation:

- Fax/modem negotiation that is **not** performed during call establishment.
- Voice-band data (VBD) mode for V.152 implementation (see [V.152 Support](#) on page 295): Fax/modem capabilities are negotiated between the device and the remote endpoint during call establishment. During a call, when a fax/modem signal is detected, transition from voice to VBD (or T.38) is automatically performed and no additional SIP signaling is required. If negotiation fails (i.e., no match is achieved for any of the transport capabilities), fallback to existing logic occurs (according to the parameter `IsFaxUsed`).

## Fax and Modem Transport Modes

The device supports the following transport modes for fax per modem type (V.22/V.23/Bell/V.32/V.34):

- T.38 fax relay (see [T.38 Fax Relay Mode](#) on the next page)
- G.711 Transport: switching to G.711 when fax/modem is detected (see [G.711 Fax and Modem Transport Mode](#) on page 285)
- Fax fallback to G.711 if T.38 is not supported (see [Fax Fallback](#) on page 285)
- Fax and modem bypass: a proprietary method that uses a high bit rate coder (see [Fax and Modem Bypass Mode](#) on page 286)
- NSE Cisco's Pass-through bypass mode for fax and modem (see [Fax and Modem NSE Mode](#) on page 288)
- Transparent with events: passing the fax / modem signal in the current voice coder with adaptations (see [Fax and Modem Transparent with Events Mode](#) on page 289)
- Transparent: passing the fax / modem signal in the current voice coder (see [Fax / Modem Transparent Mode](#) on page 290)

- RFC 2833 ANS Report upon Fax/Modem Detection (see [RFC 2833 ANS Report upon Fax and Modem Detection](#) on page 291)

'Adaptations' refer to automatic reconfiguration of certain DSP features for handling fax/modem streams differently than voice.

### T.38 Fax Relay Mode

In Fax Relay mode, fax signals are transferred using the T.38 protocol. T.38 is the ITU standard for sending fax across IP networks in real-time mode. The device currently supports only the T.38 UDP syntax.

T.38 can be configured in the following ways:

- Switching to T.38 mode using SIP re-INVITE messages (see [Switching to T.38 Mode using SIP re-INVITE](#) below)
- Automatically switching to T.38 mode without using SIP re-INVITE messages (see [Automatically Switching to T.38 Mode without SIP re-INVITE](#) on the next page)

When fax transmission ends, the reverse switching from fax relay to voice is automatically performed at both the local and remote endpoints.

You can change the fax rate declared in the SDP, using the 'Fax Relay Max Rate' parameter [FaxRelayMaxRate]. The parameter doesn't affect the actual transmission rate. You can also enable or disable Error Correction Mode (ECM) fax mode using the 'Fax Relay ECM Enable' parameter [FaxRelayECMEnable].

When using T.38 mode, you can define a redundancy feature to improve fax transmission over congested IP networks. This feature is activated using the 'Fax Relay Redundancy Depth' parameter [FaxRelayRedundancyDepth] and the 'Fax Relay Enhanced Redundancy Depth' parameter [FaxRelayEnhancedRedundancyDepth]. Although this is a proprietary redundancy scheme, it should not create problems when working with other T.38 decoders.

### Switching to T.38 Mode using SIP re-INVITE

In the Switching to T.38 mode using the SIP re-INVITE, upon detection of a fax signal, the terminating device negotiates T.38 capabilities using a re-INVITE message. If the far-end device doesn't support T.38, the fax fails. In this mode, the 'Fax Transport Mode' parameter [FaxTransportMode] is ignored.

#### ➤ To configure T.38 mode using SIP re-INVITE messages:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list [IsFaxUsed], select **T.38 Relay**:

Fax Signaling Method T.38 Relay ▼

2. On the Fax/Modem/CID Settings page, configure the following optional parameters:

- 'Fax Relay Redundancy Depth' [FaxRelayRedundancyDepth]
- 'Fax Relay Enhanced Redundancy Depth' [FaxRelayEnhancedRedundancyDepth]
- 'Fax Relay ECM Enable' [FaxRelayECMEnable]
- 'Fax Relay Max Rate' [FaxRelayMaxRate]

The terminating gateway sends T.38 packets immediately after the T.38 capabilities are negotiated in SIP. However, the originating device by default, sends T.38 (assuming the T.38 capabilities are negotiated in SIP) only after it receives T.38 packets from the remote device. This default behavior cannot be used when the originating device is located behind a firewall that blocks incoming T.38 packets on ports that have not yet received T.38 packets from the internal network. To resolve this problem, you should configure the device to send CNG packets in T.38 upon CNG signal detection [CNGDetectorMode = 1].

### Automatically Switching to T.38 Mode without SIP re-INVITE

In the Automatically Switching to T.38 mode without SIP re-INVITE, when a fax signal is detected, the channel automatically switches from the current voice coder to answer tone mode and then to T.38-compliant fax relay mode.

#### ➤ To configure Automatic T.38 mode:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **No Fax**:

Fax Signaling Method No Fax ▼

2. On the Fax/Modem/CID Settings page, configure the 'Fax Transport Mode' parameter to **T.38 Relay** [FaxTransportMode = 1].
3. Configure the following optional parameters:
  - 'Fax Relay Redundancy Depth' [FaxRelayRedundancyDepth]
  - 'Fax Relay Enhanced Redundancy Depth' [FaxRelayEnhancedRedundancyDepth]
  - 'Fax Relay ECM Enable' [FaxRelayECMEnable]
  - 'Fax Relay Max Rate' [FaxRelayMaxRate]

### Fax over IP using T.38 Transmission over RTP

The device supports Fax-over-IP (FoIP) transmission using T.38 over RTP, whereby the T.38 payload is encapsulated in the RTP packet instead of being sent in dedicated T.38 packets (out-of-band). To support this feature, configure the coder type to T.38 Over RTP.

To indicate T.38 over RTP, the SDP body uses "udptl" (Facsimile UDP Transport Layer) in the 'a=fmtp' line. The device supports T.38 over RTP according to this standard and according to the AudioCodesproprietary method:

- **Call Parties belong to AudioCodes Devices:** T.38-over-RTP method is used, whereby the device encapsulates the entire T.38 packet (payload with all its headers) in the sent RTP. For T.38 over RTP, the devices use the proprietary identifier "AcUdptl" in the 'a=fmtp' line of the SDP. For example:

```
v=0
o=AudioCodesGW 1357424688 1357424660 IN IP4 10.8.6.68
s=Phone-Call
c=IN IP4 10.8.6.68
t=0 0
m=audio 6080 RTP/AVP 18 100 96
a=ptime:20
a=sendrecv
a=rtpmap:18 G729/8000
a=fmtp:18 annexb=no
a=rtpmap:100 t38/8000
a=fmtp:100 T38FaxVersion=0
a=fmtp:100 T38MaxBitRate=0
a=fmtp:100 T38FaxMaxBuffer=3000
a=fmtp:100 T38FaxMaxDatagram=122
a=fmtp:100 T38FaxRateManagement=transferredTCF
a=fmtp:100 T38FaxUdpEC=t38UDPRedundancy
a=fmtp:100 AcUdptl
a=rtpmap:96 telephone-event/8000
a=fmtp:96 0-15
```

- **AudioCodes Call Party with non-AudioCodes Party:** The device uses the standard T.38-over-RTP method, which encapsulates the T.38 payload only, without its headers (i.e., includes only fax data) in the sent RTP packet (RFC 4612).

The T.38-over-RTP method also depends on the initiator of the call:

- **Device initiates a call:** The device always sends the SDP offer with the proprietary token "AcUdpTI" in the 'fmtp' attribute. If the SDP answer includes the same token, the device employs the proprietary T.38-over-RTP mode; otherwise, the standard mode is used.
- **Device answers a call:** If the SDP offer from the remote party contains the 'fmtp' attribute with "AcUdpTI", the device answers with the same attribute and employs the proprietary T.38-over-RTP mode; otherwise, the standard mode is used.

If both T.38 (regular) and T.38 Over RTP coders are negotiated between the call parties, the device uses T.38 Over RTP.

### G.711 Fax and Modem Transport Mode

In this mode, when the terminating device detects fax or modem signals (CED or AnsAM), it sends a re-INVITE message to the originating device, requesting it to re-open the channel in G.711 VBD with the following adaptations:

- Echo Canceller = off
- Silence Compression = off
- Echo Canceller Non-Linear Processor Mode = off
- Dynamic Jitter Buffer Minimum Delay = 40
- Dynamic Jitter Buffer Optimization Factor = 13

After a few seconds upon detection of fax V.21 preamble or super G3 fax signals, the device sends a second re-INVITE enabling the echo canceller (the echo canceller is disabled only on modem transmission).

A 'gpmd' attribute is added to the SDP according to the following format:

- **For G.711 A-law:**

```
a=gpmd:8 vbd=yes;ecan=on (or off for modems)
```

- **For G.711  $\mu$ -law:**

```
a=gpmd:0 vbd=yes;ecan=on (or off for modems)
```

The following parameters are ignored and automatically set to **Events Only**:

- 'Fax Transport Mode' [FaxTransportMode]
- 'Vxx ModemTransportType' [VxxModemTransportType]

#### ➤ To configure fax / modem transparent mode:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **G.711 Transport**:

Fax Signaling Method G.711 Transport ▼

2. Click **Apply**.

### Fax Fallback

In this mode, when the terminating device detects a fax signal, it sends a re-INVITE message to the originating device with T.38. If the remote device doesn't support T.38 (replies with SIP

response 415 "Media Not Supported"), the device sends a new re-INVITE with G.711 VBD with the following adaptations:

- Echo Canceller = on
- Silence Compression = off
- Echo Canceller Non-Linear Processor Mode = off
- Dynamic Jitter Buffer Minimum Delay = 40
- Dynamic Jitter Buffer Optimization Factor = 13

This section is applicable only to the Gateway application.

When the device initiates a fax session using G.711, a 'gpmd' attribute is added to the SDP according to the following format:

■ **For G.711A-law:**

```
a=gpmd:8 vbd=yes;ecan=on
```

■ **For G.711  $\mu$ -law:**

```
a=gpmd:0 vbd=yes;ecan=on
```

In this mode, the 'Fax Transport Mode' [FaxTransportMode] parameter is ignored and automatically set to **Disable** (transparent mode).

➤ **To configure fax fallback mode:**

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **Fax Fallback**:

Fax Signaling Method

Fax Fallback

2. Click **Apply**.

### Fax and Modem Bypass Mode

In this proprietary mode, when fax or modem signals are detected, the channel automatically switches from the current voice coder to a high bit-rate coder, according to the 'Fax/Modem Bypass Coder Type' parameter [FaxModemBypassCoderType]. The channel is also automatically reconfigured with the following fax / modem adaptations:

- Disables silence suppression
- Enables echo cancellation for fax

- Disables echo cancellation for modem
- Performs certain jitter buffering optimizations

The network packets generated and received during the bypass period are regular voice RTP packets (per the selected bypass coder), but with a different RTP payload type according to the following parameters:

- 'Fax Bypass Payload Type' [FaxBypassPayloadType]
- [ModemBypassPayloadType]

During the bypass period, the coder uses the packing factor, configured by the 'Fax/Modem Bypass Packing Factor' parameter [FaxModemBypassM]. The packing factor determines the number of coder payloads (each the size of [FaxModemBypassBasicRTTPacketInterval]) that are used to generate a single fax/modem bypass packet. When fax/modem transmission ends, the reverse switching, from bypass coder to regular voice coder is performed.

➤ **To configure fax / modem bypass mode:**

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list [IsFaxUsed], select **No Fax**.
2. On the Fax/Modem/CID Settings page, do the following:
  - Configure the 'Fax Transport Mode' parameter to **Bypass** [FaxTransportMode = 2].
  - Configure the 'V.21 Modem Transport Type' parameter to **Enable Bypass** [V21ModemTransportType = 2].
  - Configure the 'V.22 Modem Transport Type' parameter to **Enable Bypass** [V22ModemTransportType = 2].
  - Configure the 'V.23 Modem Transport Type' parameter to **Enable Bypass** [V23ModemTransportType = 2].
  - Configure the 'V.32 Modem Transport Type' parameter to **Enable Bypass** [V32ModemTransportType = 2].
  - Configure the 'V.34 Modem Transport Type' parameter to **Enable Bypass** [V34ModemTransportType = 2].
3. Configure the [BellModemTransportType] parameter to 2 (Bypass).
4. Configure the following optional parameters:
  - 'Fax/Modem Bypass Coder Type' [FaxModemBypassCoderType]
  - 'Fax Bypass Payload Type' [FaxBypassPayloadType]
  - [ModemBypassPayloadType]
  - [FaxModemBypassBasicRTTPacketInterval]
  - [FaxModemBypasDJBufMinDelay]

- When the device is configured for modem bypass and T.38 fax, V.21 low-speed modems are not supported and fail as a result.
- When the remote (non-AudioCodes) gateway uses the G.711 coder for voice and doesn't change the coder payload type for fax or modem transmission, it is recommended to use the Bypass mode with the following configuration:
  - ✓ [EnableFaxModemInbandNetworkDetection = 1].
  - ✓ 'Fax/Modem Bypass Coder Type' = same coder used for voice.
  - ✓ 'Fax/Modem Bypass Packing Factor'[FaxModemBypassM] = same interval as voice.
  - ✓ [ModemBypassPayloadType = 8] if voice coder is A-Law or 0 if voice coder is Mu-Law.

### Fax and Modem NSE Mode

In this mode, fax and modem signals are transferred using Cisco-compatible Pass-through bypass mode. Upon detection of fax or modem answering tone signal, the terminating device sends three to six special NSE RTP packets (configured by the [NSEpayloadType] parameter; usually to 100). These packets signal the remote device to switch to G.711 coder, according to the 'Fax/Modem Bypass Packing Factor' parameter. After a few NSE packets are exchanged between the devices, both devices start using G.711 packets with standard payload type (8 for G.711 A-Law and 0 for G.711 Mu-Law). In this mode, no re-INVITE messages are sent. The voice channel is optimized for fax/modem transmission (same as for usual bypass mode).

The following parameters that configure the payload type for the AudioCodes proprietary Bypass mode are not used with NSE Bypass: 'Fax Bypass Payload Type' and [ModemBypassPayloadType].

When configured for NSE mode, the device includes the following line in the SDP, where *100* is the NSE payload type:

```
a=rtpmap:100 X-NSE/8000
```

The Cisco gateway must include the following definition:

```
modem passthrough nse payload-type 100 codec g711alaw
```

#### ➤ To configure NSE mode:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **No Fax**.
2. On the Fax/Modem/CID Settings page, do the following:
  - Configure the 'Fax Transport Mode' parameter to **Bypass** [FaxTransportMode = 2].

- Configure the 'V.21 Modem Transport Type' parameter to **Enable Bypass** [V21ModemTransportType = 2].
  - Configure the 'V.22 Modem Transport Type' parameter to **Enable Bypass** [V22ModemTransportType = 2].
  - Configure the 'V.23 Modem Transport Type' parameter to **Enable Bypass** [V23ModemTransportType = 2].
  - Configure the 'V.32 Modem Transport Type' parameter to **Enable Bypass** [V32ModemTransportType = 2].
  - Configure the 'V.34 Modem Transport Type' parameter to **Enable Bypass** [V34ModemTransportType = 2].
3. Configure the [BellModemTransportType] parameter to [2] (Bypass).
  4. Configure the [NSEMode] parameter to [1] (enables NSE).
  5. parameter the [NSEPayloadType] parameter to [100].

### Fax and Modem Transparent with Events Mode

In this mode, fax and modem signals are transferred using the current voice coder with the following automatic adaptations:

- Echo Celler = on (or off for modems)
- Echo Celler Non-Linear Processor Mode = off
- Jitter buffering optimizations

#### ➤ To configure fax / modem transparent with events mode:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **No Fax**.
2. On the Fax/Modem/CID Settings page, do the following:
  - Configure the 'Fax Transport Mode' parameter to **Events Only** [FaxTransportMode = 3].
  - Configure the 'V.21 Modem Transport Type' parameter to **Events Only** [V21ModemTransportType = 3].
  - Configure the 'V.22 Modem Transport Type' parameter to **Events Only** [V22ModemTransportType = 3].
  - Configure the 'V.23 Modem Transport Type' parameter to **Events Only** [V23ModemTransportType = 3].
  - Configure the 'V.32 Modem Transport Type' parameter to **Events Only** [V32ModemTransportType = 3].

- Configure the 'V.34 Modem Transport Type' parameter to **Events Only** [V34ModemTransportType = 3].
3. Configure the [BellModemTransportType] parameter to [3] (transparent with events).

### Fax / Modem Transparent Mode

In this mode, fax and modem signals are transferred using the current voice coder without notifications to the user and without automatic adaptations. It's possible to use Profiles (see [Coders and Profiles](#) on page 661) to apply certain adaptations to the channel used for fax / modem. For example, to use the coder G.711, to set the jitter buffer optimization factor to 13, and to enable echo cancellation for fax and disable it for modem.

#### ➤ To configure fax / modem transparent mode:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **No Fax**.
2. On the Fax/Modem/CID Settings page, do the following:
  - Configure the 'Fax Transport Mode' parameter to **Disable** (FaxTransportMode = 0).
  - Configure the 'V.21 Modem Transport Type' parameter to **Disable** [V21ModemTransportType = 0].
  - Configure the 'V.22 Modem Transport Type' parameter to **Disable** [V22ModemTransportType = 0].
  - Configure the 'V.23 Modem Transport Type' parameter to **Disable** [V23ModemTransportType = 0].
  - Configure the 'V.32 Modem Transport Type' parameter to **Disable** [V32ModemTransportType = 0].
  - Configure the 'V.34 Modem Transport Type' parameter to **Disable** [V34ModemTransportType = 0].
3. Configure the [BellModemTransportType] parameter to [0] (transparent mode).
4. Configure the following optional parameters:
  - Coders in the Coders table - see [Configuring Coders Groups](#) on page 661.
  - 'Dynamic Jitter Buffer Optimization Factor' [DJBufOptFactor] - [Configuring the Dynamic Jitter Buffer](#) on page 296.
  - 'Echo Cancellor' [EnableEchoCancellor] - see [Configuring Echo Cancellation](#) on page 278.

This mode can be used for fax, but is not recommended for modem transmission. Instead, use the Bypass (see [Fax and Modem Bypass Mode](#) on page 286) or Transparent with Events modes (see [Fax and Modem Transparent with Events Mode](#) on page 289) for modem.

### RFC 2833 ANS Report upon Fax and Modem Detection

The device (terminator gateway) sends RFC 2833 ANS/ANSam events upon detection of fax and/or modem answer tones (i.e., CED tone). This causes the originator to switch to fax/modem. The parameter is applicable only when the fax or modem transport type is set to bypass, Transparent-with-Events, V.152 VBD, or G.711 transport. When the device is located on the originator side, it ignores these RFC 2833 events.

#### ➤ To configure RFC 2833 ANS Report upon fax/modem detection:

1. Open the Gateway General Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway General Settings**), and then from the 'Fax Signaling Method' drop-down list (IsFaxUsed), select **No Fax** or **Fax Fallback**.
2. On the Fax/Modem/CID Settings page, do the following:
  - Configure the 'Fax Transport Mode' parameter to **Bypass** [FaxTransportMode = 2].
  - Configure the 'V.xx Modem Transport Type' parameters to **Enable Bypass** [VxxModemTransportType = 2].
3. Configure the [FaxModemNTEMode] parameter to [1] (enables this feature).

### V.34 Fax Support

V.34 fax machines can transmit data over IP to the remote side using various methods. The device supports the following modes for transporting V.34 fax data over IP:

- T.38 Version 3 - V.34 fax relay mode
- Bypass mechanism for V.34 fax transmission (see [Bypass Mechanism for V.34 Fax Transmission](#) on the next page)
- T.38 Version 0 relay mode, i.e., fallback to T.38 (see [Relay Mode for T.30 and V.34 Faxes](#) on page 293)

To configure whether to pass V.34 over T.38 fax relay, or use Bypass over the High Bit Rate coder (e.g. PCM A-Law), use the 'V.34 Fax Transport Type' parameter (V34FaxTransportType).

You can use the 'SIP T.38 Version' parameter (SIPT38Version) to configure:

- Pass V.34 over T.38 fax relay using bit rates of up to 33,600 bps ('SIP T.38 Version' is set to Version 3).
- Use Fax-over-T.38 fallback to T.30, using up to 14,400 bps ('SIP T.38 Version' is set to Version 0).

- Interworking of T.38 Version 3 is supported only for Gateway calls. For SBC calls, the device forwards T.38 Version 3 transparently (as is) to the other leg (no transcoding).
- The CNG detector is disabled in all the subsequent examples. To disable the CNG detector, set the 'CNG Detector Mode' parameter (CNGDetectorMode) to **Disable**.

### Bypass Mechanism for V.34 Fax Transmission

In this proprietary scenario, the device uses bypass (or NSE) mode to transmit V.34 faxes, enabling the full utilization of its speed.

#### ➤ To use bypass mode for T.30 and V.34 faxes:

1. On the Fax/Modem/CID Settings page, do the following:
  - Set the 'Fax Transport Mode' parameter to **Bypass** [FaxTransportMode = 2].
  - Set the 'V.22 Modem Transport Type' parameter to **Enable Bypass** [V22ModemTransportType = 2].
  - Set the 'V.23 Modem Transport Type' parameter to **Enable Bypass** [V23ModemTransportType = 2].
  - Set the 'V.32 Modem Transport Type' parameter to **Enable Bypass** [V32ModemTransportType = 2].
  - Set the 'V.34 Modem Transport Type' parameter to **Enable Bypass** [V34ModemTransportType = 2].
2. Configure the [V34FaxTransportType] parameter to [2] (Bypass).

#### ➤ To use bypass mode for V.34 faxes, and T.38 for T.30 faxes:

1. On the Fax/Modem/CID Settings page, do the following:
  - Set the 'Fax Transport Mode' parameter to **T.38 Relay** [FaxTransportMode = 1].
  - Set the 'V.22 Modem Transport Type' parameter to **Enable Bypass** [V22ModemTransportType = 2].
  - Set the 'V.23 Modem Transport Type' parameter to **Enable Bypass** [V23ModemTransportType = 2].
  - Set the 'V.32 Modem Transport Type' parameter to **Enable Bypass** [V32ModemTransportType = 2].
  - Set the 'V.34 Modem Transport Type' parameter to **Enable Bypass** [V34ModemTransportType = 2].
2. Configure the [V34FaxTransportType] parameter to [2] (Bypass).

## Relay Mode for T.30 and V.34 Faxes

In this scenario, V.34 fax machines are forced to use their backward compatibility with T.30 faxes and operate in the slower T.30 mode.

### ➤ To use T.38 mode for V.34 and T.30 faxes:

1. On the Fax/Modem/CID Settings page, do the following:
  - Set the 'Fax Transport Mode' parameter to **T.38 Relay** (FaxTransportMode = 1).
  - Set the 'V.22 Modem Transport Type' parameter to **Disable** (V22ModemTransportType = 0).
  - Set the 'V.23 Modem Transport Type' parameter to **Disable** (V23ModemTransportType = 0).
  - Set the 'V.32 Modem Transport Type' parameter to **Disable** (V32ModemTransportType = 0).
  - Set the 'V.34 Modem Transport Type' parameter to **Disable** (V34ModemTransportType = 0).
2. Configure the [V34FaxTransportType] parameter to [1] (Relay).

### ➤ To allow V.34 fax relay over T.38:

- Set the 'SIP T.38 Version' parameter to Version 3 (SIPT38Version = 3).

### ➤ To force V.34 fax machines to use their backward compatibility with T.30 faxes and operate in the slower T.30 mode:

- Set the 'SIP T.38 Version' parameter to Version 0 (SIPT38Version = 0).

Interworking of T.38 Version 3 is supported only for Gateway calls. For SBC calls, the device forwards T.38 Version 3 transparently (as is) to the other leg (i.e., no transcoding).

## V.34 Fax Relay for SG3 Fax Machines

Super Group 3 (SG3) is a standard for fax machines that support speeds of up to 33.6 kbps through V.34 half duplex (HD) modulation. The following procedure describes how to configure V.34 (SG3) fax relay support based on ITU Specification T.38 Version 3.

### ➤ To enable support for V.34 fax relay (T.38) at SG3 speed:

1. In the IP Profiles table (see [Configuring IP Profiles](#) on page 674), add an IP Profile with the 'Fax Signaling Method' parameter configured to **T.38 Relay**.

2. In the Coders Groups table (see [Configuring Coders Groups](#) on page 661) set the coder used by the device to G.729 (or any other supported codec).
3. On the Fax/Modem/CID Settings page, do the following settings:
  - 'SIP T.38 Version' to **Version 3** (SIPT38Version = 3).
  - 'Fax Relay Max Rate' (RelayMaxRate) to **33,600bps** (default).
  - 'CNG Detector Mode' (CNGDetectorMode) to **Disable** (default).
  - 'V.21 Modem Transport Type' to **Disable** (V21ModemTransportType = 0).
  - 'V.22 Modem Transport Type' to **Disable** (V22ModemTransportType = 0).
  - 'V.23 Modem Transport Type' to **Disable** (V23ModemTransportType = 0).
  - 'V.32 Modem Transport Type' to **Disable** (V32ModemTransportType = 0).
  - 'V.34 Modem Transport Type' to **Disable** (V34ModemTransportType = 0).
  - 'CED Transfer Mode' to Fax Relay or VBD (CEDTransferMode = 0).
4. Set the ini file parameter, V34FaxTransportType to 1 (i.e., relay).
5. Set the ini file parameter, T38MaxDatagramSize to 560 (default).

- The T.38 negotiation should be completed at call start according to V.152 procedure (as shown in the INVITE example below).
- T.38 mid-call Re-INVITEs are supported.
- If the remote party supports only T.38 Version 0, the device "downgrades" the T.38 Version 3 to T.38 Version 0.

For example, the device sends or receives the following INVITE message, negotiating both audio and image media:

```
INVITE sip:2001@10.8.211.250;user=phone SIP/2.0
Via: SIP/2.0/UDP 10.8.6.55;branch=z9hG4bKac1938966220

## V.152 Support

The device supports the ITU-T recommendation V.152 (Procedures for Supporting Voice-Band Data over IP Networks). Voice-band data (VBD) is the transport of modem, facsimile, and text telephony signals over a voice channel of a packet network with a codec appropriate for such signals.

For V.152 capability, the device supports T.38 as well as VBD codecs (i.e., G.711 A-law and G.711  $\mu$ -law). The selection of capabilities is performed using the Coders Groups table (see [Configuring Coders Groups](#) on page 661).

When in VBD mode for V.152 implementation, support is negotiated between the device and the remote endpoint at the establishment of the call. During this time, initial exchange of call capabilities is exchanged in the outgoing SDP. These capabilities include whether VBD is supported and associated RTP payload types ('gpmd' SDP attribute), supported codecs, and packetization periods for all codec payload types ('ptime' SDP attribute). After this initial negotiation, no Re-INVITE messages are necessary as both endpoints are synchronized in terms of the other side's capabilities. If negotiation fails (i.e., no match was achieved for any of the transport capabilities), fallback to existing logic occurs (according to the parameter `IsFaxUsed`).

Below is an example of media descriptions of an SDP indicating support for V.152. In the example, V.152 implementation is supported (using the dynamic payload type 96 and G.711 u-law as the VBD codec) as well as the voice codecs G.711  $\mu$ -law and G.729.

```
v=0
o=- 0 0 IN IPV4 <IPAddressA>
s=-
t=0 0
p=+1
c=IN IP4 <IPAddressA>
m=audio <udpPort A> RTP/AVP 18 0
a=ptime:10
a=rtpmap:96 PCMU/8000
a=gpmid: 96 vbd=yes
```

Instead of using VBD transport mode, the V.152 implementation can use alternative relay fax transport methods (e.g., fax relay over IP using T.38). The preferred V.152 transport method is indicated by the SDP 'pmft' attribute. Omission of this attribute in the SDP content means that VBD mode is the preferred transport mechanism for voice-band data.

## RTP and RTCP Settings

This section describes configuration relating to Real-Time Transport Protocol (RTP) and RTP Control Protocol (RTCP).

### Configuring the Dynamic Jitter Buffer

Voice frames are transmitted at a fixed rate. If the frames arrive at the other end at the same rate, voice quality is perceived as good. However, some frames may arrive slightly faster or slower than the other frames. This is called jitter (delay variation) and degrades the perceived voice quality. To minimize this problem, the device uses a jitter buffer. The jitter buffer collects voice packets, stores them and sends them to the voice processor in evenly spaced intervals.

The device uses a dynamic jitter buffer that can be configured with the following:

- **Minimum delay:** Defines the starting jitter capacity of the buffer. For example, at 0 msec, there is no buffering at the start. At the default level of 10 msec, the device always buffers incoming packets by at least 10 msec worth of voice frames.
- **Optimization Factor:** Defines how the jitter buffer tracks to changing network conditions. When set at its maximum value of 12, the dynamic buffer aggressively tracks changes in delay (based on packet loss statistics) to increase the size of the buffer and doesn't decay back down. This results in the best packet error performance, but at the cost of extra delay. At the minimum value of 0, the buffer tracks delays only to compensate for clock drift and quickly decays back to the minimum level. This optimizes the delay performance but at the expense of a higher error rate.

The default settings of 10 msec Minimum delay and 10 Optimization Factor should provide a good compromise between delay and error rate. The jitter buffer 'holds' incoming packets for 10 msec before making them available for decoding into voice. The coder polls frames from the buffer at regular intervals in order to produce continuous speech. As long as delays in the network do not change (jitter) by more than 10 msec from one packet to the next, there is always a sample in the buffer for the coder to use. If there is more than 10 msec of delay at any time during the call, the packet arrives too late. The coder tries to access a frame and is not able to find one. The coder must produce a voice sample even if a frame is not available. It therefore compensates for the missing packet by adding a Bad-Frame-Interpolation (BFI) packet. This loss is then flagged as the buffer being too small. The dynamic algorithm then causes the size of the buffer to increase for the next voice session. The size of the buffer may decrease again if the device notices that the buffer is not filling up as much as expected. At no time does the buffer decrease to less than the minimum size configured by the Minimum delay parameter.

In certain scenarios, the **Optimization Factor is set to 13**: One of the purposes of the Jitter Buffer mechanism is to compensate for clock drift. If the two sides of the VoIP call are not synchronized to the same clock source, one RTP source generates packets at a lower rate, causing under-runs at the remote Jitter Buffer. In normal operation (optimization factor 0 to 12), the Jitter Buffer mechanism detects and compensates for the clock drift by occasionally dropping a voice packet or by adding a BFI packet.

Fax and modem devices are sensitive to small packet losses or to added BFI packets. Therefore, to achieve better performance during modem and fax calls, the Optimization Factor should be set to 13. In this special mode the clock drift correction is performed less frequently - only when the Jitter Buffer is completely empty or completely full. When such condition occurs, the correction is performed by dropping several voice packets simultaneously or by adding several BFI packets simultaneously, so that the Jitter Buffer returns to its normal condition.

The following procedure describes how to configure the jitter buffer using the Web interface.

➤ **To configure jitter buffer using the Web interface:**

1. Open the RTP/RTCP Settings page (**Setup** menu > **Signaling & Media** menu > **Media** folder > **RTP/RTCP Settings**). The relevant parameters are listed under the General group, as shown below:

Dynamic Jitter Buffer Minimum Delay	<input type="text" value="10"/>
Dynamic Jitter Buffer Optimization Factor	<input type="text" value="10"/>

2. Set the 'Dynamic Jitter Buffer Minimum Delay' parameter (DJBufMinDelay) to the minimum delay (in msec) for the Dynamic Jitter Buffer.
3. Set the 'Dynamic Jitter Buffer Optimization Factor' parameter (DJBufOptFactor) to the Dynamic Jitter Buffer frame error/delay optimization factor.
4. Click **Apply**.

## Enabling Comfort Noise Generation

The device can generate artificial background noise, known as *comfort noise*, in the voice channel during periods of silence when no one on the call is speaking. This feature helps reassure participants that the call remains connected, preventing the perception of sudden disconnections.

The device detects silence using its Voice Activity Detection (VAD) mechanism. When Comfort Noise Generation is enabled and silence is detected, the device transmits Silence Identifier Descriptors (SIDs), which allow the receiving side to reproduce local background noise.

The Comfort Noise Generation functionality also depends on the Silence Suppression (SCE) setting of the voice codec (G.711 or G.726) used in the voice channel. Voice coders are configured in the Coders Groups table (see [Configuring Coders Groups](#) on page 661).

The use of comfort noise is indicated by including a payload type for CN on the media ('m=') description line in the SDP. The device can use CN with a codec whose RTP time stamp clock rate is 8,000 Hz (G.711 / G.726). The static payload type 13 is used.

CN is negotiated between the call parties. If the remote side doesn't support CN, it's not used. Regardless of the device's settings, the device always attempts to adapt to the remote side's request for Comfort Noise Generation.

If you enable Comfort Noise Generation (see below procedure), the following occurs:

- If the device is the initiator, it sends a 'CN' in the SDP only if the SCE of the codec is enabled. If the remote UA responds with a 'CN' in the SDP, then CNG occurs; otherwise, CNG doesn't occur.
- If the device is the receiver and the remote SIP UA doesn't send a 'CN' in the SDP, then no CNG occurs. If the remote side sends a 'CN', the device attempts to be compatible with the remote side and even if the codec's SCE is disabled, CNG occurs.

If you disable Comfort Noise Generation, the device doesn't send 'CN' in the SDP. However, if the codec's SCE is enabled, the device performs Comfort Noise Generation.

This feature is applicable only to the Gateway application.

### ➤ To enable Comfort Noise Generation:

1. Open the RTP/RTCP Settings page (**Setup** menu > **Signaling & Media** menu > **Media** folder > **RTP/RTCP Settings**).
2. Select the 'Comfort Noise Generation Negotiation' check box (ComfortNoiseNegotiation):

Comfort Noise Generation Negotiation ☒

3. Click **Apply**.

## Configuring DTMF Transport Types

The device supports various methods for transporting DTMF digits over the IP network to the remote endpoint for Gateway calls.

This feature is applicable only to the Gateway application.

The methods and their configuration can be configured on the DTMF & Dialing page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **DTMF & Supplementary** > **DTMF & Dialing**):

Declare RFC 2833 in SDP	Yes
1st Tx DTMF Option	
2nd Tx DTMF Option	
RFC 2833 Payload Type	96

- **Using INFO message according to Nortel IETF draft:** DTMF digits are sent to the remote side in INFO messages. To enable the mode:

- Configure the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
- Configure the 'First Tx DTMF Option' parameter to **INFO Nortel** (FirstTxDTMFOption = 1).

DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).

- **Using INFO message according to Cisco's mode:** DTMF digits are sent to the remote side in INFO messages. To enable the mode:

- Configure the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
- Configure the 'First Tx DTMF Option' parameter to **INFO Cisco** (FirstTxDTMFOption = 3).

DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).

- **Using NOTIFY messages according to IETF Internet-Draft draft-mahy-sipping-signaled-digits-01:** DTMF digits are sent to the remote side using NOTIFY messages. To enable the mode:

- Configure the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
- Configure the 'First Tx DTMF Option' parameter to **NOTIFY** (FirstTxDTMFOption = 2).

DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).

- **Using RFC 2833 relay with Payload type negotiation:** DTMF digits are sent to the remote side as part of the RTP stream according to RFC 2833. To enable the mode:
  - a. Configure the 'Declare RFC 2833 in SDP' parameter to **Yes** (RxDTMFOption = 3).
  - b. Configure the 'First Tx DTMF Option' parameter to **RFC 2833** (FirstTxDTMFOption = 4).

To set the RFC 2833 payload type with a value other than its default, use the RFC2833PayloadType parameter. The device negotiates the RFC 2833 payload type using local and remote SDP and sends packets using the payload type from the received SDP. The device expects to receive RFC 2833 packets with the same payload type as configured by the parameter. If the remote side doesn't include 'telephony-event' in its SDP, the device sends DTMF digits in transparent mode (as part of the voice stream).

- **Sending DTMF digits (in RTP packets) as part of the audio stream (DTMF Relay is disabled):** This method is typically used with G.711 coders. With other low-bit rate (LBR) coders, the quality of the DTMF digits is reduced. To enable the mode:
  - a. Configure the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Configure the 'First Tx DTMF Option' parameter to **Not Supported** (FirstTxDTMFOption = 0).
  - c. Configure the ini file parameter [DTMFTransportType] to [2] (i.e., transparent).
- **Using INFO message according to Korea mode:** DTMF digits are sent to the remote side in INFO messages. To enable this mode:
  - a. Configure the 'Declare RFC 2833 in SDP' parameter to **No** (RxDTMFOption = 0).
  - b. Configure the 'First Tx DTMF Option' parameter to **INFO Cisco** (FirstTxDTMFOption = 3).

DTMF digits are removed from the audio stream (and the 'DTMF Transport Type' parameter is automatically set to **Mute DTMF**).

- The device is always ready to receive DTMF packets over IP in all possible transport modes: INFO messages, NOTIFY, and RFC 2833 (in proper payload type) or as part of the audio stream.
- To exclude RFC 2833 Telephony event parameter from the device's SDP, configure the 'Declare RFC 2833 in SDP' parameter to **No**.
- You can use the following parameters to configure DTMF digit handling:
  - ✓ [FirstTxDTMFOption], [SecondTxDTMFOption], [RxDTMFOption], [RFC2833TxPayloadType], and [RFC2833RxPayloadType]
  - ✓ [MGCPDTMFDetectionPoint], [DTMFVolume], [DTMFTransportType], [DTMFDigitLength], and [DTMFInterDigitInterval]

## Configuring RFC 2833 Payload

You can configure the RFC 2833 payload.

### ➤ To configure RFC 2833 payload:

1. Open the RTP/RTCP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **RTP/RTCP Settings**).
2. Configure the following parameters:
  - 'RTP Redundancy Depth' (RTPRedundancyDepth) - enables the device to generate RFC 2198 redundant packets.
  - **For Gateway application only:** 'Enable RTP Redundancy Negotiation' (EnableRTPRedundancyNegotiation) - enables the device to include the RTP redundancy dynamic payload type in the SDP, according to RFC 2198.
  - 'RFC 2833 TX Payload Type' (RFC2833TxPayloadType) - defines the Tx RFC 2833 DTMF relay dynamic payload type.
  - 'RFC 2833 RX Payload Type' (RFC2833RxPayloadType) - defines the Rx RFC 2833 DTMF relay dynamic payload type.
  - 'RFC 2198 Payload Type' (RFC2198PayloadType) - defines the RTP redundancy packet payload type according to RFC 2198.
3. Click **Apply**.

## Configuring RTP Base UDP Port

You can configure the range (pool) of local UDP ports from which the device allocates ports to media (RTP, RTCP, and T.38) channels (legs). The range limit of UDP ports is from 6,000 through to 65,535.

The consecutive port offset from the RTP port for RTCP and T.38 traffic is one and two, respectively (i.e., RTCP port = RTP port + 1; T.38 port = RTP port + 2). For example, if the voice session uses RTP port 6000, the device allocates port 6001 for RTCP and port 6002 for T.38.

However, you can configure the device to use the same port for RTP and T.38 packets, by configuring the [T38UseRTPPort] parameter to 1.

Within the port range, the device allocates the UDP ports per media channel (leg) in "jumps" (spacing) of 2 (see below note), 4, 5, or 10, which is configured by the [UdpPortSpacing] parameter. For example, if the port range starts at 6000 and the UDP port spacing is 10, the available ports are 6000, 6010, 6020, 6030, and so on. Within the port range, the device assigns these ports **randomly** to the different media channels. For example, it allocates port 6000 to leg 1, port 6030 to leg 2, and port 6010 to leg 3.

For UDP port spacing of 2, you must configure the device to use the same port for RTP and T.38, by configuring the [T38UseRTPPort] ini file parameter to 1. In this case, if for example the UDP port range starts at 6000 and the port spacing is 2, the available ports are 6000 (port 6000 for RTP/T.38 and port 6001 for RTCP), 6002 (port 6002 for RTP/T.38 and port 6003 for RTCP), 6004 (port 6004 for RTP/T.38 and port 6005 for RTCP), and so on.

You can configure the starting port (lower boundary) of the port range (default is 6000), using the 'RTP Base UDP Port' [BaseUDPPort] parameter. Once configured, the port range is according to the following equation:

<'RTP Base UDP Port' parameter value> to 65,535

For example: If you configure the 'RTP Base UDP Port' parameter to 6000, the port range is 6000 to 65,535.

You can also configure specific port ranges for specific SIP user agents (UAs), using Media Realms (see [Configuring Media Realms](#) on page 548). You can configure each Media Realm with a different UDP port range and then assign the Media Realm to a specific IP Group, for example. However, the port range of the Media Realm **must be within the range** configured by the 'RTP Base UDP Port' parameter.

The following procedure describes how to configure the RTP base UDP port through the Web interface.

➤ **To configure the RTP base UDP port:**

1. Open the RTP/RTCP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **RTP/RTCP Settings**).
2. In the 'RTP Base UDP Port' field, configure the lower boundary of the UDP port range.

RTP Base UDP Port

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

- The RTP port must be different from ports configured for SIP signaling traffic (i.e., ports configured for SIP Interfaces). For example, if the RTP port range is 6000 to 6999, the SIP port must either be less than 6000 or greater than 6999.

## Configuring Invalid RTP/RTCP Packet Handling

You can configure the way the device handles incoming invalid RTP and RTCP packets. This is applicable only if you configure the IP Profile parameter 'Mediation Mode' to **RTP Forwarding**.

### ➤ To configure invalid packet handling:

1. Open the RTP/RTCP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **RTP/RTCP Settings**).
2. From the 'Forward Unknown RTP Payload Types' drop-down list, select the required handling for RTP packets with unknown payload types.
3. From the 'Forward Invalid RTP Packets' drop-down list, select the required handling for invalid RTP and RTCP packets.

Forward Unknown RTP Payload Types	•	Handle as Valid Packet	▼
Forward Invalid RTP Packets	•	Forward Packets	▼

4. Click **Apply**.

Invalid packet handling configuration is applicable only to the SBC application.

## Event Detection and Notification using X-Detect Header

The device can detect certain events in the media stream and notify of their detection to a remote application server, using the SIP X-Detect header. The request for event notification is done by the application server when establishing a SIP dialog (i.e., INVITE message) or during an already established call using a re-INVITE message. The device can detect the following event types:

- **Answering Machine Detection (AMD):** Detects events that are related to the AMD feature. AMD detects whether an answering machine or live voice has answered the call. It can also be used to detect silence, or the beep sound played by an answering machine to indicate the end of the greeting message after which a voice message can be left. For more information on AMD, see [Answering Machine Detection \(AMD\)](#) on page 311.
- **Call Progress Tone (CPT):** Detects whether a specific tone, defined in the installed CPT file is received from the call. It can be used to detect the beep sound played by an answering machine (as mentioned above), Special Information Tones (SIT) which indicate call failure

with a recorded announcement describing the call failure (Gateway application only), and the busy, reorder and ring tones.

- **Fax/modem machine (Gateway application only):** Detects whether a fax has answered the call (preamble, CED, CNG, and modem).
- **PTT (Gateway application only):** Detects the start and end of voice.

- Currently, PTT is supported only for Gateway calls.
- Fax and SIT event detection is applicable only to Gateway calls.
- Event detection on SBC calls for CPT is supported only for calls using the G.711 coder.

The X-Detect header is used for event detection as follows:

- X-Detect header in the INVITE message received from the application server requesting a specific event detection:

X-Detect: Request=[event type to detect]

- X-Detect header in the SIP response message -- SIP 183 (for early dialogs) or 200 OK (for confirmed dialogs) -- sent by the device to the application server specifying which of the requested events it can detect (absence of the X-Detect header indicates that the device cannot detect any of the events):

X-Detect: Response=[supported event types]

- Each time the device detects the supported event, it sends an INFO message to the remote party with the following message body:

Content-Type: Application/X-Detect  
Type = [event type]  
Subtype = [subtype of each event type]

The table below lists the event types and subtypes that can be detected by the device. The text shown in the table are the strings used in the X-Detect header. The table also provides a summary of the required configuration.

For SBC calls, event detection is enabled using the IP Profile parameter 'Handle X-Detect' (see [Configuring IP Profiles](#) on page 674).

**Table 15-1: Supported X-Detect Event Types**

Event Type	Subtype	Description and Required Configuration
AMD	■ Voice (live voice)	Event detection using the AMD feature. For more

Event Type	Subtype	Description and Required Configuration

	modem	<p>Set the VxxModemTransportType parameter to 3.</p> <p><b>Note:</b> Applicable only to the Gateway application.</p>

Event Type	Subtype	Description and Required Configuration
PTT	<ul style="list-style-type: none"> <li>■ voice-start</li> <li>■ voice-end</li> </ul>	Set the EnabledDSIPMDetectors parameter to 1.

## SIT Event Detection

The device can detect and report the following Special Information Tones (SIT) types from the PSTN:

- SIT-NC (No Circuit found)
- SIT-IC (Operator Intercept)
- SIT-VC (Vacant Circuit - non-registered number)
- SIT-RO (Reorder - System Busy)

There are additional three SIT tones that are detected as one of the above SIT tones:

- The NC\* SIT tone is detected as NC
- The RO\* SIT tone is detected as RO
- The IO\* SIT tone is detected as VC

The device can map these SIT tones to a Q.850 cause and then map them to SIP 5xx/4xx responses, using the parameters SITQ850Cause, SITQ850CauseForNC, SITQ850CauseForIC, SITQ850CauseForVC, and SITQ850CauseForRO.

This feature is applicable only to the Gateway application.

**Table 15-2: SIT Reported by the Device**

Special Information Tones (SITs) Name	Description	First Tone Frequency Duration		Second Tone Frequency Duration		Third Tone Frequency Duration	
		(Hz)	(ms)	(Hz)	(ms)	(Hz)	(ms)
NC1	No circuit found	985.2	380	1428.5	380	1776.7	380
IC	Operator intercept	913.8	274	1370.6	274	1776.7	380
VC	Vacant	985.2	380	1370.6	274	1776.7	380

Special Information Tones (SITs) Name	Description	First Tone Frequency Duration		Second Tone Frequency Duration		Third Tone Frequency Duration	
	circuit (non registered number)						
RO1	Reorder (system busy)	913.8	274	1428.5	380	1776.7	380
NC*	-	913.8	380	1370.6	380	1776.7	380
RO*	-	985.2	274	1370.6	380	1776.7	380
IO*	-	913.8	380	1428.5	274	1776.7	380

The following example shows a SIP INFO message sent by the device to a remote application server notifying it that SIT detection has been detected:

```
INFO sip:5001@10.33.2.36 SIP/2.0

Content-Type: application/x-detect
Content-Length: 28
Type= CPT
SubType= SIT-IC
```

## Detecting Answering Machine Beeps

The device can detect the "beep" sound played by an answering machine that indicates the end of the answering machine's greeting message. This is useful in that the device can then notify, for example, a third-party, application server that it can now leave a voice message on the answering machine. The device supports the following methods for detecting and reporting beeps:

- **AMD-based Detection:** The device uses its beep detector that is integrated in the AMD feature. You can configure the beep detection timeout and beep detection sensitivity level (for more information, see [Configuring AMD](#) on page 314). To enable the AMD beep detection, the received INVITE message must contain an X-Detect header with the value "Request=AMD",

```
X-Detect: Request=AMD
```

and the [AMDBeepDetectionMode] parameter must be configured to [1] or [2]. If configured to [1], the beep is detected only after the answering machine is detected. If configured to [2], the beep is detected even if the answering machine was not detected.

- **Tone-based Detection (Call Progress Tone):** The device detects the beep according to a call progress tone (CPT). This is enabled if the device receives a specific beep tone (Tone Type #46) that is also defined in the installed CPT file and the received INVITE message contains an X-Detect header with the value "Request=CPT":

```
X-Detect: Request=CPT
```

For more information on the CPT file, see [Call Progress Tones File](#) on page 1351.

The device reports beep detections to application servers, by sending a SIP INFO message that contains a body with one of the following values, depending on the method used for detecting the beep:

- **AMD-detected Beep:**

```
Type= AMD  
SubType= Beep
```

- **CPT-detected Beep:**

```
Type= CPT  
SubType=Beep
```

## SIP Call Flow Examples of Event Detection and Notification

Two SIP call flow examples are provided below of event detection and notification:

- **Example 1:** This example shows a SIP call flow of the device's AMD and event detection feature, whereby the device detects an answering machine and the subsequent start and end of the greeting message, enabling the third-party application server to know when to play a recorded voice message to an answering machine:
  - a. Upon detection of the answering machine, the device sends the following SIP INFO message to the application server:

```
INFO sip:sipp@172.22.2.9:5060 SIP/2.0
Via: SIP/2.0/UDP 172.22.168.249;branch=z9hG4bKac1566945480

Subtype = Beep
```

## Answering Machine Detection (AMD)

The device's Answering Machine Detection (AMD) feature can detect if an outbound call has been answered by a human (including fax) or an answering machine. It analyzes the sound patterns (speech) received during the initial seconds of the call to determine what answered the call. Typically, when a human answers, there is a brief "hello" followed by silence, waiting for the other party's response. In contrast, when an answering machine answers the call, there is constant speech (i.e., answering message) followed by a beep, indicating the start of voicemail recording.

AMD is useful, for example, for outbound calling centers that implement automatic dialing applications. When the calling center establishes a call with a specific target and an answering machine is detected, the call is automatically connected to a recorded message. Once the device detects what answered the call (human or machine), it can notify a third-party application server used for automatic dialing applications. The X-Detect SIP header is used for requesting event (live voice, answering machine, silence, or beep at the end of answering machine message) detection and notification. For more information, see [Event Detection and Notification using X-Detect Header](#) on page 303. For more information on detection of beeps at the end of an answering machine's greeting message, see [Detecting Answering Machine Beeps](#) on page 307.

For the Gateway application, you can also configure the device to disconnect IP-to-Tel calls upon detection of an answering machine on the Tel side. For more information, see [Enabling IP-to-Tel Call Disconnection upon Detection of Answering Machine](#) on page 317.

### Default AMD

By default, the device's AMD feature is based on voice detection for North American English (see note below). It uses sophisticated speech detection algorithms that are derived from hundreds of real-life recordings of answered calls by live voices and answering machines in

English. The algorithms detect whether it's human or machine, based on voice and silence duration, as well as speech patterns. The algorithms of the language-based recordings are compiled into an *AMD Sensitivity* file, which is pre-installed on the device.

Because the main factor (algorithm) for determining if it's human or machine is the voice pattern and silence duration, the language on which the detection algorithm is based is in most cases not important as these factors are similar across most languages. Therefore, the default, pre-installed AMD Sensitivity file, which is based on North American English should suffice for your deployment even if the device is located in a region where a language other than English is used.

However (despite note above), if you need to implement AMD in a different language or region, or if you wish to fine-tune the default AMD algorithms to suit your specific deployment, contact your AudioCodes sales representative for more information on this service. You may be required to provide AudioCodes with a database of recorded voices (calls) in the language on which the device's AMD feature can base its voice detector algorithms. The data needed for an accurate calibration should be recorded under the following guidelines:

- **Statistical accuracy:** The number of recorded calls should be as high as possible (at least 100) and varied. The calls must be made to different people. The calls must be made in the specific location in which the device's AMD feature is to operate.
- **Real-life recording:** The recordings should simulate real-life answering of a called person picking up the phone, and without the caller speaking.
- **Normal environment interferences:** The environment in which the recordings are done should simulate real-life scenarios, in other words, not sterile but not too noisy either. Interferences could include, for example, background noises of other people talking, spikes, and car noises.

Once you provide AudioCodes with your database of recordings, AudioCodes compiles it into a loadable file, which can be installed on the device. For a brief description on file format and installation, see [Uploading an AMD Sensitivity File](#) on page 1360.

The AMD Sensitivity file always includes the default Parameter Suites 0 and 1, even if customized Parameter Suites (2 to 7) are created.

The device can support up to eight AMD algorithm suites, referred to as *Parameter Suites*. Each Parameter Suite provides a range of detection sensitivity levels for detecting whether a call is answered by a human or a machine. Sensitivity levels determine how precisely (accurately) the device distinguishes between a live voice and an answering machine. A lower sensitivity level favors detection of answering machines while a higher level favors detection of live voice. In deployments where the likelihood of a call being answered by an answering machine is low, it would be advisable to configure a high sensitivity level (which is more sensitive to human than machine). This also allows you to tweak sensitivity to comply with local regulations, such as rules designed to protect consumers when answering automated calls (for example, consumer answers and hears silence).

Parameter Suite 0 supports 8 sensitivity levels (0 to 7), while all the other Parameter Suites (1 through 7) support 16 sensitivity levels (0 to 15).

The default, pre-installed AMD Sensitivity file (based on North American English) includes two Parameter Suites:

- **Parameter Suite 0 (normal sensitivity):** 8 sensitivity levels

- **Parameter Suite 1 (high sensitivity):** 16 sensitivity levels

Because Parameter Suite 1 provides a greater range of detection sensitivity levels (i.e., higher detection resolution), it may be more suitable for your deployment, providing greater flexibility in tuning the sensitivity.

The following tables show the success rates of the default, pre-installed AMD Sensitivity file (based on North American English) for accurately detecting "live" human voices and answering machines. The detected AMD type (human or machine) and the success of correctly detecting the type are sent in CDRs and syslog messages. For more information, see [Syslog Fields for Answering Machine Detection \(AMD\)](#) on page 1621.

**Table 15-3: Approximate AMD Normal Detection Sensitivity - Parameter Suite 0 (Based on North American English)**

AMD Detection Sensitivity	Performance	
	Success Rate for Live Calls	Success Rate for Answering Machine
<b>0</b> (Best for Answering Machine)	-	-
<b>1</b>	82.56%	97.10%
<b>2</b>	85.87%	96.43%
<b>3</b>	88.57%	94.76%
<b>4</b>	88.94%	94.31%
<b>5</b>	90.42%	91.64%
<b>6</b>	90.66%	91.30%
<b>7</b> (Best for Live Calls)	94.72%	76.14%

**Table 15-4: Approximate AMD High Detection Sensitivity - Parameter Suite 1 (Based on North American English)**

AMD Detection Sensitivity	Performance	
	Success Rate for Live Calls	Success Rate for Answering Machine
<b>0</b> (Best for Answering Machine)	72%	97%
<b>1</b>	77%	96%
<b>2</b>	79%	95%
<b>3</b>	80%	95%
<b>4</b>	84%	94%
<b>5</b>	86%	93%
<b>6</b>	87%	92%
<b>7</b>	88%	91%
<b>8</b>	90%	89%
<b>9</b>	90%	88%
<b>10</b>	91%	87%
<b>11</b>	94%	78%
<b>12</b>	94%	73%
<b>13</b>	95%	65%
<b>14</b>	96%	62%
<b>15</b> (Best for Live Calls)	97%	46%

## Configuring AMD

You can configure AMD for all calls using global AMD parameters, or for specific calls using IP Profiles. The procedure below describes how to configure AMD for all calls. To configure AMD for specific calls, use the AMD parameters in the IP Profiles table (see [Configuring IP Profiles](#) on page 674)

For the Gateway application, you can configure AMD per call based on the called number or Trunk Group. This is done by configuring AMD for a specific IP Profile and then assigning the IP Profile to a Trunk Group in the IP-to-Tel Routing table (see [Configuring IP-to-Tel Routing Rules](#) on page 960).

➤ **To configure AMD for all calls:**

1. Open the DSP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **DSP Settings**).
2. Select the 'IPMedia Detectors' check box [EnabledDSPIPMDetectors]:

IPMedia Detectors

3. Scroll down to the Answer Machine Detector group:

ANSWER MACHINE DETECTOR

Answer Machine Detector Sensitivity Parameter Suite	0
Answer Machine Detector Sensitivity	3
Answer Machine Detector Sensitivity Level	8
Answer Machine Detector Beep Detection Timeout	200
Answer Machine Detector Beep Detection Sensitivity	0

It's **highly recommended** to use the device's default AMD settings, which is suitable for most deployments.

4. Configure the detection sensitivity tradeoff between live voice over answering machine:
  - a. From the 'Answer Machine Detector Sensitivity Parameter Suite' drop-down list (AMDSensitivityParameterSuit), select the required Parameter Suite in the installed AMD Sensitivity file.

Each Parameter Suite contains a table with sensitivity levels. Some Parameter Suites are more sensitive to live voice while others are more sensitive to answering machines. The available Parameter Suites depends on the installed AMD Sensitivity file. The default, pre-installed AMD Sensitivity file, which is based on North American English, includes two Parameter Suites:

- ◆ **Parameter Suite #0:** Provides normal sensitivity and has 8 sensitivity levels (0-8). (See note below.)
- ◆ **Parameter Suite #1:** Provides high sensitivity and has 16 sensitivity levels (0-15).

If you configure the [AMDDetectionSensitivity] parameter to 3 (default), the device ignores Parameter Suite #0 sensitivity table. In this case, the [AMDSensitivityLevel] parameter is not relevant and sensitivity is hard-coded and similar to sensitivity level 3 of Parameter Suite #0.

If you configure the [AMDDetectionSensitivity] parameter to any value other than 3, use the [AMDSensitivityLevel] parameter to specify the sensitivity level of Parameter Suite #0.

- b. In the 'Answer Machine Detector Sensitivity' field (AMDDetectionSensitivity), configure the sensitivity level (0 to 7; default 3) of the device's core voice answer detector (VAD) that is used by the AMD algorithm to distinguish between voice and silence.

A lower value increases sensitivity, allowing detection of low-level speech parts, but may also lead to more false detections due to background noise. Conversely, a higher value decreases sensitivity and reduces the likelihood of false detections caused by background noise but may cause quieter speech parts to go undetected. It's recommended to keep the parameter at its default (unless your deployment requires a specific adjustment).

- c. In the 'Answer Machine Detector Sensitivity Level' field (AMDSensitivityLevel), configure the sensitivity level of the selected Parameter Suite (see 'Answer Machine Detector Sensitivity Parameter Suite' above) for detecting live voice over answering machine (tradeoff between them). A lower sensitivity level favors detection of answering machines while a higher level favors detection of live voice. For sensitivity levels and their tradeoff between live voice and answering machine detection, see the tables in [Answering Machine Detection \(AMD\)](#) on page 311.

The 'Answer Machine Detector Sensitivity Level' field (AMDSensitivityLevel) is not relevant for Parameter Suite #0.

5. Configure the answering machine beep detection:
  - a. In the 'Answer Machine Detector Beep Detection Timeout' field [AMDBeepDetectionTimeout], configure the maximum duration that the device takes to detect a beep played at the end of an answering machine message.
  - b. In the 'Answer Machine Detector Beep Detection Sensitivity' field [AMDBeepDetectionSensitivity], configure the AMD beep detection sensitivity level for detecting beeps at the end of an answering machine message. The higher the value, the more sensitive.

6. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

For a complete list of AMD-related parameters, see [IP Media Parameters](#) on page 2126.

## Enabling IP-to-Tel Call Disconnection upon Detection of Answering Machine

The device can disconnect an IP-to-Tel (ISDN) call upon detection of an answering machine on the Tel side. Once detected, the device disconnects the call after the receipt of an ISDN Connect from the Tel side and then sends a SIP BYE message to the IP side to disconnect the call. You can enable this feature for all calls (globally) using the [AMDmode] parameter (see procedure below) or for specific calls using IP Profiles where the IP Profile parameter 'AMD Mode' is configured to **Disconnect on AMD** (see [Configuring IP Profiles](#) on page 674).

This feature can also be used for SBC calls (e.g., when the device interfaces with VoiceAI Connect ).

### ➤ To enable disconnection of IP-to-Tel call upon detection of answering machine:

1. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**).
2. From the 'AMD Mode' drop-down list, select **Disconnect on AMD**:

AMD Mode

Disconnect on AMD ▼

3. Click **Apply**.

## Configuring the Answer Detector Feature

The device's Answer Detect (AD) feature detects voice activity in a call. The AD feature detects the following events:

- Speech - speech is detected.
- End of speech - silence (no speech) for the configured duration (see below) is detected.

### ➤ To configure AD:

1. Open the DSP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **DSP Settings**).
2. Scroll down to the Answer Detector group:

ANSWER DETECTOR	
Enable Answer Detector	<input checked="" type="checkbox"/>
Answer Detector Activity Delay	<input type="text" value="2"/>
Answer Detector Silence Time	<input type="text" value="10"/>
Answer Detector Redirection	<input type="text" value="No"/>
Answer Detector Sensitivity	<input type="text" value="0"/>

3. Select the 'Enable Answer Detector' check box to enable the feature.
4. In the 'Answer Detector Activity Delay' field, enter the time (in 100-msec resolution) between when the device activates the Answer Detector feature and when it actually starts to detect. This delay may increase the device's immunity to noises and non-speech signals at the beginning of a conversation.
5. In the 'Answer Detector Silence Time' field, enter the silence duration from when no speech input is detected until the device reports an End Of Speech event.
6. From the 'Answer Detector Redirection' drop-down list, select if the Answer Detector is applied to the IP network side (**Yes**) instead of the PSTN side (**No**).
7. In the 'Answer Detector Sensitivity' field, enter the Answer Detector's sensitivity, where 0 is the highest and 7 the lowest.
8. Click **Apply**.

## Automatic Gain Control (AGC)

Automatic Gain Control (AGC) adjusts the energy of the output signal to a required level (volume). This feature compensates for near-far gain differences. AGC estimates the energy of the incoming signal from the IP or Tel side, determined by the 'AGC Redirection' parameter, calculates the essential gain, and then performs amplification. Feedback ensures that the output signal is not clipped. You can configure the required Gain Slope in decibels per second using the 'AGC Slope' parameter and the required signal energy threshold using the 'AGC Target Energy' parameter.

When the AGC first detects an incoming signal, it begins operating in Fast Mode, which allows the AGC to adapt quickly when a conversation starts. This means that the Gain Slope is 8 dB/sec for the first 1.5 seconds. After this period, the Gain Slope is changed to the user-defined value. You can disable or enable the AGC's Fast Mode feature, using the 'AGC Disable Fast Adaptation' parameter. After Fast Mode is used, the signal should be off for two minutes in order to have the feature turned on again.

### ➤ To configure AGC:

1. Open the DSP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **DSP Settings**).

2. Select the 'IPMedia Detectors' check box [EnabledDSIPMDetectors]:

IPMedia Detectors ☒ ⚡

3. Under the AGC group, configure the following AGC parameters:
  - 'Enable AGC' [EnableAGC] - enables the AGC mechanism.
  - 'AGC Slope' [AGCGainSlope] - defines the AGC convergence rate.
  - 'AGC Redirection' [AGCRedirection] - defines the AGC direction.
  - 'AGC Target Energy' - defines the signal energy value (dBm) that the AGC attempts to attain.
  - 'AGC Minimum Gain' [AGCMinGain] - defines the minimum gain (in dB) by the AGC when activated.
  - 'AGC Maximum Gain' [AGCMaxGain] - defines the maximum gain (in dB) by the AGC when activated.
  - 'AGC Disable Fast Adaptation' [AGCDisableFastAdaptation] - enables the AGC Fast Adaptation mode.

AGC	
Enable AGC	<input checked="" type="checkbox"/> ⚡
AGC Slope	<input type="text" value="3"/>
AGC Redirection	<input type="text" value="0"/> ▼
AGC Target Energy	<input type="text" value="19"/>
AGC Minimum Gain	<input type="text" value="20"/> ⚡
AGC Maximum Gain	<input type="text" value="15"/> ⚡
AGC Disable Fast Adaptation	<input type="checkbox"/> ⚡

4. Configure the 'Transcoding Mode' [TranscodingMode] parameter to **Force** when using AGC for SBC calls. You can configure this using the global parameter or per IP Profile.
5. Click **Apply**, and then restart the device with a burn-to-flash for your settings to take effect.

## Media Security

This section describes configuration for securing the media.

## Configuring SRTP

The device supports Secured RTP (SRTP) according to RFC 3711. SRTP is used to encrypt RTP and RTCP transport for protecting VoIP traffic. SRTP requires a cryptographic key exchange mechanism to negotiate the keys. To negotiate the keys, the device supports the Session Description Protocol Security Descriptions (SDES) protocol (according to RFC 4568), or Datagram Transport Layer Security (DTLS) protocol for SBC calls. For more information on DTLS, see [SRTP using DTLS Protocol](#) on page 324.

Key exchange is done by adding the 'a=crypto' attribute to the SDP. This attribute is used (by both sides) to declare the various supported cipher suites and to attach the encryption key. If negotiation of the encryption data is successful, the call is established. Typically, 'a=crypto' is included in secured media (RTP/SAVP). However, there is also support for including 'a=crypto' in non-secured media (RTP/AVP). In such cases, the media is handled as if the device received two identical media: one secured and one not.

SRTP supports the following cipher suites (all other suites are ignored):

- AES\_CM\_128\_HMAC\_SHA1\_32
- AES\_CM\_128\_HMAC\_SHA1\_80
- ARIA\_CM\_128\_HMAC\_SHA1\_80
- ARIA\_CM\_192\_HMAC\_SHA1\_80
- AES\_256\_CM\_HMAC\_SHA1\_32 (RFC 6188)
- AES\_256\_CM\_HMAC\_SHA1\_80 (RFC 6188)

When the device is the offering side (SDP offer), it can generate a Master Key Identifier (MKI). You can configure the MKI size globally, using the [SRTPTxPacketMKISize] parameter, or per SIP entity, using the IP Profile parameter 'MKI Size'. The length of the MKI is limited to four bytes. If the remote side sends a longer MKI, the key is ignored.

- Gateway application: The device only initiates the MKI size.
- SBC application: The device can forward MKI size transparently for SRTP-to-SRTP media flows or override the MKI size during negotiation (inbound or outbound leg).

The key lifetime field is not supported. However, if it is included in the key it is ignored and the call doesn't fail. For SBC calls belonging to a specific SIP entity, you can configure the device to remove the lifetime field in the 'a=crypto' attribute, using the IP Profile parameter 'SBC Remove Crypto Lifetime in SDP'.

For SDDES, the keys are sent in the SDP body ('a=crypto') of the SIP message and are typically secured using SIP over TLS (SIPS). The encryption of the keys is in plain text in the SDP. The device supports the following session parameters:

- UNENCRYPTED\_SRTP
- UNENCRYPTED\_SRTCP

## ■ UNAUTHENTICATED\_SRTP

Session parameters should be the same for the local and remote sides. When the device is the offering side, the session parameters are configured by the following parameters - 'Authentication on Transmitted RTP Packets', 'Encryption on Transmitted RTP Packets, and 'Encryption on Transmitted RTCP Packets'. When the device is the answering side, the device adjusts these parameters according to the remote offering. Unsupported session parameters are ignored, and do not cause a call failure.

Below is an example of crypto attributes usage:

```
a=crypto:1 AES_CM_128_HMAC_SHA1_80
inline:PsKoMpHICg+b5X0YLuSvNrImEh/dAe
a=crypto:2 AES_CM_128_HMAC_SHA1_32
inline:lsPtLoGkBf9a+c6XVzRuMqHIDnEiAd
```

The device also supports symmetric MKI negotiation, whereby it can forward the MKI size received in the SDP offer 'a=crypto' line in the SDP answer. You can enable symmetric MKI globally, using the global parameter [EnableSymmetricMKI], or per SIP entity, using the IP Profile parameter 'Symmetric MKI' and for SBC calls 'SBC Enforce MKI Size'. For more information on symmetric MKI, see [Configuring IP Profiles](#) on page 674.

You can configure the enforcement policy of SRTP, by the [EnableMediaSecurity] parameter and IP Profile parameter 'SBC Media Security Mode' parameter for SBC calls. For example, if negotiation of the cipher suite fails or if incoming calls exclude encryption information, the device can be configured to reject the calls.

You can also enable the device to validate the authentication of packets for SRTP tunneling for RTP and RTCP. This applies only to SRTP-to-SRTP SBC calls and where the endpoints use the same key. This is enabled using the 'SRTP Tunneling Authentication for RTP' and 'SRTP Tunneling Authentication for RTCP' parameters.

- For a detailed description of the SRTP parameters, see [Configuring IP Profiles](#) on page 674 and [SRTP Parameters](#) on page 1804.
- When SRTP is used, channel capacity may be reduced.
- To configure specific SRTP cipher suites for an IP Profile, see [Configuring SRTP Crypto Suite Groups](#) on the next page.

The procedure below describes how to configure SRTP through the Web interface.

### ➤ To enable SRTP globally (for all calls):

1. Open the Media Security page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Media Security**).

GENERAL		AUTHENTICATION & ENCRYPTION	
Media Security	<input checked="" type="checkbox"/>	Authentication on Transmitted RTP Packets	Active
Media Security Behavior	Preferable	Encryption on Transmitted RTP Packets	Active
Offered SRTP Cipher Suites	All	Encryption on Transmitted RTCP Packets	Active
		SRTP Tunneling Authentication for RTP	<input type="checkbox"/>
		SRTP Tunneling Authentication for RTCP	<input type="checkbox"/>
MASTER KEY IDENTIFIER		GATEWAY SETTINGS	
Master Key Identifier (MKI) Size	0	Enable Rekey After 181	<input type="checkbox"/>
Symmetric MKI	<input type="checkbox"/>		

GENERAL		AUTHENTICATION & ENCRYPTION	
Media Security	<input checked="" type="checkbox"/>	Authentication on Transmitted RTP Packets	Active
Media Security Behavior	Preferable	Encryption on Transmitted RTP Packets	Active
Offered SRTP Cipher Suites	All	Encryption on Transmitted RTCP Packets	Active
ARIA Protocol Support	<input type="checkbox"/>	SRTP Tunneling Authentication for RTP	<input type="checkbox"/>
		SRTP Tunneling Authentication for RTCP	<input type="checkbox"/>
MASTER KEY IDENTIFIER		GATEWAY SETTINGS	
Master Key Identifier (MKI) Size	0	Enable Rekey After 181	<input type="checkbox"/>
Symmetric MKI	<input type="checkbox"/>		

2. Select the 'Media Security' check box [EnableMediaSecurity] to enable SRTP.
3. From the 'Offered SRTP Cipher Suites' drop-down list [SRTPofferedSuites], select the supported cipher suite.
4. Configure the other SRTP parameters as required.
5. Click **Apply**.

## Configuring SRTP Crypto Suite Groups

The SBC Crypto Suite Groups table lets you configure groups of SRTP crypto suites, which you can then assign to IP Profiles. Therefore, instead of configuring a single crypto suite for all calls using the global parameter 'Offered SRTP Cipher Suites' (as described in [Configuring SRTP](#) on page 320), you can use the SBC Crypto Suite Groups table to configure specific crypto suites for specific calls (IP Profiles). To assign an SBC Crypto Suite Group to an IP Profile, use the IP Profile's 'Crypto Suites Group' parameter (see [Configuring IP Profiles](#) on page 674).

You configure an SBC Crypto Suite Group using two tables with "parent-child" relationship:

- **SBC Crypto Suite Groups table ("parent"):** Defines the name of the SBC Crypto Suite Group. You can configure up to 10 SBC Crypto Suite Groups.
- **Crypto Suites table ("child"):** Defines the crypto suites for the SBC Crypto Suite Group. You can configure each SBC Crypto Suite Group with up to 4 crypto suites.

This feature is applicable only to the SBC application.

The following procedure describes how to configure SBC Crypto Suite Groups through the Web interface. You can also configure it through other management platforms:

- **SBC Crypto Suite Groups table:** *ini* file [CryptoSuitesGroups] or CLI (`configure voip > media crypto-suites-groups`)
- **Crypto Suites table:** *ini* file [CryptoSuites] or CLI (`configure voip > media crypto-suites-groups > crypto-suites`)

➤ **To configure an SBC Crypto Suite Group:**

1. Open the SBC Crypto Suite Groups table (**Setup** menu > **Signaling & Media** tab > **Media** folder > **SBC Crypto Suite Groups**).
2. Click **New**; the following dialog box appears:

*SBC Crypto Suite Groups* - x

---

GENERAL

Index

Name

3. Configure a name for the SBC Crypto Suite Group according to the parameters described in the table below.
4. Click **Apply**.

**Table 15-5: SBC Crypto Suite Groups Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' crypto-suites-group-name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> The parameter value must be unique.

5. In the SBC Crypto Suite Groups table, select the row for which you want to configure crypto suites, and then click the **Crypto Suites** link located below the table; the Crypto Suites table appears.
6. Click **New**; the following dialog box appears:

*Crypto Suites* - x

---

GENERAL

Index

Supported Crypto Suite

7. Configure a rule according to the parameters described in the table below.

8. Click **New**, and then save your settings to flash memory.

**Table 15-6: Crypto Suites Table Parameter Descriptions**

Parameter	Description
General	
'Index' crypto-suites <index/index> [CryptoSuiteIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Supported Crypto Suite' crypto-suite [CryptoSuite]	Defines the SRTP crypto suite.  <ul style="list-style-type: none"> <li>■ [63] All</li> <li>■ [1] AES-CM-128-HMAC-SHA1-80</li> <li>■ [2] AES-CM-128-HMAC-SHA1-32</li> <li>■ [16] AES-256-CM-HMAC-SHA1-80</li> <li>■ [32] AES-256-CM-HMAC-SHA1-32</li> </ul> <b>Note:</b> You can configure up to four crypto suites in the Crypto Suites table (i.e., per SBC Crypto Suite Groups). Therefore, if you configure the parameter to <b>All</b> (which means all four crypto suites), no additional table rows can be added to the table.

## SRTP using DTLS Protocol

For SBC calls, you can configure the device to use the Datagram Transport Layer Security (DTLS) protocol to secure UDP-based traffic (according to RFC 4347 and 6347) for specific SIP entities, using IP Profiles. DTLS allows datagram-based applications to communicate in a way that is designed to prevent eavesdropping, tampering or message forgery. The DTLS protocol is based on the stream-oriented TLS protocol, providing similar security. The device can therefore interwork in mixed environments where one network may require DTLS and the other may require Session Description Protocol Security Descriptions (SDS) or even non-secure RTP. The device supports DTLS negotiation for RTP-to-SRTP and SRTP-to-SRTP calls.

DTLS support is important for deployments with WebRTC. WebRTC requires that media channels be encrypted through DTLS for SRTP key exchange. Negotiation of SRTP keys through DTLS is done during the DTLS handshake between WebRTC client and peer. For more information on WebRTC, see [WebRTC](#) on page 1269.

In contrast to SDS, DTLS key encryption is done over the media channel (UDP) and not over the signaling channel. Thus, DTLS-SRTP is generally known as "secured key exchange over media". DTLS is similar to TLS, but runs over UDP, whereas TLS is over TCP. Before the DTLS handshake, the peers exchange DTLS parameters (fingerprint and setup) and algorithm types in the SDP

body of the SIP messages exchanged for establishing the call (INVITE request and response). The peers participate in a DTLS handshake during which they exchange certificates. These certificates are used to derive a symmetric key, which is used to encrypt data (SRTP) flow between the peers. A hash value calculated over the certificate is transported in the SDP using the 'a=fingerprint' attribute. At the end of the handshake, each side verifies that the certificate it received from the other side fits the fingerprint from the SDP. To indicate DTLS support, the SDP offer/answer of the SIP message uses the 'a=setup' attribute. The 'a=setup:actpass' attribute value is used in the SDP offer by the device. This indicates that the device is willing to be either a client ('act') or a server ('pass') in the handshake. The 'a=setup:active' attribute value is used in the SDP answer by the device. This means that the device wishes to be the client ('active') in the handshake.

```
a=setup:actpass
a=fingerprint: SHA-1
\4A:AD:B9:B1:3F:82:18:3B:54:02:12:DF:3E:5D:49:6B:19:E5:7C:AB
```

DTLS cipher suite reuses the TLS cipher suite. The DTLS handshake is done for every new call configured for DTLS. In other words, unlike TLS where the connection remains "open" for future calls, a new DTLS connection is required for every new call. Note that the entire authentication and key exchange for securing the media traffic is handled in the media path through DTLS. The signaling path is used only to verify the peers' certificate fingerprints. DTLS messages are multiplexed onto the same ports that are used for the media.

➤ **To configure DTLS:**

1. In the TLS Context table (see [Configuring TLS Certificate Contexts](#) on page 227), configure a TLS Context with the desired DTLS version using the 'DTLS Version' parameter.
2. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then for the IP Group associated with the SIP entity, assign it the TLS Context for DTLS, using the 'Media TLS Context' parameter.
3. Open the IP Profiles table (see [Configuring IP Profiles](#) on page 674), and then for the IP Profile associated with the SIP entity, configure the following:
  - Configure the 'SBC Media Security Mode' parameter to **Secured** or **Both**.
  - Configure the 'Media Security Method' parameter to **DTLS**.
  - Configure the 'RTCP Mux' parameter to **Supported**. Multiplexing is required as the DTLS handshake is done for the port used for RTP and thus, RTCP and RTP must be multiplexed onto the same port.
  - Configure the ini file parameter [SbcDtlsMtu] (or CLI command `configure voip > sbc settings > sbc-dtls-mtu`) to define the maximum transmission unit (MTU) size for the DTLS handshake.

4. Configure the minimum interval that the device waits between transmission of DTLS packets in the same DTLS handshake, using the ini file parameter [DTLSTimeBetweenTransmissions].

- The 'Cipher Server' parameter must be configured to "ALL".
- The device doesn't support forwarding of DTLS transparently between endpoints.

## 16 Services

This section describes configuration for various supported services.

### DHCP Server Functionality

The device can serve as a Dynamic Host Configuration Protocol (DHCP) server that assigns and manages IP addresses from a user-defined address pool for DHCP clients. The DHCP server can also be configured to supply additional information to the requesting client such as the IP address of the TFTP server, DNS server, NTP server, and default router (gateway). The DHCP server functionality complies with IETF RFC 2131 and RFC 2132.

The DHCP server can service up to 800 DHCP clients. The DHCP clients are typically IP phones that are connected to the device's LAN port.

The DHCP server is activated when you configure a valid entry in the DHCP Servers table (see [Configuring the DHCP Server](#) below) and associate it with an active IP network interface listed in the IP Interfaces table. When an IP phone on the LAN requests an IP address, the DHCP server allocates one from the address pool. In scenarios of duplicated IP addresses on the LAN (i.e., an unauthorized network device using one of the IP addresses of the DHCP address pool), the DHCP server detects this condition using an Address Resolution Protocol (ARP) request and temporarily blacklists the duplicated address.

You can also configure the DHCP server to respond **only** to DHCPDiscover requests from DHCP clients that contain a specific value for Option 60 (Vendor Class Identification). For more information, see [Configuring the Vendor Class Identifier](#) on page 333.

### Configuring the DHCP Server

The DHCP Servers table lets you configure the device's DHCP server (only one). The DHCP Server table configures the DHCP server implementation. This includes configuring the DHCP IP address pool from where IP addresses are allocated to requesting DHCP clients, as well as configuring other information such as IP addresses of the DNS server, NTP server, default router (gateway), and SIP proxy server. The DHCP server sends the information in DHCP Options. The table below lists the DHCP Options that the DHCP server sends to the DHCP client and which are configurable in the DHCP Servers table.

**Table 16-1: Configurable DHCP Options in DHCP Servers Table**

DHCP Option Code	DHCP Option Name
Option 53	DHCP Message Type
Option 54	DHCP Server Identifier
Option 51	IP Address Lease Time

DHCP Option Code	DHCP Option Name
Option 1	Subnet Mask
Option 3	Router
Option 6	Domain Name Server
Option 44	NetBIOS Name Server
Option 46	NetBIOS Node Type
Option 42	Network Time Protocol Server
Option 2	Time Offset
Option 66	TFTP Server Name
Option 67	Boot file Name
Option 120	SIP Server

Once you have configured the DHCP server, you can configure the following:

- DHCP Vendor Class Identifier names (DHCP Option 60) - see [Configuring the Vendor Class Identifier](#) on page 333
- Additional DHCP Options - see [Configuring Additional DHCP Options](#) on page 334
- Static IP addresses for DHCP clients - see [Configuring Static IP Addresses for DHCP Clients](#) on page 337

If you configure additional DHCP Options in the DHCP Option table, they override the default ones, which are configured in the DHCP Servers table. For example, if you configure Option 67 in the DHCP Option table, the device uses the value configured in the DHCP Option table instead of the value configured in the DHCP Servers table.

To view and delete currently serviced DHCP clients, see [Viewing and Deleting DHCP Clients](#) on page 338.

The following procedure describes how to configure the DHCP server through the Web interface. You can also configure it through ini file [DhcpServer] or CLI (`configure network > dhcp-server server <index>`).

➤ **To configure the device's DHCP server:**

1. Open the DHCP Servers page (**Setup** menu > **IP Network** tab > **Advanced** folder > **DHCP Servers**).
2. Click **New**; the following dialog box appears:

**DHCP Servers**

**GENERAL**

Index: 0

Interface Name: -- [View](#)

Start IP Address: 192.168.0.100

End IP Address: 192.168.0.149

Subnet Mask: 255.255.255.0

Lease Time: 1440

**TIME AND DATE**

NTP Server 1: 0.0.0.0

NTP Server 2: 0.0.0.0

Time Offset: 0

**BOOT FILE**

TFTP Server Name:

Boot File Name:

Expand Boot-File Name: Yes

**ROUTER**

Override Router: 0.0.0.0

3. Configure a DHCP server according to the parameters described in the table below.

4. Click **Apply**.

**Table 16-2: DHCP Servers Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' dhcp server <index>	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Each row must be configured with a unique index.</li> <li>Currently, only one index row can be configured.</li> </ul>
'Interface Name' network-if [DhcpServer_ InterfaceName]	<p>Associates an IP network interface on which the DHCP server operates. The IP interfaces are configured in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159). By default, no value is defined.</p>
'Start IP Address' start-address [DhcpServer_ StartIPAddress]	<p>Defines the starting IP address (IPv4 address in dotted-decimal format) of the IP address pool range used by the DHCP server to allocate addresses.</p> <p>The default value is 192.168.0.100.</p> <p><b>Note:</b> The IP address must belong to the same subnet as the associated interface's IP address.</p>

Parameter	Description
'End IP Address' end-address [DhcpServer_ EndIPAddress]	<p>Defines the ending IP address (IPv4 address in dotted-decimal format) of the IP address pool range used by the DHCP server to allocate addresses.</p> <p>The default value is 192.168.0.149.</p> <p><b>Note:</b> The IP address must belong to the same subnet as the associated interface's IP address and must be "greater or equal" to the starting IP address defined in 'Start IP Address'.</p>
'Subnet Mask' subnet-mask [DhcpServer_ SubnetMask]	<p>Defines the subnet mask (for IPv4 addresses) for the DHCP client. The value is sent in DHCP Option 1 (Subnet Mask).</p> <p>The default value is 0.0.0.0.</p> <p><b>Note:</b> The value must be "narrower" or equal to the subnet mask of the associated interface's IP address. If set to "0.0.0.0", the subnet mask of the associated interface is used.</p>
'Lease Time' lease-time [DhcpServer_ LeaseTime]	<p>Defines the duration (in minutes) of the lease time to a DHCP client for using an assigned IP address. The client needs to request a new address before this time expires. The value is sent in DHCP Option 51 (IP Address Lease Time).</p> <p>The valid value range is 0 to 214,7483,647. The default is 1440. When set to 0, the lease time is infinite.</p>
DNS	
'DNS Server 1' dns-server-1 [DhcpServer_ DNSServer1]	<p>Defines the IP address (IPv4) of the primary DNS server that the DHCP server assigns to the DHCP client. The value is sent in DHCP Option 6 (Domain Name Server).</p> <p>The default value is 0.0.0.0.</p>
'DNS Server 2' dns-server-2 [DhcpServer_ DNSServer2]	<p>Defines the IP address (IPv4) of the secondary DNS server that the DHCP server assigns to the DHCP client. The value is sent in DHCP Option 6 (Domain Name Server).</p> <p>The default value is 0.0.0.0.</p>
NetBIOS	
'NetBIOS Name Server' netbios-server [DhcpServer_ NetbiosNameServer]	<p>Defines the IP address (IPv4) of the NetBIOS WINS server that is available to a Microsoft DHCP client. The value is sent in DHCP Option 44 (NetBIOS Name Server).</p> <p>The default value is 0.0.0.0.</p>
'NetBIOS Node Type' netbios-node-	<p>Defines the node type of the NetBIOS WINS server for a Microsoft DHCP client. The value is sent in DHCP Option 46</p>

Parameter	Description
<code>type</code> <code>[DhcpServer_</code> <code>NetbiosNodeType]</code>	(NetBIOS Node Type). <ul style="list-style-type: none"> <li>■ [0] <b>Broadcast</b> (default)</li> <li>■ [1] <b>peer-to-peer</b></li> <li>■ [4] <b>Mixed</b></li> <li>■ [8] <b>Hybrid</b></li> </ul>
Time and Date	
'NTP Server 1' <code>ntp-server-1</code> <code>[DhcpServer_</code> <code>NTPServer1]</code>	Defines the IP address (IPv4) of the primary NTP server that the DHCP server assigns to the DHCP client. The value is sent in DHCP Option 42 (Network Time Protocol Server). The default value is 0.0.0.0.
'NTP Server 2' <code>ntp-server-2</code> <code>[DhcpServer_</code> <code>NTPServer2]</code>	Defines the IP address (IPv4) of the secondary NTP server that the DHCP server assigns to the DHCP client. The value is sent in DHCP Option 42 (Network Time Protocol Server). The default value is 0.0.0.0.
'Time Offset' <code>time-offset</code> <code>[DhcpServer_</code> <code>TimeOffset]</code>	Defines the Greenwich Mean Time (GMT) offset (in seconds) that the DHCP server assigns to the DHCP client. The value is sent in DHCP Option 2 (Time Offset). The valid range is -43200 to 43200. The default is 0.
Boot File	
'TFTP Server Name' <code>tftp-server-name</code>  <code>[DhcpServer_</code> <code>TftpServer]</code>	Defines the IP address or name of the TFTP server that the DHCP server assigns to the DHCP client. The TFTP server typically stores the boot file image, defined in the 'Boot file name' parameter (see below). The value is sent in DHCP Option 66 (TFTP Server Name). The valid value is a string of up to 80 characters. By default, no value is defined.
'Boot File Name' <code>boot-file-name</code> <code>[DhcpServer_</code> <code>BootFileName]</code>	Defines the name of the boot file image for the DHCP client. The boot file stores the boot image for the client. The boot image is typically the operating system the client uses to upload (from a boot server). The value is sent in DHCP Option 67 (Bootfile Name). To define the server storing the file, use the 'TFTP Server' parameter (see above). The valid value is a string of up to 256 characters. By default, no value is defined.

Parameter	Description
	<p>The name can also include the following case-sensitive placeholder strings that are replaced with actual values if the 'Expand Boot-file Name' parameter is set to <b>Yes</b>:</p> <ul style="list-style-type: none"> <li>■ <b>&lt;MAC&gt;</b>: Replaced by the MAC address of the client (e.g., <i>boot_&lt;MAC&gt;.ini</i>). The MAC address is obtained in the client's DHCP request.</li> <li>■ <b>&lt;IP&gt;</b>: Replaced by the IP address assigned by the DHCP server to the client.</li> </ul>
'Expand Boot-File Name' expand-boot-file-name [DhcpServer_ExpandBootfileName]	<p>Enables the use of the placeholders in the boot file name, defined in the 'Boot file name' parameter.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b> (default)</li> </ul>
Router	
'Override Router' override-router-address [DhcpServer_OverrideRouter]	<p>Defines the IP address (IPv4 in dotted-decimal notation) of the default router that the DHCP server assigns the DHCP client. The value is sent in DHCP Option 3 (Router).</p> <p>The default value is 0.0.0.0. If not specified (empty or "0.0.0.0"), the IP address of the default gateway configured in the IP Interfaces table for the IP network interface that you associated with the DHCP server (see the 'Interface Name' parameter above) is used.</p>
SIP	
'SIP Server' sip-server [DhcpServer_SipServer]	<p>Defines the IP address or DNS name of the SIP server that the DHCP server assigns the DHCP client. The client uses this SIP server for its outbound SIP requests. The value is sent in DHCP Option 120 (SIP Server). After defining the parameter, use the 'SIP server type' parameter (see below) to define the type of address (FQDN or IP address).</p> <p>The valid value is a string of up to 256 characters. The default is 0.0.0.0.</p>
'SIP Server Type' sip-server-type [DhcpServer_SipServerType]	<p>Defines the type of SIP server address. The actual address is defined in the 'SIP server' parameter (see above). Encoding is done per SIP Server Type, as defined in RFC 3361.</p> <ul style="list-style-type: none"> <li>■ [0] <b>DNS names</b> = (Default) The 'SIP server' parameter is configured with an FQDN of the SIP server.</li> </ul>

Parameter	Description
	■ [1] <b>IP address</b> = The 'SIP server' parameter configured with an IP address of the SIP server.

## Configuring the Vendor Class Identifier

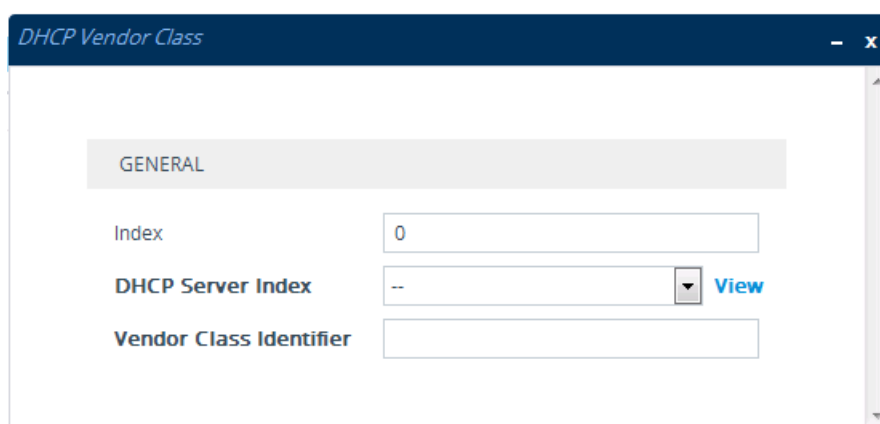

The DHCP Vendor Class table lets you configure up to 10 Vendor Class Identifier (VCI) names (DHCP Option 60). When the table is configured, the device's DHCP server responds only to DHCPDiscover requests that contain Option 60 and that match one of the DHCP VCIs configured in the table. If you have not configured any entries in the table, the DHCP server responds to all DHCPDiscover requests, regardless of the VCI.

The VCI is a string that identifies the vendor and functionality of a DHCP client to the DHCP server. For example, Option 60 can show the unique type of hardware (e.g., "AudioCodes 440HD IP Phone") or firmware of the DHCP client. The DHCP server can then differentiate between DHCP clients and process their requests accordingly.

The following procedure describes how to configure the DHCP VCIs through the Web interface. You can also configure it through ini file [DhcpVendorClass] or CLI (`configure network > dhcp-server vendor-class`).

### ➤ To configure DHCP Vendor Class Identifiers:

1. Open the DHCP Servers table (see [Configuring the DHCP Server](#) on page 327).
2. Select the row of the desired DHCP server for which you want to configure VCIs, and then click the **DHCP Vendor Class** link located below the table; the DHCP Vendor Class table opens.
3. Click **New**; the following dialog box appears:

4. Configure a VCI for the DHCP server according to the parameters described in the table below.
5. Click **Apply**.

**Table 16-3: DHCP Vendor Class Table Parameter Descriptions**

Parameter	Description
'Index' dhcp vendor- class <index> [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'DHCP Server Index' dhcp-server- number [DhcpServerIndex]	Associates the VCI table entry with a DHCP server that you configured in <a href="#">Configuring the DHCP Server</a> on page 327. <b>Note:</b> You can configure only one DHCP server (Index 0) and therefore, the parameter value is always 0.
'Vendor Class Identifier' vendor-class [VendorClassId]	Defines the value of the VCI DHCP Option 60. The valid value is a string of up to 80 characters. By default, no value is defined.

## Configuring Additional DHCP Options

The DHCP Option table lets you configure up to 10 additional DHCP Options that the DHCP server can use to service the DHCP client. These DHCP Options are included in the DHCP Offer response sent by the DHCP server.

The following procedure describes how to configure DHCP Options through the Web interface. You can also configure it through ini file [DhcpOption] or CLI (`configure network > dhcp-server option`).

The additional DHCP Options configured in the DHCP Option table override the default ones, which are configured in the DHCP Servers table. In other words, if you configure Option 67 in the DHCP Option table, the device uses the value configured in the DHCP Option table instead of the value configured in the DHCP Servers table.

### ➤ To configure DHCP Options:

1. Open the DHCP Servers table (see [Configuring the DHCP Server](#) on page 327).
2. Select the row of the desired DHCP server for which you want to configure additional DHCP Options, and then click the **DHCP Option** link located below the table; the DHCP Option table opens.
3. Click **New**; the following dialog box appears:

DHCP Option

4. Configure additional DHCP Options for the DHCP server according to the parameters described in the table below.
5. Click **Apply**.

Table 16-4: DHCP Option Table Parameter Descriptions

Parameter	Description
'Index' dhcp option [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'DHCP Server Index' dhcp-server-number [DhcpServerIndex]	Associates the DHCP Option table entry with a DHCP server that you configured in <a href="#">Configuring the DHCP Server</a> on page 327. <b>Note:</b> Currently, only one DHCP server (Index 0) can be configured and therefore, the parameter is always set at 0.
'Option' option [Option]	Defines the code of the DHCP Option. The valid value is 1 to 254. The default is 159. For example, for DHCP Option 150 (Cisco proprietary for defining multiple TFTP server IP addresses), enter the value 150.
'Type' type [Type]	Defines the format (type) of the DHCP Option value that is configured in the 'Value' parameter (see below).  ■ [0] <b>ASCII</b> = (Default) Plain-text string (e.g., when the value is a domain name).

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>IP address</b> = IPv4 address.</li> <li>■ [2] <b>Hexadecimal</b> = Hexadecimal-encoded string.</li> </ul> <p>For example, if you configure the 'Value' parameter to "company.com" (without quotation marks), you need to configure the 'Type' parameter to <b>ASCII</b>.</p>
'Value' value [Value]	<p>Defines the value of the DHCP Option. For example, if you are using Option 66, the parameter is used for specifying the TFTP provisioning server (e.g., <code>http://192.168.3.155:5000/provisioning/</code>).</p> <p>The valid value is a string of up to 256 characters. By default, no value is defined. For IP addresses, the value can be one or more IPv4 addresses, each separated by a comma (e.g., <code>192.168.10.5,192.168.10.20</code>). For hexadecimal values, the value is a hexadecimal string (e.g., <code>c0a80a05</code>).</p> <p>You can also configure the parameter with case-sensitive placeholder strings that are replaced with actual values if the 'Expand Value' parameter (see below) is set to <b>Yes</b>:</p> <ul style="list-style-type: none"> <li>■ <b>&lt;MAC&gt;</b>: Replaced by the MAC address of the client. The MAC address is obtained from the client's DHCP request. For example, the parameter can be set to:  <code>http://192.168.3.155:5000/provisioning/cfg_&lt;MAC&gt;.txt</code></li> <li>■ <b>&lt;IP&gt;</b>: Replaced by the IP address assigned by the DHCP server to the client. For example, the parameter can be set to:  <code>http://192.168.3.155:5000/provisioning/cfg_&lt;IP&gt;.txt</code></li> </ul>
'Expand Value' expand-value [ExpandValue]	<p>Enables the use of the special placeholder strings, "&lt;MAC&gt;" and "&lt;IP&gt;" for configuring the 'Value' parameter (see above).</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b> (default)</li> </ul> <p><b>Note:</b> The parameter is applicable only to values of type ASCII (see the 'Type' parameter, above).</p>

## Configuring Static IP Addresses for DHCP Clients

The DHCP Static IP table lets you configure up to 100 DHCP clients with static IP addresses. The static IP address is a "reserved" IP address for a specified DHCP client defined by MAC address. In other words, instead of assigning the DHCP client with a different IP address upon each IP address lease renewal request, the DHCP server assigns the client the same IP address. For DHCP clients that are not listed in the table, the DHCP server assigns a random IP address from its address pool, as in normal operation.

The following procedure describes how to configure static IP addresses for DHCP clients through the Web interface. You can also configure it through ini file [DhcpStaticIP] or CLI (configure network > dhcp-server static-ip <index>).

➤ **To configure static IP addresses for DHCP clients:**

1. Open the DHCP Servers table (see [Configuring the DHCP Server](#) on page 327).
2. Select the row of the desired DHCP server for which you want to configure static IP addresses for DHCP clients, and then click the **DHCP Static IP** link located below the table; the DHCP Static IP table opens.
3. Click **New**; the following dialog box appears:

4. Configure a static IP address for a specific DHCP client according to the parameters described in the table below.
5. Click **Apply**.

**Table 16-5: DHCP Static IP Table Parameter Descriptions**

Parameter	Description
'Index' dhcp static-ip <index>	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
[Index]	
'DHCP Server Index' dhcp-server-number [DhcpServerIndex]	Associates the DHCP Static IP table entry with a DHCP server that you configured in <a href="#">Configuring the DHCP Server</a> on page 327. <b>Note:</b> Currently, only one DHCP server (Index 0) can be configured and therefore, the parameter value is always 0.
'IP Address' ip-address [IPAddress]	Defines the "reserved", static IP address (IPv4) to assign the DHCP client. The default is 0.0.0.0.
'MAC Address' mac-address [MACAddress]	Defines the DHCP client by MAC address (in hexadecimal format). The valid value is a string of up to 20 characters. The format includes six groups of two hexadecimal digits, each separated by a colon. The default MAC address is 00:90:8f:00:00:00.

## Viewing and Deleting DHCP Clients

The DHCP Clients table lets you view currently serviced DHCP clients by the DHCP server. The table also lets you delete DHCP clients. If you delete a client, the DHCP server ends the lease of the IP address to the client and the IP address becomes available for allocation by the DHCP server to another client.

The following procedure describes how to view DHCP clients through the Web interface. You can also view this through CLI:

- To view DHCP clients:

```
# show network dhcp clients
```

- To view DHCP clients according to IP address:

```
# show network dhcp ip
```

- To view DHCP clients according to MAC address:

```
# show network dhcp mac
```

- To view DHCP clients that have been blacklisted from DHCP implementation (due to duplicated IP addresses in the network, where another device is using the same IP address as the one assigned to the client):

```
# show network dhcp black-list
```

➤ **To view or delete DHCP clients:**

1. Open the DHCP Servers table (see [Configuring the DHCP Server](#) on page 327).
2. Select the row of the desired DHCP server for which you want to view DHCP clients, and then click the **DHCP Clients** link located below the table; the DHCP Clients table opens:

INDEX ↕	DHCP SERVER INDEX	IP ADDRESS	MAC ADDRESS	LEASE EXPIRATION
---------	-------------------	------------	-------------	------------------

The table displays the following per client:

- **Index:** Table index number.
  - **DHCP Server Index:** The index number of the configured DHCP server scope in the DHCP Server table (see [Configuring the DHCP Server](#) on page 327) with which the client is associated.
  - **IP Address:** IP address assigned to the DHCP client by the DHCP server.
  - **MAC Address:** MAC address of the DHCP client.
  - **Lease Expiration:** Date on which the lease of the DHCP client's IP address obtained from the DHCP server expires.
3. To delete a client:
    - a. Select the table row index of the DHCP client that you want to delete.
    - b. Click the **Action** button, and then from the drop-down menu, choose **Delete**; a confirmation message appears.
    - c. Click **OK** to confirm deletion.

## SIPREC SIP-based Media Recording

This section describes the device's support for SIPREC.

### SIPREC Overview

The device can record SIP-based media (RTP/SRTP) call sessions traversing it. The device can record not only audio streams, but also video streams for audio-video calls. The media recording support is in accordance with the Session Recording Protocol (SIPREC), which describes architectures for deploying session recording solutions and specifies requirements for extensions to SIP that will manage delivery of RTP media to a recording device. The device's SIPREC feature is in compliance with the following:

- RFC 6341 (Use Cases and Requirements for SIP-Based Media Recording)
- Session Recording Protocol (draft-ietf-siprec-protocol-02)

- Architecture (draft-ietf-siprec-architecture-03)
- RFC 7865 (Session Initiation Protocol (SIP) Recording Metadata)

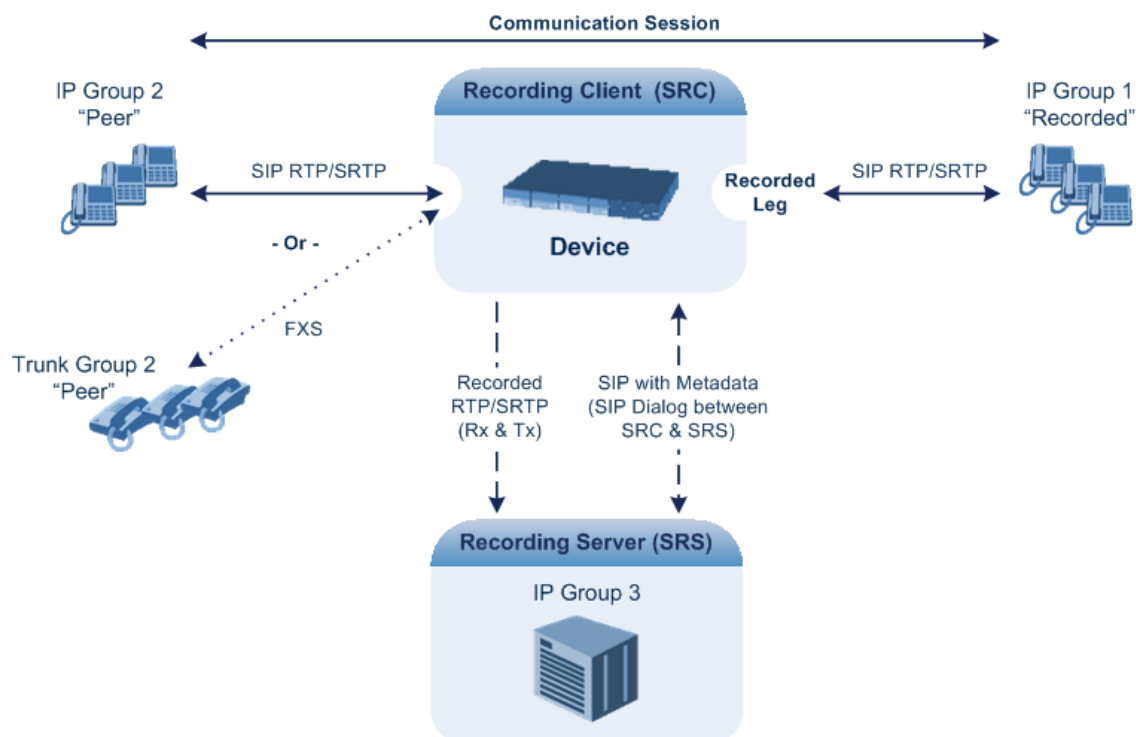

**Warning for Deployments in France:** The device supports SIPREC according to RFC 6341. As such, you must adhere to the Commission Nationale Informatique et Liberté's (CNIL) [directive](#) and be aware that article R226-15 applies penalties to the malicious interception, diversion, use or disclosure of correspondence sent, transmitted or received by means of telecommunication, or the setting up of a device designed to produce such interceptions.

- The SIPREC feature is available only if your device is installed with a License Key (see [License Key](#) on page 1362) that includes this feature. The License Key specifies the maximum number of supported SIPREC sessions. For audio-video calls, video recording needs additional SBC media channel resources.
- For maximum concurrent SIPREC sessions, refer to the device's *Release Notes* (click [here](#)).
- The device can record the following media streams: audio only, text only, audio and video, or audio and text.
- You can view active and historical SIPREC call information, using the CLI command `show voip calls`.
- You can customize SBC CDRs generated by the device to include the field "Is Recorded", which indicates if the SBC leg was recorded or not. For more information, see [Customizing CDRs for SBC Calls and Test Calls](#) on page 1578.

Session recording is a critical requirement in many business communications environments such as call centers and financial trading floors. In some of these environments, all calls must be recorded for regulatory and compliance reasons. In others, calls may be recorded for quality control or business analytics. Recording is typically performed by sending a copy of the session media to the recording devices.

The SIPREC protocol specifies the use of SIP, SDP, and RTP to establish a Recording Session (RS) from the Session Recording Client (SRC), which is on the path of the Communication Session (CS), to a Session Recording Server (SRS) at the recording equipment. The device functions as the SRC, sending recording sessions to a third-party SRS, as shown in the figure below.

The device can record calls between two IP Groups, or between an IP Group and a Trunk Group for Gateway calls. The type of calls to record can be specified by source and/or destination prefix number or SIP Request-URI, as well as by call initiator. The side ("leg") on which the recording is done must be specified. Specifying the leg is important as it determines the various call media attributes of the recorded RTP (or SRTP) such as coder type.

### SIP Message Flow for SIPREC

The device initiates a recording session by sending an INVITE message to the SRS when the call to be recorded is connected. The SIP From header contains the identity of the SRC and the To header contains the identity of the SRS. The SIP message body of the INVITE contains the following:

#### ■ SDP body:

- Two 'm=' lines that represent the two RTP/SRTP streams (Rx and Tx).
- Two 'a=label:' lines that identify the streams.

If the recorded leg includes a video stream, the SDP not only includes the two audio streams ('m=audio'), but also two video streams ('m=video') in send-only RTP mode ('a=sendonly') - one for Tx and one for Rx.

#### ■ XML body (also referred to as metadata), which provides information on the participants of the call session:

- <group id>: Logging Session ID (displayed as [SID:nnnnn] in syslog), converted to hex (or Base64 format). This number remains the same even if the call is forwarded or transferred. This is important for recorded calls.

- <session id>: SIP Call-ID header value of the recorded leg, which the device represents as a unique hashed number.
- <group-ref>: Same as <group id>.
- <participant id>: SIP From / To user.
- <nameID aor>: From/To user@host.
- <send> and <recv>: IDs for the RTP/SRTP streams in hex (or Base64 format) - bits 0-31 are the same as group, bits 32-47 are the RTP port.
- <stream id>: Same as <send> for each participant.
- <label>: 1 and 2 (same as in the SDP's 'a=label:' line).
- RFC 7865 only:
  - ◆ <sessionrecordingassoc>: Session association data.
  - ◆ <participantsessionassoc>: Data for association between participant and session.
  - ◆ <participantstreamassoc>: Data for association between participant and stream.

If the recorded leg includes a video stream, the metadata body contains two additional <stream> sections, which denote the Tx and Rx recording streams of the video payload. When RFC 7865 is chosen as the metadata format, the <participantstreamassoc> sections also contain this additional pair of streams.

You can configure the format of the recording metadata (i.e., based on RFC 7865 or "legacy") generated by the device. For more information, see [Configuring Format of SIPREC Metadata](#) on page 355.

The SRS can respond with 'a=recvonly' for immediate recording or 'a=inactive' if recording is not yet needed, and send a re-INVITE at any later stage with the desired RTP/SRTP mode change. If a re-INVITE is received in the original call (e.g., when a call is on hold), the device sends another re-INVITE with two 'm=' lines to the SRS with the updated RTP/SRTP data. If the recorded leg uses SRTP, the device can send the media streams to the SRS as SRTP; otherwise, the media streams are sent as RTP to the SRS.

Below is an example of an INVITE sent by the device to the SRS, showing the legacy and RFC 7865 metadata formats (only one of these is generated in real-life scenarios):

```
INVITE sip:VSRP@1.9.64.253 SIP/2.0

### SIPREC for SRTP Calls

The device can also record SRTP calls and send it to the SRS in RTP, or vice versa. For this functionality, configure the 'SBC Media Security Mode' parameter of the IP Profile that is associated with the SRS's IP Group to **Secured** or **Not Secured**, respectively. If you need to record the call in a coder that is different to the coder used in the call, the device can also be located between an SRS and an SRC to perform coder transcoding. In this setup, the device receives SIP recording sessions from the SRC and transcodes the media between the SRC and SRS, and then forwards the recording to the SRS in the transcoded media format.

## SIPREC for Real-Time Text

The device can record real-time text (RTT) in SBC sessions. RTT is carried in RTP and allows text to be sent immediately as it's created through wireless handsets that use IP-based technology on networks that support RTT.

For recording audio with RTT calls (i.e., two media streams), additional SBC media channel resources are required. For example, recording 100 SBC sessions of which 30 contain RTT, the following licenses are required: "SIPREC Streams" = 100, "SBC Sessions" = 100, and "SBC Media" = 60 (30 for the RTT sessions + 30 for the RTT sessions sent to SRS).

Recording of RTT is applicable only to the SBC application.

## Sending SIPREC to Multiple SRSs

The device can send recorded SBC calls to multiple SRSs. To achieve this, you need to configure groups of SRSs, where each group can contain one SRS (standalone) or two SRSs operating in an active-standby (1+1) mode for SRS redundancy. For the maximum number of supported SRSs, see the note below.

For standalone SRSs, the device sends both SIP signaling and RTP to all SRSs. For SRS redundancy, the device sends SIP signaling to all SRSs (active and standby), but sends RTP only to the active SRSs. If during a recorded call session, the standby SRS detects that the active SRS has gone offline, the standby SRS sends a re-INVITE to the device and the device then sends the recorded RTP to the standby SRS instead (which now becomes the active SRS). For new calls, if the device receives no response or a reject response from the active SRS to its' sent INVITE message, the device sends the recorded call to the standby SRS.

- For Gateway calls, the device can send recordings of a call to only one SRS.
- For SIPREC that is triggered by the device's REST API, the device can send recordings of a call to only one SRS.
- The device can send recordings (media) to up to six active SRSs. In other words, any one of the following configurations are supported:
  - ✓ Up to six standalone (active) SRSs.
  - ✓ Up to six active-standby SRS pairs (i.e., 12 SRSs, but recordings are sent to the six active SRSs only).
  - ✓ Combination of standalone SRSs and active-standby SRS pairs, for example:
    - > One standalone (active) SRS and five active-standby SRS pairs.
    - > Five standalone (active) SRSs and one active-standby SRS pair.
- SRS active-standby functionality must also be supported by the third-party SRS. For supported third-party SRS vendors, contact your AudioCodes sales representative.
- SRS active-standby redundancy is a license-dependent feature and is available only if it is included in the License Key installed on the device (see [Viewing the License Key](#) on page 1362). Therefore, the SIPREC feature can require two licenses – the regular license ("SIPREC Streams") for standalone (active) SRSs and a license for SRS active-standby redundancy ("SIPREC Redundancy Streams"). If you are implementing only standalone SRSs, you only need the "SIPREC Streams" license. If you are implementing SRS active-standby redundancy, you need both licenses.
- The "SIPREC Streams" license defines the maximum number of sessions for active SRSs (standalone SRS and the active SRS in the active-standby redundancy pair). The "SIPREC Redundancy Streams" license defines the maximum number of SIPREC sessions for the standby SRS in the active-standby redundancy pair. For example, if you want to support 10 SIPREC sessions per SRS, the required licenses for various scenarios are as follows:
  - ✓ One standalone SRS: "SIPREC Streams" = 10
  - ✓ Two standalone SRSs: "SIPREC Streams" = 20
  - ✓ One active-standby redundancy pair: "SIPREC Streams" = 10; "SIPREC Redundancy Streams" = 10
  - ✓ Two active-standby redundancy pairs: "SIPREC Streams" = 20; "SIPREC Redundancy Streams" = 20
  - ✓ One standalone SRS and two active-standby redundancy pairs: "SIPREC Streams" = 30; "SIPREC Redundancy Streams" = 20

### Load Balancing SIPREC SRSs using IP Group Set

The device can send SIPREC sessions to a group of IP Groups (SRSs) that are defined by an IP Group Set. An IP Group Set is a group of IP Groups and is used for load balancing of calls (configured in [Configuring IP Group Sets](#) on page 1223). Each time the device sends a SIPREC session, it chooses the IP Group (SRS) based on the IP Group Set's load-balancing policy (i.e., round-robin, homing, or random weight).

When you configure a SIP Recording rule (see [Configuring SIP Recording Rules](#) on the next page), the IP Group Set is defined by the 'Recording Server (SRS) IP Group Set' parameter.

This feature is applicable only to the SBC application.

## Configuring SIP Recording Rules

The SIP Recording Rules table lets you configure up to 30 SIP-based media recording (SIPREC) rules. A SIP Recording rule defines call routes that you want to record. For an overview of the feature, see [SIPREC SIP-based Media Recording](#) on page 339.

- To configure the device's timestamp format (local or UTC) in SIP messages sent to the SRS, see the [SIPRecTimeStamp] parameter.
- When recording SRTP-to-SRTP calls, if you want to send the recorded media to the SRS as RTP (i.e., decrypted), add an IP Profile for the SRS and configure its 'SBC Media Security Mode' parameter to **Not Secured** (see [Configuring IP Profiles](#) on page 674).
- If you configure a SIP Recording rule for calls that have also been configured for direct media (media bypass) by a SIP Interface ('Direct Media' parameter) or an IP Profile ('Direct Media Tag' parameter), the device automatically disables direct media for these calls (during their SIP signaling setup). This ensures that media traverses the device so that it can be recorded and sent to the SRS. However, if you enable direct media using the [SBCDirectMedia] global parameter (i.e., all calls), or calls whose incoming SIP dialog-initiating request contain the proprietary header X-AC-Action with the value 'direct-media' (i.e., 'X-AC-Action: direct-media'), direct media is always enforced and calls aren't recorded.
- To view the number of currently active SIPREC signaling sessions, use the CLI command `show voip calls statistics siprec`. For more information, refer to the document [CLI Reference Guide](#).

The following procedure describes how to configure SIP Recording rules through the Web interface. You can also configure it through ini file [SIPRecRouting] or CLI (`configure voip > sip-definition sip-recording sip-rec-routing`).

### ➤ To configure a SIP Recording rule:

1. Open the SIP Recording Rules table (**Setup** menu > **Signaling & Media** tab > **SIP Recording** folder > **SIP Recording Rules**).
2. Click **New**; the following dialog box appears:

SIP Recording Rules

GENERAL		RECORDING SERVER	
Index	0	Recording Server (SRS) IP Group	-- View
Recorded IP Group	Any View	Redundant Recording Server (SRS) IP Group	-- View
Recorded Source Pattern	*	Recording Server (SRS) IP Group Set	-- View
Recorded Destination Pattern	*		
Condition	-- View		
Peer IP Group	Any View		
Peer Trunk Group ID	-1		
Caller	Both		
Trigger	Call Connect		
Recording Server Role			

The following configuration records calls made by IP Group "ITSP" to IP Group "IP-PBX" that have the destination number prefix "1800". The device records the calls from the leg interfacing with IP Group "IP PBX" (peer) and sends the recorded media to IP Group "SRS-1". SRS redundancy has also been configured, where IP Group "SRS-1" is the active SRS and IP Group "SRS-2" the standby SRS.

- 'Recorded IP Group': "ITSP"
- 'Recorded Destination Pattern': "1800"
- 'Peer IP Group': "IP-PBX"
- 'Caller': **Peer Party**
- 'Recording Server (SRS) IP Group': "SRS-1"
- 'Redundant Recording Server (SRS) IP Group': "SRS-2"

1. Configure a SIP recording rule according to the parameters described in the table below.
2. Click **Apply**, and then save your settings to flash memory.

**Table 16-6: SIP Recording Rules Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table record.
'Recorded IP Group' recorded-ip-group-name [RecordedIPGroupName]	<p>Assigns an IP Group from the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591) to represent the entity participating in the call. Recording is done on the leg interfacing with this IP Group.</p> <p>The default is <b>Any</b> (i.e., all IP Groups).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ For an SBC RTP-SRTP session, the recorded IP Group must be set to the RTP leg if recording is required to be RTP, or set to the SRTP leg if recording is required to be SRTP.</li> </ul>
'Recorded Source Pattern' recorded-src-pattern [RecordedSourcePrefix]	<p>Defines calls to record based on source number or SIP URI.</p> <p>You can use special patterns (notations) to denote the number or URI. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". For available</p>

Parameter	Description
	<p>patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any source number or URI.</p>
'Recorded Destination Pattern' recorded-dst-prefi [RecordedDestinationPrefix]	<p>Defines calls to record based on destination number or URI.</p> <p>You can use special patterns (notations) to denote the number or URI. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any destination number or URI.</p>
'Condition' condition-name [ConditionName]	<p>Assigns a Message Condition rule from the Message Conditions table ( see <a href="#">Configuring Message Condition Rules</a> on page 865) to the rule, which starts (activates) call recording upon a specific condition.</p> <p>For more information on using conditions with SIPREC, see <a href="#">Starting a SIPREC Session using Message Conditions</a> on page 354.</p>
'Peer IP Group' peer-ip-group-name [PeerIPGroupName]	<p>Assigns an IP Group from the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591) to represent the peer IP Group that is participating in the call.</p> <p>The default is <b>Any</b> (i.e., all IP Groups).</p>
'Peer Trunk Group ID' peer-trunk-group-id [PeerTrunkGroupID]	<p>Defines the peer Trunk Group that is participating in the call. To configure Trunk Groups, see <a href="#">Configuring Trunk Groups</a> on page 934.</p> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
'Caller' caller [Caller]	<p>Defines which calls to record according to which party is the caller.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Both</b> = (Default) Caller can be peer or recorded side</li> <li>■ [1] <b>Recorded Party</b> (in Gateway, IP-to-Tel call)</li> <li>■ [2] <b>Peer Party</b> (in Gateway, Tel-to-IP call)</li> </ul>

Parameter	Description
'Trigger' trigger [RecordingTrigger]	<p>Defines what triggers (starts) the device to record the call for this rule.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Call Connect</b> = (Default) Call recording is triggered when the call is established (200 OK or ACK received).</li> <li>■ [1] <b>REST</b> = Call recording is triggered when the device receives a REST request. For more information on SIPREC triggered by REST, see <a href="#">On-Demand SIPREC using REST</a> on page 361.</li> <li>■ [2] <b>Media Start</b> = Call recording is triggered upon the start of media. This can include early media (18x response prior to 200 OK, e.g., to play ring tone) or media after connect.</li> </ul> <p><b>Note:</b> For alternate call routing or forking scenarios, if SIPREC was triggered due to early media and another SIP 183/200 OK changes the destination which is not configured for recording, the device continues recording the call.</p>
'Recording Server Role' srs-role [SRSRole]	<p>Defines a condition (optional) based on role value for matching the rule when the recording is triggered by a REST request. For this rule to be chosen, the 'role' field in the incoming REST request message must contain this same value.</p> <p>The valid value is a string of up to 20 characters. By default, no value is defined.</p> <p>For more information on SIPREC triggered by REST, see <a href="#">On-Demand SIPREC using REST</a> on page 361.</p> <p><b>Note:</b> The parameter is applicable only when you configure the 'Trigger' parameter to <b>REST</b>.</p>
Recording Server	
'Recording Server (SRS) IP Group' srs-ip-group-name [SRSIPGroupName]	<p>Assigns an IP Group from the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591) to represent the SRS.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter, use the default settings (i.e., not configured) for the 'Recording</li> </ul>

Parameter	Description
	<p>Server (SRS) IP Group Set' parameter.</p> <ul style="list-style-type: none"> <li>■ The SIP Interface for communicating with the SRS is according to the SRD that is assigned to the SRS IP Group (in the IP Groups table). If two SIP Interfaces are associated with the SRD - one for "SBC" and one for "GW" – the device uses the "SBC" SIP Interface. If no SBC SIP Interface type is configured, the device uses the "GW" interface (which means that SRS redundancy isn't supported).</li> </ul>
<p>'Redundant Recording Server (SRS) IP Group'</p> <p><code>srs-red-ip-group-name</code></p> <p>[SRSRedundantIPGroupName]</p>	<p>Assigns an IP Group from the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591) to represent the redundant SRS in the active-standby pair for SRS redundancy.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ SRS redundancy is applicable only to the SBC application.</li> <li>■ The IP Group of the redundant SRS must be different to the IP Group of the main SRS (see the 'Recording Server (SRS) IP Group' parameter).</li> <li>■ If you configure the parameter, use the default settings (i.e., not configured) for the 'Recording Server (SRS) IP Group Set' parameter.</li> </ul>
<p>'Recording Server (SRS) IP Group Set'</p> <p><code>srs-ip-group-set-name</code></p> <p>[SRSIPGroupSetName]</p>	<p>Assigns an IP Group Set from the IP Group Set table (see <a href="#">Configuring IP Group Sets</a> on page 1223) to represent a group of SRSs (IP Groups) for load balancing. Each time the device sends SIPREC, it chooses a specific IP Group based on the IP Group Set's policy (i.e., round-robin, homing, or random weight).</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This parameter is applicable only to the SBC application.</li> <li>■ If you configure this parameter, use the default settings (i.e., not configured) for the 'Recording Server (SRS) IP Group' and 'Redundant Recording Server (SRS) IP Group' parameters.</li> </ul>

## Starting a SIPREC Session using Message Conditions

You can start and stop the recording of calls (SIPREC) based on user-defined conditions. The condition is configured as a Message Condition rule in the Message Conditions table, which is then assigned to the SIP Recording rule in the SIP Recording Rules table. Only if the condition is met will the device start recording the call. The feature is typically configured using Message Condition rules together with Call Setup rules.

For this feature, you can use only the following keywords for the syntax of the Message Condition rule:

- var.global
- var.session.0
- srctags/dsttags

For more information on using the above syntax for message manipulation, refer to the *Syntax for SIP Message Manipulation Reference Guide*.

The following procedure provides a SIP Recording configuration example for using a condition with the "srctags" keyword to start recording a call for IP Group "ITSP" if the incoming SIP message contains the header, "X-Record:yes".

### ➤ To use conditions for SIPREC:

1. In the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809), click **New**, and then configure a Call Setup rule with the following properties:
  - 'Index': 0
  - 'Rules Set ID': 1
  - 'Condition': header.X-Record=='yes'
  - 'Action Subject': srctags
  - 'Action Type': Modify
  - 'Action Value': 'record'
1. In the IP Groups table (see [Configuring IP Groups](#) on page 591), assign the Call Setup rule that you configured in the previous step to the IP Group that you want to record (i.e., the "Recorded IP Group"):
  - 'Call Setup Rules Set ID': 1
2. In the Message Conditions table (see [Configuring Message Condition Rules](#) on page 865), click **New**, and then configure a Message Condition rule with the following properties:
  - 'Index': 0
  - 'Name': CallRec
  - 'Condition': srctags == 'record'

3. In the SIP Recording Rules table, configure a SIP Recording rule as desired and assign it the Message Condition rule that you configured in the previous step:
  - 'Recorded IP Group': ITSP
  - 'Condition': CallRec

## Configuring Format of SIPREC Metadata

You can configure the format of the XML-based recording metadata that the device generates and includes in the SIP messages that it sends to the recording server (SRS). It is important that the device generates the metadata in a format that is acceptable by the SRS.

The device supports the following formats:

- **RFC 7865** - the device generates the recording metadata in a format that is according to RFC 7865, whereby all IDs (e.g., participant ID) are in Base64 format. This metadata format also includes additional XML tags with association information (e.g., "<participantsessionassoc>").
- **Legacy** (default) - The device generates the recording metadata in a "legacy" format, whereby the user part of the participant URI (source or destination) is used as the ID.

### ➤ To configure the format of the metadata:

1. Open the SIP Recording Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Recording** folder > **SIP Recording Settings**).

**Figure 16-1: Configuring SIPREC Metadata Format**

2. From the 'SIP Recording Metadata Format' drop-down list, select the desired format.
3. Click **Apply**.

## Configuring Video Recording Synchronization

If you also want to record the video stream of audio-video calls, you need to configure a video synchronization timeout. When the video stream is also recorded, the device operates as follows:

1. Once the call is answered by the called UA (i.e., connected), the UAs' audio streams are connected and the device sends a SIP INVITE to the SRS. However, for correct video synchronization, the UAs' video streams are not yet connected at this stage.
2. When a SIP 200 OK response is received from the SRS and the UAs' ports have been negotiated, the device connects all video streams - the UAs' video stream and the recorded video stream (the recorded audio stream is also sent to the SRS at this stage). However, if the 200 OK from the SRS is not received within a user-defined video synchronization timeout, the device connects the video stream between the UAs.

➤ **To configure video synchronization timeout:**

1. Open the SIP Recording Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Recording** folder > **SIP Recording Settings**).

**Figure 16-2: Configuring Video Recording Synchronization**

2. In the 'Video Recording Sync Timeout' field, enter a timeout for receiving the SIP 200 OK from the SRS.
3. Click **Apply**.

## On-demand SIPREC

The device supports on-demand SIPREC sessions that can be triggered by the following:

- SIP INFO messages - see [On-Demand SIPREC using SIP INFO Messages](#) below
- SIP 200 OK responses - see [On-Demand SIPREC using SIP 200 OK Responses](#) on page 359
- REST API - see [On-Demand SIPREC using REST](#) on page 361

### On-Demand SIPREC using SIP INFO Messages

The device supports on-demand SIPREC sessions that are triggered by the receipt of SIP INFO messages. The device can be triggered to start, pause, resume, or stop recording at any stage of a connected call. Therefore, this allows the device to do multiple recordings of a call.

- This feature doesn't require any configuration in the SIP Recording Rules table.
- The device can also be triggered to start a SIPREC session by the receipt of a SIP 200 OK response. For more information, see [On-Demand SIPREC using SIP 200 OK Responses](#) on page 359.
- The feature is applicable only to the SBC application.

The device starts, pauses, resumes, or stops recording upon the receipt of a SIP INFO message that contains AudioCodes proprietary X-AC-Action header. The syntax of the X-AC-Action header for SIPREC is shown below:

```
X-AC-Action: <Recording Action>;<SRS Type>=<SRS Entity>;recorded-
side=peer;call-recording-dest-username=<User Part>
```

Where:

- *<Recording Action>* specifies the recording action:
  - **start-siprec**: Starts recording.
  - **pause-siprec**: Pauses recording.

- **resume-siprec**: Resumes recording after it was paused.
  - **stop-siprec**: Stops recording.
- **<SRS Type>** indicates the device entity used to represent the SRS:
- **recording-ip-group**: SRS is defined by individual IP Groups (see [Configuring IP Groups](#) on page 591).
  - **recording-ip-group-set**: SRS is defined by IP Group Sets (see [Configuring IP Group Sets](#) on page 1223).
- **<SRS Entity>** specifies the SRS as an IP Group or IP Group Set by name or index number. Use a comma-separated list (without spaces) to specify multiple IP Groups or IP Group Sets.
- **recorded-side=peer** is an optional parameter, which you can use to indicate that recording be done on the peer side (i.e., not the side receiving this X-AC-Action header). This parameter is applicable only to the **start-siprec** recording action.
- **call-recording-dest-username** is an optional parameter, which defines the SIP user part of the Request-URI in the INVITE message (To header) that the sends to the SRS. The field can contain up to 60 characters. If this field is present, its value overrides the 'Recording Server (SRS) Destination Username' parameter settings, as described in [Configuring SIP User Part for SRS](#) on page 363.

The following shows an example of an incoming SIP INFO message that triggers the device to start a SIPREC session for the call and using IP Groups "SRS-SiteA" and "SRS-SiteB" as the SRSs:

```
INFO sip:alice@pc33.example.com SIP/2.0
Via: SIP/2.0/UDP 192.0.2.2:5060;branch=z9hG4bKnabcdef
To: Bob <sip:bob@example.com>;tag=a6c85cf
From: Alice <sip:alice@example.com>;tag=1928301774
Call-Id: a84b4c76e66710@pc33.example.com
CSeq: 314333 INFO
X-AC-Action: start-siprec;recording-ip-group="SRS-SiteA,SRS-SiteB";call-
recording-dest-username=username_abc
Content-Length: 0
```

If a parameter's value contains one or more spaces (e.g., `recording-ip-group="SIPREC SRS"`) or the parameter has multiple values, which must be separated by commas (e.g., `recording-ip-group="SRS-SiteA,SRS-SiteB"`), enclose the value in double quotation marks ("...").

You can specify different SRS IP Groups or IP Group Sets per recording action for the same call. For example, the SIPREC session can be started (`start-siprec`) on SRS IP Groups *x*, *y* and *z*, and then later paused (`pause-siprec`) on SRS IP Group *y* only.

If the X-AC-Action header contains only **start-siprec**, use the device's Message Manipulation feature (see [Configuring SIP Message Manipulation](#) on page 856) to add 'recording-ip-

group="<SRS IP Groups or IP Group Sets>" and optionally, 'recorded-side=peer' to indicate if recording should be done on the peer sided. Assign the Message Manipulation Set ID to the IP Group of the sender of the SIP INFO message (i.e., not the SRS IP Group). The following shows an example of such a Message Manipulation rule:

- 'Name': SRS IP Group for Start SIPREC
- 'Manipulation Set ID': 0
- 'Message Type': **Info**
- 'Condition': **Header.X-AC-Action contains 'start-siprec'**
- 'Action Subject': **Header.X-AC-Action**
- 'Action Type': **Modify**
- 'Action Value': **'start-siprec;recording-ip-group="IPGroup\_2"'**

The manipulated parameters of the X-AC-Action header in the incoming INFO message are not reflected in the message of the outgoing leg.

- For stopping recordings, if the X-AC-Action header contains the **recording-ip-group** or **recording-ip-group-set** parameter, only recording towards the specified SRS IP Group(s) / IP Group Set(s) is stopped. If the header doesn't contain these parameters, all recordings that were triggered by INFO messages are stopped.
- The device rejects the INFO message (with a 500 response) if any of the following scenarios exist (**call is not affected**):
  - ✓ The **recording-ip-group** or **recording-ip-group-set** parameter doesn't exist.
  - ✓ The X-AC-Action header contains no parameters.
  - ✓ Starting, pausing, resuming, or stopping recording were not all triggered by SIP INFO messages (as described in this section). For example, if starting recording was triggered by the normal SIP Recording Rules table and stopping recording was triggered by a SIP INFO message containing the X-AC-Action header with the **stop-siprec** parameter, the device rejects the INFO message.
  - ✓ The X-AC-Action header contains the **stop-siprec**, **pause-siprec**, or **resume-siprec** parameter even though SIP recording wasn't started.
  - ✓ The X-AC-Action header contains the **resume-siprec** parameter even though SIP recording wasn't paused.
  - ✓ The X-AC-Action header contains the **start-siprec** parameter on a recorded-side while there is an active SIPREC session on the other side.
  - ✓ The X-AC-Action header contains the **recorded-side=peer** parameter when triggered to pause, resume or stop recording. In this scenario, the trigger (e.g., pause) is activated even though a SIP 500 is sent.
  - ✓ Six recording sessions are already in progress (maximum).
- The device forwards information in SIP INFO messages such as the transcript of the call from the SRS to the initiator of the on-demand SIPREC session.

## On-Demand SIPREC using SIP 200 OK Responses

The device supports on-demand SIPREC sessions that are triggered (started) by the receipt of SIP 200 OK responses. The 200 OK response must contain AudioCodes proprietary X-AC-Action header with the value 'start-siprec' to initiate recording.

Once the device is triggered by a 200 OK response to start a SIPREC session, it can then be triggered to pause, resume, or stop recording at any stage of the call by the receipt of SIP INFO messages. For more information, see [On-Demand SIPREC using SIP INFO Messages](#) on page 356.

- This feature applies only to SIP 200 OK messages received in response to **initial** SIP INVITE requests.
- This feature doesn't require any configuration in the SIP Recording Rules table.
- Upon the receipt of a SIP 200 OK response with the X-AC-Action header, the device doesn't trigger SIPREC in the following scenarios:
  - ✓ The X-AC-Action header doesn't contain any parameters.
  - ✓ The X-AC-Action header contains the 'start-siprec' parameter, but not the 'recording-ip-group' or 'recording-ip-group-set' parameter.
  - ✓ Six SIPREC sessions are currently active (maximum).
  - ✓ The X-AC-Action header contains the 'start-siprec' parameter on a recorded-side while there is an active SIPREC session on the other side.
- The feature is applicable only to the SBC application.

The X-AC-Action header in the incoming SIP 200 OK response can also indicate the IP Group representing the SIPREC Session Recording Server (SRS), and the leg of the call to record. This information is provided in the X-AC-Action header using the following parameters and syntax:

**X-AC-Action: start-siprec;<SRS Type>=<SRS Name>;recorded-side=peer;call-recording-dest-username=<User Part>**

where:

- **<SRS Type>** indicates if the SRS is an IP Group or IP Group Set:
  - **recording-ip-group** - SRS is defined by an IP Group(s). For configuring IP Groups, see [Configuring IP Groups](#) on page 591.
  - **recording-ip-group-set** - SRS is defined by an IP Group Set(s). For configuring IP Group Sets, see [Configuring IP Group Sets](#) on page 1223.
- **<SRS Name>** specifies the name or index number of the IP Group or IP Group Set. To specify multiple IP Groups or IP Group Sets, separate each with a comma (without spaces).
- **recorded-side=peer** is an optional parameter indicating that recording must be done on the peer side. If this parameter is absent, the device records the side that received the X-AC-Action header.
- **call-recording-dest-username** is an optional parameter, which defines the SIP user part of the Request-URI in the INVITE message (To header) that the sends to the SRS. The field can

contain up to 60 characters. If this field is present, its value overrides the 'Recording Server (SRS) Destination Username' parameter settings, as described in [Configuring SIP User Part for SRS](#) on page 363.

The following shows an example of an incoming SIP 200 OK response that triggers the device to start a SIPREC session for the call and uses IP Group "SIPREC SRS" as the SRS:

```
SIP/2.0 200 OK
Via: SIP/2.0/UDP 127.0.0.1;branch=z9hG4bKac1275750210
From: <sip:100@127.0.0.1;user=phone>;tag=1c232314132
To: <sip:200@127.0.0.1;user=phone>;tag=KQFIDPYDOBRHFIBVVBVE
Call-ID: 179268804129202415845@127.0.0.1CSeq: 1 INVITE
Contact: <sip:100@127.0.0.1>
X-AC-Action: start-siprec;recording-ip-group="SIPREC SRS";call-recording-
dest-username=username_abc
Supported: em,100rel,timer,replaces
Allow:
REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK,REFER,INFO,SUBSCRIBE
Server: Sip Message Generator V2.2.2.0
Content-Type: application/sdp
Content-Length: 214
```

- If a parameter's value contains one or more spaces (e.g., recording-ip-group="SIPREC SRS") or the parameter has multiple values, which must be separated by commas (e.g., recording-ip-group="SRS-SiteA,SRS-SiteB"), you must enclose the value in double quotation marks ("...").
- If you want to record calls whose incoming SIP 200 OK responses lack the 'X-AC-Action: start-siprec' header, use SIP Message Manipulation rules to add the header.

If the X-AC-Action header contains only **start-siprec**, use the device's Message Manipulation feature (see [Configuring SIP Message Manipulation](#) on page 856) to add the parameters 'recording-ip-group' and optionally, 'recorded-side=peer'. The following shows an example of a Message Manipulation rule that indicates the use of a specific IP Group:

- 'Name': SRS for Start SIPREC by 200 OK
- 'Manipulation Set ID': 0
- 'Message Type': **Message.Response.200**
- 'Condition': **Header.X-AC-Action contains 'start-siprec'**
- 'Action Subject': **Header.X-AC-Action**
- 'Action Type': **Modify**
- 'Action Value': **'start-siprec;recording-ip-group="SIPREC SRS"'**

Once configured, assign the Manipulation Set ID to the IP Group that sends the SIP 200 OK responses (i.e., not IP Group of SRS).

- The manipulated parameters of the X-AC-Action header in the incoming 200 OK response are not reflected in the message of the outgoing leg.
- If you want to record calls whose incoming SIP 200 OK responses lack the 'X-AC-Action: start-siprec' header, you can also use SIP Message Manipulation rules to add the header.

### On-Demand SIPREC using REST

The device supports on-demand SIPREC sessions that are triggered through the device's REST API (in HTTP POST requests) at the REST URL <device's IP address>/api/v1/sip/sipRecording. This method can trigger the device to start or stop recording a call (beginning of the call or during the call).

The incoming REST message for triggering SIPREC includes the following fields:

- **command:** (Mandatory) This field tells the device to start ("start") or stop ("stop") recording.
- **callKey:** (Mandatory) This field contains a "Call Key" value that the device uses to determine which call to record. This is required because REST messages are sent out of call context (i.e., not in SIP messages).

To associate a "Call Key" value with incoming calls belonging to a specific IP Group for which you want to record (according to the rules in the SIP Recording Rules table), you need to use SIP message manipulation to obtain this value from some element in the incoming SIP INVITE message (for example, from a specific header). The "Call Key" is specified in message manipulation using the syntax variable *Param.Call.HashKey* or *Param.Peer-Call.HashKey* in the 'Action Subject' parameter. If the device receives a REST request whose "CallKey" field contains the same value as the "Call Key" value obtained by message manipulation, then the device records this call.

The usage of the syntax variable *Param.Call.HashKey* and *Param.Peer-Call.HashKey* in message manipulation rules depends on the following:

- If the rule is assigned using the 'Inbound Message Manipulation Set' parameter for the source IP Group:
  - ◆ *Param.Call.HashKey* represents the incoming call leg.
  - ◆ *Param.Peer-Call.HashKey* represents the outgoing call leg.
- If the rule is assigned using the 'Outbound Message Manipulation Set' parameter for the destination IP Group:
  - ◆ *Param.Call.HashKey* represents the outgoing call leg.
  - ◆ *Param.Peer-Call.HashKey* represents the incoming call leg.

Such rules are used internally **only** by the device (to store the "Call Key" value) and don't modify the outgoing INVITE message.

- **role:** (Optional) This field is used by the device as an additional condition in the SIP Recording Rules table ('Recording Server Role' parameter) for finding a matching rule. If the value of this field is the same as that configured in the SIP Recording Rules table, the device uses the rule. The field can contain up to 20 characters.
- **callRecordingDestUsername:** (Optional) This field defines the SIP user part of the Request-URI in the INVITE message (To header) that the device sends to the SRS. The field can contain up to 60 characters. If this field is present, its value overrides the 'Recording Server (SRS) Destination Username' parameter settings, as described in [Configuring SIP User Part for SRS](#) on the next page.
- **headers:** (Optional and applicable only to Command: "start") This is an array of objects that defines up to 10 additional headers (**name** field) and their values (**value** field) to include in the SIP INVITE message that the device sends to the SRS.

When the REST request contains the "Command: stop":

- If it also contains **only** the "callKey" field, the device stops the recording of all REST-triggered SIPREC sessions that have the same call key value and that don't have a role defined for them.
- If it also contains the "callKey" and "role: <a value>" fields, the device stops the recording of all REST-triggered SIPREC sessions that have the same call key value and whose rule in the SIP Recording Rules table was matched by the same role value ('Recording Server Role' parameter).
- If it also contains **only** the "callKey" and "callRecordingDestUsername" fields, the device stops the recording of all REST-triggered SIPREC sessions that have the same call key value, had an empty "role" field, and used the same destination username as specified by "callRecordingDestUsername".
- If it also contains the "callKey" and "role: <a value>", and "callRecordingDestUsername", the device stops the recording of all REST-triggered SIPREC sessions that have the same call key value, had the same "role" value, and same destination username as specified by "callRecordingDestUsername".

The following are examples of REST requests for triggering SIPREC:

- REST request to start recording, containing only mandatory fields:

```
{
  "command": "start"
  "callKey": "aaa",
}
```

- REST request to start recording, containing all fields:

```
{
  "command": "start",
  "callKey": "aaa",
  "role": "agent_assist",
  "callRecordingDestUsername": "username_abc",
  "headers": [
    {
      "name": "x1-header",
      "value": "x1-header_value"},
    {
      "name": "x2-header",
      "value": "x2-header_value"
    }
  ]
}
```

➤ **To configure SIPREC triggered by REST:**

1. Open the SIP Recording Rules table (see [Configuring SIP Recording Rules](#) on page 349), and then add a rule that is also configured with the following parameters:
  - 'Trigger' = **REST**
  - (Optional) 'Recording Server Role' = <same value as will be in the "role" field of REST requests>
2. Configure SIP message manipulation rule to obtain the "Call Key" value, using the syntax *Param.Call.HashKey* or *Param.Peer-Call.HashKey*. For example, the following rule in the Message Manipulations table obtains the call key value from the SIP header "X-ConversationId":

The screenshot shows the 'Message Manipulations' configuration window. It is divided into two main sections: 'GENERAL' and 'ACTION'.

**GENERAL Section:**

- Index: 0
- Name: SIPREC: CallKey
- Manipulation Set ID: 0
- Row Role: Use Current Condition

**MATCH Section:**

- Message Type: Invite Request
- Condition: Header:X-ConversationId exists

**ACTION Section:**

- Action Subject: Param.Call.HashKey
- Action Type: Modify
- Action Value: Header:X-ConversationId

3. Assign the Message Manipulation rule (Set ID) to the IP Group (see beginning of this section regarding inbound and outbound manipulation).

## Configuring SIP User Part for SRS

You can configure the SIP user part of the Request-URI for the recording server (SRS). The device inserts this user part in the SIP To header of the INVITE message sent to the SRS.

➤ **To configure the SIP user part for SRS:**

1. Open the SIP Recording Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Recording** folder > **SIP Recording Settings**).
2. In the 'Recording Server (SRS) Destination Username' field, enter a user part value (string of up to 50 characters).

Recording Server (SRS) Destination Username

3. Click **Apply**.

When SIPREC is triggered by REST, the incoming REST message may also specify the user part name. If this occurs, the above 'Recording Server (SRS) Destination Username' parameter is ignored. For more information on REST-triggered SIPREC, see [On-Demand SIPREC using REST](#) on page 361.

## **Sending DTMF Digits Notifications using SIP INFO Messages to SRS**

You can configure the device to send DTMF digits notifications to the SIPREC SRS. These notifications are sent using SIP INFO messages. On the incoming leg (caller), all DTMF formats (i.e., RFC 2833, INFO, or in-band) are supported; on the outgoing leg (callee), only DTMF digits from SIP INFO messages are supported.

For example (assuming "A" is the caller):

- "A" sends DTMF (any format): The device sends an INFO message to the SRS and to "B" (which must support sending and receiving INFO messages).
- "B" sends DTMF in INFO message: The device forwards the INFO message to the SRS and sends the DTMF to "A" in the required format.

➤ **To send SIP INFO messages with DTMF to SRS:**

1. Open the SIP Recording Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Recording** folder > **SIP Recording Settings**).
2. From the 'Forward Signaling to SIPREC' drop-down list, select **DTMF SIP INFO**:

Forward Signaling to SIPREC

DTMF SIP INFO

3. Click **Apply**.

- The device adds the Remote-Party-ID header to the SIP INFO message that is sent to the SRS. The header's value is the URI of the sender of the DTMF digits.
- This feature is applicable only to the SBC application.

## Interworking SIP-based Media Recording with Third-Party Vendors

The device can interwork the SIP-based Media Recording feature with third-party vendors, as described in the following subsections.

### SIPREC with Genesys Equipment

The device's SIP-based media recording can interwork with Genesys' equipment. Genesys sends its proprietary X-Genesys-CallUUID header (which identifies the session) in the first SIP message, typically in the INVITE and the first 18x response. If the device receives a SIP message with Genesys SIP header, it adds the header's information to the AudioCodes' proprietary tag in the XML metadata of the SIP INVITE that it sends to the recording server, as shown below:

```
<ac:GenesysUUID  
xmlns="urn:ietf:params:xml:ns:Genesys">4BOKLLA3VH66JF112M1CC9VHKS14  
F0KP</ac:GenesysUUID>
```

No configuration is required for this support.

### SIPREC with Avaya Equipment

The device's SIP-based media recording can interwork with Avaya equipment. The Universal Call Identifier (UCID) is Avaya's proprietary call identifier used to correlate call records between different systems and identifies sessions. Avaya generates this in outgoing calls. If the device receives a SIP INVITE from Avaya, it adds the UCID value, received in the User-to-User SIP header to the AudioCodes proprietary tag in the XML metadata of the SIP INVITE that it sends to the recording server. For example, if the received SIP header is:

```
User-to-User: 00FA080019001038F725B3;encoding=hex
```

the device includes the following in the XML metadata:

```
xml metadata:  
<ac:AvayaUCID xmlns="urn:ietf:params:xml:ns:Avaya">  
FA080019001038F725B3</ac:AvayaUCID>
```

For calls sent from the device to Avaya equipment, the device can generate the Avaya UCID, if required. To configure this support, use the following parameters:

- 'UUI Format' in the IP Groups table - enables Avaya support.
- 'Network Node ID' - defines the Network Node Identifier of the device for Avaya UCID.

## Customizing Recorded SIP Messages Sent to SRS

The original SIP headers of recorded legs are not included in the INVITE messages that the device sends to the SRS. If you need to include SIP headers, you can use Message Manipulation rules (see [Configuring SIP Message Manipulation](#) on page 856) to add them to these INVITE messages. The following examples describe how to configure this using Message Manipulation rules:

- **Example 1** - Adding a specific SIP header called "My-header" to the INVITE that is sent to the SRS:
  - a. The example uses two Message Manipulation rules - one for storing the header by using manipulation syntax for session variables, and one for adding the header to the INVITE.

Parameter	Value
Index	0
Name	Store My-header in var.session
Manipulation Set ID	11
Message Type	Any
Condition	Header.My-header exists And Header.My-header != "
Action Subject	Var.Session.0
Action Type	Modify
Action Value	Header.My-header
Index	1
Name	Send My-header to SRS
Manipulation Set ID	12
Message Type	Invite.Request
Condition	Var.Session.0 != "
Action Subject	Header.My-header
Action Type	Add
Action Value	Var.Session.0

- b. Assign the above manipulation rules to the relevant IP Groups:

- ◆ In the IP Group of the recorded call leg which sends this header, configure the 'Inbound Message Manipulation Set' parameter to 11 (i.e., rule configured in Index 0).
- ◆ In the IP Group of the SRS, configure the 'Outbound Message Manipulation Set' parameter to 12 (i.e., rule configured in Index 1).

■ **Example 2** - Adding multiple (three) SIP headers called "My-header1", "My-header2" and "My-header3" to the INVITE that is sent to the SRS:

- a. The example uses regex (regular expression) with manipulation rules for extracting each header (a comma is used to separate headers).

Parameter	Value
Index	0
Name	Store headers in var.session
Manipulation Set ID	11
Message Type	Any
Condition	Header.My-header1 exists And Header.My-header2 exists And Header.My-header3 exists
Action Subject	Var.Session.0
Action Type	Modify
Action Value	Header.My-header1+', '+ Header.My-header2+', '+ Header.My-header3
Row Rule	Use Current Condition
Index	1
Name	Send My-header1 to SRS
Manipulation Set ID	12
Message Type	Invite.Request
Condition	Var.Session.0 regex (.*),(.*),(.*)
Action Subject	Header.My-header1
Action Type	Add
Action Value	\$1

Parameter	Value
Row Rule	Use Current Condition
Index	2
Name	Send My-header2 to SRS
Manipulation Set ID	12
Message Type	Invite.Request
Condition	Var.Session.0 regex (.*),(.*),(.*)
Action Subject	Header.My-header2
Action Type	Add
Action Value	\$2
Row Rule	Use Previous Condition
Index	3
Name	Send My-header3 to SRS
Manipulation Set ID	12
Message Type	Invite.Request
Condition	Var.Session.0 regex (.*),(.*),(.*)
Action Subject	Header.My-header3
Action Type	Add
Action Value	\$3
Row Rule	Use Previous Condition

**b.** Assign the above manipulation rules to the relevant IP Groups:

- ◆ In the IP Group of the recorded call leg which sends this header, configure the 'Inbound Message Manipulation Set' parameter to 11 (i.e., rule configured in Index 0).
- ◆ In the IP Group of the SRS, configure the 'Outbound Message Manipulation Set' parameter to 12 (i.e., rules configured in Index 1, 2 and 3).

## RADIUS-based Services

The device supports Remote Authentication Dial In User Service (RADIUS) by acting as a RADIUS client. You can use RADIUS for the following:

- Authentication and authorization of management users (login username and password) to gain access to the device's management interface.
- Accounting where the device sends accounting data of SIP calls as call detail records (CDR) to a RADIUS Accounting server (for third-party billing purposes).

The device also supports the following user login authentication methods:

- LDAP-based authentication (see [LDAP-based Services](#) on page 378)
- OAuth-based authentication (see [OAuth-based User Login Authentication and Authorization](#) on page 417)

## Enabling RADIUS Services

Before you can implement any RADIUS services, you must enable the RADIUS feature, as described in the procedure below.

### ➤ To enable RADIUS:

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).
2. Select the 'Enable RADIUS Access Control' check box:

Enable RADIUS Access Control

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Configuring RADIUS Servers

The RADIUS Servers table lets you configure up to three RADIUS servers. You can use RADIUS servers for RADIUS-based management-user login authentication and/or RADIUS-based accounting (sending of SIP CDRs to the RADIUS server).

When multiple RADIUS servers are configured, RADIUS server redundancy can be implemented. When the primary RADIUS server is offline, the device sends a RADIUS request twice (one retransmission) by default. If both requests fail (i.e., no response), the device considers the server as offline and attempts to send requests to the next server. The device continues sending RADIUS requests to the redundant RADIUS server even if the primary server returns to service later on. However, if a device restart occurs or an HA switchover occurs in a High-Availability (HA) system, the device sends RADIUS requests to the primary RADIUS server. By default, the device waits for up to two seconds (i.e., timeout) for a response from the RADIUS server for RADIUS requests and retransmission before it considers the server as offline.

You can configure the number of retransmission attempts with the RADIUS server before the device considers it as offline. For more information, see [Configuring RADIUS Packet Retransmission](#) on page 373.

For each RADIUS server, an IP address, IP Interface, port, and shared secret can be configured. Each RADIUS server can be defined for RADIUS-based login authentication and/or RADIUS-based accounting. By setting the relevant port (authentication or accounting) to "0" disables the corresponding functionality. If both ports are configured, the RADIUS server is used for authentication and accounting. All servers configured with non-zero Authorization ports form an Authorization redundancy group and the device sends authorization requests to one of them, depending on their availability. All servers configured with non-zero Accounting ports form an Accounting redundancy group and the device sends accounting CDRs to one of them, depending on their availability. Below are example configurations:

- Only one RADIUS server is configured and used for authorization and accounting purposes (no redundancy). Therefore, both the Authorization and Accounting ports are defined.
- Three RADIUS servers are configured:
  - Two servers are used for authorization purposes only, providing redundancy. Therefore, only the Authorization ports are defined, while the Accounting ports are set to 0.
  - One server is used for accounting purposes only (i.e., no redundancy). Therefore, only the Accounting port is defined, while the Authorization port is set to 0.
- Two RADIUS servers are configured and used for authorization and accounting purposes, providing redundancy. Therefore, both the Authorization and Accounting ports are defined.

The status of the RADIUS servers can be viewed through CLI:

```
# show system radius servers status
```

The example below shows the status of two RADIUS servers in redundancy mode for authorization and accounting:

```
servers 0
ip-address 10.4.4.203
auth-port 1812
auth-ha-state "ACTIVE"
acc-port 1813
acc-ha-state "ACTIVE"
servers 1
ip-address 10.4.4.202
auth-port 1812
auth-ha-state "STANDBY"
acc-port 1813
acc-ha-state "STANDBY"
```

Where *auth-ha-state* and *acc-ha-state* display the authentication and accounting redundancy status respectively. "ACTIVE" means that the server was used for the last sent authentication or accounting request; "STANDBY" means that the server was not used in the last sent request.

- To configure RADIUS-based accounting, see [Configuring RADIUS Accounting](#) on page 1588.
- The device can send up to 201 concurrent RADIUS requests per RADIUS service type (Accounting or Authentication), per RADIUS server (up to three servers per service type), and per local port (up to 1 local port).

The following procedure describes how to configure a RADIUS server through the Web interface. You can also configure it through ini file [RadiusServers] or CLI (`configure system > radius servers`).

➤ **To configure a RADIUS server:**

1. Open the RADIUS Servers table (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **RADIUS Servers**).
2. Click **New**; the following dialog box appears:

3. Configure a RADIUS server according to the parameters described in the table below.
4. Click **Apply**.

**Table 16-7: RADIUS Servers Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'IP Address' ip-address [IPAddress]	Defines the IP address (IPv4 or IPv6) of the RADIUS server. By default, no value is defined (i.e., 0.0.0.0). <b>Note:</b> The IP address version (IPv4 or IPv6) of the

Parameter	Description
	RADIUS server's address and the assigned IP Interface (see 'Interface Name' parameter) must be the same.
'Authentication Port' auth-port [AuthenticationPort]	<p>Defines the port of the RADIUS Authentication server for authenticating the device with the RADIUS server. When set to any value other than 0, the RADIUS server is used by the device for RADIUS-based management-user login authentication. When set to 0, RADIUS-based login authentication is not implemented.</p> <p>The valid value is 0 to any integer. The default is 1645.</p>
'Accounting Port' acc-port [AccountingPort]	<p>Defines the port of the RADIUS Accounting server to where the device sends accounting data of SIP calls as call detail records (CDR). When set to any value other than 0, the RADIUS server is used by the device for RADIUS-based accounting (CDR). When set to 0, RADIUS-based accounting is not implemented.</p> <p>The valid value is 0 to any integer. The default is 1646.</p>
'Shared Secret' shared-secret [SharedSecret]	<p>Defines the shared secret (password) for authenticating the device with the RADIUS server. This should be a cryptically strong password. The shared secret is also used by the RADIUS server to verify the authentication of the RADIUS messages sent by the device (i.e., message integrity).</p> <p>The valid value is up to 48 characters. By default, no value is defined.</p> <p><b>Note:</b> The password cannot be configured with wide characters.</p>
'Interface Name' network-interface [InterfaceName]	<p>Assigns an IP Interface from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for RADIUS communication.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The IP address version (IPv4 or IPv6) of the IP Interface and the RADIUS server's address (see 'IP Address' parameter above) must be the same.</p>

## Configuring RADIUS Packet Retransmission

You can configure the device to resend packets to the RADIUS server if no response is received from the server. This functionality is applicable to RADIUS-based user authentication and RADIUS-based accounting.

### ➤ To configure RADIUS packet retransmission:

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).

RADIUS Response Timeout [sec]	<input type="text" value="2"/>
RADIUS Packets Retransmission	<input type="text" value="1"/>

2. Under the RADIUS group, do the following:
  - In the 'RADIUS Packets Retransmission' field (RADIUSRetransmission), enter the maximum number of RADIUS retransmissions that the device performs if no response is received from the RADIUS server.
  - In the 'RADIUS Response Time Out' field (RadiusTO), enter the interval (in seconds) that the device waits for a response before sending a RADIUS retransmission.
3. Click **Apply**.

## Configuring the RADIUS Vendor ID

The vendor-specific attribute (VSA) identifies the device to the RADIUS server using the Vendor ID (as registered with the Internet Assigned Numbers Authority or IANA). The device's default vendor ID is 5003 which can be changed, as described in the following procedure. For an example of using the Vendor ID, see [Setting Up a Third-Party RADIUS Server](#) on page 375. The procedure is applicable to both RADIUS-based user authentication and RADIUS-based accounting.

The Vendor ID must be the same as the Vendor ID set on the third-party RADIUS server. See the example for setting up a third-party RADIUS server in [Setting Up a Third-Party RADIUS Server](#) on page 375.

### ➤ To configure the RADIUS Vendor ID:

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).

RADIUS VSA Vendor ID	<input type="text" value="5003"/>
----------------------	-----------------------------------

2. Under the RADIUS group, in the 'RADIUS VSA Vendor ID' field, enter the **same** vendor ID number as set on the third-party RADIUS server.

3. Click **Apply**.

## Securing RADIUS Messages with Message-Authenticator Attribute

For RADIUS-based user authentication, you can configure the device to secure RADIUS messages, using RADIUS attribute 80 (Message-Authenticator). This attribute ensures the integrity of RADIUS packets, safeguarding against unauthorized access (login) to the device (e.g., "man-in-the-middle" attacks).

You can configure this feature for incoming and outgoing RADIUS messages:

- **Outgoing RADIUS Messages:** You can enable the device (acting as a Network Access Server / NAS or RADIUS client) to include the Message-Authenticator attribute in all Access-Request RADIUS packets that it sends to the RADIUS server. This is applicable only to the Password Authentication Protocol (PAP) user authentication method. To enable this functionality, use the ini file parameter [RadiusPapRequireMsgAuthTx] or CLI command `rad-pap-req-msg-auth-tx`.

For RADIUS-based SIP message authentication, this parameter is not needed as it uses the digest protocol, which inherently includes the Message-Authenticator attribute.

- **Incoming RADIUS Messages:** You can enable the device to require the presence of the Message-Authenticator attribute in incoming Accept-Accept RADIUS messages received from the RADIUS server. If the attribute is not present, the device rejects the message and denies user login. This functionality is applicable to Digest or PAP authentication methods. To enable this functionality, use the ini file parameter [RadiusRequireMsgAuthRx] or CLI command `rad-req-msg-auth-rx`.

## RADIUS-based User Login Authentication

You can enhance security for your device by implementing Remote Authentication Dial-In User Service (RADIUS per RFCs 2865) for authenticating multiple management user accounts of the device's embedded Web and Telnet (CLI) servers. RADIUS also prevents unauthorized access to your device.

When RADIUS authentication is not used, the user's login username and password are locally authenticated by the device using the Local Users table (see [Configuring Local Management User Accounts](#) on page 55). However, you can configure the device to use the Local Users table as a fallback mechanism if the RADIUS server doesn't respond.

Both RADIUS and LDAP (see [Enabling LDAP-based User Login Authentication](#) on page 381) based login methods can't be used together; configure only one of them as the login method.

If you enable RADIUS-based user login authentication, when users with Security Administrator privilege level log in to the device's CLI, they are automatically given access to the CLI privileged mode (“#”). For all other user privilege levels, the user needs to run the **enable** command and then enter the password to access the CLI privileged mode.

When RADIUS authentication is used, the RADIUS server stores the user accounts - usernames, passwords, and access levels (authorization). When a management user (client) tries to access the device, the device sends the RADIUS server the user's username and password for authentication. The RADIUS server replies with an acceptance or a rejection notification. During the RADIUS authentication process, the device's Web interface is blocked until an acceptance response is received from the RADIUS server. Communication between the device and the RADIUS server is done using a shared secret, which is not transmitted over the network.

To implement RADIUS, you need to do the following:

- Set up a RADIUS server (third-party) to communicate with the device - see [Setting Up a Third-Party RADIUS Server](#) below
- Configure the device as a RADIUS client for communication with the RADIUS server - see [Configuring RADIUS-based User Authentication](#) on page 377

### Setting Up a Third-Party RADIUS Server

The following procedure provides an example for setting up a third-party RADIUS sever, *FreeRADIUS* which can be downloaded from [www.freeradius.org](http://www.freeradius.org). Follow the instructions on this Web site for installing and configuring the server. If you use a RADIUS server from a different vendor, refer to its appropriate documentation.

#### ➤ To set up a third-party RADIUS server (e.g., *FreeRADIUS*):

1. Define the device as an authorized client of the RADIUS server, with the following:

- Predefined *shared secret* (password used to secure communication between the device and the RADIUS server)
- Vendor ID (configured on the device in [Configuring the RADIUS Vendor ID](#) on page 373)

Below is an example of the *clients.conf* file (FreeRADIUS client configuration):

```
#
# clients.conf - client configuration directives
#
client 10.31.4.47 {
    secret      = FutureRADIUS
    shortname    = my_device
}
```

2. If access levels are required, set up a Vendor-Specific Attributes (VSA) dictionary for the RADIUS server and select an attribute ID that represents each user's access level. The example below shows a dictionary file for FreeRADIUS that defines the attribute "ACL-Auth-Level" with "ID=35". For the device's user access levels and their corresponding numeric representation in RADIUS servers, see [Configuring Local Management User Accounts](#) on page 55.

```
#
# AudioCodes VSA dictionary
#
VENDOR AudioCodes 5003
ATTRIBUTE ACL-Auth-Level 35 integer AudioCodes
VALUE ACL-Auth-Level ACL-Auth-UserLevel 50
VALUE ACL-Auth-Level ACL-Auth-AdminLevel 100
VALUE ACL-Auth-Level ACL-Auth-SecurityAdminLevel 200
```

3. Define the list of users authorized to use the device, using one of the password authentication methods supported by the server implementation. The example below shows a user configuration file for FreeRADIUS using a plain-text password:

```
# users - local user configuration database
john  Auth-Type := Local, User-Password == "qwerty"
      Service-Type = Login-User,
      ACL-Auth-Level = ACL-Auth-SecurityAdminLevel
sue   Auth-Type := Local, User-Password == "123456"
      Service-Type = Login-User,
      ACL-Auth-Level = ACL-Auth-UserLevel
```

4. Record and retain the IP address, port number, shared secret code, vendor ID, and VSA access level identifier (if access levels are implemented) used by the RADIUS server.

## Configuring RADIUS-based User Authentication

The following procedure describes how to configure RADIUS-based login authentication. For a detailed description of the RADIUS parameters, see [RADIUS Parameters](#) on page 2142.

➤ **To configure RADIUS-based login authentication:**

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).
2. From the 'Use RADIUS for Web/Telnet Login' drop-down list, select **Enable** to enable RADIUS authentication for Web and Telnet login:
3. When implementing Web user access levels, do one of the following:
  - **If the RADIUS server response includes the access level attribute:** In the 'RADIUS VSA Access Level Attribute' field, enter the code that indicates the access level attribute in the VSA section of the received RADIUS packet. For defining the RADIUS server with access levels, see [Setting Up a Third-Party RADIUS Server](#) on page 375.

RADIUS VSA Access Level Attribute

35

- **If the RADIUS server response doesn't include the access level attribute:** From the 'Default Access Level' drop-down list, select the default access level that is applied to these users authenticated by the RADIUS server.

Default Access Level

Security Administrator

4. Configure RADIUS timeout handling:
  - a. From the 'Behavior upon Authentication Server Timeout' drop-down list, select the option if the RADIUS server doesn't respond within five seconds:
    - ◆ **Deny Access:** device denies user login access.
    - ◆ **Verify Access Locally:** device checks the username and password configured locally for the user in the Local Users table (see [Configuring Local Management User Accounts](#) on page 55), and if correct, allows access.
  - b. In the 'Password Local Cache Timeout' field, enter a time limit (in seconds) after which the username and password verified by the RADIUS server becomes invalid and a username and password needs to be re-validated with the RADIUS server.
  - c. From the 'Password Local Cache Mode' drop-down list, select the option for the local RADIUS password cache timer:
    - ◆ **Reset Timer Upon Access:** upon each access to a Web page, the timer resets (reverts to the initial value configured in the previous step).

- ◆ **Absolute Expiry Timer:** when you access a Web page, the timer doesn't reset, but continues its count down.

5. Configure when the Local Users table is used to authenticate users. From the 'Use Local Users Table for Authentication' drop-down list, select one of the options (for a description, see ['Use Local Users Table for Authentication'](#) on page 2140):

Use Local Users Table for Authentication

When No Auth Server Defined ▼

6. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Securing RADIUS Communication

RADIUS authentication requires HTTP basic authentication (according to RFC 2617). However, this is insecure as the usernames and passwords are transmitted in clear text over plain HTTP. Thus, as digest authentication is not supported with RADIUS, it is recommended that you use HTTPS with RADIUS so that the usernames and passwords are encrypted. To enable the device to use HTTPS, configure the 'Secured Web Connection (HTTPS)' parameter to **HTTPS Only** (see [Configuring Secured \(HTTPS\) Web and REST Access](#) on page 75).

## RADIUS-based User Authentication in URL

RADIUS authentication of the management user is typically done after the user accesses the Web interface by entering only the device's IP address in the Web browser's URL field (for example, <http://10.13.4.12/>) and then entering the username and password credentials in the Web interface's login screen. However, authentication with the RADIUS server can also be done immediately after the user enters the URL, if the URL also contains the login credentials. For example:

<http://10.4.4.112/Form-s/RadiusAuthentication?WSBackUserName=John&WSBackPassword=1234>.

This feature allows up to five simultaneous users only.

## RADIUS-based CDR Accounting

Once you have configured a RADIUS server(s) for accounting in [Configuring RADIUS Servers](#) on page 369, you need to enable and configure RADIUS-based CDR accounting (see [Configuring RADIUS Accounting](#) on page 1588).

## LDAP-based Services

The device supports the Lightweight Directory Access Protocol (LDAP) application protocol and can operate with third-party, LDAP-compliant servers such as Microsoft Active Directory (AD).

You can use LDAP for the following LDAP services:

- **SIP-related (Control) LDAP Queries:** LDAP can be used for routing and manipulation (e.g., calling name and destination address).

The device connects and binds to the remote LDAP server (IP address or DNS/FQDN) during the service's initialization (at device start-up) or whenever you change the LDAP server's IP address and port. Binding to the LDAP server is based on username and password (Bind DN and Password). Service makes 10 attempts to connect and bind to the remote LDAP server, with a timeout of 20 seconds between attempts. If connection fails, the service remains in disconnected state until the LDAP server's IP address or port is changed. If connection to the LDAP server later fails, the service attempts to reconnect.

For the device to run a search, the path to the directory's subtree, known as the distinguished name (DN), where the search is to be done must be configured (see [Configuring LDAP DNs \(Base Paths\) per LDAP Server](#) on page 392). The search key (filter), which defines the exact DN to search and one or more attributes whose values must be returned to the device must also be configured. For more information on configuring these attributes and search filters, see [Routing for Microsoft Teams or Skype for Business using Microsoft Entra ID](#) on page 406.

The device can store recent LDAP queries and responses in its local cache. The cache is used for subsequent queries and/or in case of LDAP server failure. For more information, see [Configuring the Device's LDAP Cache](#) on page 396.

If connection with the LDAP server disconnects (broken), the device sends the SNMP alarm, `acLDAPLostConnection`. Upon successful reconnection, the alarm clears. If connection with the LDAP server is disrupted during the search, all search requests are dropped and an alarm indicating a failed status is sent to client applications.

- **Management-related LDAP Queries:** LDAP can be used for authenticating and authorizing management users (Web and CLI) and is based on the user's login username and password (credentials) when attempting login to one of the device's management platforms. When configuring the login username (LDAP Bind DN) and password (LDAP Password) to send to the LDAP server, you can use templates based on the dollar (\$) sign, which the device replaces with the actual username and password entered by the user during the login attempt. You can also configure the device to send the username and password in clear-text format or encrypted using TLS (SSL).

The device connects to the LDAP server (i.e., an LDAP session is created) only when a login attempt occurs. The LDAP Bind operation establishes the authentication of the user based on the username-password combination. The server typically checks the password against the `userPassword` attribute in the named entry. A successful Bind operation indicates that the username-password combination is correct; a failed Bind operation indicates that the username-password combination is incorrect.

Once the user is successfully authenticated, the established LDAP session may be used for further LDAP queries to determine the user's management access level and privileges (Operator, Admin, or Security Admin). This is known as the user authorization stage. To determine the access level, the device searches the LDAP directory for groups of which the user is a member, for example:

```
CN=\# Support Dept,OU=R&D
Groups,OU=Groups,OU=APC,OU=Japan,OU=ABC,DC=corp,DC=abc,DC=com
CN=\#AllCellular,OU=Groups,OU=APC,OU=Japan,OU=ABC,DC=corp,DC=abc,DC=com
```

The device then assigns the user the access level configured for that group (in [Configuring Access Level per Management Groups Attributes](#) on page 394). The location in the directory where you want to search for the user's member group(s) is configured using the following:

- Search base object (distinguished name or DN, e.g., "ou=ABC,dc=corp,dc=abc,dc=com"), which defines the location in the directory from where the LDAP search begins and is configured in [Configuring LDAP DN's \(Base Paths\) per LDAP Server](#) on page 392.
- Search filter, for example, (&(objectClass=person)(sAMAccountName=JohnD)), which filters the search in the subtree to include only the specific username. The search filter can be configured with the dollar (\$) sign to represent the username, for example, (sAMAccountName=\$). To configure the search filter, see [Configuring the LDAP Search Filter Attribute](#) on page 393.
- Management attribute (e.g., memberOf), from where objects that match the search filter criteria are returned. This shows the user's member groups. The attribute is configured in the LDAP Servers table (see [Configuring LDAP Servers](#) on page 385).

If the device finds a group, it assigns the user the corresponding access level and permits login; otherwise, login is denied. Once the LDAP response has been received (success or failure), the device ends the LDAP session.

■ **LDAP-based Management services:** This LDAP service works together with the LDAP-based management account (described above), allowing you to use different LDAP service accounts for user authentication and user authorization:

- **Management-type LDAP server:** This LDAP server account is used only for user authentication. For more information about how it works, see Management-related LDAP Queries, above.
- **Management Service-type LDAP server:** This LDAP server account is used only for user authorization (i.e., the user's management access level and privileges). The device has an always-on connection with the LDAP server and uses a configured (fixed) LDAP username (Bind Name) and password. Only if user authentication succeeds, does the device query this **Management Service-type** LDAP server account for user authorization. Thus, management groups and DN's are configured only for this LDAP server account (instead of for the regular LDAP-based management account).

Therefore, user authorization is done only by a specific LDAP "administrator", which has a fixed username and password. In contrast, user authentication is done by the user itself (i.e., binding to the LDAP account with each user's username and password). Having a

dedicated LDAP account for user authorization may provide additional security to the network by preventing users from accessing the authorization settings in the LDAP server.

The device also supports the following user login authentication methods:

- RADIUS-based authentication (see [RADIUS-based User Login Authentication](#) on page 374)
- OAuth-based authentication (see [OAuth-based User Login Authentication and Authorization](#) on page 417)

For all the previously discussed LDAP services, the following additional LDAP functionality is supported:

- Search method for searching DN object records between LDAP servers and within each LDAP server (see [Configuring LDAP Search Methods](#)).
- Default access level that is assigned to the user if the queried response doesn't contain an access level.
- Local Users table for authenticating users instead of the LDAP server (for example, when a communication problem occurs with the server). For more information, see [Configuring Fallback Options to Local Users Table](#) on page 400.

## Enabling the LDAP Service

Before you can configure LDAP support, you need to enable the LDAP service.

### ➤ To enable LDAP:

1. Open the LDAP Settings page (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Settings**).
2. Select the 'LDAP Service' check box:

LDAP service

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Enabling LDAP-based User Login Authentication

The LDAP service can be used for authenticating and authorizing device management users (Web and CLI) based on the user's login username and password (credentials). At the same, it can also be used to determine users' management access levels (privileges). Before you can configure LDAP-based login authentication, you must enable this type of LDAP service.

Both LDAP and RADIUS (see [RADIUS-based User Login Authentication](#) on page 374) based login methods can't be used together; configure only one of them as the login method.

If you enable LDAP-based user login authentication, when users with Security Administrator privilege level log in to the device's CLI, they are automatically given access to the CLI privileged mode (“#”). For all other user privilege levels, the user needs to run the **enable** command and then enter the password to access the CLI privileged mode.

➤ **To enable LDAP-based login authentication:**

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).
2. Select the 'Use LDAP for Web/Telnet Login' check box:

Use LDAP for Web/Telnet Login

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Configuring LDAP Server Groups

The LDAP Server Groups table lets you configure up to 41 LDAP Server Groups. An LDAP Server Group is a logical configuration entity that contains up to two LDAP servers. LDAP servers are assigned to LDAP Server Groups in the LDAP Servers table (see [Configuring LDAP Servers](#) on page 385). To use a configured LDAP server, you must assign it to an LDAP Server Group.

You can configure the following types of LDAP Server Groups (configured by the 'Type' parameter described below):

- **Control:** To use an LDAP server for call routing, you need to configure the LDAP Server Group as a **Control** type, and then assign the LDAP Server Group to a Routing Policy. The Routing Policy in turn needs to be assigned to the relevant routing rule(s). You can assign a Routing Policy to only one LDAP Server Group. Therefore, for multi-tenant deployments where multiple Routing Policies are employed, each tenant can be assigned a specific LDAP Server Group through its unique Routing Policy.
- **Management:** To use an LDAP server for management where it does user login authentication and user authorization, you need to configure the LDAP Server Group as a **Management** type. Additional LDAP-based management parameters need to be configured, as described in [Enabling LDAP-based User Login Authentication](#) on the previous page and [Configuring LDAP Servers](#) on page 385.
- **Management Service:** To use two different LDAP server accounts for management, where one LDAP account does user authentication and the other LDAP account does user authorization, you need to configure two LDAP Server Groups. Configure the LDAP Server Group for user authentication as a **Management** type and the LDAP Server Group for user authorization as a **Management Service** type. In this setup, configure all the user-authorization settings (i.e., Management LDAP Groups and LDAP Server Search Base DN)

for the **Management Service**-type LDAP Server Group only, instead of for the **Management**-type LDAP Server Group.

The following procedure describes how to configure an LDAP Server Group through the Web interface. You can also configure it through ini file [LDAPServerGroups] or CLI (`configure system > ldap ldap-server-groups`).

The device provides a preconfigured LDAP Server Group ("DefaultCTRLServersGroupin") in the LDAP Server Groups table, which can be modified or deleted.

➤ **To configure an LDAP Server Group:**

1. Open the LDAP Server Groups table (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Server Groups**).
2. Click **New**; the following dialog box appears:

3. Configure an LDAP Server Group according to the parameters described in the table below.
4. Click **Apply**.

**Table 16-8: LDAP Server Groups Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 20 characters. <b>Note:</b> ■ Configure each row with a unique name.

Parameter	Description
	<ul style="list-style-type: none"> <li>The parameter value cannot contain a forward slash (/).</li> </ul>
'Type' server-type [ServerType]	<p>Defines whether the servers in the group are used for SIP-related LDAP queries (Control) or management login authentication-related LDAP queries (Management).</p> <ul style="list-style-type: none"> <li>[0] <b>Control</b> (default)</li> <li>[1] <b>Management</b></li> <li>[2] <b>Management Service</b></li> </ul> <p>For more information on the different optional LDAP services, see <a href="#">LDAP-based Services</a> on page 378.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>For table row Index #0, the parameter can only be configured to <b>Control</b>.</li> <li>Only one LDAP Server Group can be configured for management.</li> </ul>
'Server Search Method' server-search-method [SearchMethod]	<p>Defines the method for querying between the two LDAP servers in the group.</p> <ul style="list-style-type: none"> <li>[0] <b>Parallel</b> = (Default) The device queries the LDAP servers at the same time.</li> <li>[1] <b>Sequential</b> = The device first queries one of the LDAP servers and if the DN object is not found or the search fails, it queries the second LDAP server.</li> </ul>
'DN Search Method' search-dn-method [SearchDnsMethod]	<p>Defines the method for querying the Distinguished Name (DN) objects within each LDAP server.</p> <ul style="list-style-type: none"> <li>[0] <b>Sequential</b> = (Default) The query is done in each DN object, one by one, until a result is returned. For example, a search for the DN object record "JohnD" is first run in DN object "Marketing" and if a result is not found, it searches in "Sales", and if not found, it searches in "Administration", and so on.</li> <li>[1] <b>Parallel</b> = The query is done in all DN objects at the same time. For example, a search for the DN object record "JohnD" is done at the same time in the "Marketing", "Sales" and "Administration" DN objects.</li> </ul>

Parameter	Description
<b>Cache</b> To refresh the LDAP cache, see <a href="#">Refreshing LDAP Cache for LDAP Server Groups</a> on page 399. To clear the LDAP cache, see <a href="#">Clearing LDAP Cache</a> on page 400.	
'Cache Entry Timeout' cache-entry-timeout [LdapServersGroups_ CacheEntryTimeout]	Defines the duration (in minutes) that an entry in the device's LDAP cache is valid. If the timeout expires, the cached entry is used only if there is no connectivity with the LDAP server.  The valid range is 0 to 35791. The default is 1200. The value 0 means that the LDAP entry is always valid.
'Cache Entry Removal Timeout' cache-entry-removal-timeout [CacheEntryRemovalTimeout]	Defines the duration (in hours) after which the LDAP entry is deleted from the device's LDAP cache.  The valid range is 0 to 596. The default is 0 (i.e., entry is never deleted).

## Configuring LDAP Servers

The LDAP Servers table lets you configure up to 82 LDAP servers. The table defines the address and connectivity settings of the LDAP server. The LDAP server can be configured for SIP-related queries (e.g., routing and manipulation) or LDAP-based management user login authentication and authorization (username-password).

The following procedure describes how to configure an LDAP server through the Web interface. You can also configure it through ini file [LdapConfiguration] or CLI (`configure system > ldap-configuration`).

When you configure an LDAP server, you need to assign it an LDAP Server Group. Therefore, before you can configure an LDAP server in the table, you must first configure at least one LDAP Server Group in the LDAP Server Groups table (see [Configuring LDAP Server Groups](#) on page 382).

### ➤ To configure an LDAP server:

1. Open the LDAP Servers table (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Servers**).
2. Click **New**; the following dialog box appears:

3. Configure an LDAP server according to the parameters described in the table below.

4. Click **Apply**.

**Table 16-9: LDAP Servers Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'LDAP Servers Group' server-group [Group]	Assigns the LDAP server to an LDAP Server Group, configured in the LDAP Server Groups table (see <a href="#">Configuring LDAP Server Groups</a> on page 382). <b>Note:</b> <ul style="list-style-type: none"> <li>The parameter is mandatory and must be set before configuring the other parameters in the table.</li> <li>You can assign up to two LDAP servers to the same LDAP Server Group.</li> </ul>
'LDAP Network Interface' interface-type [Interface]	Assigns one of the device's IP Interfaces (see <a href="#">Configuring IP Network Interfaces</a> on page 159) through which communication with the LDAP server is done. By default, no value is defined and the device uses the IPv4 OAMP interface. <b>Note:</b> <ul style="list-style-type: none"> <li>The parameter is mandatory.</li> <li>The IP address version (IPv4 or IPv6) of the assigned IP Interface and the LDAP server's address (see 'LDAP Server IP' parameter below)</li> </ul>

Parameter	Description
	must be the same.
'Use TLS' use-tls [useTLS]	<p>Enables the device to encrypt the username and password (for Control and Management related queries) using TLS when sending them to the LDAP server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Username and password are sent in clear-text format.</li> <li>■ [1] <b>Yes</b></li> </ul>
'TLS Context' tls-context [ContextName]	<p>Assigns a TLS Context (TLS configuration) for the connection with the LDAP server.</p> <p>By default, no value is defined and the device uses the default TLS Context (ID 0).</p> <p>To configure TLS Contexts, see <a href="#">TLS Certificates</a> on page 227.</p> <p><b>Note:</b> The parameter is applicable only if the 'Use TLS' parameter is configured to <b>Yes</b>.</p>
'Verify Certificate' verify-certificate [VerifyCertificate]	<p>Enables certificate verification when the connection with the LDAP server uses TLS.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Yes</b> = The device verifies the authentication of the certificate received from the LDAP server. The device authenticates the certificate against the trusted root certificate store associated with the associated TLS Context (see 'TLS Context' parameter above) and if ok, allows communication with the LDAP server. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also configured for the associated TLS Context.</li> </ul> <p><b>Note:</b> The parameter is applicable only if the 'Use TLS' parameter is configured to <b>Yes</b>.</p>
'Verify Certificate Subject Name'	Enables the verification of the TLS certificate subject

Parameter	Description
verify-subject-Name [VerifySubjectName]	<p>name (Common Name / CN or Subject Alternative Name / SAN) that is used in the incoming connection request from the LDAP server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) No verification is done.</li> <li>■ [1] <b>Enable</b> = The device verifies the subject name of the certificate received from the LDAP server with the hostname or IP address configured for the LDAP server. If authentication fails, the device denies communication (i.e., handshake fails).</li> </ul> <p><b>Note:</b> The parameter is applicable only if the 'Use TLS' parameter is configured to <b>Yes</b>.</p>
<b>Connection</b>	
'LDAP Server IP' server-ip [LdapConfServerIp]	<p>Defines the IP address (IPv4 or IPv6) of the LDAP server.</p> <p>By default, no IP address is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ If you want to use an FQDN for the LDAP server, leave the parameter undefined and configure the FQDN in the 'LDAP Server Domain Name' parameter (see below).</li> <li>■ The IP address version (IPv4 or IPv6) of the LDAP server's address and the assigned IP Interface (see 'LDAP Network Interface' parameter above) must be the same.</li> </ul>
'LDAP Server Port' server-port [LdapConfServerPort]	<p>Defines the port number of the LDAP server.</p> <p>The valid value range is 0 to 65535. The default port number is 389.</p>
'LDAP Server Max Respond Time' max-respond-time [LdapConfServerMaxRespondTime]	<p>Defines the duration (in msec) that the device waits for LDAP server responses.</p> <p>The valid value range is 0 to 86400. The default is 3000.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the response time expires, you can configure</li> </ul>

Parameter	Description
	<p>the device to use the Local Users table for authenticating the user. For more information, see <a href="#">Configuring Fallback Options to Local Users Table</a> on page 400.</p> <ul style="list-style-type: none"> <li>■ Activation of this timeout depends on connection type: <ul style="list-style-type: none"> <li>✓ Normal TCP connection: The device starts the timer when it sends the LDAP request. If no response is received from the LDAP server within the configured time, the device closes the connection.</li> <li>✓ TLS connection: The device first performs the TLS handshake and once negotiation completes, it sends the LDAP request. The device starts the timer only from the first TLS message sent during the handshake (and not from the LDAP request).</li> </ul> </li> </ul>
<p>'LDAP Server Domain Name'</p> <p>domain-name</p> <p>[LdapConfServerDomainName]</p>	<p>Defines the domain name (FQDN) of the LDAP server. The device tries to connect to the LDAP server according to the IP address listed in the received DNS query. If there is no connection to the LDAP server or the connection to the LDAP server fails, the device tries to connect to the LDAP server with the next IP address in the DNS query list.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the 'LDAP Server IP' parameter, the 'LDAP Server Domain Name' parameter is ignored. Therefore, if you want to use an FQDN, leave the 'LDAP Server IP' parameter undefined.</li> <li>■ The IP address version (IPv4 or IPv6) of the DNS-resolved IP addresses and the assigned IP Interface (see 'LDAP Network Interface' parameter above) must be the same.</li> </ul>
<p>'Server's Connection Status'</p> <p>connection-status</p> <p>[ConnectionStatus]</p>	<p>(Read-only) Displays the connection status with the LDAP server.</p> <ul style="list-style-type: none"> <li>■ "Not Applicable"</li> <li>■ "LDAP Connection Broken"</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ "Connecting"</li> <li>■ "Connected"</li> </ul> <p>For more information about a disconnected LDAP connection, see your syslog messages generated by the device.</p> <p><b>Note:</b> When the LDAP server is assigned to an LDAP Server Group that is for management (see <a href="#">Configuring LDAP Server Groups</a> on page 382), the connection status of the LDAP server is always "Not Applicable".</p>
<b>Query</b>	
'LDAP Password' password [LdapConfPassword]	<p>Defines the user password for accessing the LDAP server during connection and binding operations. The valid value of the parameter depends on the type of LDAP Server Group (defined by the 'Type' parameter in the LDAP Server Groups table):</p> <ul style="list-style-type: none"> <li>■ <b>Control:</b> (LDAP-based SIP queries) The parameter is the password used by the device to authenticate itself (as a client) to obtain LDAP service from the LDAP server.</li> <li>■ <b>Management or Management Service:</b> (LDAP-based user login authentication) The parameter represents the login password entered by the user during a login attempt. You <b>must</b> configure the parameter to the dollar sign (\$). This triggers the device to automatically replace the \$ with the user's login password in the search filter which it sends to the LDAP server for authenticating the user's username-password combination.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ By default, the device sends the password in clear-text format. You can enable the device to encrypt the password using TLS (see the 'Use TLS' parameter in this table).</li> <li>■ The password cannot be configured with wide characters.</li> </ul>

Parameter	Description
'LDAP Bind DN' <code>bind-dn</code> <code>[LdapConfBindDn]</code>	<p>Defines the LDAP server's bind Distinguished Name (DN) or username.</p> <ul style="list-style-type: none"> <li>■ LDAP-based SIP queries: The DN is used as the username during connection and binding to the LDAP server. The DN is used to uniquely name an AD object. Below are example parameter settings:               <ul style="list-style-type: none"> <li>✓ <code>cn=administrator,cn=Users,dc=domain,dc=com</code></li> <li>✓ <code>administrator@domain.com</code></li> <li>✓ <code>domain\administrator</code></li> </ul> </li> <li>■ LDAP-based user login authentication: The parameter represents the login username entered by the user during a login attempt. You can use the \$ (dollar) sign in this value to enable the device to automatically replace the \$ sign with the user's login username in the search filter, which it sends to the LDAP server for authenticating the user's username-password combination. An example configuration for the parameter is <code>\$@sales.local</code>, where the device replaces the \$ with the entered username, for example, <code>JohnD@sales.local</code>. The username can also be configured with the domain name of the LDAP server.</li> </ul> <p><b>Note:</b> By default, the device sends the username in clear-text format. You can enable the device to encrypt the username using TLS (see the 'Use TLS' parameter in this table).</p>
'Management Attribute' <code>mgmt-attr</code> <code>[MngmAuthAtt]</code>	<p>Defines the LDAP attribute name to query, which contains a list of groups to which the user is a member. For Active Directory, this attribute is typically "memberOf". The attribute's values (groups) are used to determine the user's management access level; the group's corresponding access level is configured in <a href="#">Configuring Access Level per Management Groups Attributes</a> on page 394.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only to LDAP-based login authentication and authorization (i.e., the 'Type' parameter is set to <b>Management</b>).</li> <li>■ If this functionality is not used, the device assigns the user the configured default access level. For more information, see <a href="#">Configuring Access Level per Management Groups Attributes</a> on page 394.</li> </ul>
'No Op Timeout' noop-timeout [NoOpTimeout]	<p>Defines the timeout (in minutes) of inactivity in the connection between the device and the LDAP server, after which the device sends an LDAP "abandon" request to keep the LDAP connection alive (i.e., LDAP persistent connection).</p> <p>The valid value to enable this feature is any value greater than 0. The default is 0 (i.e., if there is no activity on the connection, the device doesn't send "abandon" requests and the LDAP server may disconnect).</p> <p><b>Note:</b> The parameter is applicable only to LDAP connections that are used for routing (i.e., the 'Type' parameter is configured to <b>Control</b>).</p>

## Configuring LDAP DN's (Base Paths) per LDAP Server

The LDAP Search DN table lets you configure LDAP base paths. The table is a "child" of the LDAP Servers table (see [Configuring LDAP Servers](#) on page 385) and configuration is done per LDAP server. For the device to run a search using the LDAP service, the base path to the directory's subtree, referred to as the distinguished name object (or DN), where the search is to be done must be configured. For each LDAP server, you can configure up to three base paths.

The following procedure describes how to configure DN's per LDAP server through the Web interface. You can also configure it through ini file [LdapServersSearchDNs] or CLI (`configure system > ldap-configuration > ldap-servers-search-dns`).

### ➤ To configure an LDAP base path per LDAP server:

1. Open the LDAP Servers table (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Servers**).
2. In the table, select the row of the LDAP server for which you want to configure DN base paths, and then click the **LDAP Servers Search Based DN's** link located below the table; the LDAP Server Search Base DN table opens.
3. Click **New**; the following dialog box appears:

4. Configure an LDAP DN base path according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-10:LDAP Server Search Base DN Table Parameter Descriptions**

Parameter	Description
'Index' set internal- index [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Base DN' set base- path [Base_Path]	Defines the full path (DN) to the objects in the AD where the query is done.  The valid value is a string of up to 256 characters.  For example: OU=NY,DC=OCSR2,DC=local. In this example, the DN path is defined by the LDAP names, OU (organizational unit) and DC (domain component).

## Configuring the LDAP Search Filter Attribute

When the LDAP-based login username-password authentication succeeds, the device searches the LDAP server for all groups of which the user is a member. The LDAP query is based on the following LDAP data structure:

- **Search base object (distinguished name or DN, e.g., "ou=ABC,dc=corp,dc=abc,dc=com"):**  
The DN defines the location in the directory from which the LDAP search begins and is configured in [Configuring LDAP DN \(Base Paths\) per LDAP Server](#) on the previous page.
- **Filter (e.g., "(&(objectClass=person)(sAMAccountName=johnd))"):** This filters the search in the subtree to include only the login username (and excludes others). This is configured by the 'LDAP Authentication Filter' parameter, as described in the following procedure. You must use the dollar (\$) sign to represent the username. For example, when configured to "(sAMAccountName=\*)" and the user attempts to log in with the username "SueM", the LDAP search is done only for the attribute sAMAccountName that equals "SueM".

- **Attribute (e.g., "memberOf") to return from objects that match the filter criteria:** The attribute is configured by the 'Management Attribute' parameter in the LDAP Servers table (see [Configuring LDAP Servers](#) on page 385).

Therefore, the LDAP response includes only the groups of which the specific user is a member.

- The search filter is applicable only to LDAP-based login authentication and authorization queries.
- The search filter is a global setting that applies to all LDAP-based login authentication and authorization queries, across all configured LDAP servers.

➤ **To configure the LDAP search filter for management users:**

1. Open the LDAP Settings page (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Settings**).
2. In the 'LDAP Authentication Filter' field, enter the LDAP search filter attribute for searching the login username for user authentication:

LDAP Authentication Filter

3. Click **Apply**.

## Configuring Access Level per Management Groups Attributes

The Management LDAP Groups table lets you configure LDAP group objects and their corresponding management user access level. The table is a "child" of the LDAP Servers table (see [Configuring LDAP Servers](#) on page 385) and configuration is done per LDAP server. For each LDAP server, you can configure up to three row entries of LDAP group(s) with their corresponding access level (only one row can be configured for each level).

- The Management LDAP Groups table is applicable only to LDAP-based login authentication and authorization queries.
- If the LDAP response received by the device includes multiple groups of which the user is a member and you have configured different access levels for some of these groups, the device assigns the user the highest access level. For example, if the user is a member of two groups where one has access level **Monitor** and the other **Admin**, the device assigns the user the **Admin** access level.
- When the access level is unknown, the device assigns the default access level to the user, configured by the 'Default Access Level' parameter as used also for RADIUS (see [Configuring RADIUS-based User Authentication](#) on page 377). This can occur in the following scenarios:
  - ✓ The user is not a member of any LDAP group.
  - ✓ The group of which the user is a member is not configured on the device (as described in this section).
  - ✓ The device is not configured to query the LDAP server for a management attribute (see [Configuring LDAP Servers](#) on page 385).

Group objects represent groups in the LDAP server of which the user is a member. The access level represents the user account's permissions and rights in the device's management interface (e.g., Web and CLI). The access level can either be **Monitor**, **Admin**, or **Security Admin**. For an explanation on the privileges of each level, see [Configuring Local Management User Accounts](#) on page 55.

When the username-password authentication with the LDAP server succeeds, the device searches the LDAP server for all groups of which the user is a member. The LDAP query is based on the following LDAP data structure:

- Search base object (distinguished name or DN, e.g., "ou=ABC,dc=corp,dc=abc,dc=com"), which defines the location in the directory from which the LDAP search begins. This is configured in [Configuring LDAP DN \(Base Paths\) per LDAP Server](#) on page 392.
- Filter (e.g., "(&(objectClass=person)(sAMAccountName=johnd))"), which filters the search in the subtree to include only the login username (and excludes others). For configuration, see [Configuring the LDAP Search Filter Attribute](#) on page 393.
- Attribute (e.g., "memberOf") to return from objects that match the filter criteria. This attribute is configured by the 'Management Attribute' parameter in the LDAP Servers table.

The LDAP response includes all the groups of which the specific user is a member, for example:

```
CN=\# Support Dept,OU=R&D Groups,OU-
U=Groups,OU=APC,OU=Japan,OU=ABC,DC=corp,DC=abc,DC=com
CN=\#AllCellular,OU=Groups,OU=APC,OU=Japan,OU=ABC,DC=corp,DC=abc,DC=com
```

The device searches this LDAP response for the group names that you configured in the Management LDAP Groups table to determine the user's access level. If the device finds a group name, the user is assigned the corresponding access level and login is permitted; otherwise, login is denied. Once the LDAP response has been received (success or failure), the LDAP session terminates.

The following procedure describes how to configure an access level per management groups through the Web interface. You can also configure it through ini file [MgmtLDAPGroups] or CLI (configure system > ldap-configuration > mgmt-ldap-groups).

➤ **To configure management groups and corresponding access level:**

1. Open the LDAP Servers table (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Servers**).
2. In the table, select the row of the LDAP server for which you want to configure management groups with a corresponding access level, and then click the **Management LDAP Groups** link located below the table; the Management LDAP Groups table opens.
3. Click **New**; the following dialog box appears:

**Management LDAP Groups**

**GENERAL**

Index: 1

Level: Monitor

Groups:

4. Configure a group name(s) with a corresponding access level according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-11: Management LDAP Groups Table Parameter Descriptions**

Parameter	Description
'Index' [MgmntLDAPGroups_ GroupIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Level' level [MgmntLDAPGroups_ Level]	Defines the access level of the group(s). <ul style="list-style-type: none"> <li>■ [0] <b>Monitor</b> (Default)</li> <li>■ [1] <b>Admin</b></li> <li>■ [2] <b>Security Admin</b></li> </ul> <b>Note:</b> You can configure only one row in the Management LDAP Groups table per access level.
'Groups' groups [MgmntLDAPGroups_ Group]	Defines the attribute names of the groups in the LDAP server. The valid value is a string of up to 256 characters. To define multiple groups, separate each group name with a semicolon (;). <b>Note:</b> The value is case-insensitive.

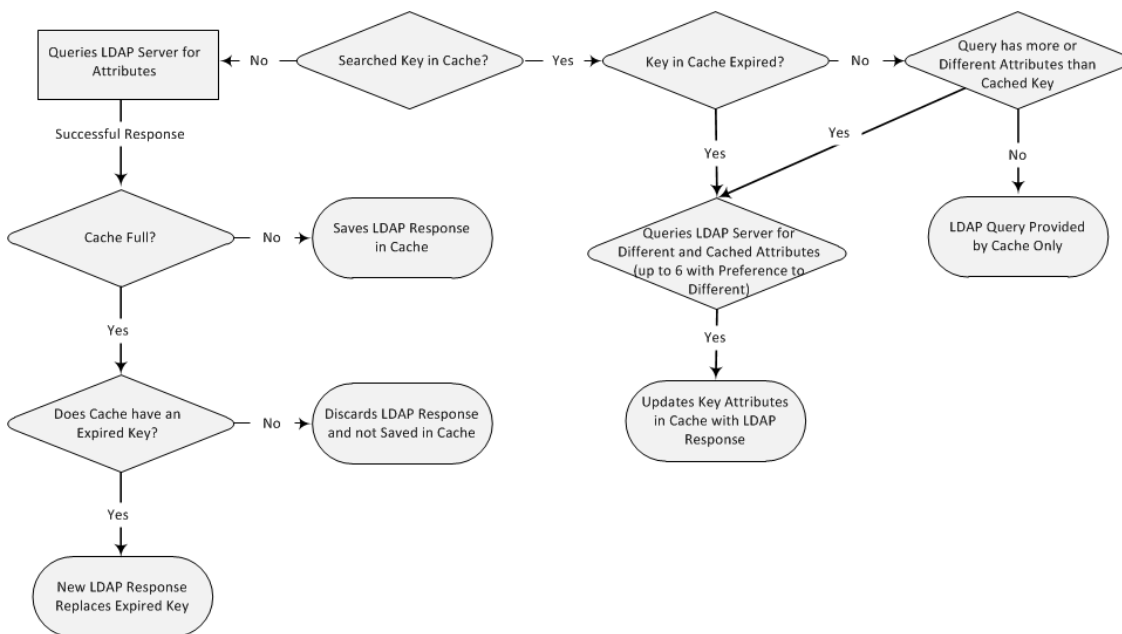

## Configuring the Device's LDAP Cache

The device can optionally store LDAP queries of LDAP Attributes for a searched key with an LDAP server and the responses (results) in its local cache. The cache is used for subsequent queries or in case of LDAP server failure. The benefits of this feature include the following:

- Improves routing decision performance by using local cache for subsequent LDAP queries

- Reduces number of queries performed on an LDAP server and corresponding bandwidth consumption
- Provides partial survivability in case of intermittent LDAP server failure (or network isolation)

The handling of LDAP queries using the device's LDAP cache is shown in the flowchart below:

If an LDAP query is required for an Attribute of a key that is already cached with that same Attribute, instead of sending a query to the LDAP server, the device uses the cache. However, if an LDAP query is required for an Attribute that doesn't appear for the cached key, the device queries the LDAP server, and then saves the new Attribute (and response) in the cache for that key.

If the device queries the LDAP server for different Attributes for a cached key, the device also includes already cached Attributes of the key, while adhering to the maximum number of allowed saved Attributes (see note below), with preference to the different Attributes. In other words, if the cached key already contains the maximum Attributes and an LDAP query is required for a different Attribute, the device sends an LDAP query to the server for the different Attribute and for the five **most recent** Attributes already cached with the key. Upon the LDAP response, the new Attribute replaces the **oldest** cached Attribute while the values of the other Attributes are refreshed with the new response.

The following table shows an example of different scenarios of LDAP queries of a cached key whose cached Attributes include *a*, *b*, *c*, and *d*, where *a* is the oldest and *d* the most recent Attribute:

Table 16-12:Example of LDAP Query for Cached Attributes

Attributes Requested in New LDAP Query for Cached Key	Attributes Sent in LDAP Query to LDAP Server	Attributes Saved in Cache after LDAP Response
e	e, a, b, c, d	e, a, b, c, d
e, f	e, f, a, b, c, d	e, f, a, b, c, d
e, f, g, h,i	e, f, g, h, i, d	e, f, g, h,i, d
e, f, g, h, i, j	e, f, g, h, i, j	e, f, g, h, i, j

- The LDAP Cache feature is applicable only to LDAP-based SIP queries (Control).
- The maximum LDAP cache size is 10,000 entries.
- The device can save up to six LDAP Attributes in the cache per searched LDAP key.
- The device also saves in the cache queried Attributes that do not have any values in the LDAP server.

The following procedure describes how to configure the device's LDAP cache globally.

- You can also configure LDAP caching per LDAP Server Group (see [Configuring LDAP Server Groups](#) on page 382).
- Before enabling LDAP caching, you must first enable the LDAP service (see [Enabling the LDAP Service](#) on page 381).
- To clear the LDAP cache, see [Clearing LDAP Cache](#) on page 400.

➤ **To enable and configure LDAP cache:**

1. Open the LDAP Settings page (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Settings**).
2. Select the 'LDAP Cache Service' check box to enable LDAP cache.

LDAP Cache Service

3. Configure the following LDAP caching settings:
  - a. In the 'LDAP Cache Entry Timeout' field, enter the duration (in minutes) that an entry in the device's LDAP cache is valid. If the timeout expires, the cached entry is used only if there is no connectivity with the LDAP server.
  - b. In the 'LDAP Cache Entry Removal Timeout' field, enter the duration (in hours) after which the LDAP entry is removed from the device's LDAP cache.

LDAP Cache Entry Timeout [min]	<input type="text" value="1200"/>
LDAP Cache Entry Removal Timeout [hrs]	<input type="text" value="0"/>

4. Click **Apply**, and then restart the device with a burn-to-flash for your settings to take effect.

### Refreshing LDAP Cache for LDAP Server Groups

You can refresh values of LDAP Attributes associated with a specified LDAP search key that are stored in the device's LDAP cache. The device sends an LDAP query to the LDAP server for the cached Attributes of the specified search key and replaces the old values in the cache with the new values received in the LDAP response.

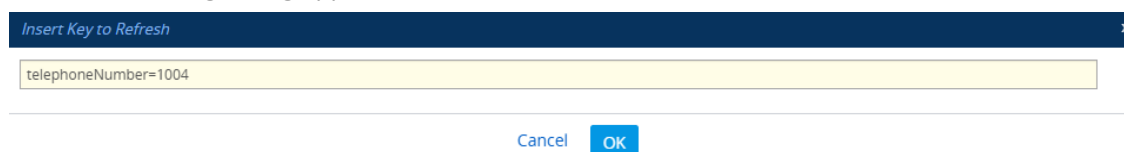

For example, assume the cache contains a previously queried LDAP Attribute "telephoneNumber=1004" whose associated Attributes include "displayName", "mobile" and "ipPhone". If you perform a cache refresh based on the search key "telephoneNumber=1004", the device sends an LDAP query to the server requesting values for the "displayName", "mobile" and "ipPhone" Attributes of this search key. When the device receives the LDAP response, it replaces the old values in the cache with the new values received in the LDAP response.

➤ **To refresh LDAP cache:**

1. Open the LDAP Server Groups table (see [Configuring LDAP Server Groups](#) on page 382).
2. Refresh the cache of a specific LDAP Server Group or all of them:
  - **Refresh specific LDAP Server Group:** Select the LDAP Server Group row, click **Action**, and then from the drop-down menu, choose **Refresh Line**.
  - **Refresh all LDAP Server Groups:** Click **Action**, and then from the drop-down menu, choose **Refresh All Cache**.

The following dialog appears:

3. In the 'Insert Key to Refresh' field, enter the LDAP search key that you want to refresh (e.g., telephoneNumber=1004).
4. Click **OK**; if a request with the specified key exists in the cache, a request is sent to the LDAP server for the attributes associated in the cache with the search key.

### Clearing LDAP Cache

You can clear the entire cache of LDAP queries of attributes for searched keys with the configured LDAP Server Groups and the responses (results).

➤ **To clear LDAP cache:**

1. Open the LDAP Server Groups table (see [Configuring LDAP Server Groups](#) on page 382).
2. Click **Action**, and then from the drop-down menu, choose **Clear Cache**.

### Configuring Fallback Options to Local Users Table

When you are using an Authentication server to authenticate users, you can configure when or if the device uses the Local Users table (see [Configuring Local Management User Accounts](#) on page 55). By default, the device uses the Local Users table if you haven't configured an Authentication server.

- This feature is applicable to LDAP and RADIUS.
- This feature is applicable only to user management authentication.

➤ **To configure when Local Users table used for user authentication:**

1. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**).

2. Under the General group, do the following:
  - a. Configure when the Local Users table is used to authenticate users. From the 'Use Local Users Table for Authentication' drop-down list, select one of the options (for a description, see ['Use Local Users Table for Authentication'](#) on page 2140).
  - b. Configure whether the Local Users table is to be used to authenticate users upon connection timeout with the server. From the 'Behavior upon Authentication Server Timeout' drop-down list, select one of the following:
    - ◆ **Deny Access:** User is denied access.
    - ◆ **Verify Access Locally:** The device verifies the user's credentials in the Local Users table.

Use Local Users Table for Authentication

When No Auth Server Defined ▼

Behavior upon Authentication Server Timeout

Verify Access Locally ▼

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## LDAP-based Login Authentication Example

To facilitate your understanding on LDAP entry data structure and how to configure the device to use and obtain information from this LDAP directory, a brief configuration example is described in this section. The example applies to LDAP-based user login authentication and authorization (access level), and assumes that you are familiar with other aspects of LDAP configuration (e.g., LDAP server's address).

The LDAP server's entry data structure schema in the example is as follows:

- **DN (base path):** OU=testMgmt,OU=QA,DC=testqa,DC=local. The DN path to search for the username in the directory is shown below:

Path: CN=John Doe,OU=testMgmt,OU=QA,DC=testqa,DC=local,10.3.9.93 [testqa.testqa.local]

The screenshot shows the Active Directory Explorer interface. On the left, the directory tree is expanded to show the path: 10.3.9.93 [testqa.testqa.local] > DC=testqa,DC=local > CN=Builtin > CN=Computers > CN=Deleted Objects > OU=Domain Controllers > CN=ForeignSecurityPrincipals > CN=Infrastructure > CN=LostAndFound > CN=NTDS Quotas > CN=Program Data > OU=QA > CN=Aapaul50digitsL > CN=Aapaul51digitsL > CN=AjohnA > CN=BjohnB > CN=CjohnC > CN=DjohnD > CN=EjohnE > CN=Firstaaa Lastbbbb > CN=FjohnF > CN=George Harrison > CN=GjohnG > CN=HjohnH > CN=IjohnI > CN=JjohnJ > CN=John Doe > CN=John Doe Bind > CN=KjohnK > CN=LjohnL > OU=Misc > CN=MjohnM > CN=NjohnN > CN=OjohnO > CN=PjohnP > CN=QjohnQ > CN=ran\_shidi > CN=RjohnR > CN=SjohnS > OU=test1000 > OU=testBSP > OU=testCP > OU=testEMS > OU=testMgmt > CN=2 > CN=John Doe. The user 'CN=John Doe' is selected.

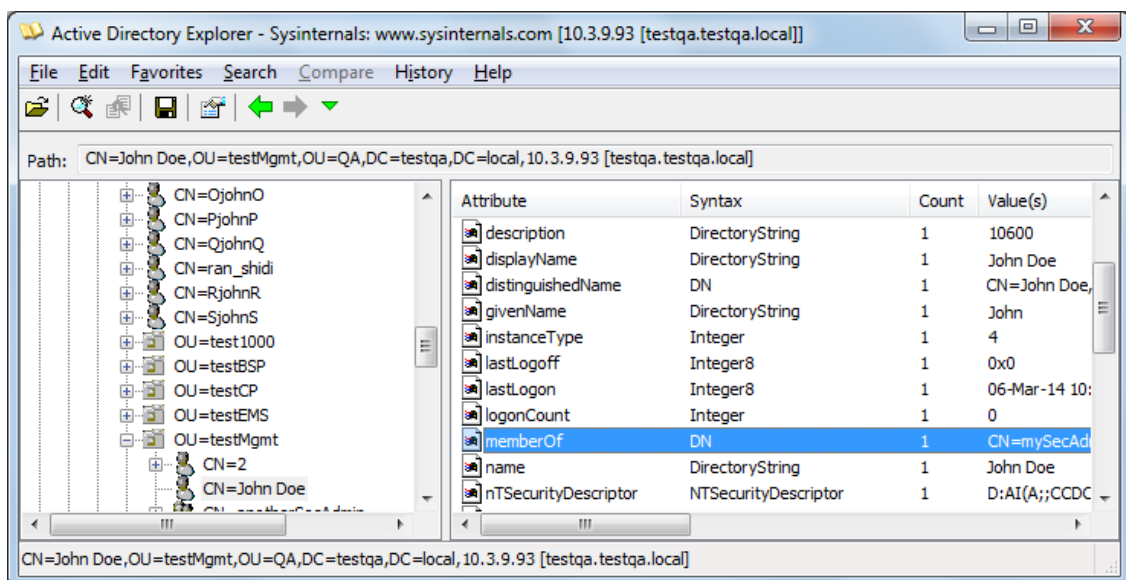

On the right, the 'Attributes' tab is displayed, showing a list of attributes for the selected user. The table below represents the data shown in the screenshot.

Attribute	Syntax	Count	Value(s)
accountExpires	Integer8	1	0x7FFFFFFFFFFFFFFF
badPasswordTime	Integer8	1	06-Mar-14 10:03:18 AM

- **Search Attribute Filter:** (sAMAccountName=). The login username is found based on this attribute (where the attribute's value equals the username):

- **Management Attribute:** `memberOf`. The attribute contains the member groups of the user:

- **Management Group:** `mySecAdmin`. The group to which the user belongs, as listed under the `memberOf` attribute:

The configuration to match the above LDAP data structure schema is as follows:

- LDAP-based login authentication (management) is enabled in the LDAP Server Groups table (see [Configuring LDAP Server Groups](#) on page 382):

- The DN is configured in the LDAP Server Search Base DN table (see [Configuring LDAP DNs \(Base Paths\) per LDAP Server](#) on page 392):

- The search attribute filter based on username is configured by the 'LDAP Authentication Filter' parameter (see [Configuring the LDAP Search Filter Attribute](#) on page 393):

GENERAL	
<b>LDAP Service</b>	• Enable 
<b>LDAP Authentication Filter</b>	(\$AMAccountName=*)

- The group management attribute is configured by the 'Management Attribute' parameter in the LDAP Servers table:

LDAP Servers	
LDAP Servers Group: #1 [login-auth]	
GENERAL	CONNECTION
Index: 0	LDAP Server IP: 10.3.9.93
LDAP Network Interface: #0 [O+M+C] <a href="#">View</a>	LDAP Server Port: 389
Use TLS: No	LDAP Server Max Respond Time [msec]: 3000
TLS Context: -- <a href="#">View</a>	LDAP Server Domain Name:
	Connection Status:
QUERY	Verify Certificate: No
LDAP Password:	
LDAP Bind DN: \$@testqa.local	
Management Attribute: memberOf	

- The management group and its corresponding access level is configured in the Management LDAP Groups table (see [Configuring Access Level per Management Groups Attributes](#) on page 394):

Management LDAP Groups	
GENERAL	
Index	0
Level	Security Admin
Groups	mySecAdmin

## Enabling LDAP Searches for Numbers with Characters

Typically, the device performs LDAP searches in the AD for complete numbers where the digits are adjacent to one another (e.g., 5038234567). However, if the number is defined in the AD with characters (such as spaces, hyphens and periods) separating the digits (e.g., 503-823 4567), the LDAP query returns a failed result.

To enable the device to search the AD for numbers that may contain characters between its digits, you need to specify the Attribute (up to five) for which you want to apply this functionality, using the [LDAPNumericAttributes] parameter. For example, the telephoneNumber Attribute could be defined in AD with the telephone number "503-823-4567" (i.e., hyphens), "503.823.4567" (i.e., periods) or "503 823 4567" (i.e., spaces). If the device performs an LDAP search on this Attribute for the number 5038234567, the LDAP query will return results only if you configure the [LDAPNumericAttributes] parameter with the telephoneNumber Attribute (e.g., [LDAPNumericAttributes] configured to telephoneNumber). To search for the number with characters, the device inserts the asterisk (\*) wildcard between all digits in the LDAP query (e.g., telephoneNumber = 5\*0\*3\*8\*2\*3\*4\*5\*6\*7). As the AD server recognizes the \* wildcard as representing any character, it returns all possible results to the device. Note that the wildcard represents only a character; a query result containing a digit in place of a wildcard is discarded and the device performs another query for the same Attribute. For example, it may return the numbers 533-823-4567 (second digit "3" and hyphens) and 503-823-4567. As the device discards query results where the wildcard results in a digit, it selects 503-823-4567 as the result. The correct query result is cached by the device for subsequent queries and/or in case of LDAP server failure.

## Routing for Microsoft Teams or Skype for Business using Microsoft Entra ID

Typically, companies wishing to deploy Microsoft® Teams or Skype for Business are faced with a complex, call routing dial plan when migrating users from their existing PBX or IP PBX to the Teams / Skype for Business environment. As more and more end-users migrate to the new voice system, dialing plan management and PBX link capacity can be adversely impacted. To resolve this issue, companies can employ Microsoft Entra ID (formerly, Microsoft Active Directory), which provides a central database to manage and maintain information regarding user's availability, presence, and location.

The device supports outbound IP call routing decisions based on information stored on Microsoft Entra ID. Based on queries sent to Microsoft Entra ID, the device can route the call to one of the following IP domains:

- Teams / Skype for Business client - users connected to Teams / Skype for Business
- PBX or IP PBX - users not yet migrated to Teams / Skype for Business
- Mobile - mobile number
- Private - private telephone line for Teams / Skype for Business users (in addition to the primary telephone line)

This section describes an earlier implementation for configuring routing based on Microsoft Entra ID. For new deployments, it's **recommended** to use Call Setup Rules (see [Configuring Call Setup Rules](#) on page 809). Call Setup Rules provide more flexibility and easier implementation. You can view examples in [Examples of Call Setup Rules](#) on page 820.

## Querying Microsoft Entra ID and Routing Priority

The device queries Microsoft Entra ID using the initial destination number (i.e., called number). The query can return up to four user phone numbers, each pertaining to one of the IP domains (i.e., private number, Skype for Business number, PBX / IP PBX number, and mobile number). The configuration parameters listed in the table below are used to configure the query attribute keys that defines the Microsoft Entra ID attribute that you wish to query Microsoft Entra ID:

**Table 16-13:Parameters for Configuring Query Attribute Key**

Parameter	Queried User Domain (Attribute) in Microsoft Entra ID	Query or Query Result Example
<b>MSLDAPPBXNumAttributeName</b>	PBX or IP PBX number (e.g., "telephoneNumber" - default)	telephoneNumber=+3233554447
<b>MSLDAPOCSTNumAttributeName</b>	Mediation Server / Skype for Business client number (e.g., "msRTCSIP-Line")	msRTCSIP-Line=john.smith@company.com
<b>MSLDAPMobileNumAttributeName</b>	Mobile number (e.g., "mobile")	mobile=+3247647156
<b>MSLDAPPrivateNumAttributeName</b>	Any attribute (e.g., "msRTCSIP-PrivateLine") <b>Note:</b> Used only if set to same value as Primary or Secondary key.	msRTCSIP-PrivateLine=+3233554480
<b>MSLDAPPrimaryKey</b>	Primary Key query search instead of PBX key - can be any Microsoft Entra ID attribute	msRTCSIP-PrivateLine=+3233554480
<b>MSLDAPSecondaryKey</b>	Secondary Key query key search if Primary Key fails - can be any attribute	-

The process for querying Microsoft Entra ID and subsequent routing based on the query results is as follows:

1. If the Primary Key is configured, it uses the defined string as a primary key instead of the one defined in `MSLDAPPBXNumAttributeName`. It requests the attributes which are described below.
2. If the primary query is not found in Microsoft Entra ID and the Secondary Key is configured, it does a second query for the destination number using a second Microsoft Entra ID attribute key name, configured by the `MSLDAPSecondaryKey` parameter.
3. If none of the queries are successful, it routes the call to the original dialed destination number according to the routing rule matching the "LDAP\_ERR" destination prefix number value, or rejects the call with a SIP 404 "Not Found" response.
4. For each query (primary or secondary), it queries the following attributes (if configured):
  - `MSLDAPPBXNumAttributeName`
  - `MSLDAPOCSNumAttributeName`
  - `MSLDAPMobileNumAttributeName`

In addition, it queries the special attribute defined in `MSLDAPPrivateNumAttributeName`, only if the query key (primary or secondary) is equal to its value.

5. If the query is found: Microsoft Entra ID returns up to four attributes - Skype for Business, PBX / IP PBX, private (only if it equals Primary or Secondary key), and mobile.
6. The device adds unique prefix keywords to the query results in order to identify the query type (i.e., IP domain). These prefixes are used as the prefix destination number value in the Tel-to-IP Routing table to denote the IP domains:
  - "PRIVATE" (PRIVATE:<private\_number>): used to match a routing rule based on query results of the private number (`MSLDAPPrivateNumAttributeName`).
  - "OCS" (OCS:<Skype for Business\_number>): used to match a routing rule based on query results of the Skype for Business client number (`MSLDAPOCSNumAttributeName`).
  - "PBX" (PBX:<PBX\_number>): used to match a routing rule based on query results of the PBX / IP PBX number (`MSLDAPPBXNumAttributeName`).
  - "MOBILE" (MOBILE:<mobile\_number>): used to match a routing rule based on query results of the mobile number (`MSLDAPMobileNumAttributeName`).
  - "LDAP\_ERR": used to match a routing rule based on a failed query result when no attribute is found in Microsoft Entra ID.

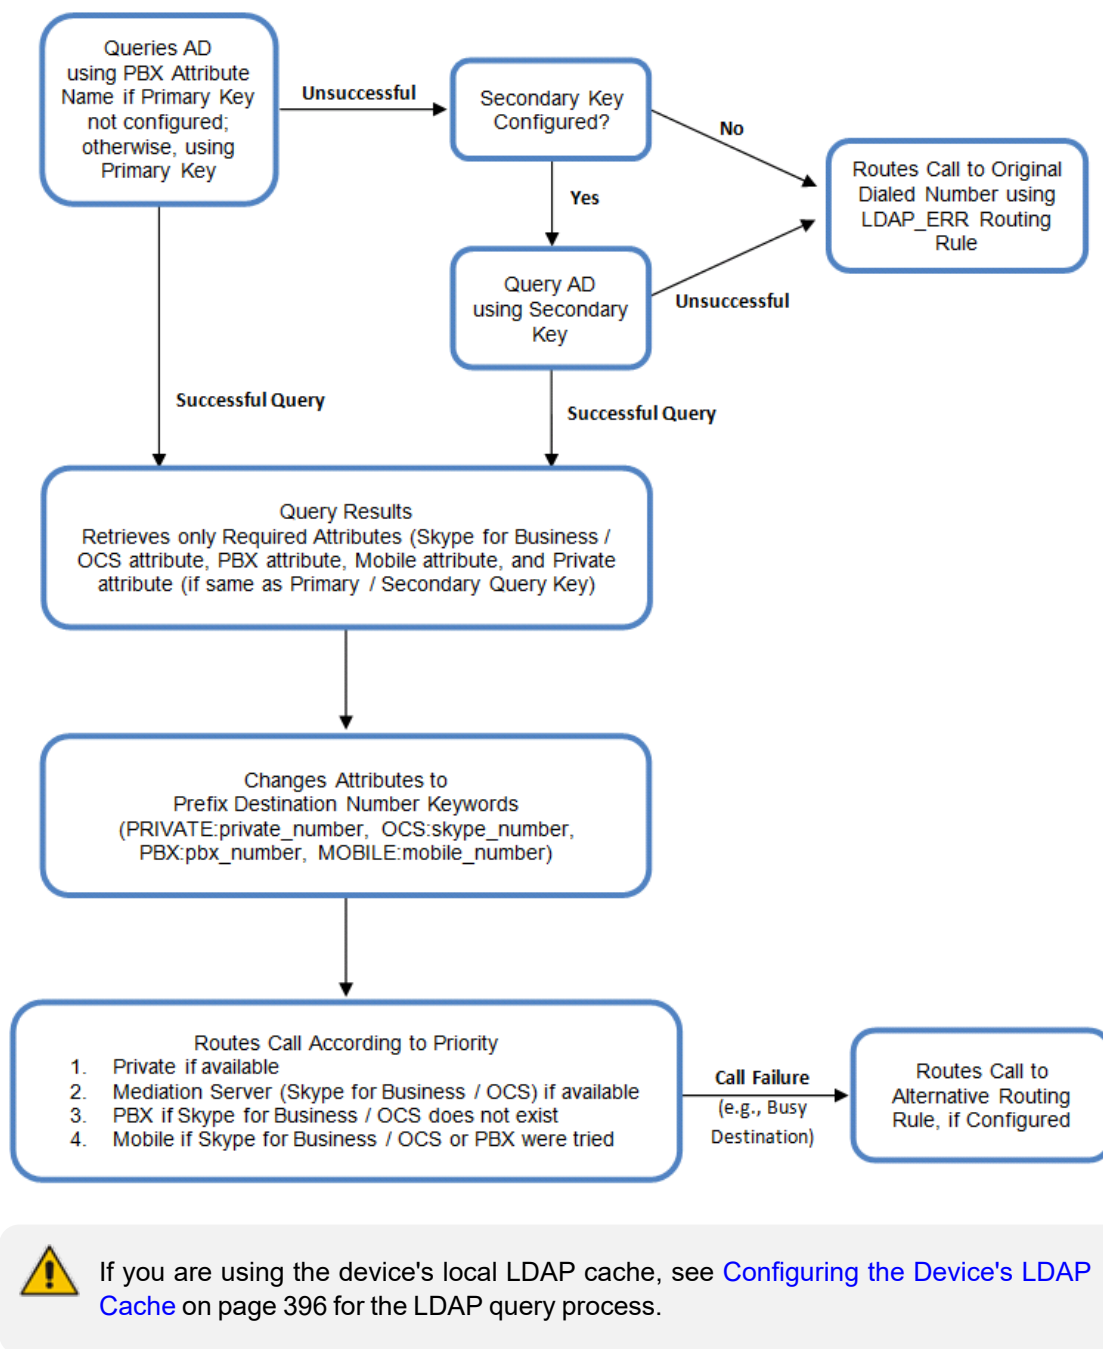

These prefixes are involved only in the routing and manipulation processes; they are not used as the final destination number.

7. The device uses the Tel-to-IP Routing table to route the call based on the LDAP query result. The device routes the call according to the following priority:
  - a. **Private line:** If the query is done for the private attribute and it's found, the device routes the call according to this attribute.
  - b. **Mediation Server SIP address (Skype for Business):** If the private attribute doesn't exist or is not queried, the device routes the call to the Mediation Server (which then routes the call to the Skype for Business client).
  - c. **PBX / IP PBX:** If the Skype for Business client is not found in Microsoft Entra ID, it routes the call to the PBX / IP PBX.
  - d. **Mobile number:** If the Skype for Business client (or Mediation Server) is unavailable (e.g., SIP response 404 "Not Found" upon INVITE sent to Skype for Business client), and the PBX / IP PBX is also unavailable, the device routes the call to the user's mobile number (if exists in Microsoft Entra ID).
  - e. **Alternative route:** If the call routing to all the above fails (e.g., due to unavailable destination - call busy), the device can route the call to an alternative destination if an alternative routing rule is configured.
  - f. **"Redundant" route:** If the query failed (i.e., no attribute found in Microsoft Entra ID), the device uses the routing rule matching the "LDAP\_ERR" prefix destination number value.

For digital interfaces (Gateway application): For Enterprises implementing a PBX / IP PBX system, but yet to migrate to Skype for Business, if the PBX / IP PBX system is unavailable or has failed, the device uses the Microsoft Entra ID query result for the user's mobile phone number, routing the call through the PSTN to the mobile destination.

The flowchart below summarizes the device's process for querying Microsoft Entra ID and routing the call based on the query results:

### Configuring Routing Rules based on Microsoft Entra ID

The following procedure describes how to configure outbound IP routing based on LDAP queries.

#### ➤ To configure LDAP-based IP routing for Skype for Business:

1. Configure the LDAP server parameters, as described in [Configuring LDAP Servers](#) on page 385.
2. Configure the Microsoft Entra ID attribute names used in the LDAP query:

- a. Open the LDAP Settings page (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **LDAP Settings**).

ACTIVE DIRECTORY	
<b>LDAP Numeric Attributes</b>	<input type="text"/>
LDAP OCS Number Attribute Name	<input type="text" value="msRTCSIP-Line"/>
MS LDAP PBX Number Attribute Name	<input type="text" value="telephoneNumber"/>
LDAP MOBILE Number Attribute Name	<input type="text" value="mobile"/>
LDAP DISPLAY Name Attribute Name	<input type="text" value="displayName"/>
LDAP PRIVATE Number Attribute Name	<input type="text" value="msRTCSIP-PrivateLine"/>
LDAP Primary Key	• <input type="text" value="telephoneNumber"/>
LDAP Secondary Key	<input type="text"/>

- b. Configure the LDAP attribute names as desired.
3. **Gateway application:** Configure Tel-to-IP routing rules:
    - a. Open the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946).
    - b. Configure query-result routing rules for each IP domain (private, PBX / IP PBX, Teams / Skype for Business clients, and mobile), using the LDAP keywords (case-sensitive) for the prefix destination number:
      - ◆ PRIVATE: Private number
      - ◆ OCS: Skype for Business client number
      - ◆ PBX: PBX / IP PBX number
      - ◆ MOBILE: Mobile number
      - ◆ LDAP\_ERR: LDAP query failure
    - c. Configure a routing rule for routing the initial Tel call to the LDAP server, using the value "LDAP" (without quotation marks) for denoting the IP address of the LDAP server.
    - d. For alternative routing, enable the alternative routing mechanism and configure corresponding SIP reasons for alternative routing. For this feature, alternative routing starts from the table row located under the LDAP query row.
  4. **SBC application:** Configure IP-to-IP routing rules:
    - a. Open the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186).
    - b. Configure query-result routing rules for each IP domain (private, PBX / IP PBX, Teams / Skype for Business clients, and mobile), using the LDAP keywords (case-sensitive) in the 'Destination Username Pattern' field:
      - ◆ PRIVATE: Private number

- ◆ OCS: Skype for Business client number
  - ◆ PBX: PBX / IP PBX number
  - ◆ MOBILE: Mobile number
  - ◆ LDAP\_ERR: LDAP query failure
- c. Configure a routing rule for routing the initial call (LDAP query) to the LDAP server, by setting the 'Destination Type' field to LDAP for denoting the IP address of the LDAP server.
  - d. For alternative routing, enable the alternative routing mechanism and configure corresponding SIP reasons for alternative routing. For this feature, alternative routing starts from the table row located under the LDAP query row.

The table below shows an example for configuring Tel-to-IP routing rules based on Microsoft Entra ID in the Tel-to-IP Routing table:

**Table 16-14: Examples of Tel-to-IP Routing Rules based on Microsoft Entra ID**

Index	Destination Phone Prefix	Destination IP Address
1	PRIVATE:	10.33.45.60
2	PBX:	10.33.45.65
3	OCS:	10.33.45.68
4	MOBILE:	10.33.45.100
5	LDAP_ERR	10.33.45.80
6	*	LDAP
7	*	10.33.45.72

The table below shows an example for configuring SBC routing rules based on Microsoft Entra ID in the IP-to-IP Routing Table:

**Table 16-15: Examples of SBC IP-to-IP Routing Rules based on Microsoft Entra ID**

Index	Destination Username Pattern	Destination Type	Destination Address
1	PRIVATE:	Dest Address	10.33.45.60
2	PBX:	Dest Address	10.33.45.65
3	OCS:	Dest Address	10.33.45.68
4	MOBILE:	Dest Address	10.33.45.100

Index	Destination Username Pattern	Destination Type	Destination Address
5	LDAP_ERR	Dest Address	10.33.45.80
6	*	LDAP	-
7	*	Dest Address	10.33.45.72

The configured routing rule example is explained below:

- **Rule 1:** Sends call to private telephone line (at 10.33.45.60) upon successful Microsoft Entra ID query result for the private attribute.
- **Rule 2:** Sends call to IP PBX (at 10.33.45.65) upon successful Microsoft Entra ID query result for the PBX attribute.
- **Rule 3:** Sends call to the client (i.e., Mediation Server at 10.33.45.68) upon successful Microsoft Entra ID query result for the Skype for Business attribute.
- **Rule 4:** Sends call to user's mobile phone number (to PSTN through the device's IP address at 10.33.45.100) upon Microsoft Entra ID query result for the Mobile attribute.
- **Rule 5:** Sends call to IP address of device (10.33.45.80) upon Microsoft Entra ID query failure (e.g., no response from LDAP server or attribute not found).
- **Rule 6:** Sends query for original destination number of received call to the LDAP server.
- **Rule 7:** Alternative routing rule that sends the call of original dialed number to IP destination 10.33.45.72. This rule is applied in any of the following cases
  - LDAP functionality is disabled.
  - LDAP query is successful but call fails (due to, for example, busy line) to all the relevant attribute destinations (private, Skype for Business, PBX, and mobile), and a relevant Tel-to-IP Release Reason (see [Alternative Routing for Tel-to-IP Calls](#) on page 969) or SBC Alternative Routing Reason (see [Configuring SIP Response Codes for Alternative Routing Reasons](#) on page 1214) has been configured.

Once the device receives the original incoming call, the first rule that it uses is Rule 6, which queries Microsoft Entra ID. When Microsoft Entra ID replies, the device searches the table, from the first rule down, for the matching destination phone prefix (i.e., "PRIVATE:", "PBX:", "OCS:", "MOBILE:", and "LDAP\_ERR:"), and then sends the call to the appropriate destination.

### Querying Microsoft Entra ID for Calling Name

The device can retrieve the calling name (display name) from an LDAP-compliant server (for example, Microsoft Entra ID) for Tel-to-IP calls that are received without a calling name.

The device uses the calling number (PBX or mobile number) for the LDAP query. Upon an incoming INVITE, the device queries Microsoft Entra ID based on the Calling Number search key (tries to match the calling number with the appropriate "telephoneNumber" or "mobile" number Microsoft Entra ID attribute entry). It then searches for the corresponding calling name

attribute, configured by the `MSLDAPDisplayNameAttributeName` parameter (e.g., "displayName"). The device uses the resultant calling name as the display name parameter in the SIP From header of the outgoing INVITE message.

To configure this feature, the following keywords are used in the Calling Name Manipulation for Tel-to-IP Calls table for the 'Prefix/Suffix to Add' fields, which can be combined with other characters:

- "\$LDAP-PBX": LDAP query using the `MSLDAPPBXAttrName` parameter as the search key
- "\$LDAP-MOBILE": LDAP query using `MSLDAPMobileAttrName` parameter as the search key

If the source (calling) number of the Tel-to-IP call matches the PBX / MOBILE (e.g., "telephoneNumber" and "mobile") number in Microsoft Entra ID, the device uses the resultant Display Name instead of the keyword(s).

For example, assume the following configuration in the Calling Name Manipulation for Tel-to-IP Calls table:

- 'Source Phone Pattern' field is set to "4".
- 'Prefix to Add' field is set to "\$LDAP-PBX Office".

If the calling number is 4046 and the resultant LDAP query display name is "John Doe", the device sends the INVITE message with the following From header:

From: John Doe <sip:4064@company.com>

- The Calling Name Manipulation for Tel-to-IP Calls table uses the numbers before manipulation, as inputs.
- The LDAP query uses the calling number after source number manipulation, as the search key value.
- This feature is applicable only to the Gateway application.

## OAuth 2.0 Based Authentication Services

You can configure the device to use the OAuth 2.0 authentication protocol for authenticating the following:

- Incoming SIP messages - see [OAuth 2.0 Based SIP Message Authentication](#) on page 433
- device management users - [OAuth-based User Login Authentication and Authorization](#) on page 417

## Configuring OAuth 2.0 Servers

The OAuth Servers table lets you configure a single OAuth server. You can use the OAuth server for OAuth-based login authentication of users and authentication of incoming SIP message authentication.

The following procedure describes how to configure the OAuth server through the Web interface. You can also configure it through ini file [OAuthServers] or CLI (`configure system > oauth-servers`).

➤ **To configure an OAuth server:**

1. Open the OAuth Servers table (**Setup** menu > **IP Network** tab > **AAA Servers** folder > **OAuth Servers**).
2. Click **New**; the following dialog box appears:

GENERAL	
Index	0
Name	
Server Type	Azure
Base URL	https://login.microsoftonline.com/common
Authorization Endpoint	/oauth2/v2.0/authorize
Device Code Endpoint	/oauth2/v2.0/devicecode
Token Endpoint	/oauth2/v2.0/token
Keys Endpoint	/discovery/v2.0/keys
Logout Endpoint	/oauth2/v2.0/logout
Keys Refresh Time (min)	720
Application ID	
REST API 'aud' Prefix	api://

3. Configure the OAuth server according to the parameters described in the table below.
4. Click **Apply**.

**Table 16-16:OAuth Servers Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' server-name [OAuthServerName]	Defines an arbitrary name to easily identify the row. The valid value is a string of up to 20 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter is mandatory.</li> </ul>
'Server Type' server-type [OAuthServerType]	Defines the provider of the OAuth service. <ul style="list-style-type: none"> <li>■ [0] <b>Azure</b> (default)</li> </ul>

Parameter	Description
	<b>Note:</b> The parameter is mandatory.
'Base URL' base-url [OAuthBaseURL]	Defines the base URL. The endpoints configured by the below parameters follow this base URL. For example, the full URL path of the default authorization endpoint is "https://login.microsoftonline.com/common/oauth2/v2.0/authorize". The default is "https://login.microsoftonline.com/common". <b>Note:</b> The parameter is mandatory.
'Authorization Endpoint' authorization-endpoint [OAuthAuthorizeEndpoint]	Defines the authorization endpoint URL path (which follows the base URL). The default is "/oauth2/v2.0/authorize".
'Device Code Endpoint' devicecode-endpoint [OAuthDeviceCodeEndpoint]	Defines the device code endpoint URL. The default is "/oauth2/v2.0/devicecode".
'Token Endpoint' token-endpoint [OAuthTokenEndpoint]	Defines the token endpoint URL. The default is "/oauth2/v2.0/token".
'Keys Endpoint' keys-endpoint [OAuthKeysEndpoint]	Defines the key endpoint. The default is "/discovery/v2.0/keys". <b>Note:</b> The parameter is mandatory.
'Logout Endpoint' logout-endpoint [OAuthLogoutEndpoint]	Defines the logout endpoint URL. The default is "/oauth2/v2.0/logout".
'Keys Refresh Time' keys-refresh-time [OAuthKeysRefreshTime]	Defines the periodic time (in minutes) to refresh the public keys (by requesting them from Azure Microsoft Entra ID). The valid value range is 360 to 1440. The default is 720. <b>Note:</b> The parameter is mandatory.
'Application ID' application-id [OAuthAppId]	Defines the Application (client) ID assigned by your Azure Microsoft Entra ID account for the app created (registered) for the device in Microsoft Entra ID.

Parameter	Description
	By default, no value is defined. <b>Note:</b> The parameter is mandatory.
'REST API 'aud' Prefix' rest-api-aud-prefix [RestApiAudPrefix]	Defines the REST API 'aud' prefix. This is used when validating the 'aud' specified when the validation request is from the REST API. The default is "api://".
'TLS Context' tls-context [TLSContext]	Assigns a TLS Context from the TLS Contexts table (see <a href="#">Configuring TLS Certificate Contexts</a> on page 227). By default, no value is defined (and TLS Context #0 is used).
'Verify Certificate' verify-certificate [VerifyCertificate]	Enables the verification of the TLS certificate that is used in the incoming connection request from the OAuth server. <ul style="list-style-type: none"><li>■ [0] <b>Disable</b> = (Default) No certificate verification is done.</li><li>■ [1] <b>Enable</b> = The device verifies the authentication of the certificate received from OVOC. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context (see 'TLS Context' parameter above) and if ok, allows communication with the server. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying an Online Certificate Status Protocol (OCSP) server if the certificate has been revoked. This is also configured for the associated TLS Context.</li></ul>
'Network Interface' network-interface [NetworkInterface]	Assigns an IP network interface from the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159) for communication with the OAuth server. By default, no value is defined (and OAMP interface is used). <b>Note:</b> The parameter is mandatory.

## OAuth-based User Login Authentication and Authorization

You can use Microsoft Entra ID (formerly, Azure Active Directory) to authenticate and authorize users that are logging in to the device. This can be implemented for the Web interface, CLI, and REST API management interfaces.

Authentication of a user verifies that the combination of username and password (login credentials) is correct. Authorization of a user determines the user's privilege level (e.g., Security Administrator or Monitor).

The device also supports the following user login authentication methods:

- RADIUS-based authentication (see [RADIUS-based User Login Authentication](#) on page 374)
- LDAP-based authentication (see [LDAP-based Services](#) on page 378)

## Setting Up Microsoft Entra ID for User Login OAuth Authentication

To allow OAuth-based user login authentication using Microsoft Entra ID, you need to set up your Microsoft Entra ID account (<https://portal.azure.com>). Below summarizes the required steps. For a detailed description, contact AudioCodes support.

1. Register a new application (e.g., called "SBC") and define the 'Redirect URI', which is the URL (i.e., device's IP address or host name) to where Microsoft Entra ID sends its authentication response after successfully authenticating the user.
2. Create App Roles, which represent the device's user privilege levels (i.e., Administrator and Monitor).
3. Assign each User (or Group) to the desired Role (privilege level).
4. Note down the values of the following fields, which are required when you configure the Microsoft Entra ID on the device:
  - Application (client) ID
  - Directory (tenant) ID
  - Redirect URI
5. To support CLI user login authentication, contact AudioCodes support.
6. To support REST API client login authentication, contact AudioCodes support.

## Registering Application in Microsoft Entra ID

To enable login through Microsoft Entra ID, you need to first register an application for the device's authentication login feature in your Microsoft Entra ID portal.

### ➤ To register an app in Microsoft Entra ID:

1. Sign in to the [Azure portal](#) using your organization's Microsoft account.
2. If your account gives you access to more than one tenant, click the **Directories + subscriptions** filter  icon on the toolbar to select the tenant in which you want to register an application.
3. Search for and select the **Microsoft Entra ID** service  icon:

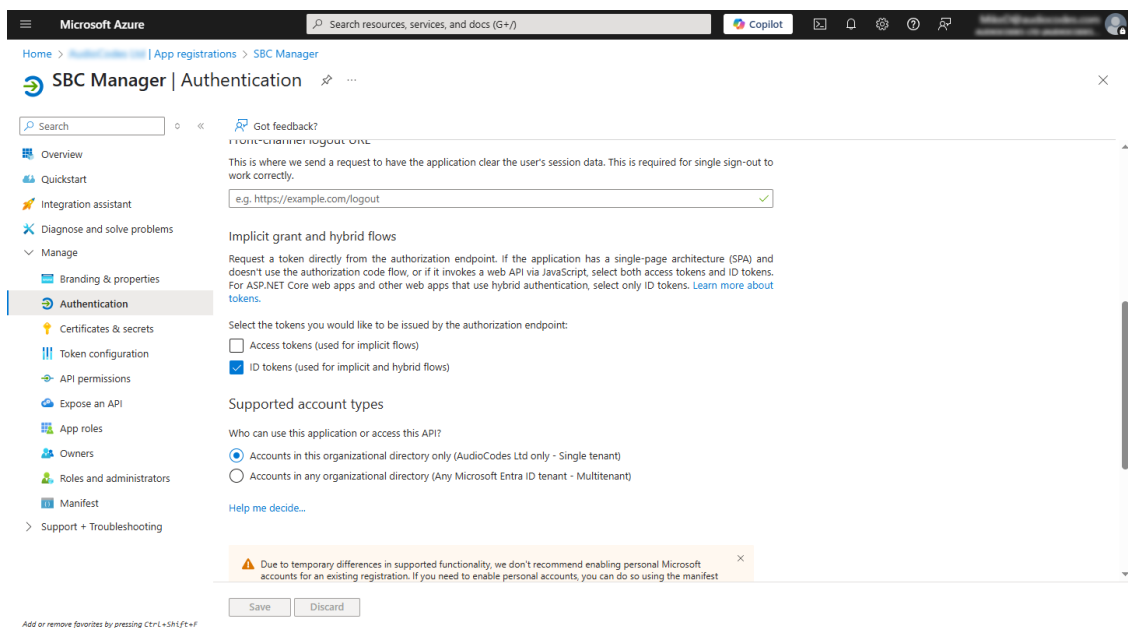

4. From the Navigation pane, select  **App registrations**, and then click **New registration**:

The Register an application page appears:

5. Do the following:
- Under the Name group, enter a meaningful name for the application (e.g., "SBC Manager").
  - Under the Supported account types group, select which accounts you would like your application to support:
    - ◆ If you want to allow users from your organization only to access the application, choose **Accounts in this organizational directory only**.

- ◆ If you want to allow users from any organization to access the application, choose **Accounts in any organizational directory**.
  - c. Under the Redirect URI group, select **Single-page application (SPA)** from the drop-down list, and then enter the redirect URI in the format, `https://<FQDN or IP address of device>`. Upon successful authentication, this is the address to which the user is redirected (i.e., the device).
  - d. Click **Register**; Microsoft Entra ID assigns a unique application (client) ID to your app.
6. From the Navigation menu, select  **Authentication**, and then under the **Implicit grant and hybrid flows** group, select the **ID tokens** check box, and then click **Save**:

7. From the Navigation menu, select  **App roles**, and then click **Create app role**; the Create app role page appears:

8. Create the roles you have in your device (Monitor, Administrator, and Security Administrator):

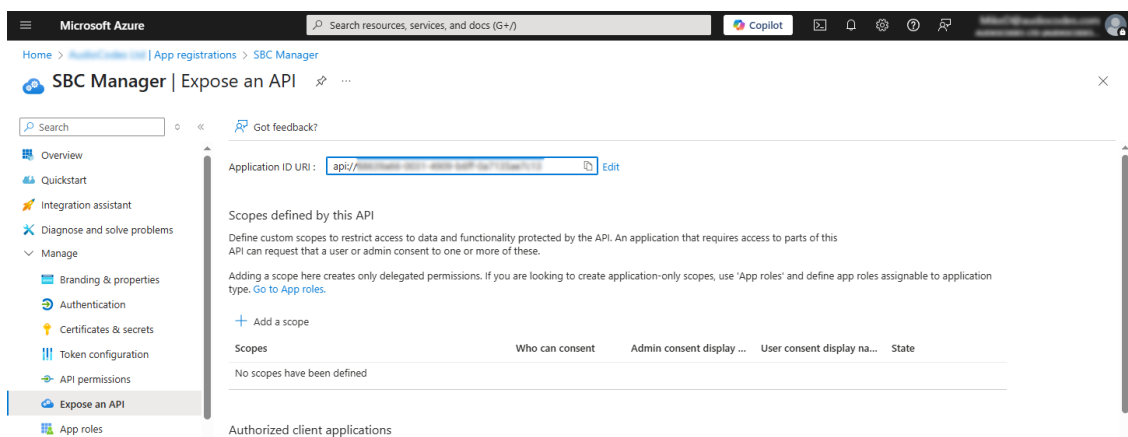

- 'Display name': Define a meaningful display name for each role
- 'Allowed member types': For each role, select **Both (Users/Groups + Applications)**
- 'Value': Enter the following value for the appropriate role:
  - ◆ **Monitor**
  - ◆ **Administrator**
  - ◆ **Security\_Administrator**
- 'Description': Define a meaningful description for each role

Select the **Do you want to enable this app role** check box, and then click **Apply**.

The following step enables programmatic access to the device through REST API. If you don't need such access, skip this step.

- From the Navigation menu, select  **Expose an API**. If an Application ID URI is not configured yet, click **Set**, and then enter the following value: **api://<client ID>** (replace <client ID> with Entra ID application's 'Application (client) ID', which you can obtain from the Overview page), and then click **Save**:

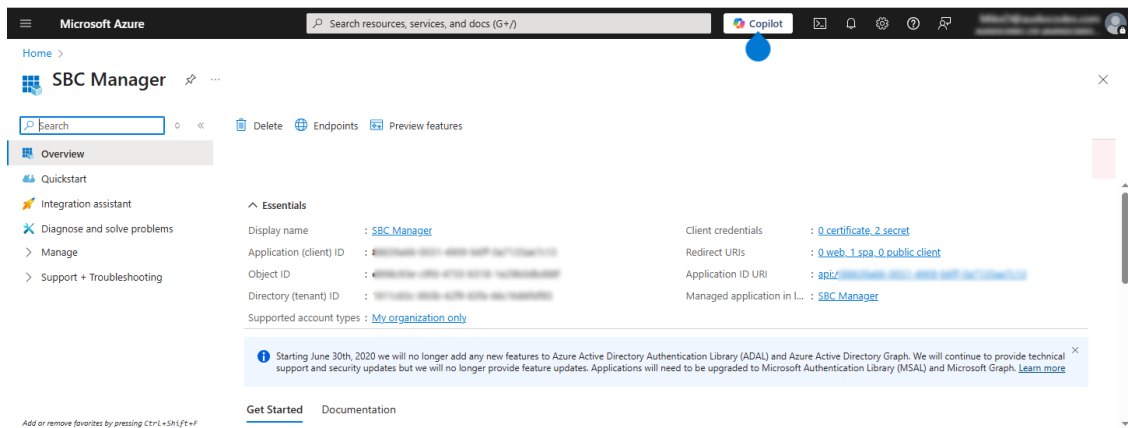

The following step enables CLI access to the device through the serial console or SSH. If you don't need such access, skip this step.

- From the Navigation menu, select  **Authentication**, and then under the **Allow public client flows** group, enable the mobile and desktop flows, by clicking **Yes**, and then clicking **Save**:

- From the Navigation menu, select **Overview**, and then make a note of the 'Application (client) ID' and 'Directory (tenant) ID' values; you will need them when you configure the device.

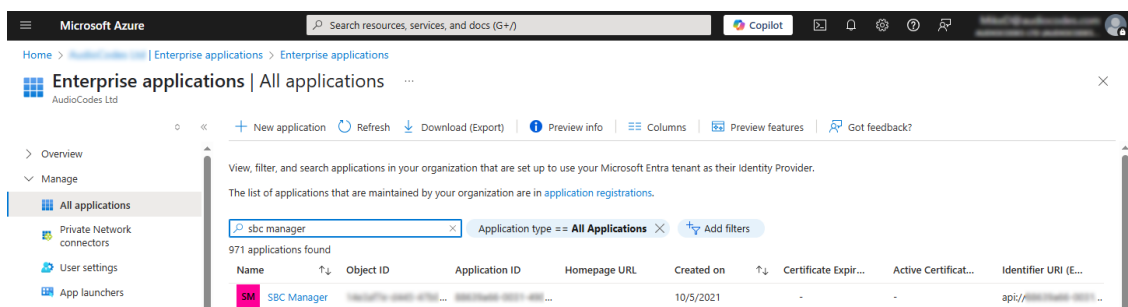

## Assigning Access to Application for User-Groups

Once you have registered the application in Azure (see [Registering Application in Microsoft Entra ID](#) on page 418), you can grant access for specific users and groups.

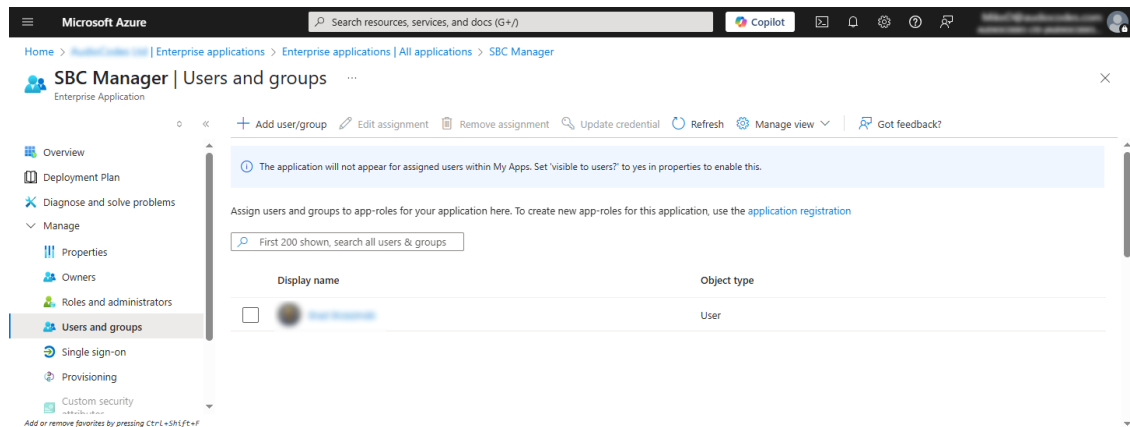

### ➤ To grant access to user/groups:

- From the Navigation pane, select **Enterprise applications**, and then search for your registered application (e.g. "SBC Manager") by setting 'Application type' to **All applications** and typing the application name (e.g. "SBC Manager") into the search field:

2. Click searched for application, and then from the Navigation pane, select  **Users and groups**:

3. For each user or group that you want to grant access to the application:
  - a. Click **Add user/group**.
  - b. Select the user or group.
  - c. Select the role (**Monitor**, **Administrator**, or **Security\_Administrator**).
  - d. Click **Assign**.

## Device Configuration Summary

This section provides a summary of the required configuration of the device for OAuth-based user login authentication using Microsoft Entra ID.

1. Configure a TLS certificate:
  - a. Open the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227), and then select TLS Context #0.
  - b. Click the **Change Certificate** link at the bottom of the page, and then in the load a proper device certificate (see [Assigning CSR-based Certificates to TLS Contexts](#) on page 234).
  - c. Navigate back to the TLS Contexts table, and click the **Trusted Root Certificates** link at the bottom of the page, and then import the [TLS certificates used by Azure](#).
2. Open the Web Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Web Settings**), and then configure the following:
  - a. Select the 'Local Users Table Can Be Empty' check box:

**Local Users Table can be Empty** ☒

- b. From the 'Secured Web Connection (HTTPS)' drop-down list, select **HTTPS Only** or **HTTPS Redirect**.

Secured Web Connection (HTTPS)

• HTTPS Only ▼

- c. In the 'Web Server Name' field, enter the FQDN assigned to the device's management IP address (assigned to eth0 front-end IP on Internal Load Balancer).

Web Server Name

• sbcols1.eastus.12345.com

3. Open the OAuth Servers table (see [Configuring OAuth 2.0 Servers](#) on page 414), and then configure an OAuth Server with the following settings:
  - 'Name': Microsoft Entra ID
  - 'Base URL': https://login.microsoftonline.com/<tenant-id>  
 The <tenant-id> should be the 'Directory (tenant) ID' value from the registered application in Microsoft Entra ID (see [Registering Application in Microsoft Entra ID](#) on page 418) if it is configured to allow access only for users from its organization (single-tenant). The <tenant-id> should be "common" if the application is configured to allow access only for users from all organizations (multi-tenant).
  - 'Application ID': The 'Application (client) ID' value of the registered application in Microsoft Entra ID (see [Registering Application in Microsoft Entra ID](#) on page 418)
  - 'Network Interface': Select the network interface that has the public IP address (e.g., eth2)
  - 'Verify Certificate': **Enable** (requires that you load Microsoft Entra ID CA certificates as trusted roots for TLS Context #0 as described in Step 1 above, or other TLS context configured in TLS Context table)
4. Open the Login OAuth Servers table (see [Configuring OAuth Servers for User Login Authentication](#) on page 429), and then configure a Login OAuth Server with the following settings:
  - 'Name': Microsoft Entra ID
  - 'OAuth Server': Select **Microsoft Entra ID** (created in previous step)
  - 'Service Activation': **Enable**
5. Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**), and then from the 'Use OAuth for Login' drop-down list, select **Enable with local login**.
6. Restart the device to activate the new configuration.

After the device restarts, the Web Login page also displays the **Login with Azure AD** button. You may log in using your Microsoft Entra ID credentials by clicking this button, or log in using your local (device) credentials by entering your username and password in the 'Username' and 'Password' fields respectively.

## Web Login

 Login with Azure AD

OR

**Username**

**Password**

Remember Username ☒

7. Verify that you can log in through Microsoft Entra ID.
8. (Optional) If your login through Microsoft Entra ID is successful, you can disable the login method using local credentials (Local Users table):
  - Open the Authentication Server page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Server**), and then from the 'Use OAuth for Login' drop-down list, select **Enable without local login**. Upon the next log in, the Web Login page only displays the **Login with Azure AD** button.
  - (Optional) Delete all users in the Local Users table (see [Deleting All Users in Local Users Table](#) on page 64).

## Microsoft Entra ID Login to Device's Web Interface

If you configure the device to enable login through Microsoft Entra ID, the Web Login page includes both the **Login with Azure AD** button, and the 'Username' and 'Password' fields for local login using the Local Users table (or using RADIUS or LDAP).

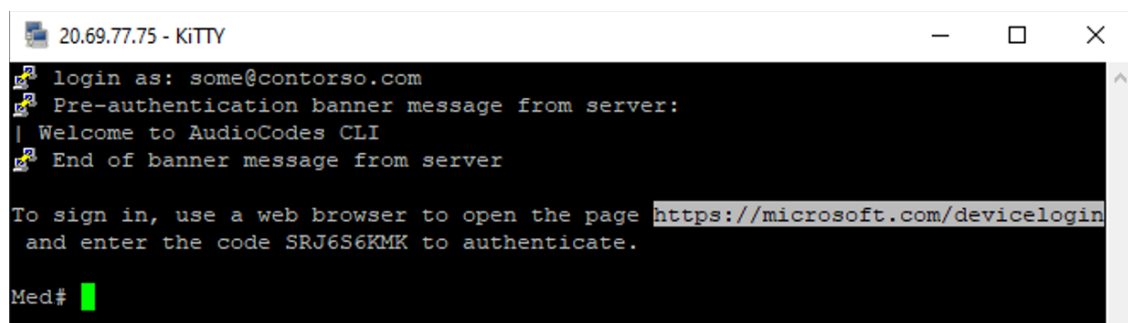

If you configure the device to enable login **only** through Microsoft Entra ID, the Web Login page only displays the **Login with Azure AD** button.

If you click **Login with Azure AD**, you are prompted to enter your Microsoft Entra ID credentials (which may include two-factor authentication). When login authentication completes successfully you are redirected back to the device's Web interface and logged in with the access level according to the Role assigned to you by Microsoft Entra ID.

## Microsoft Entra ID Login to Device's CLI

When you log in to the device through CLI (SSH or serial console), you should enter any string that contains the "@" sign as the username. For example, you may enter your Microsoft Entra ID User ID (email) such as user@contorso.com.

You are prompted to open your Web browser and go to <https://microsoft.com/devicelogin>, and then enter the authentication code shown in the CLI:

```
20.69.77.75 - KITTY
login as: some@contorso.com
Pre-authentication banner message from server:
| Welcome to AudioCodes CLI
End of banner message from server

To sign in, use a web browser to open the page https://microsoft.com/devicelogin
and enter the code SRJ6S6KMK to authenticate.

Med#
```

When the authentication process completes, you will be logged in to the CLI session.

## Microsoft Entra ID Login to Device's REST API

This section describes the login to the device's REST API through Microsoft Entra ID.

### Creating Microsoft Entra ID Application for REST Client

To log in to the device through REST API, you need to create a Microsoft Entra ID Application that represents your REST client and grant this application access to the Microsoft Entra ID Application that represents device.

#### ➤ To create a Microsoft Entra ID Application for REST client:

1. Sign in to the [Azure portal](#) using your organization's Microsoft account.

2. If your account gives you access to more than one tenant, click the **Directories + subscriptions** filter  icon on the toolbar to select the tenant in which you want to register an application.
3. From the Navigation pane, select  **App registrations**, and then click **New registration**.
4. Under the Name group, enter a meaningful name for the application (e.g., "My REST Client"), leave 'Redirect URI' empty, and then click **Register**.
5. From the Navigation menu, select **Overview**, and then make a note of the 'Application (client) ID' and 'Directory (tenant) ID' values; you will need them later.
6. From the Navigation pane, select  **Certificates & secrets**, and then click **New client secret**.
7. Enter a description for the new secret, select the expiration time, and then click **Add**.
8. Copy the value of the generated client secret and store it for future use.
9. From the Navigation pane, select  **API permissions**, and then click **Add a permission** to add new permission.
10. Click the **My APIs** tab, and then select the Azure application that represents the device (e.g., "SBC Manager"):

11. Select **Application permissions**, choose an appropriate role (e.g., Administrator), and then click **Add permissions**.
12. Request from your Microsoft Entra ID administrator to grant admin consent to your app permissions.
13. Wait until your Microsoft Entra ID administrator completes the task and then verify that the status of your application permissions changes to "Granted".

### Acquiring the Access Token

Prior to accessing the device's REST API, you need to acquire the access token using the REST Client application credentials.

➤ **To acquire access token:**

1. Send a POST request to Microsoft identity platform's token endpoint:

```
// Line breaks are for legibility only
POST https://login.microsoftonline.com/<tenant_id>/oauth2/v2.0/token
FORM DATA: {
grant_type=client_credentials
client_id=<rest_client_id>
client_secret=<rest_client_secret>
scope=api://<sbcm_manager_client_id>/default
}
```

Replace the following:

- <tenant\_id> with your tenant ID.
- <rest\_client\_id> and <rest\_client\_secret> with the client ID and secret of the REST Client application.
- <sbcm\_manager\_client\_id> with the client ID of the device's application (e.g., "SBC manager").

Example:

```
curl --location --request POST 'https://login.microsoftonline.com/1911c65c-893b-42f9-83fa-66c1b86fdf85/oauth2/v2.0/token'
--form grant_type="client_credentials"
--form client_id="a26aff59-0bba-42bc-b0a0-87c1e292ef89"
--form client_secret="HMMx3_.pb6XQ26gwiHY45BttS7~Axt_yBH"
--form scope="api://faea2ec7-659a-4c46-8d2a-83436882fdd7/default"
```

2. A successful response contains the access token:

```
200 OK
Content-Type: application/json
{
  "token_type": "Bearer",
  "expires_in": 3599,
  "ext_expires_in": 3599,
  "access_token": "eyJ0eXAiOiJKV1QiLCJhbGciOiJSUzI1NiIs..."
```

### Accessing REST API using Access Token

To access the device's REST API, you need to use the access token that you acquired in [Acquiring the Access Token](#) on the previous page as the Bearer token.

1. Include the access token in the Authorization header when accessing the device's (e.g., "SBC manager") REST API endpoints:

```
GET https://<sbcmgr>/api/v1/status
Authorization: Bearer eyJ0eXAiOiJKV1QiLCJhbGciOiJSUzI1NiIs...
```

2. If you need to send multiple REST API requests, use the session cookie returned in the response to the first request, in the next requests.

## Configuring OAuth Servers for User Login Authentication

The Login OAuth Servers table lets you configure a single interface (Microsoft Entra ID tenant) with the OAuth 2.0 server for OAuth-based user login authentication. OAuth-based login authentication is applicable to the device's Web interface, CLI, and REST API.

The following procedure describes how to configure the OAuth server through the Web interface. You can also configure it through ini file [LoginOAuthServers] or CLI (`configure system > login-oauth-servers`).

### ➤ To configure an OAuth server for user login authentication:

1. Open the Login OAuth Servers table (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Login OAuth Servers**).
2. Click **New**; the following dialog box appears:

3. Configure the login OAuth server according to the parameters described in the table below.
4. Click **Apply**.

**Table 16-17: Login OAuth Servers Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name'	Defines an arbitrary name to easily identify the row (tenant ID).

Parameter	Description
server-name [Name]	The valid value is a string of up to 20 characters. By default, no value is defined. <b>Note:</b> Configure each row with a unique name.
'OAuth Server' oauth-server [OAuthServer]	Assigns an OAuth server, which is configured in the OAuth Servers table (see <a href="#">Configuring OAuth 2.0 Servers</a> on page 414). By default, no value is defined.
'Service Activation' service-activation [ServiceActivation]	Enables this OAuth-based login authentication rule.  ■ [0] <b>Disable</b> (default)  ■ [1] <b>Enable</b>
'Max Response Time' max-resp-time [MaxRespTime]	Defines the maximum time (in seconds) that the device waits for a response from the OAuth server. If no response is received within this period, the device considers it a response timeout (and no retries are done).  The valid value is 1 to 30. The default is 3.

### Enabling OAuth-based User Login Authentication

In addition to configuring the OAuth 2.0 server for user login authentication based on the OAuth 2.0 protocol (see [Configuring OAuth Servers for User Login Authentication](#) on the previous page and [Configuring OAuth 2.0 Servers](#) on page 414, you need to enable OAuth-based login authentication.

You can enable OAuth-based login authentication only. In this configuration setup, the Web Login page is displayed as below. To log in, click **Login with Azure AD**. You are redirected to Microsoft login page to start the login process. If login fails, you are redirected to the Web Login page and a failure message is displayed.

Alternatively, you can enable OAuth-based login authentication with local (or RADIUS or LDAP) login authentication. Local authentication uses the Local Users table (see [Configuring Local Management User Accounts](#) on page 55) to authenticate the user's login credentials (username and password). This means that the user can choose to log in to the device using any one of these authentication methods. In this configuration setup, the Web Login page is displayed as below:

## Web Login

 Login with Azure AD

OR

**Username**

**Password**

Remember Username ☒

To log in using OAuth 2.0 authentication, click **Login with Azure AD**. To log in using local (or RADIUS or LDAP) authentication, enter your username and password, and then click **Log In**.

For OAuth user login authentication, you also need to enable the OAuth server used for login authentication ('Service Activation' parameter) in the Login OAuth Servers table (see [Configuring OAuth Servers for User Login Authentication](#) on page 429).

➤ **To enable OAuth-based login authentication:**

1. Open the Authentication Settings page (**Setup** menu > **Administration** tab > **Web & CLI** folder > **Authentication Settings**).
2. From the 'Use OAuth for Web Login' drop-down list, select one of the following:

- **Disable:** Disables OAuth-based login authentication
- **Enable with local login:** Enables both OAuth-based login authentication and local login authentication (using the Local Users table)
- **Enable without local login:** Enables OAuth-based login authentication only

Use OAuth for Web Login

■ Enable with local login ▼

Redirect URI

https://10.15.7.96

The 'Redirect URI' read-only field displays the URL (i.e., device's IP address, or hostname if configured) that the user is redirected to (e.g., by Microsoft Entra ID) after it has been successfully authenticated (and is then logged in).

3. Click **Apply**.

## OAuth 2.0 Based SIP Message Authentication

You can use the following methods to authenticate incoming SIP messages using the OAuth 2.0 protocol:

- [Authenticating SIP Messages using Device's OAuth 2.0 Server with Microsoft Entra ID](#) below
- [Authenticating SIP Messages with External OAuth 2.0 Server](#) on the next page

### Authenticating SIP Messages using Device's OAuth 2.0 Server with Microsoft Entra ID

You can configure the device to use Microsoft Entra ID (formerly, Azure Active Directory) to authenticate incoming SIP messages based on the OAuth 2.0 protocol. Microsoft Entra ID is a cloud-based identity and access management service, designed for Internet-based applications.

As Microsoft Entra ID doesn't support OAuth Token Introspection, the device validates the received token using its embedded NGINX server, which simulates an OAuth 2.0 Introspection endpoint.

The SIP UA obtains its token using the Microsoft Entra ID APIs for identification and token generation, in JSON Web Token (JWT) format, which is a secure signed and encrypted JSON document identifying the user, and includes it in the Authorization header of SIP requests sent to the device. For the device to validate the JWT, it needs the public keys from Microsoft Entra ID, which it downloads periodically (Microsoft Entra ID refreshes keys daily).

When the device receives a SIP request that needs validation, it extracts the token from the 'Authorization: Bearer <token>' header of the SIP message and sends it the NGINX server. NGINX then decrypts the token using the public keys and validates them.

➤ **To configure OAuth 2.0 authentication with Microsoft Entra ID:**

1. Make sure that the settings of your Microsoft Entra ID are appropriately defined to operate with the device. For more information, contact your AudioCodes sales representative.
2. Configure a Remote Web Service to represent the device's embedded NGINX server, acting as the OAuth 2.0 Introspection endpoint:
  - a. Open the Remote Web Services table (see [Configuring Remote Web Services](#) on page 438), and then configure a Remote Web Service with the following settings:
    - ◆ 'Name': "InternalOauth"
    - ◆ 'Type': **General**
    - ◆ 'Path': "introspect"
  - b. Select the Remote Web Service that you configured, click the **HTTP Remote Hosts** link located below the table, and then configure an HTTP Remote Host to represent the device's embedded NGINX (OAuth) server, with the following settings:
    - ◆ 'Address': "127.0.0.1"
    - ◆ 'Port': "321"
    - ◆ 'Transport Type': **HTTP**
3. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then configure an IP Group for the source of the incoming SIP messages with the following settings:
  - 'Authentication Mode': **SBC as Server**
  - 'Authentication Method List': "register/setup-invite"
  - 'SBC Server Authentication Type': **Authenticate with OAuth Server**
  - 'OAuth HTTP Service': **Internal Oauth** (i.e., Remote Web Service that you configured previously)
4. Make sure that you have configured a DNS server for the local IP network interface in the IP Interfaces table (see [Configuring IP Network Interfaces](#) on page 159).
5. Open the OAuth Servers table (see [Configuring OAuth 2.0 Servers](#) on page 414), and then configure the OAuth 2.0 server for Microsoft Entra ID with the following settings:
  - 'Base URL': "https://login.microsoftonline.com/<tenant ID, obtained from your Microsoft Entra ID account>"
  - 'Application ID': Copy-and-paste the Application (client) ID, obtained from your Microsoft Entra ID account.

### **Authenticating SIP Messages with External OAuth 2.0 Server**

The device supports the OAuth 2.0 authentication protocol (RFC 7662 and Internet Draft "draft-ietf-sipcore-sip-authn-02"), allowing it to authenticate any specified incoming SIP request (e.g.,

REGISTER and INVITE) with a third-party OAuth 2.0 authorization server over HTTP/S.

OAuth-based authentication is applicable only to the SBC application.

To authenticate SIP messages using the device's embedded NGINX server (acting as the Introspection endpoint) with Microsoft Entra ID, see [Authenticating SIP Messages using Device's OAuth 2.0 Server with Microsoft Entra ID](#).

OAuth authorization consists of the following main stages:

1. (This stage doesn't involve the device.) The client application requires an OAuth Access Token for the user. There are multiple schemes to do this. For example, it may use the Authorization Code method, whereby the client application refers the user to the OAuth Authorization server to request an Authorization Code. The client application then uses the received Authorization Code to request an Access Token (and a Refresh Token) for the user from the Authorization server.
2. When the user wants to register with the device or make a call, the client application (e.g., Web browser for the WebRTC application) through which the user communicates with the device, sends a SIP REGISTER or INVITE request that includes the user's Access Token in the SIP Authorization header ("Bearer" value), as shown in the following REGISTER message example:

```
REGISTER sip:server.com SIP/2.0
Via: SIP/2.0/WSS 9rihbeck4vat.invalid;branch=z9hG4bK2426139
Max-Forwards: 69
To: <sip:alice@example.com>
From: "alice" <sip:alice@example.com>;tag=mstg4hpof6
Call-ID: 0il6hahess4ndc1pdlleqj
CSeq: 1 REGISTER
```

```
Authorization: Bearer eyJhbGciOiJSUzI1...
...zLbbMmZ06JA
```

```
Contact: <sip:lnumvv6i@9rihbeck4vat.invalid;transport=ws>;+sip.ice;reg-id=1;
+sip.instance="<urn:uuid:1007ed30-98a3-492e-966f
67b6f6eb99c5>";expires=600
Expires: 600
Allow:
INVITE,ACK,CANCEL,BYE,UPDATE,MESSAGE,OPTIONS,REFER,INFO
Supported: path,gruu,outbound
User-Agent: Example WebRTC phone
Content-Length: 0
```

3. The device authenticates the SIP request, by sending (HTTP POST) an HTTP Introspection request with the user's Access Token to the OAuth Authorization server, as shown in the following example:

```
POST /realms/demo/protocol/openid-connect/token/introspect HTTP/1.1
Host: authorizationhost.com
Content-Type: application/x-www-form-urlencoded
Content-Length:...
Authorization: Basic
dGVzdEludHJvc3BIY3Q6NTliZDA4NGUtMTJlNi00N2I5LWJmNz
token=<Access Token from Bearer in SIP Authorization header>
```

4. The OAuth Authorization server checks (*introspects*) if the token is currently active (or if it has expired or revoked). Upon a successful introspection, the OAuth Authorization server sends to the device a 200 OK response containing a JSON body ("application/ json").
5. The device checks the following attributes in the received JSON body:
  - "active": A "true" value indicates a valid token and the device allows the user access to its resources and continues with the regular handling and processing of the SIP request (e.g., registers user or processes the call). A "false" value indicates an invalid token and the device responds to the SIP request with a 401 (Unauthorized) response containing the header 'WWW-Authenticate: Bearer error="invalid-token"', indicating authentication failure.
  - "username": (Optional attribute) When it exists, the device compares it to the AOR of the SIP message. For REGISTER requests, the AOR is taken from the To header; for all other requests, the AOR is taken from the From header. If the username includes a "@" character, the entire AOR is compared; otherwise, only the user-part of the AOR is compared. If comparison fails, the device responds to the SIP request with a 401 (Unauthorized) response containing the header 'WWW-Authenticate: Bearer error="invalid\_request"', indicating authentication failure.

The main configuration required for OAuth-based authentication, includes the following:

- Configuring a Remote Web Service to represent the OAuth Authentication server

- Configuring the source IP Group (client) to authenticate by an OAuth Authorization server

The following provides a step-by-step example of configuring OAuth authentication.

➤ **To configure OAuth-based authentication:**

1. Open the Remote Web Services table (see [Configuring Remote Web Services](#) on the next page), and then configure a Remote Web Service to represent the OAuth Authentication server:

Parameter	Value	Comment
'Name'	"OAuth-Server"	Any descriptive name.
'Type'	<b>General</b>	-
'Path'	"realms/demo/protocol/openid-connect/token/introspect"	Relative URL for the introspection service on the server.
'Username'	"device234"	Username that the device uses for authenticating the HTTP POST introspection request which it sends to the OAuth server.
'Password'	"12abMt"	Password that the device uses for authenticating the HTTP POST introspection request which it sends to the OAuth server. <b>Note:</b> The password cannot be configured with wide characters.

2. Select the Remote Web Service that you configured in Step 1, click the **HTTP Remote Hosts** link located below the table, and then configure an HTTP Remote Host:

Parameter	Value	Comment
'Address'	"oauth.example.com"	Address of the Authentication server.
'Port'	"443"	Port number of the Authentication server.
'Transport Type'	<b>HTTPS</b>	Secured HTTP.

3. Configure OAuth-based authentication for the source IP Group (client that the device needs to authenticate):

Parameter	Value	Comment
'Authentication Mode'	<b>SBC as Server</b>	The device authenticates as a server.
'Authentication Method List'	"register/setup-invite"	The SIP methods that the device needs to authenticate.
'SBC Server Authentication Type'	<b>Authenticate with OAuth Server</b>	The device authenticates the SIP requests with an OAuth Authentication server.
'OAuth HTTP Service'	<b>OAuth-Server</b>	Assigns the Remote Web Service that you configured (in Step 1) for the OAuth Authentication server.

## Remote Web Services

This section describes configuration for remote Web services.

To debug remote Web services, see [Debugging Web Services](#) on page 1662.

## Configuring Remote Web Services

The Remote Web Services table lets you configure up to seven Web-based (HTTP/S) services (*Remote Web Services*) provided by third-party, remote HTTP/S hosts (*HTTP Remote Hosts*). The following types of services can be offered by the remote hosts: Routing service, Call Status service, Topology Status service, QoS service, General service, and Registration Status service. For more information on these services, see the description of the 'Type' parameter below.

Remote Web Services are configured using two tables with "parent-child" relationship:

- **Remote Web Services table ("parent"):** Defines the name of the Remote Web Service as well as other settings (e.g., type of service). This table is described below.
- **HTTP Remote Hosts table ("child"):** Defines remote HTTP hosts (e.g., IP address) per Remote Web Service. For more information, see [Configuring Remote HTTP Hosts](#) on page 447.

- You can configure only **one** Remote Web Service for each of the following service types: **Routing**, **Call Status**, **Topology Status**, **QoS**, **Registration Status**, and **Remote Monitoring**.
- The Routing service also includes the Call Status and Topology Status services.
- The device supports HTTP redirect responses (3xx) only during connection establishment with the host. Upon receipt of a redirect response, the device attempts to open a new socket with the host and if this is successful, closes the current connection.

The following procedure describes how to configure Remote Web Services through the Web interface. You can also configure it through ini file [HTTPRemoteServices] or CLI (`configure system > http-services > http-remote-services`).

➤ **To configure a remote Web service:**

1. Open the Remote Web Services table (**Setup** menu > **IP Network** tab > **Web Services** folder > **Remote Web Services**).
2. Click **New**; the following dialog box appears:

3. Configure a remote Web service according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 16-18: Remote Web Services Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Each row must be configured with a unique index.</li> <li>■ The parameter is mandatory.</li> </ul>
'Name'	Defines a descriptive name, which is used when

Parameter	Description
rest-name [Name]	<p>associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter is mandatory.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
'Type' rest-message-type [HTTPType]	<p>Defines the type of service provided by the HTTP remote host:</p> <ul style="list-style-type: none"> <li>■ [0] <b>Routing</b> = (Default) This option provides a call routing service, whereby the host (ARM) determines the next hop of an incoming call on the path to its final destination. For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451. This option also includes the services provided by the <b>Call Status</b> and <b>Topology Status</b> options.</li> <li>■ [1] <b>Call Status</b> = This option provides a call status service for calls processed by the device. The device provides call status to the host by sending CDRs.</li> <li>■ [2] <b>Topology Status</b> = This option provides a topology status service, which refers to all device configuration changes (add, edit and delete actions). The device sends topology status to the HTTP host, using the REST API command, TopologyStatus. For this service to be functional, you also need to enable the Topology Status service as described in <a href="#">Enabling Topology Status Services</a> on page 450.</li> </ul> <p>Topology status includes the following:</p> <ul style="list-style-type: none"> <li>✓ IP Group Connectivity: Status is reported when the keep-alive mechanism, enabled for the associated Proxy Set, detects that the IP Group is unavailable, or when CAC thresholds (configured in the Admission Control table) associated with the IP Group are crossed.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Trunk Group Availability: Status is reported when the trunk's physical state indicates that the trunk is unavailable. (Applicable only to the Gateway application.)</li> <li>✓ Configuration Status: Status is reported when IP Groups, Trunk Groups, (Gateway application only) or SIP Interfaces that are configured to be used by remote Web-based services (i.e., the UsedByRoutingServer parameter is set to 1 - Used) are created or deleted. If you subsequently change the settings of the UsedByRoutingServer parameter or the 'Name' parameter, the device reports the change as a creation or deletion of the corresponding configuration entity.</li> <li>■ [5] <b>QoS</b> = This option provides a call routing service based on Quality of Service (QoS). For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</li> <li>■ [8] <b>General</b> = This option can be used for the following services: <ul style="list-style-type: none"> <li>✓ Generating and sending CDRs to a REST server through REST API. The REST server is configured as an HTTP-based server (Remote Web Service). For more information, see <a href="#">Configuring CDR Reporting to REST Server</a> on page 1515.</li> <li>✓ Querying (GET) HTTP servers using Call Setup Rules. The response from the server can be used for various functionality such as tag-based classification and routing. When configuring the Call Setup Rule, you need to configure the 'Request Target' parameter to the name of this Remote Web Service. For more information on Call Setup Rules, see <a href="#">Configuring Call Setup Rules</a> on page 809.</li> <li>✓ Requesting a Push Notification Server to wake a SIP user agent (typically, a mobile device)</li> </ul> </li> </ul>

Parameter	Description
	<p>that is registered with the server for Push Notification Service, through REST API. The REST server (Push Notification Server) is configured as an HTTP-based server (Remote Web Service). For more information, see <a href="#">Configuring Push Notification Service</a> on page 1288.</p> <ul style="list-style-type: none"> <li>■ [9] <b>Registration Status</b> = This option provides a call routing service based on registration status. The device periodically synchronizes its database of registered user agents (endpoints) with ARM (HTTP host) to keep it up to date, enabling ARM to use this information to perform correct and optimal routing decisions. For this service to be functional, you also need to enable the Registration Status service as described in <a href="#">Enabling Registration Status Services</a> on page 450.</li> <li>■ [10] <b>Remote Monitoring</b> = This option provides a remote monitoring of the device service when the device is located behind a NAT. The device sends its monitoring reports to this Remote Web Service (HTTP host). To enable remote monitoring and to select the report types that you want sent, see <a href="#">Remote Monitoring of Device behind NAT</a> on page 1599.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure only one Remote Web Service for each of the following service types: <b>Routing</b>, <b>Call Status</b>, <b>Topology Status</b>, <b>QoS</b>, <b>Registration Status</b>, and <b>Remote Monitoring</b>.</li> <li>■ The <b>Routing</b> option also includes the Call Status and Topology Status services.</li> <li>■ If you don't configure the parameter to <b>QoS</b>, the device sends QoS reports to the Topology server.</li> <li>■ For the Registration Status service, if you have not configured the parameter to <b>Registration Status</b> for any Remote Web Service, the device provides the service to the Remote Web Service for which you have configured the parameter to <b>Topology Status</b>.</li> </ul>

Parameter	Description
'Path' rest-path [Path]	Defines the path (prefix) to the REST APIs. The valid value is a string of up to 80 characters. The default is "api".
'Number of Connections' http-num-connections [NumOfSockets]	Defines the number of sockets that the device opens per HTTP remote host. The valid value is 3. The default is 1.
Policy	
'Policy in Group' http-policy [Policy]	<p>Defines the mode of operation between hosts in a group, which are configured in the HTTP Remote Hosts table for the specific remote Web service.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Round Robin</b> = (Default) The device does load balancing of traffic across all the hosts in the group. Every consecutive message is sent to the next available host. The priority of the hosts determines the order in which the device sends the traffic.</li> <li>■ [1] <b>Sticky Primary</b> = The device always attempts to send traffic to the host that has the highest priority in the group. If the host doesn't respond, the device sends the traffic to the next available host that has the highest priority. If the host that has the highest priority becomes available again, the device sends the traffic to this host.</li> <li>■ [2] <b>Sticky Next</b> = The device initially attempts to send traffic to the host that has the highest priority in the group. If this host becomes unavailable (or is initially unavailable), the device sends the traffic to the next available host that has the highest priority and continues sending traffic to this host even if the highest-priority host later becomes available again.</li> </ul> <p><b>Note:</b> If you have configured multiple hosts with the same priority, their priority is determined by their order of appearance in the HTTP Remote Hosts table. For example, if two hosts are configured in rows Index 0 and Index 1 with priority 0, the host in Index 0 is considered higher priority.</p>

Parameter	Description
'Policy between Groups' <code>http-policy-between-groups</code> <code>[BetweenGroupsPolicy]</code>	<p>Defines the mode of operation between groups of hosts, which are configured in the HTTP Remote Hosts table for the specific remote Web service.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Sticky Primary</b> = (Default) The device always attempts to send traffic to the group that has the highest priority (e.g., Group 0). If none of the hosts in this group respond, the device attempts to send traffic to a host in a group that has the next highest priority (e.g., Group 1), and so on. Whenever a host in the group that has the highest priority (e.g., Group 0) becomes available again, the device sends the traffic to the host in this group.</li> <li>■ [2] <b>Sticky Next</b> = The device initially attempts to send traffic to the group of hosts that has the highest priority (e.g., Group 0). If none of the hosts in the group respond, the device attempts to send traffic to a host in a group that has the next highest priority (e.g., Group 1). Even if the group of hosts that has the highest priority (e.g., Group 0) becomes available again, the device continues sending traffic to this lower priority group (e.g., Group 1) .</li> </ul>
'Automatic Reconnect' <code>http-persistent-connection</code> <code>[PersistentConnection]</code>	<p>Defines whether the HTTP connection with the host remains open or is only opened per request.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = The HTTP connection is created per client (user) request and remains connected until the server closes the connection.</li> <li>■ [1] <b>Enable</b> = (Default) The device creates the HTTP connection once you have configured the service. If the server closes the connection, the device re-opens it. If the keep-alive timeout is configured, the device uses HTTP keep-alive messages to keep the connection open all the time.</li> </ul>
Login Needed <code>http-login-needed</code> <code>[LoginNeeded]</code>	<p>Enables the use of the AudioCodes proprietary REST API Login and Logout commands for connecting to the remote host. The commands verify specific information (e.g., software version) before allowing connectivity with the device.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Commands are not used.</li> <li>■ [1] <b>Enable</b> (default)</li> </ul> <p><b>Note:</b> The parameter is applicable only if you configure the 'Type' parameter to any value other than <b>General</b>.</p>
Authentication	
'Username' rest-user-name [AuthUserName]	Defines the username for HTTP authentication. The valid value is a string of up to 80 characters. The default is "user".
'Password' rest-password [AuthPassword]	Defines the password for HTTP authentication. The valid value is a string of up to 80 characters. The default is "password". <p><b>Note:</b> The password cannot be configured with wide characters.</p>
Security	
'TLS Context' rest-tls-context [TLSContext]	Assigns a TLS Context (TLS configuration) for connection with the remote host. By default, no value is defined. To configure TLS Contexts, see <a href="#">TLS Certificates</a> on page 227. <p><b>Note:</b> The parameter is applicable only if the connection is HTTPS.</p>
'Verify Certificate' rest-verify-certificates [VerifyCertificate]	Enables certificate verification when connection with the host is based on HTTPS. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Enable</b> = The device verifies the authentication of the certificate received from the HTTPS peer. The device authenticates the certificate against the trusted root certificate store associated with the associated TLS Context (see 'TLS Context' parameter above) and if ok, allows communication with the HTTPS peer. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the</li> </ul>

Parameter	Description
	<p>certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also configured for the associated TLS Context.</p> <p><b>Note:</b> The parameter is applicable only if the connection is HTTPS.</p>
<p>'Verify Certificate Subject Name'</p> <p>verify-cert-subject-name</p> <p>[VerifyCertificateSubjectName]</p>	<p>Enables the verification of the TLS certificate subject name (Common Name / CN or Subject Alternative Name / SAN) when connection with the host is based on HTTPS.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Off</b> = (Default) No verification is done.</li> <li>■ [1] <b>On</b> = The device verifies the subject name of the certificate received from the HTTPS peer. If the server's URL contains a hostname, it verifies the certificate against the hostname; otherwise, it verifies the certificate against the server's IP address. If authentication fails, the device denies communication (i.e., handshake fails).</li> </ul> <p><b>Note:</b> The parameter is applicable only if the connection is HTTPS.</p>
Timeouts	
<p>'Response Timeout'</p> <p>rest-timeout</p> <p>[TimeOut]</p>	<p>Defines the TCP response timeout (in seconds) from the remote host. If one of the remote hosts doesn't respond to a request (e.g., HTTP GET method) within the specified timeout, the device closes the corresponding socket and attempts to connect to the next remote host.</p> <p>The valid value is 1 to 65535. The default is 5.</p> <p><b>Note:</b> The global parameter for response timeout is described in <a href="#">Configuring a Routing Response Timeout</a> on page 1214.</p>
<p>'Keep-Alive Timeout'</p> <p>rest-ka-timeout</p> <p>[KeepAliveTimeOut]</p>	<p>Defines the duration/timeout (in seconds) in which HTTP-REST keep-alive messages are sent by the device if no other messages are sent. Keep-alive messages may be required for HTTP services that expire upon inactive sessions. For Remote Web Service whose 'Type' is <b>Routing</b>, <b>Call Status</b>, <b>Topology Status</b>, or</p>

Parameter	Description
	<p><b>QoS</b>, proprietary keep-alive messages are sent. For 'Type' that is <b>General</b>, HTTP OPTIONS keep-alive messages are sent.</p> <p>The valid value is 0 to 65535. The default is 0 (i.e., no keep-alive messages are sent).</p>
Status	
'Status'	<p>(Read-only) Displays the status of the host associated with the Web service.</p> <ul style="list-style-type: none"> <li>■ "Connected": At least one of the hosts is connected.</li> <li>■ "Disconnected": All hosts are disconnected.</li> </ul>
'Active Group'	<p>(Read-only) Displays the currently active Group (by ID) that is associated with the Web service. This is the host group to where the device is currently sending traffic.</p>
'Active Host'	<p>(Read-only) Displays the currently active host (by name) that is associated with the Web service. This is the host (within the active group) to where the device is currently sending traffic.</p> <p><b>Note:</b> If traffic is sent to the hosts in a round-robin fashion (i.e., 'Policy in Group' parameter is configured to <b>Round Robin</b>), then this field displays "NA".</p>

## Configuring Remote HTTP Hosts

The HTTP Remote Hosts table lets you configure up to 10 remote HTTP hosts per Remote Web Service. The HTTP Remote Hosts table is a "child" of the Remote Web Services table (configured in [Configuring Remote Web Services](#) on page 438).

The following procedure describes how to configure HTTP Remote hosts through the Web interface. You can also configure it through ini file [HTTPRemoteHosts] or CLI (`configure system > http-services > http-remote-hosts`).

### ➤ To configure a remote HTTP host:

1. Open the Remote Web Services table (**Setup** menu > **IP Network** tab > **Web Services** folder > **Remote Web Services**).
2. In the table, select the required remote Web service index row, and then click the **HTTP Remote Hosts** link located below the table; the HTTP Remote Hosts table appears.

3. Click **New**; the following dialog box appears:

The screenshot shows a configuration window titled "HTTP Remote Hosts". It contains four sections: GENERAL, GROUPING, TRANSPORT, and STATUS. In the GENERAL section, the Index is set to 0, and there is a Name field. In the TRANSPORT section, the Address is 0.0.0.0, Port is 80, and Transport Type is HTTP. The GROUPING section shows Group ID and Priority in Group both set to 0. The STATUS section has a Status field.

4. Configure an HTTP remote host according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-19: HTTP Remote Hosts Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' <code>rest-servers</code> [HTTPRemoteHosts_ RemoteHostindex]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Each row must be configured with a unique index.</li> <li>The parameter is mandatory.</li> </ul>
'Name' [HTTPRemoteHosts_ Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Configure each row with a unique name.</li> <li>The parameter is mandatory.</li> </ul>
<b>Transport</b>	
'Address' <code>rest-address</code> [HTTPRemoteHosts_ Address]	<p>Defines the address (IPv4 or IPv6 address, or FQDN) of the remote host.</p> <p>The valid value is a string of up to 80 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>If the address is an FQDN and the DNS resolution results in multiple IP addresses, the device attempts to establish multiple connections (sessions) for each IP address. Only the first 10 resolved IP addresses are used regardless of the</li> </ul>

Parameter	Description
	<p>number of hosts.</p> <ul style="list-style-type: none"> <li>■ DNS resolution is also performed (immediately) when connection is subsequently "closed" (by timeout or by the remote host) and connections are updated accordingly. In addition, the device periodically (every 15 minutes) performs DNS name resolution to ensure that the list of resolved IP addresses has not changed. If a change is detected, the device updates its' list of IP addresses and re-establishes connections accordingly.</li> <li>■ In addition to multiple HTTP sessions, the device establishes multiple (TCP) connections per session, thereby enhancing data exchange capabilities with the host.</li> </ul>
'Port' rest-port [HTTPRemoteHosts_ Port]	<p>Defines the port of the host.</p> <p>The valid value is 0 to 65535. The default is 80.</p>
'Interface' rest-interface [HTTPRemoteHosts_ Interface]	<p>Assigns one of the device's IP network interfaces (configured in <a href="#">Configuring IP Network Interfaces</a> on page 159) through which communication with the remote host is done.</p> <p>By default, no value is defined and the IPv4 OAMP interface is used.</p> <p><b>Note:</b> The address version (IPv4 or IPv6) of the IP Interface and the HTTP remote host (see 'Address' field above) must be the same.</p>
'Transport Type' rest-transport- type [HTTPRemoteHosts_ HTTPTransportType]	<p>Defines the protocol for communicating with the remote host:</p> <ul style="list-style-type: none"> <li>■ [0] <b>HTTP</b> (default)</li> <li>■ [1] <b>HTTPS</b></li> </ul>
Grouping	
'Group ID' group-id [HTTPRemoteHosts_ GroupID]	<p>Defines the host's group ID. The group number (ID) reflects the priority of the group. The device sends traffic to host groups according to the configuration of the 'Policy between Groups' parameter in the Remote Web Services table.</p> <p>The valid value is 0 to 4, where 0 is the highest priority and 4 the lowest. The default is 0.</p>

Parameter	Description
'Priority in Group' host-priority-in-group [HTTPRemoteHosts_PriorityInGroup]	<p>Defines the priority level of the host within the assigned group. The device sends traffic to hosts within the group according to the configuration of the 'Policy in Group' parameter in the Remote Web Services table.</p> <p>The valid value is 0 to 9, where 0 is the highest priority and 9 the lowest. The default is 0.</p> <p><b>Note:</b> If you have configured multiple hosts in the group with the same priority, their priority is determined by their order of appearance in the table. For example, if two hosts are configured in rows Index 0 and Index 1 with priority 0, the host in Index 0 is considered higher priority.</p>
Status	
'Status'	<p>(Read-only) Displays the status of the connection with the remote host.</p> <ul style="list-style-type: none"> <li>■ "Connected": The host is connected.</li> <li>■ "Disconnected": The host is disconnected.</li> </ul>

## Enabling Topology Status Services

You can enable the device to send device configuration (topology) status (add, edit and delete) for Web-based services (Remote Web Services). Once enabled, you need to add a Remote Web Service with the 'Type' parameter configured to **Topology Status** (see [Configuring Remote Web Services](#) on page 438).

### ➤ To enable Topology Status services:

1. Open the Web Service Settings page (**Setup** menu > **IP Network** tab > **Web Services** folder > **Web Service Settings**).
2. Select the 'Topology Status' check box [RoutingServerGroupStatus]:

Topology Status

3. Click **Apply**.

## Enabling Registration Status Services

You can enable the device to periodically synchronize its registration database of SIP user agents (endpoints) with ARM (Remote Web Service). ARM can then use this information for routing decisions. Once enabled, you need to add a Remote Web Service with the 'Type'

parameter configured to **Registration Status** (see [Configuring Remote Web Services](#) on page 438).

For more information on routing by ARM, see [Centralized Routing by ARM \(AudioCodes Routing Manager\)](#) below.

➤ **To enable Registration Status services:**

1. Open the Web Service Settings page (**Setup** menu > **IP Network** tab > **Web Services** folder > **Web Service Settings**).
2. Select the 'Routing Server Registration Status' check box [RoutingServerRegistrationStatus]:

Routing Server Registration Status • ☒

3. Click **Apply**.

## Centralized Routing by ARM (AudioCodes Routing Manager)

You can employ ARM (AudioCodes Routing Manager) -- *Remote Web Service* configuration entity -- to handle call routing decisions in deployments consisting of multiple AudioCodes devices. ARM can be used to handle SBC, Tel-to-IP, and IP-to-Tel calls. ARM replaces the need for the device's routing tables--IP-to-IP Routing table for SBC calls, and Tel-to-IP Routing table and IP-to-Tel Routing table for Tel-to-IP and IP-to-Tel calls respectively--to determine call destination.

For more information on ARM, refer to the documents *ARM User's Manual* and *ARM Installation Manual*, which can be downloaded from AudioCodes [website](#).

For SBC calls, when the device receives an incoming call (SIP INVITE, NOTIFY or MESSAGE), it searches the IP-to-IP Routing table for a matching routing rule. If the routing rule is configured to use ARM ('Destination Type' parameter configured to **Routing Server**), the device sends a request to ARM for an appropriate destination.

For Gateway calls, when the device receives an incoming call (SIP INVITE, NOTIFY or MESSAGE), it disregards the routing tables and instead, immediately sends a request to ARM for an appropriate destination.

The request is sent to ARM using an HTTP Get Route message. The request contains information about the call (SIP message) and for IP-to-Tel calls, the source IP Group based on the associated Proxy Set.

ARM uses its own algorithms and logic in determining the best route path. ARM manages the call route between devices in "hops", which may be spread over different geographical locations. The destination to each hop (device) can be an IP address (with a port) or IP Group or Trunk Group. If the destination is an IP address, even though the destination type (in the IP-to-IP Routing table) is an IP Group, the device only uses the IP Group for profiling (i.e., associated

IP Profile etc.). If multiple devices exist in the call routing path, ARM sends the IP address only to the last device ("node") in the path.

Once the device receives the resultant destination hop from ARM, it sends the call to that destination. ARM can provide the device with an appropriate route or reject the call. However, if for the **initial** request (first sent Get Route request for the call), ARM cannot find an appropriate route for the call or it doesn't respond, for example, due to connectivity loss (i.e., ARM sends an HTTP 404 "Not Found" message), the device routes the call using its routing tables. If the Get Route request is not the first one sent for the call (e.g., in call forwarding or alternative routing) and ARM responds with an HTTP 404 "Not Found" message, the device rejects the call.

This HTTP request-response transaction for the routing path occurs between ARM and each device in the route path (hops) as the call traverses the devices to its final destination. Each device in the call path connects to ARM, which responds with the next hop in the route path. Each device considers the call as an incoming call from an IP Group or Trunk Group. The session ID (SID) is generated by the first device in the path and then passed unchanged down the route path, enabling ARM to uniquely identify requests belonging to the same call session.

Communication between the device and ARM is through the device's embedded Representational State Transfer (RESTful) API. The RESTful API is used to manage the routing-related information exchanged between ARM (RESTful server) and the device (RESTful client). When you have configured the device with connection settings of the routing sever or ARM and the device starts-up, it connects to ARM and activates the RESTful API, which triggers the routing-related API commands.

The following figure provides an example of information exchange between devices and ARM for routing calls:

ARM can also manipulate call data such as calling name, if required. It can also create new IP Groups and associated configuration entities (e.g., IP Profiles), if necessary for routing. Multiple ARM instances can also be employed, whereby each device in the chain path can use a specific

ARM instance. Alternatively, a single ARM can be employed and used for all devices ("stateful" ARM server).

The device automatically updates (sends) ARM with its' configuration topology regarding SIP routing-related entities (Trunk Groups, SRDs, SIP Interfaces, IP Profiles, and IP Groups) that have been configured for use by ARM. For example, if you add a new IP Group and enable it for use by ARM, the device sends this information to ARM. Routing of calls associated with routing-related entities that are disabled for use by ARM (default) are handled only by the device.

In addition to regular routing, ARM also supports the following:

- **Alternative Routing:** If a call fails to be established, the device "closest" to the failure and configured to send "additional" routing requests (through REST API - "additionalRoute" attribute in HTTP Get Route request) to ARM, sends a new routing request to ARM. ARM may respond with a new route destination, thereby implementing alternative routing. Alternatively, it may enable the device to return a failure response to the previous device in the route path chain and respond with an alternative route to this device. Therefore, alternative routing can be implemented at any point in the route path. If ARM sends an HTTP 404 "Not Found" message for an alternative route request, the device rejects the call. If ARM is configured to handle alternative routing, the device doesn't make any alternative routing decisions based on its alternative routing tables.

If the device sends an HTTP Get Route request and ARM responds with a REST API attribute "action" that is set to the value 'continue', the device routes the call using its IP-to-IP Routing table. It uses the routing rule located after the original routing rule used to query ARM ('Destination Type' set to **Routing Server**) whose 'Alternative Route Options' parameter is configured to **Route Row**. This routing can be used at any stage of the call (e.g., after alternative routing failure by ARM, or after receiving a REFER/3xx).

- **Call Forking:** The device can fork calls according to ARM. When the device finds a matching routing rule in the IP-to-IP Routing table that is configured with the **Routing Server** destination, it sends an HTTP Get Route request to ARM. When it receives a successful response from the server or ARM, the device sends an INVITE message to a destination based on the response. If the routingMethod in the response from ARM is "fork", the device sends another HTTP Get Route request to the server or ARM and upon a successful response, sends another INVITE to another destination based on the response, and so on. This call forking process continues until no routingMethod is received from the server or ARM, or it is set to "seq", or there is a failed response from the server or ARM. If all the contacts fail (4xx), the device falls back to an alternative route, if exists, from ARM. If 3xx is received for any of the forked destinations, the device handles it after all the forked INVITEs have been terminated.

ARM can also provide the device with a "no-answer timeout" in the response. If the called IP party doesn't answer the call within this interval, the device disconnects the session or forks the call (*delayed call forking*). If provided, this value overrides the [SBCAlertTimeout] parameter for SBC calls and [PSTNAlertTimeout] parameter for Gateway calls.

- **Call Status:** The device can report call status to ARM to indicate whether a call has successfully been established or failed (disconnected). The device can also report when an

IP Group (Proxy Set) is unavailable, detected by the keep-alive mechanism, or when the CAC thresholds permitted per IP Group have been crossed. For Trunk Groups, the device reports when the trunk's physical state indicates that the trunk is unavailable.

- **Credentials for Authentication:** ARM can provide user (e.g., IP Phone caller) credentials (username-password) in the Get Route response, which can be used by the device to authenticate outbound SIP requests if challenged by the outbound peer, for example, Microsoft Skype for Business (per RFC 2617 and RFC 3261). If multiple devices exist in the call routing path, ARM sends the credentials only to the last device ("node") in the path.

Alternatively, the device can authenticate incoming SIP requests (INVITE or REGISTER) from User-type IP Groups, by first obtaining (REST-based API query) the user's password from ARM where it is stored. When this feature is enabled and the device receives an incoming SIP dialog-initiating request, it sends the REST API command `getCredentials` in the Get request to ARM. The name of the user whose credentials are requested is obtained from the SIP From header when authenticating an INVITE message, and from the To header when authenticating a REGISTER message. ARM sends a 200 response to the device containing the password (if the requested user exists). The device then sends the challenge back to the user. The user resends the request with a SIP Authorization header (containing a response to the challenge), and the authentication process continues in the usual manner. If the device doesn't receive a password, it rejects the incoming dialog (SIP 404). To enable this authentication type, you need to configure the IP Group's 'SBC Server Authentication Type' parameter to **ARM Authentication** (see [Configuring IP Groups](#) on page 591). Note that ARM doesn't authenticate users, but only helps the device to process the SIP Digest authentication by providing the user credentials.

- **QoS:** The device can report QoS metrics per IP Group to ARM which it can use to determine the best route (i.e., QoS-based routing). For more information, see [Configuring QoS-based Routing by ARM](#) on the next page.
- **Call Preemption for Emergency Calls:** If you enable call preemption for emergency calls (e.g., 911) on the device, ARM determines whether or not the incoming call is an emergency call and if so, handles the routing decision accordingly (i.e., preempts a non-emergency call if the maximum call capacity of the device is reached in order to allow the emergency call to be routed). To enable call preemption for emergency calls, use the [SBCPreemptionMode] parameter for SBC calls and the [CallPriorityMode] parameter for Gateway calls.
- **Registration status:** The device can periodically synchronize its registration database of SIP user agents (endpoints) with ARM to keep it up to date, enabling ARM to use this information to perform correct and optimal routing decisions. To enable this functionality, see [Enabling Registration Status Services](#) on page 450.

➤ **To configure routing based on ARM:**

1. For each configuration entity (e.g., IP Group or IP Profile) that you want routing done by ARM, configure the entity's 'Used By Routing Server' parameter to **Used**:

Used By Routing Server Used

2. Configure an additional Security Administrator user account in the Local Users table (see [Configuring Local Management User Accounts](#) on page 55) that is used by ARM (REST client) to log in to the device's management interface.
3. Configure the address and connection settings of ARM, referred to as a *Remote Web Service* and an HTTP remote host (see [Configuring Remote Web Services](#) on page 438). You must configure the 'Type' parameter of the Remote Web Service to **Routing**, as shown in the example:

Remote Web Services

GENERAL	
Index	<input style="width: 90%;" type="text" value="0"/>
Name	<input style="width: 90%;" type="text" value="Routing Server"/>
Type	<span style="border: 1px solid #ccc; padding: 2px 10px;">Routing</span>

4. (SBC Application Only) In the IP-to-IP Routing table, configure the 'Destination Type' parameter of the routing rule to **Routing Server** (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186):

ACTION	
Destination Type	<span style="border: 1px solid #ccc; padding: 2px 10px;">Routing Server</span>

5. (Gateway Application Only) Open the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**), and then enable routing by ARM, by selecting the 'Gateway Routing Server' check box (GWRoutingServer):

Gateway Routing Server ☒

## Configuring QoS-based Routing by ARM

You can configure the device to allow ARM to route calls based on QoS metrics (media and signaling). The device collects QoS metrics per IP Group that you have configured to operate with ARM ('Used by Routing Server' parameter configured to **Used** in the IP Groups table). The metrics include the following:

- **Signaling:** ASR, NER, and ACD
- **Media:** Packet loss (Rx/Tx), packet delay (local/remote), jitter (local/remote), MOS (local/remote), audio bandwidth (Rx/Tx), video bandwidth (Rx/Tx), and total bandwidth (Rx/Tx)

The device collects QoS metrics for both incoming call traffic and outgoing traffic from the remote endpoint. It sends the QoS reports to ARM, where each report can contain the status of up to 100 IP Groups. If more than 100 IP Groups exist, the device sends multiple QoS reports (sequentially) to ARM. The device sends the reports every user-defined period. The routing logic of where to route calls based on QoS ("good", "fair", and "bad") is configured on ARM.

For media metrics calculations, the device's License Key must include voice quality monitoring and RTCP XR.

#### ➤ To configure QoS-based routing by ARM:

1. Open the Web Service Settings page (**Setup** menu > **IP Network** tab > **Web Services** folder > **Web Service Settings**), and then do the following:
  - a. Select the 'Quality Status' check box [RoutingServerQualityStatus] to enable QoS-based routing.
  - b. In the 'Quality Status Rate' field (RoutingServerQualityStatusRate), enter the rate (in sec) at which the device sends QoS reports.

Quality Status	<input checked="" type="checkbox"/>
Quality Status Rate	<input type="text" value="60"/>

- c. Click **Apply**.
2. Open the Remote Web Services table (see [Configuring Remote Web Services](#) on page 438), and then for the Remote Web Service entry that you configured for ARM, do the following:
  - a. From the 'Type' drop-down list, select **QoS**.
  - b. Click **Apply**.
3. Enable voice quality monitoring and RTCP XR, using the 'Enable RTCP XR' [VQMonEnable] parameter (see [Configuring RTCP XR](#) on page 1506).

## Configuring an HTTP GET Web Service

You can query (HTTP GET) an HTTP server and use the response for various functionality such as routing or saving it, for example, as a session variable in order to use it in SIP message manipulations.

You need to configure a Remote Web Service to represent the HTTP server and a Call Setup Rule to define the search query and the action you want done based on the HTTP response. The following example queries an HTTP server (at IP address 52.7.189.10) using the caller's (source) user name in the server's path */v3/phone*. When a response is received from the HTTP server, the device adds the value of the HTTP response body ("Alice") to the From header in the outgoing SIP message.

➤ **To configure an HTTP GET operation:**

1. Open the Remote Web Services table, and then configure a Remote Web Service for the HTTP server:
  - 'Name': **MyHTTP**
  - 'Type': **General**
  - 'Path': **v3/phone**
  - 'Username': **adminuser1**
  - 'Password': **1234**
2. Open the HTTP Remote Hosts table of the Remote Web Service that you configured in Step 1, and then configure the following:
  - 'Name': **MyHTTPHost**
  - 'Address': **52.7.189.10**
3. Open the Call Setup Rules table, and then configure the following rule:
  - 'Rule Set ID': **1**
  - 'Request Type': **HTTP GET**
  - 'Request Target': **MyHTTP**
  - 'Request Key': **Param.Call.Src.User+'?account\_sid=SID&auth\_token=TOKEN'**
  - 'Action Subject': **Param.Call.Src.Name**
  - 'Action Type': **Modify**
  - 'Action Value': **HTTP.Response.Body**
4. Assign your Call Setup Rule to the relevant SIP Interface, for example.

An example of the HTTP and SIP messages of the above configuration is shown below:

1. Incoming SIP message:

```
INVITE sip:2000@10.7.7.246;user=phone SIP/2.0
Via: SIP/2.0/UDP 10.7.2.15;branch=z9hG4bKLRGQTOQHILSSMGAQJQSU
From: <sip:
15551234567

```

## Configuring HTTP POST Web Service

You can use HTTP POST messages to simply notify an HTTP server about a call, and use HTTP POST messages for querying information like HTTP GET messages. The example provided in this section describes how to configure the device to send HTTP POSTs to notify an HTTP server of incoming 911 calls. You need to configure a Remote Web Service to represent the HTTP server (IP address 52.7.189.10). You also need to configure Call Setup Rules that instruct the device to send an HTTP POST message, containing the 911 caller's user name and host name, to the server (at path */path/query/notify-emergency-call*) if a 911 call is received.

### ➤ To configure an HTTP POST notification operation:

1. Open the Remote Web Services table, and then configure a Remote Web Service for the HTTP server:
  - 'Name': **MyHTTP**
  - 'Type': **General**
  - 'Username': **adminuser1**
  - 'Password': **1234**
2. Open the HTTP Remote Hosts table of the Remote Web Service that you configured in Step 1, and then configure the following:
  - 'Name': **MyHTTPHost**
  - 'Address': **52.7.189.10**
3. Open the Call Setup Rules table, and then configure the following rules (Rule Set ID 1):
  - If the destination number of the incoming call is not 911, then don't process these Call Setup Rules:
    - ◆ 'Index': **1**
    - ◆ 'Rule Set ID': **1**
    - ◆ 'Condition': **Param.Call.Dst.User != '911'**
    - ◆ 'Action Type': **Exit**
    - ◆ 'Action Value': **True**
  - Set the Content-Type header in the HTTP POST message to the value "application/json":
    - ◆ 'Index': **2**
    - ◆ 'Rule Set ID': **1**
    - ◆ 'Action Subject': **HTTP.Request.Content-Type**
    - ◆ 'Action Type': **Modify**
    - ◆ 'Action Value': **'application/json'**

- Add JSON parameters to the body of the HTTP POST message so that it includes the 911 caller's (source) number and host name:
  - ◆ 'Index': **3**
  - ◆ 'Rule Set ID': **1**
  - ◆ 'Action Subject': **HTTP.Request.Body**
  - ◆ 'Action Type': **Add**
  - ◆ 'Action Value': **{ "user": ""+Param.Call.Src.User+"", "host": ""+Param.Call.Src.Host+""}'**
- Send the HTTP POST message to the specified server and folder path:
  - ◆ 'Index': **4**
  - ◆ 'Rule Set ID': **1**
  - ◆ 'Request Type': **HTTP POST Notification**
  - ◆ 'Request Target': **MyHTTP**
  - ◆ 'Request Key': **'/path/query/notify-emergency-call'**

**4.** Assign your Call Setup Rules (i.e., Rule Set ID 1) to the relevant SIP Interface (for example).

An example of the HTTP and SIP messages of the above configuration is shown below:

**1.** Incoming SIP message from 911 caller:

```
INVITE sip:911@10.7.7.246;user=phone SIP/2.0
Via: SIP/2.0/UDP 10.7.2.15;branch=z9hG4bKLRGQTOQHILSSMGAQJQSU
From: <sip:15551234567@10.7.2.15;user=phone>;tag=RJFNXMKDOHELDUMEWG
To: <sip:911@10.7.7.246;user=phone>
Call-ID: UBBKFKBCXFPESMYOPDTB@10.7.2.15
CSeq: 1 INVITE
Contact: <sip:1000@10.7.2.15>
Supported: em,100rel,timer,replaces
Allow: REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK,REFER,INFO,SUBSCRIBE
User-Agent: Sip Message Generator V1.0.0.5
```

**2.** Outgoing HTTP POST message notifying server of 911 call:

```
Header=POST /path/query/notify-emergency-call HTTP/1.1
Content-Type: application/json
Host: 52.7.189.114
Connection: keep-alive
```

```
Content-Length: 47
Cache-Control: no-cache
User-Agent: 1
```

```
{ "user": "15551234567", "host": "10.7.2.15" }
```

## Least Cost Routing

This section describes the device's Least Cost Routing (LCR) feature.

### Overview of LCR

The LCR feature enables the device to choose the outbound IP destination routing rule based on lowest call cost. This is useful in that it enables service providers to optimize routing costs for customers. For example, you may wish to define different call costs for local and international calls or different call costs for weekends and weekdays (specifying even the time of call). The device sends the calculated cost of the call to a syslog server (as Information messages), thereby enabling billing by third-party vendors.

LCR is implemented by defining Cost Groups and assigning them to routing rules in the Tel-to-IP Routing table (for Gateway calls) or IP-to-IP Routing table (for SBC calls). The device searches the routing table for matching routing rules and then selects the rule with the lowest call cost. If two routing rules have identical costs, the rule appearing higher up in the table is used (i.e., first-matched rule). If the selected route is unavailable, the device selects the next least-cost routing rule.

Even if a matched routing rule is not assigned a Cost Group, the device can select it as the preferred route over other matched rules that are assigned Cost Groups. This is determined according to the settings of the 'Default Call Cost' parameter configured for the Routing Policy (associated with the routing rule for SBC calls). To configure the Routing Policy, see [Configuring a Gateway Routing Policy Rule](#) on page 967 for Gateway calls and [Configuring SBC Routing Policies](#) on page 1218 for SBC calls.

The Cost Group defines a fixed connection cost (*connection cost*) and a charge per minute (*minute cost*). Cost Groups can also be configured with time segments (*time bands*), which define connection cost and minute cost based on specific days of the week and time of day (e.g., from Saturday through Sunday between 6:00 and 18:00, and Monday through Sunday between 18:00 and 5:00). If multiple time bands are configured per Cost Group and a call spans multiple time bands, the call cost is calculated according to minute cost per time band and the connection cost of the time band in which the call was initially established.

In addition to Cost Groups, the device can calculate the call cost using an optional, user-defined average call duration value. The logic in using this option is that a Cost Group may be cheap if the call duration is short, but due to its high minute cost, may prove very expensive if the duration is lengthy. Thus, together with Cost Groups, the device can use this option to determine least cost routing. The device calculates the Cost Group call cost as follows:

*Total Call Cost = Connection Cost + (Minute Cost \* Average Call Duration)*

The below table shows an example of call cost when taking into consideration call duration. This example shows four defined Cost Groups and the total call cost if the average call duration is 10 minutes:

**Table 16-20: Call Cost Comparison between Cost Groups for different Call Durations**

Cost Group	Connection Cost	Minute Cost	Total Call Cost per Duration	
			1 Minute	10 Minutes
A	1	6	7	61
B	0	10	10	100
C	0.3	8	8.3	80.3
D	6	1	7	16

If four matching routing rules are located in the routing table and each one is assigned a different Cost Group as listed in the table above, then the rule assigned Cost Group "D" is selected. Note that for one minute, Cost Groups "A" and "D" are identical, but due to the average call duration, Cost Group "D" is cheaper. Therefore, average call duration is an important factor in determining the cheapest routing role.

Below are a few examples of how you can implement LCR:

- **Example 1:** This example uses two different Cost Groups for routing local calls and international calls:

Two Cost Groups are configured as shown below:

Cost Group	Connection Cost	Minute Cost
1. "Local Calls"	2	1
2. "International Calls"	6	3

The Cost Groups are assigned to routing rules for local and international calls:

Routing Index	Dest Phone Prefix	Destination IP	Cost Group ID
1	2000	x.x.x.x	1 "Local Calls"
2	00	x.x.x.x	2 "International Calls"

- **Example 2:** This example shows how the device determines the cheapest routing rule in the Tel-to-IP Routing table:

The 'Default Call Cost' parameter in the Routing Policy rule is configured to **Lowest Cost**, meaning that if the device locates other matching routing rules (with Cost Groups assigned), the routing rule without a Cost Group is considered the lowest cost route.

- The following Cost Groups are configured:

Cost Group	Connection Cost	Minute Cost
1. "A"	2	1
2. "B"	6	3

- The Cost Groups are assigned to routing rules:

Routing Index	Dest Phone Prefix	Destination IP	Cost Group
1	201	x.x.x.x	"A"
2	201	x.x.x.x	"B"
3	201	x.x.x.x	0
4	201	x.x.x.x	"B"

The device calculates the optimal route in the following index order: 3, 1, 2, and then 4, due to the following logic:

- Index 1 - Cost Group "A" has the lowest connection cost and minute cost
- Index 2 - Cost Group "B" takes precedence over Index 4 entry based on the first-matched method rule
- Index 3 - no Cost Group is assigned, but as the 'Default Call Cost' parameter is configured to **Lowest Cost**, it is selected as the cheapest route
- Index 4 - Cost Group "B" is only second-matched rule (Index 1 is the first)

■ **Example 3:** This example shows how the cost of a call is calculated if the call spans over multiple time bands:

Assume Cost Group "CG Local" is configured with two time bands, as shown below:

Cost Group	Time Band	Start Time	End Time	Connection Cost	Minute Cost
CG Local	TB1	16:00	17:00	2	1
	TB2	17:00	18:00	7	2

Assume that the call duration is 10 minutes, occurring between 16:55 and 17:05. In other words, the first 5 minutes occurs in time band "TB1" and the next 5 minutes occurs in "TB2", as illustrated below:

The device calculates the call cost as follows:

- For the first 5 minutes of the call (16:55 to 17:00), the call is in time band "TB1" and the call cost for this period is calculated as follows:

$$\text{Connection Cost of "TB1"} + [\text{Minute Cost of "TB1"} \times \text{call duration}] = 2 + [1 \times 5 \text{ min}] = 7$$

- For the next 5 minutes of the call (17:00 to 17:05), the call is in time band "TB2" and the call cost for this period is calculated as follows:

$$\text{Minute Cost of "TB2"} \times \text{call duration} = 2 \times 5 \text{ min} = 10$$

- Therefore, the total call cost is the summation of above:

$$\text{"TB1" call cost} + \text{"TB2" call cost} = 7 + 10 = 17$$

## Configuring LCR

To configure LCR, perform the following main steps:

- Enable LCR:
  - Gateway application: see [Configuring a Gateway Routing Policy Rule](#) on page 967
  - SBC application: [Configuring SBC Routing Policies](#) on page 1218
- Configure Cost Groups - see [Configuring Cost Groups](#) below.
- Configure Time Bands for a Cost Group - see [Configuring Time Bands for Cost Groups](#) on page 466.
- Assign Cost Groups to outbound IP routing rules - see [Assigning Cost Groups to Routing Rules](#) on page 468.

## Configuring Cost Groups

The Cost Groups table lets you configure up to 10 Cost Groups. A Cost Group defines a fixed call connection cost and a call rate (charge per minute). Once configured, you can configure Time Bands per Cost Group (see [Configuring Time Bands for Cost Groups](#) on page 466).

The following procedure describes how to configure Cost Groups through the Web interface. You can also configure it through ini file [CostGroupTable] or CLI (`configure voip > sip-definition least-cost-routing cost-group`).

➤ **To configure a Cost Group:**

1. Open the Cost Groups table (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Least Cost Routing** > **Cost Groups**).
2. Click **New**; the following dialog box appears:

3. Configure a Cost Group according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 16-21:Cost Groups Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' cost-group-name [CostGroupName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Each row must have a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Default Connection Cost' default-connection-cost [DefaultConnectionCost]	Defines the call connection cost (added as a fixed charge to the call) for a call outside the time bands. The valid value range is 0-65533. The default is 0. <b>Note:</b> When calculating the cost of a call, if the current time of the call is not within a time band configured for the Cost Group, then this default connection cost is used.

Parameter	Description
'Default Minute Cost' default-minute-cost [DefaultMinuteCost]	<p>Defines the call charge per minute for a call outside the time bands.</p> <p>The valid value range is 0-65533. The default is 0.</p> <p><b>Note:</b> When calculating the cost of a call, if the current time of the call is not within a time band configured for the Cost Group, then this default charge per minute is used.</p>

### Configuring Time Bands for Cost Groups

The Time Band table lets you configure Time Bands per Cost Group. A Time Band defines a day and time range (e.g., from Saturday 05:00 to Sunday 24:00) and a fixed call connection charge and call rate per minute for this interval. You can configure up to 70 Time Bands, where up to 21 Time Bands can be assigned to each Cost Group.

- You cannot configure overlapping Time Bands.
- If a Time Band is not configured for a specific day and time range, the default connection cost and default minute cost configured for the Cost Group in the Cost Groups table is applied.
- To configure Cost Groups, see [Configuring Cost Groups](#) on page 464.

The following procedure describes how to configure Time Bands per Cost Group through the Web interface. You can also configure it through ini file [CostGroupTimebands] or CLI (configure voip > sip-definition least-cost-routing cost-group-time-bands).

#### ➤ To configure a Time Band per Cost Group:

1. Open the Cost Groups table (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Least Cost Routing** > **Cost Groups**).
2. Select a Cost Group for which you want to assign Time Bands, and then click the **Time Band** link located below the table; the Time Band table for the selected Cost Group appears.
3. Click **New**; the following dialog box appears:

**Time Band**

**GENERAL**

Index: 0

Start Time (ddd:hh:mm):

End Time (ddd:hh:mm):

Connection Cost: 0

Minute Cost: 0

4. Configure a Time Band according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-22:Time Band Table Description**

Parameter	Description
'Index' timeband-index [CostGroupTimebands_ TimebandIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Start Time' start-time [CostGroupTimebands_ StartTime]	Defines the day and time of day from when this time band is applicable. The format is ddd:hh:mm, where: <ul style="list-style-type: none"> <li>■ <i>ddd</i> is the day of the week, represented by the first three letters (case-insensitive) of the day (i.e., mon, tue, wed, thu, fri, sat, or sun).</li> <li>■ <i>hh</i> and <i>mm</i> denote the time of day, where <i>hh</i> is the hour (00-23) and <i>mm</i> the minutes (00-59)</li> </ul> For example, sat:22:00 denotes Saturday at 10 pm.
'End Time' end-time [CostGroupTimebands_ EndTime]	Defines the day and time of day until when this time band is applicable. For a description of the valid values, see the parameter above.
'Connection Cost' connection-cost [CostGroupTimebands_ ConnectionCost]	Defines the call connection cost during the time band. This is added as a fixed charge to the call. The valid value range is 0-65533. The default is 0. <b>Note:</b> The entered value must be a whole number (i.e., not a decimal).

Parameter	Description
'Minute Cost' minute-cost [CostGroupTimebands_ MinuteCost]	Defines the call cost per minute charge during the time band. The valid value range is 0-65533. The default is 0.  <b>Note:</b> The entered value must be a whole number (i.e., not a decimal).

### Assigning Cost Groups to Routing Rules

To use your configured Cost Groups, you need to assign them to routing rules:

- Gateway application: Tel-to-IP Routing table - see [Configuring Tel-to-IP Routing Rules](#) on page 946
- SBC application: IP-to-IP Routing table - see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186

## HTTP-based Proxy Services

The device can be configured as an HTTP Proxy (or a non-HTTP Proxy) to intermediate between clients (e.g., HTTP requests) and servers (hosts). The client sends an HTTP GET request specifying the destination (URL), and the device (acting as an HTTP Proxy), forwards it to the host, and vice versa.

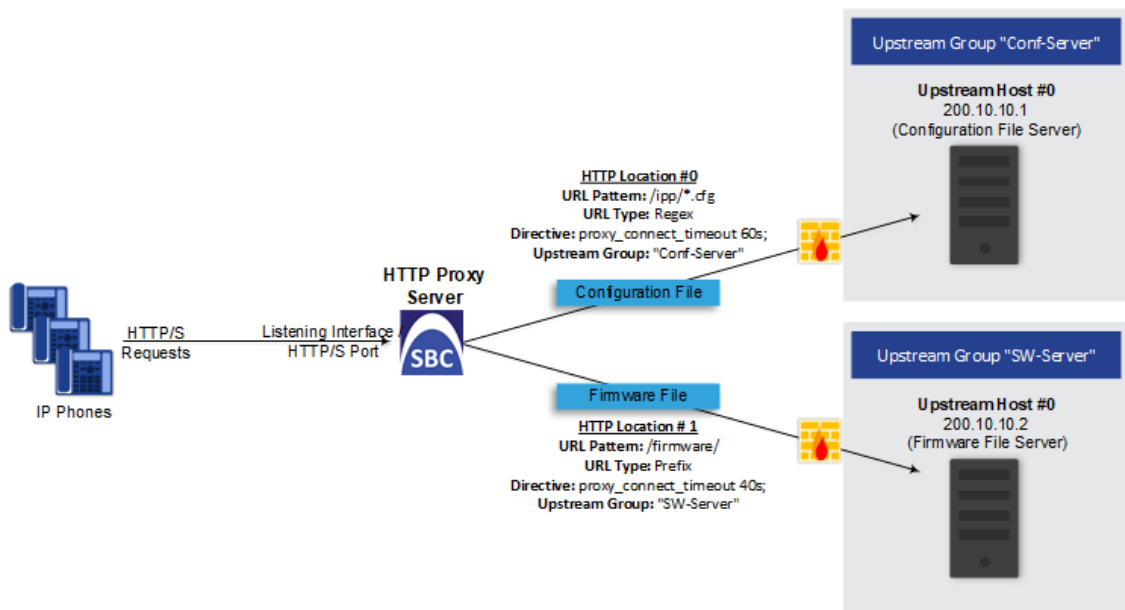

This feature integrates the NGINX platform, which is an open source proxy server. When you enable the HTTP Proxy application, the NGINX daemon is launched. When you then configure the various HTTP Proxy tables, the configuration is reflected in the NGINX configuration file (nginx.conf). Each parameter has its own NGINX Directive notation syntax, which is shown in the nginx.conf file. For example, if you have configured an Upstream Host (discussed later in this section), it is displayed in the NGINX file as "server host:port". You can also configure and apply additional NGINX Directives that do not have any corresponding parameters in the device's Web interface. For more information, see [Configuring HTTP Directive Sets](#) on page 487.

The device supports the following proxy services:

- **HTTP Reverse Proxy for managing equipment behind NAT:** You can configure the device to function as a Reverse HTTP Proxy server. You can use this for many HTTP-based applications. For example, you can use it to intermediate between REST API clients and a REST server.

Another example is to use the HTTP Proxy to intermediate between IP Phones and remote servers for file download. The figure below illustrates this example where IP Phones (clients) retrieve their configuration and firmware files from remote file servers (Upstream Hosts) and where the device (HTTP Proxy) intermediates between the two. The HTTP hosts are located in the cloud and the clients are located behind NAT. The HTTP Proxy listens for incoming HTTP requests (Listening Interface and HTTP/S Listening Port) from the clients and then forwards the requests to the relevant HTTP host, based on the URL (HTTP Location) in the incoming HTTP GET request. If the URL matches the pattern "/firmware/",

the HTTP Proxy sends the request to the firmware file server; if the URL matches the pattern `"/ipp/*.cfg"`, the requests are sent to the configuration file server. In addition, customized NGINX directives have been configured for each HTTP Location to define the maximum time to wait for an HTTP connection.

A summary of the required configuration for this example is listed below:

- Enable the HTTP Proxy application (see [Enabling the HTTP Proxy Application](#) on the next page).
  - Configure two Upstream Groups, where each is configured with an Upstream Host that defines the IP address of the HTTP host (i.e., firmware and configuration file servers). See [Configuring Upstream Groups](#) on page 483.
  - Configure two NGINX directives for proxy timeout connection (see [Configuring HTTP Directive Sets](#) on page 487).
  - Configure a local, listening IP network interface for the leg interfacing with the HTTP clients (see [Configuring IP Network Interfaces](#) on page 159) or use the default.
  - Configure a local, IP network interface for the outbound leg interfacing with the HTTP hosts (or use the default).
  - Configure the HTTP Proxy server, by assigning it the listening IP network interface and configuring a listening HTTP/S port (see [Configuring HTTP Proxy Servers](#) on page 472).
  - Configure two HTTP Locations for the HTTP Proxy server, where each is configured with a URL pattern to match the incoming HTTP requests for determining the destination host (Upstream Group-Upstream Host). In addition, assign it the relevant HTTP Directive Set. See [Configuring HTTP Locations](#) on page 475.
- **Non-HTTP Proxy (referred to as TCP/UDP Proxy Server):** The device can serve as a proxy for other applications that are not based on HTTP. For example, it can be used to intermediate between clients and a DNS server for DNS lookup, or between clients and an

NTP server for clock synchronization. For more information, see [Configuring TCP-UDP Proxy Servers](#) on page 479.

- **HTTP-based OVOC service for AudioCodes equipment located behind NAT that are managed by the AudioCodes OVOC server:** For more information, see [Configuring an HTTP-based OVOC Service](#) on page 490

## Enabling the HTTP Proxy Application

Before you can configure HTTP-based proxy services, you must enable the HTTP Proxy application, as described in the following procedure. Once enabled, the Web interface displays menus in the Navigation pane that are relevant to the HTTP Proxy application.

The HTTP Proxy application is a license-based feature and is available only if it is included in the License Key installed on the device. For ordering the feature, please contact the sales representative of your purchased device. For installing a new License Key, see [License Key](#) on page 1362.

### ➤ To enable the HTTP Proxy application:

1. Open the HTTP Proxy Settings page (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Settings**)
2. Select the 'HTTP Proxy Application' check box:

HTTP Proxy application

3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

## Debugging Remote HTTP Services

You can enable the device to generate debug messages for remote Web (HTTP) services and have them sent to a syslog server.

### ➤ To enable debugging of HTTP services:

1. Open the HTTP Proxy Settings page (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Settings**)
2. From the 'HTTP Proxy Debug Level' drop-down list, select a debug level:

GENERAL

HTTP Proxy Debug Level

• Basic ▼

3. Click **Apply**.

## Caching HTTP Responses

You can enable the device to cache all received HTTP responses. This reduces the need for the device to request the same information (responses) repeatedly from a remote upstream server.

### ➤ To enable caching of HTTP responses:

1. Open the HTTP Proxy Settings page (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Settings**).
2. Select the 'HTTP Cache Enable' check box:

HTTP Cache Enable ☒

3. Click **Apply**.

## Configuring a DNS Server for HTTP Services

You can configure the DNS server (primary and secondary for redundancy) that you want to use for your HTTP services. If you configure a proxy server with an FQDN, this is the DNS server that the device uses for resolving the domain name into an IP address.

### ➤ To configure DNS servers for HTTP services:

1. Open the HTTP Proxy Settings page (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Settings**):
2. In the 'Primary DNS Server IP' field, enter the IP address of your main DNS server.
3. (Optional) In the 'Secondary DNS Server IP' field, enter the IP address of the secondary DNS server.

#### DNS

Primary DNS Server IP

Secondary DNS Server IP

4. Click **Apply**.

- The DNS servers that are configured for IP Interfaces (see [Configuring IP Network Interfaces](#) on page 159) are not used for HTTP services. Only the DNS servers configured in this section are used for HTTP services.
- When generating the NGINX configuration file, the device includes the resolver directive, specifying the primary and secondary DNS servers, as configured above. However, NGINX supports optional parameters that allow you to fine-tune the behavior of the DNS resolution. You can include these additional parameters using the ini file parameter [NginxResolverParams], which is added to the resolver directive when the device generates the NGINX configuration file. For more information on these optional parameters, go to [http://nginx.org/en/docs/http/nginx\\_http\\_core\\_module.html#resolver](http://nginx.org/en/docs/http/nginx_http_core_module.html#resolver).

## Configuring HTTP Proxy Servers

The HTTP Proxy Servers table lets you configure up to 10 HTTP Proxy servers. Once configured, you can configure HTTP Locations for the HTTP Proxy Server (see [Configuring HTTP Locations](#) on page 475).

The following procedure describes how to configure HTTP Proxy Servers through the Web interface. You can also configure it through ini file [HTTPServer] or CLI (`configure network > http-proxy > http-server`).

### ➤ To configure an HTTP Proxy Server:

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the HTTP Proxy Server table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Servers**).
3. Click **New**; the following dialog box appears:

GENERAL	
Index	1
Name	
Domain Name	
Listening Interface	-- View
HTTP Listening Port	
HTTPS Listening Port	
TLS Context	-- View
Bind To Device	Enable
Verify Client Certificate	No
Additional Directive Set	-- View

4. Configure an HTTP Proxy server according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-23: HTTP Proxy Servers Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Each row must be configured with a unique index.</li> <li>The parameter is mandatory.</li> </ul>
'Name' name [ServiceName]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Configure each row with a unique name.</li> <li>The parameter is mandatory.</li> <li>The parameter value cannot contain a forward slash (/).</li> </ul>
'Domain Name' domain-name [DomainName]	<p>Defines a domain name (FQDN). This is configured only when multiple DNS domains share the same IP address.</p> <p><b>Note:</b> The NGINX directive for this parameter is "server_name".</p>
'Listening Interface' listening-int [ListeningInterface]	<p>Assigns an IP Interface to the HTTP Proxy service. To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is mandatory.</li> <li>The NGINX directive for this parameter is "listen ip".</li> </ul>
'HTTP Listening Port' http-port [HTTPListeningPort]	<p>Defines the HTTP listening port, which is the local port for incoming packets for the HTTP service.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The port number must not conflict with the ports used for the Web interface, which is usually 80 for HTTP and 443 for HTTPS.</li> <li>You must configure at least one port (HTTP or HTTPS port).</li> <li>The NGINX directive for this parameter is "listen ip:port".</li> </ul>
'HTTPS Listening Port'	<p>Defines the HTTPS listening port, which is the local port for</p>

Parameter	Description
https-port [HTTPSListeningPort]	<p>incoming packets for the HTTP service.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The port number must not conflict with the ports used for the Web interface, which is usually 80 for HTTP and 443 for HTTPS.</li> <li>■ You must configure at least one port (HTTP or HTTPS port).</li> <li>■ The NGINX directive for this parameter is "listen ip:port ssl".</li> </ul>
'TLS Context' tls-context [TLSContext]	<p>Assigns a TLS Context (TLS configuration). This is required if you have specified an HTTPS listening port (see the 'HTTPS Listening Port' parameter above). To configure TLS Contexts, see <a href="#">Configuring TLS Certificate Contexts</a> on page 227.</p> <p><b>Note:</b> The NGINX directives for this parameter is "tls-context", "ssl_certificate", "ssl_certificate_key", "ssl_ciphers", "ssl_protocols", and "ssl_password_file".</p>
'Bind To Device' bind-to-device [BindToDevice]	<p>Enables the NGINX to bind the HTTP Proxy interface to a specific device network interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b> (default)</li> </ul>
'Verify Client Certificate' verify-client-cert [VerifyCertificate]	<p>Enables the verification of the client TLS certificate, where the client is the device or user that issues the HTTPS request.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Yes</b> = The device verifies the authentication of the certificate received from the HTTPS client. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context (see 'TLS Context' parameter above) and if ok, allows communication with the HTTPS client. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also configured for the associated TLS Context.</li> </ul>
'Additional Directive Set' directive-set	<p>Assigns an NGINX Directive Set for the HTTP service. To configure HTTP Directive Sets, see <a href="#">Configuring HTTP Directive</a></p>

Parameter	Description
[AdditionalDirectiveSet]	<a href="#">Sets</a> on page 487.

## Configuring HTTP Locations

The HTTP Locations table lets you configure up to 40 HTTP Locations. Locations are specified for each HTTP proxy server to map the incoming requests received by that server. Mapping is based on matching the URL in the request. Each location specifies the URL prefix or pattern to match and the target Upstream Group to which the request is to be forwarded to.

The HTTP Locations table is a "child" of the HTTP Proxy Servers table (see [Configuring HTTP Proxy Servers](#) on page 472), reflecting the nesting of Location contexts within Server contexts in the NGINX configuration file. This may be used to specify unique handling of URLs by file type (using a regex pattern) or by pathname (using a Prefix or Exact Match pattern).

The following procedure describes how to configure HTTP Locations through the Web interface. You can also configure it through ini file [HTTPLocation] or CLI (`configure network > http-proxy > location`).

### ➤ To configure an HTTP Location:

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the HTTP Proxy Servers table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Servers**).
3. In the table, select the required HTTP Proxy Server, and then click the **HTTP Locations** link located below the table; the HTTP Locations table appears.
4. Click **New**; the following dialog box appears:

The screenshot shows the 'HTTP Locations' configuration window. It has two tabs: 'GENERAL' and 'SSL'. The 'GENERAL' tab is selected and contains the following fields:

- Index:** 0
- URL Pattern:** /
- URL Pattern Type:** Prefix (dropdown)
- Upstream Scheme:** HTTP (dropdown)
- Upstream Group:** .. (dropdown with a 'View' link)
- Upstream Path:** (empty text field)
- Outbound Interface:** .. (dropdown with a 'View' link)
- Additional Directive Set:** .. (dropdown with a 'View' link)
- Cache:** Yes (checkbox)

The 'SSL' tab is also visible and contains:

- TLS Context:** .. (dropdown with a 'View' link)
- Verify Certificate:** No (checkbox)

5. Configure an HTTP Location according to the parameters described in the table below.
6. Click **Apply**, and then save your settings to flash memory.

**Table 16-24:HTTP Locations Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Each row must be configured with a unique index.</li> <li>■ The parameter is mandatory.</li> </ul>
'URL Pattern' url-pattern [URLPattern]	<p>Defines the URL pattern. Received GET or POST requests are matched against the locations in the HTTP Locations table by matching the URL in the received request to the URL configured by this parameter. If there is a match, the prefix is stripped from the request and then forwarded in the outgoing HTTP request.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The pattern must be based on the pattern type configured in the 'URL Pattern Type' parameter (see below).</li> <li>■ The NGINX directive for this parameter is "location modifier pattern".</li> </ul>
'URL Pattern Type' url-pattern-type [URLPatternType]	<p>Defines the type of URL pattern used for configuring the 'URL Pattern' parameter (see above).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Prefix</b> = For Example, "/" matches any URL beginning with a forward slash "/". For NGINX, this option has no modifier.</li> <li>■ [1] <b>Exact</b> = Defines an exact pattern to match, for example, "/abc/def" matches only the file "/abc/def". For NGINX, this option is specified using the "=" modifier.</li> <li>■ [2] <b>Regex</b> = Regex-based pattern (case sensitive), for example, "/files/*.img" matches all files ending in .img in the directory /files. For NGINX, this option is specified using the "~" modifier.</li> <li>■ [3] <b>Case-Insensitive Regex</b> = Regex-based pattern that is case-insensitive, for example, "*.img" matches abc.IMG as well as xyz.img. For NGINX, this option is specified using the "~*" modifier.</li> <li>■ [4] <b>Prefix Ignore Regex</b> = For NGINX, this option is specified using the "^~" modifier.</li> </ul>

Parameter	Description
	<p>For example, assume that you have configured the following URL patterns for four HTTP Locations:</p> <ul style="list-style-type: none"> <li>■ 1) /files – <b>Prefix</b> pattern type</li> <li>■ 2) /files/phone – <b>Prefix</b> pattern type</li> <li>■ 3) /files/firmware -- <b>Prefix-Ignore-Regex</b> pattern type</li> <li>■ 4) *.jpg – <b>Regex</b> pattern type</li> </ul> <p>Therefore, the request URL "/files/phone/aaa" matches Location 2 and the request URL "/files/phone/logo.jpg" matches Location 4. The request URL "/files/firmware/logo.jpg" matches Location 3 (and not Location 4).</p> <p><b>Note:</b> The NGINX directive for this parameter is "location modifier pattern". For more information on NGINX modifiers, see <a href="http://nginx.org/en/docs/http/ngx_http_core_module.html">ngx_http_core_module.html</a>.</p>
'Upstream Scheme' upstream-scheme [UpstreamScheme]	<p>Defines the protocol for sending requests to the Upstream Group.</p> <ul style="list-style-type: none"> <li>■ [0] HTTP (default)</li> <li>■ [1] HTTPS</li> </ul> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_pass scheme://upstream".</p>
'Upstream Group' upstream-group [UpstreamGroup]	<p>Assigns a group of servers (Upstream Group) to handle the HTTP requests. To configure Upstream Groups, see <a href="#">Configuring Upstream Groups</a> on page 483.</p> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_pass scheme://upstream".</p>
'Upstream Path' upstream-path [UpstreamPath]	<p>Defines a path to prepend to the URL before sending the request to the Upstream Group.</p> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_pass scheme://upstream/path".</p>
'Outbound Interface' outbound-intfc [OutboundInterface]	<p>Assigns a local, IP network interface for sending requests to the Upstream Group. To configure IP network interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The NGINX directive for this parameter is "proxy_bind".</li> </ul>
'Additional Directive Set' directive-set [AdditionalDirectiveSet]	Assigns an NGINX directive set for the HTTP location. To configure NGINX directives, see <a href="#">Configuring HTTP Directive Sets</a> on page 487.
'Cache' cache [Cache]	<p>Enables the caching of files in this location.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b> (default)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Currently, this feature is not supported.</li> <li>■ The NGINX directive for this parameter is "proxy_cache zone off".</li> </ul>
<b>SSL</b>	
'TLS Context' tls-context [TLSContext]	<p>Assigns a TLS Context for the TLS connection with the HTTP location.</p> <p>To configure TLS Contexts, see <a href="#">TLS Certificates</a> on page 227.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the connection protocol is HTTPS (configured in the 'Upstream Scheme' parameter, above).</li> <li>■ The NGINX directives for this parameter are "proxy_ssl_certificate", "proxy_ssl_certificate_key", "proxy_ssl_ciphers", "proxy_ssl_protocols", and "proxy_ssl_password_file".</li> </ul>
'Verify Certificate' verify-cert [VerifyCertificate]	<p>Enables TLS certificate verification when the connection with the location is based on HTTPS. It verifies the certificate of the incoming connection request from the Upstream Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Yes</b> = The device verifies the authentication of the certificate received from the HTTPS location. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context (see 'TLS Context' parameter above) and if ok, allows communication with the HTTPS location. If authentication fails, the device denies communication (i.e., handshake</li> </ul>

Parameter	Description
	<p>fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also configured for the associated TLS Context.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the connection protocol is HTTPS (configured in the 'Upstream Scheme' parameter, above).</li> <li>■ The NGINX directive for this parameter is "proxy_ssl_verify".</li> </ul>

## Configuring TCP-UDP Proxy Servers

The TCP/UDP Proxy Servers table lets you configure up to 10 TCP/UDP proxy servers. This table allows you to configure the device as a proxy for other applications that are not based on HTTP. For example, it can be used to intermediate between clients and a DNS server for DNS lookup, or between clients and an NTP server for clock synchronization.

The following procedure describes how to configure a TCP-UDP Proxy Server through the Web interface. You can also configure it through ini file [TcpUdpServer] or CLI (`configure network > http-proxy > tcp-udp-server`).

### ➤ To configure a TCP/UDP Proxy Server:

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the TCP/UDP Proxy Servers table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **TCP/UDP Proxy Servers**).
3. Click **New**; the following dialog box appears:

4. Configure a TCP/UDP Proxy Server according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-25:TCP/UDP Proxy Servers Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Each row must be configured with a unique index.</li> <li>■ The parameter is mandatory.</li> </ul>
'Name' name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter is mandatory.</li> </ul>
'Additional Directive Set' directive-set [AdditionalDirectiveSet]	<p>Assigns an NGINX Directive Set for the HTTP service. To configure HTTP Directive Sets, see <a href="#">Configuring HTTP Directive Sets</a> on page 487.</p>
Listen Parameters	
'Listening Interface' listen-interface [ListeningInterface]	<p>Assigns a local IP network interface for the listening (source) interface for communication with the TCP-UDP proxy server. To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ The NGINX directive for this parameter is "listen ip".</li> </ul>
'TCP Listening Port' tcp-port [TCPListeningPort]	<p>Defines the TCP port of the listening interface.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You must configure a TCP and/or UDP port.</li> <li>■ The NGINX directive for this parameter is "listen ip:port".</li> <li>■ The source ports used for outgoing TCP connections are not configurable and are dynamically determined by the device in the range of 32,768-61,000.</li> </ul>

Parameter	Description
'UDP Listening Port' udp-port [UDPListeningPort]	<p>Defines the TCP port of the listening interface.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You must configure a TCP and/or UDP port.</li> <li>The NGINX directive for this parameter is "listen ip:port udp".</li> </ul>
'Listen Side SSL' listen-use-ssl [ListenUseSSL]	<p>Enables TLS on the listening side (i.e., listening to incoming connection requests).</p> <ul style="list-style-type: none"> <li>[0] <b>Disable</b> (default)</li> <li>[1] <b>Enable</b></li> </ul> <p><b>Note:</b> The NGINX directive for this parameter is "listen ip:port ssl".</p>
'Listen TLS Context' listen-tls-context [ListenTLSContext]	<p>Assigns a TLS Context (TLS certificate) for the listening side. This is required if you have configured the 'Listen Side SSL' parameter to <b>Enable</b> (see above). To configure TLS Contexts, see <a href="#">Configuring TLS Certificate Contexts</a> on page 227.</p> <p><b>Note:</b> The NGINX directives for this parameter is "ssl_certificate", "ssl_certificate_key", "ssl_ciphers", "ssl_protocols", and "ssl_password_file".</p>
Upstream Parameters	
'Upstream Group' upstream-group [UpstreamGroup]	<p>Assigns a group of servers (Upstream Group) to which to forward connection requests. To configure Upstream Groups, see <a href="#">Configuring Upstream Groups</a> on page 483.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Only Upstream Groups with TCP/UDP interfaces can be assigned.</li> <li>The NGINX directive for this parameter is "proxy_pass upstream".</li> </ul>
'Outbound Interface' outbound-interface [OutboundInterface]	<p>Assigns a local, IP network interface for communicating with the Upstream Group. To configure IP network interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is mandatory.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The NGINX directive for this parameter is "proxy_bind".</li> </ul>
'Upstream Side SSL' upstream-use-ssl [UpstreamUseSSL]	<p>Enables TLS for securing connection requests with the Upstream Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If configured to <b>Enable</b>, you must assign a TLS Context (see the 'Upstream TLS Context' parameter below).</li> <li>■ The NGINX directive for this parameter is "proxy_ssl on".</li> </ul>
'Upstream TLS Context' upstream-tls-context [UpstreamTLSContext]	<p>Assigns a TLS Context for the TLS connection with the HTTP location. To configure TLS Contexts, see <a href="#">Configuring TLS Certificate Contexts</a> on page 227.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the 'Upstream Side SSL' parameter is configured to <b>Enable</b> (see above).</li> <li>■ The NGINX directives for this parameter are "proxy_ssl_certificate", "proxy_ssl_certificate_key", "proxy_ssl_ciphers", "proxy_ssl_protocols", and "proxy_ssl_password_file".</li> </ul>
'Upstream Verify Certificate' upstream-verify-cert [UpstreamVerifyCertificate]	<p>Enables TLS certificate verification of the Upstream Host on outgoing connection requests to the Upstream Group, when the connection is TLS.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Yes</b> = The device verifies the authentication of the certificate received from the host. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context (see 'Upstream TLS Context' parameter above) and if ok, allows communication with the host. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also</li> </ul>

Parameter	Description
	<p>configured for the associated TLS Context.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only if the 'Upstream Side SSL' parameter is configured to <b>Enable</b> (see above).</li> <li>The NGINX directive for this parameter is "proxy_ssl_verify".</li> </ul>

## Configuring Upstream Groups

The Upstream Groups table lets you configure up to 10 Upstream Groups. Once configured, you can configure Upstream Hosts for the Upstream Group (see [Configuring Upstream Hosts](#) on page 485).

An Upstream Group is a set of one or more hosts (*Upstream Host*) that can serve a particular set of data. The HTTP Proxy distributes the requests among the members (hosts) of the Upstream Group according to the specified load balancing mode.

The Upstream Group may be made up of one or more primary hosts and zero or more backup hosts. HTTP requests for the Upstream Group are distributed among all the primary hosts. Backup hosts do not receive requests unless all the primary hosts are down.

The following procedure describes how to configure Upstream Groups through the Web interface. You can also configure it through ini file [UpstreamGroup] or CLI (`configure network > http-proxy > upstream-group`).

### ➤ To configure an Upstream Group:

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the Upstream Groups table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **Upstream Groups**).
3. Click **New**; the following dialog box appears:

Upstream Groups

GENERAL

Index

0

Name

Protocol

HTTP/HTTPS

Load Balancing Mode

Round Robin

Max Connections

0

4. Configure an Upstream Group according to the parameters described in the table below.

5. Click **Apply**, and then save your settings to flash memory.

**Table 16-26:Upstream Groups Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Each row must be configured with a unique index.</li> <li>■ The parameter is mandatory.</li> </ul>
'Name' name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The NGINX directive for this parameter is "upstream name { ... }".</li> <li>■ The parameter is mandatory.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
'Protocol' protocol [Protocol]	<p>Defines the protocol.</p> <ul style="list-style-type: none"> <li>■ [0] <b>HTTP/HTTPS</b> (default)</li> <li>■ [1] <b>TCP/UDP</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To assign the Upstream Group to a TCP/UDP Proxy Server, configure the parameter to TCP/UDP. To configure TCP/UDP Proxy Servers, see <a href="#">Configuring TCP-UDP Proxy Servers</a> on page 479.</li> <li>■ To assign the Upstream Group to an HTTP Proxy Server, configure the parameter to HTTP/HTTPS. To configure HTTP Proxy Servers, see <a href="#">Configuring HTTP Proxy Servers</a> on page 472.</li> <li>■ For NGINX, the parameter determines nesting within the "http" or "stream" context.</li> </ul>
'Load Balancing Mode' load-balancing-	<p>Defines the load-balancing of traffic method for the hosts belonging to the Upstream Group.</p>

Parameter	Description
mode [LoadBalancingMode]	<ul style="list-style-type: none"> <li>■ [0] <b>Round Robin</b> = (Default) Traffic requests are balanced across all hosts. Every consecutive request is sent to the next available host.</li> <li>■ [1] <b>IP Hash</b> = All requests from a given client (by IP address) is sent to the same host, regardless of current load.</li> <li>■ [2] <b>Least Connections</b> = New requests are sent to the host with the fewest active connections.</li> </ul> <p><b>Note:</b> The NGINX directive for this parameter is "ip-hash (1)", "least-conn (2)", and "round-robin (0)".</p>
'Max Connections' max-connections [MaxConnections]	<p>Defines the maximum number of simultaneous active connections to the proxied Upstream Host server. Configuring the parameter to a non-zero value activates connection re-use and limits the number of connections towards the upstream server.</p> <p>The default is 0, meaning unlimited connections (i.e., a new upstream connection is opened for every incoming HTTP or HTTPS request).</p> <p><b>Note:</b> To fully utilize the connection re-use capability, you must also include the following directives at the HTTP Location level:</p> <pre>proxy_http_version 1.1; proxy_set_header Connection "";</pre> <p>For more information on adding directives, see <a href="#">Configuring HTTP Directives</a> on page 489.</p>

## Configuring Upstream Hosts

The Upstream Hosts table lets you configure up to 50 Upstream Hosts. The Upstream Hosts table is a "child" of the Upstream Group table (see [Configuring Upstream Groups](#) on page 483) and therefore, Upstream Hosts are configured per Upstream Group. Up to 5 Upstream Hosts can be configured per Upstream Group.

The following procedure describes how to configure Upstream Hosts through the Web interface. You can also configure it through ini file [UpstreamHost] or CLI (`configure network > http-proxy > upstream-host`).

The device activates a keep-alive mechanism to ensure that the hosts configured in the Upstream Hosts table are accessible through HTTP. If an HTTP server goes offline, the device raises an alarm. The device also notifies this event in syslog messages if you have configured the 'HTTP Proxy Debug Level' parameter to **Info** or **Notice**.

➤ **To configure an Upstream Host:**

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the Upstream Groups table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **Upstream Groups**).
3. In the table, select the required Upstream Group index row, and then click the **Upstream Hosts** link located below the table; the Upstream Hosts table appears.
4. Click **New**; the following dialog box appears:

Upstream Hosts - x

GENERAL

Index	<input style="width: 80%;" type="text" value="q"/>
Host	<input style="width: 80%;" type="text"/>
Port	<input style="width: 80%;" type="text"/>
Weight	<input style="width: 80%;" type="text" value="1"/>
Backup	<input style="width: 80%;" type="text" value="Disable"/>

5. Configure an Upstream Host according to the parameters described in the table below.
6. Click **Apply**, and then save your settings to flash memory.

**Table 16-27: Upstream Hosts Table Parameter Descriptions**

Parameter	Description
'Index' [UpstreamHost_HostIndex]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Each row must be configured with a unique index.</li> <li>■ The parameter is mandatory.</li> </ul>
'Host' host [UpstreamHost_Host]	<p>Defines the address of the host as an FQDN or IP address (in dotted-decimal notation).</p> <p><b>Note:</b> The NGINX directive for this parameter is "server host:port".</p>

Parameter	Description
'Port' port [UpstreamHost_Port]	<p>Defines the port number.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the Upstream Group to which the host belongs is configured to use the TCP/UDP protocol, then this parameter must be configured.</li> <li>■ The NGINX directive for this parameter is "server ip:port". If not configured, NGINX defaults to 80 for HTTP and 443 for HTTPS.</li> </ul>
'Weight' weight [UpstreamHost_Weight]	<p>Defines the weight for the load balancer. The load balancer distributes the requests among the hosts in the Upstream Group based on the weight of each host. For example, if host A is configured with a weight of 3, host B with a weight of 1, and host C with a weight of 1, then in each cycle, the load balancer will send three requests to host A, one request to host B and one request to host C.</p> <p>The valid range is 1 to 100. The default is 1 (i.e., each host in the Upstream Group has equal weight).</p> <p><b>Note:</b> The NGINX directive for this parameter is "server ip:port weight=n".</p>
'Backup' backup [UpstreamHost_Backup]	<p>Enables the host to serve as a backup host. The backup host doesn't receive any requests unless all the primary hosts in the Upstream Group are down.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> The NGINX directive for this parameter is "server ip:port backup".</p>

## Configuring HTTP Directive Sets

The HTTP Directive Sets table lets you configure up to 30 HTTP Directive Sets. The table lets you configure additional custom directives to HTTP Proxy server configuration. These directives are reflected in the configuration file generated for the NGINX HTTP Proxy. The directives of each HTTP Directive Set is configured in the HTTP Directives table (see [Configuring HTTP Directives](#) on page 489), which is a "child" of the HTTP Directive Sets table.

Directives are grouped into Directive Sets, which you can then assign to HTTP Proxy Servers (see [Configuring HTTP Proxy Servers](#) on page 472), HTTP Locations (see [Configuring HTTP Locations](#)

on page 475), and TCP/UDP Proxy Servers (see [Configuring TCP-UDP Proxy Servers](#) on page 479), using the 'Additional Directive Set' parameter in their respective tables.

For example, to control behavior of specific encoding and communication parameters relating to a particular location, you can configure the following NGINX directives:

```
chunked_transfer_encoding off;
keepalive_timeout 50s;
```

- The device doesn't validate Directive Sets, which it passes directly to the NGINX configuration file. If the configured directives are not entered using the correct syntax, NGINX rejects the new configuration. For more information, refer to the NGINX documentation at <http://nginx.org/en/docs>. An alphabetical index to all directives can be found at <http://nginx.org/en/docs/dirindex.html>.
- By default, the device is configured with an HTTP Directive Set for rate limiting. This directive ensures that priority is given to network traffic carrying SIP signaling and media over HTTP traffic. It is highly recommended to configure these limitations on the HTTP Proxy. This HTTP Directive Set includes the following directives:
  - ✓ "limit\_conn": Specifies the maximum number of simultaneous client connections (default 100).
  - ✓ "limit\_rate": Specifies the bandwidth limit per connection (bytes per second). This syntax supports a suffix of "k" for kilobytes and "m" for megabytes. The default is 0.

The following procedure describes how to configure HTTP Directive Sets through the Web interface. You can also configure it through ini file [HTTPODirectiveSets] or CLI (`configure network > http-proxy > directive-sets`).

#### ➤ To configure an HTTP Directive Set:

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the HTTP Directive Sets table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Directive Sets**).
3. Click **New**; the following dialog box appears:

GENERAL	
Index	0
Set Name	
Description	

4. Configure an HTTP Directive Set according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

6. Configure directives for the HTTP Directive Set (see [Configuring HTTP Directives](#) below).

**Table 16-28: HTTP Directive Sets Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> <ul style="list-style-type: none"> <li>Each row must be configured with a unique index.</li> <li>The parameter is mandatory.</li> </ul>
'Set Name' set-name [SetName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. By default, no value is defined. <b>Note:</b> The parameter value cannot contain a forward slash (/).
'Description' set-description [Description]	Defines a brief description for the HTTP Directive Set. The valid value is a string of up to 100 characters. By default, no value is defined.

### Configuring HTTP Directives

The HTTP Directives table lets you configure up to 500 HTTP Directives. The table is a "child" of the HTTP Directive Sets table (see [Configuring HTTP Directive Sets](#) on page 487).

When generating the NGINX configuration file, the device includes the resolver directive, specifying the primary and secondary DNS servers, as configured in [Configuring a DNS Server for HTTP Services](#) on page 471. However, NGINX supports optional parameters that allow you to fine-tune the behavior of the DNS resolution. You can include these additional parameters using the ini file parameter [NginxResolverParams], which is added to the resolver directive when the device generates the NGINX configuration file. For more information on these optional parameters, go to the [NGINX forum](#).

The following procedure describes how to configure HTTP Directives through the Web interface. You can also configure it through ini file [HTTPEndirectives] or CLI (`configure network > http-proxy > directives`).

#### ➤ To configure an HTTP Directive:

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.

2. Open the HTTP Directive Sets table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Directive Sets**).
3. In the table, select the required HTTP Directive Set index row, and then click the **HTTP Directives** link located below the table; the HTTP Directives table appears.
4. Click **New**; the following dialog box appears:

5. Configure an HTTP Directive according to the parameters described in the table below.
6. Click **Apply**, and then save your settings to flash memory.

**Table 16-29:HTTP Directives Table Parameter Descriptions**

Parameter	Description
'Index' [HTTPOirectives_ RowIndex]	Defines an index number for the new table row. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Each row must be configured with a unique index.</li> <li>■ The parameter is mandatory.</li> </ul>
' Directive' directive [HTTPOirectives_ Directive]	Defines an NGINX directive. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ Make sure that you end the directive with a semicolon (;).</li> </ul>

## Configuring an HTTP-based OVOC Service

The OVOC Services table lets you configure a single HTTP-based AudioCodes One Voice Operations Center (OVOC) service. You can configure the device to act as an HTTP Proxy that enables OVOC to manage AudioCodes equipment (such as IP Phones) over HTTP when the equipment is located behind NAT (e.g., in the LAN) and OVOC is located in a public domain (e.g., in the WAN). This setup resolves NAT traversal issues. The IP Phones register with the device to allow communication between the IP Phones and OVOC. Once setup, the OVOC administrator can access the Web-based management interfaces of each IP Phone .

A summary of the steps required to configure an HTTP Proxy for this OVOC service is listed below:

1. Enable the HTTP Proxy application (see [Enabling the HTTP Proxy Application](#) on page 470).

2. Configure two local, listening IP network interfaces - one for OVOC and one for the IP Phones (see [Configuring IP Network Interfaces](#) on page 159).
3. Configure the OVOC service in the OVOC Services table (described below). This entails specifying the IP network interfaces as well as the port number within each interface to which the HTTP Proxy must listen to.
4. Configure the device's firewall (Firewall table) to allow incoming traffic from OVOC. For more information, see [Configuring Firewall Rules to Allow Incoming OVOC Traffic](#) on page 261.

- It is recommended **not** to use port 80 as this is the default port used by IP Phones for their Web-based management interface.
- No special configuration is required on the managed equipment.

The following procedure describes how to configure an OVOC service through the Web interface. You can also configure it through ini file [OVOCService] or CLI (`configure network > http-proxy > ovoc-serv`).

➤ **To configure an OVOC Service:**

1. Enable the HTTP Proxy application, as described in [Enabling the HTTP Proxy Application](#) on page 470.
2. Open the OVOC Services table (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **OVOC Services**).
3. Click **New**; the following dialog box appears:

4. Configure an OVOC Service according to the parameters described in the table below.
5. Click **Apply**, and then save your settings to flash memory.

**Table 16-30:OVOC Services Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b>

Parameter	Description
	<ul style="list-style-type: none"> <li>Each row must be configured with a unique index.</li> <li>The parameter is mandatory.</li> </ul>
'Name' service-name [ServiceName]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>Configure each row with a unique name.</li> <li>The parameter is mandatory.</li> </ul>
<b>Device</b>	
'Device Login Interface' device-login-interface [DeviceLoginInterface]	<p>Assigns an IP network interface (local, listening HTTP interface:port) for communication with the client. To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is mandatory.</li> <li>The NGINX directive for this parameter is "proxy_bind".</li> </ul>
'Device Login Port' device-login-port [DeviceLoginPort]	<p>Defines the login port of the requesting client.</p> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_bind".</p>
'Device Scheme' device-scheme [DeviceScheme]	<p>Defines the protocol for communication with the requesting client.</p> <ul style="list-style-type: none"> <li>[0] HTTP (default)</li> <li>[1] HTTPS</li> </ul> <p><b>Note:</b> If configured to <b>HTTPS</b>, you must assign a TLS Context (see the 'Device Login TLS Context' parameter, below).</p>
'Device Login TLS Context' device-login-tls-context	<p>Assigns a TLS Context (TLS configuration) for the interface with the requesting client. This is required if you have configured the 'Device Scheme'</p>

Parameter	Description
[LoginInterfaceTLSContext]	<p>parameter to <b>HTTPS</b> (see above). To configure TLS Contexts, see <a href="#">Configuring TLS Certificate Contexts</a> on page 227.</p> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_ssl_certificate", "proxy_ssl_certificate_key", "proxy_ssl_ciphers", and "proxy_ssl_protocols".</p>
'Device Login Interface Verify Certificate' device-interface-verify-cert [LoginInterfaceVerifyCert]	<p>Enables the verification of the TLS certificate that is used in the incoming client connection request.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Yes</b> = The device verifies the authentication of the certificate received from the client. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context (see 'Device Login TLS Context' parameter above) and if ok, allows communication with the client. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also configured for the associated TLS Context.</li> </ul> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_ssl_verify".</p>
<b>OVOC</b>	
'OVOC Listening Interface' ovoc-interface [OVOCListeningInterface]	<p>Assigns an IP network interface (local, listening HTTP interface:port) for communication with OVOC. To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ The NGINX directive for this parameter is "proxy_bind".</li> </ul>
'OVOC Listening Port' ovoc-port	<p>Defines the listening port for the OVOC interface.</p> <p><b>Note:</b> The NGINX directive for this parameter is</p>

Parameter	Description
[OVOCListeningPort]	"proxy_bind".
'OVOC Scheme' ovoc-scheme [OVOCScheme]	<p>Defines the security scheme for the connection with OVOC.</p> <ul style="list-style-type: none"> <li>■ [0] <b>HTTP</b> (default)</li> <li>■ [1] <b>HTTPS</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If configured to <b>HTTPS</b>, you must assign a TLS Context (see the 'OVOC Interface TLS Context' parameter, below).</li> <li>■ The NGINX directive for this parameter is "proxy_pass scheme://upstream".</li> </ul>
'OVOC Interface TLS Context' ovoc-interface-tls-context [OVOCInterfaceTLSContext]	<p>Assigns a TLS Context (TLS configuration) for the OVOC listening interface. This is required if you have configured the 'OVOC Scheme' parameter to <b>HTTPS</b> (see above). To configure TLS Contexts, see <a href="#">Configuring TLS Certificate Contexts</a> on page 227.</p> <p><b>Note:</b> The NGINX directive for this parameter is "proxy_ssl_certificate", "proxy_ssl_certificate_key", "proxy_ssl_ciphers", and "proxy_ssl_protocols".</p>
'OVOC Interface Verify Certificate' ovoc-verify-cer [OVOCInterfaceVerifyCert]	<p>Enables the verification of the TLS certificate that is used in the incoming connection request from OVOC.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) No certificate verification is done.</li> <li>■ [1] <b>Yes</b> = The device verifies the authentication of the certificate received from OVOC. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context (see 'OVOC Interface TLS Context' parameter above) and if ok, allows communication with OVOC. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is also configured for the associated TLS Context.</li> </ul>

Parameter	Description
	<p><b>Note:</b> The NGINX directive for this parameter is "proxy_ssl_verify".</p>
'OVOC Primary Server' primary-server [PrimaryServer]	<p>Defines the address (IPv4 or IPv6) of the primary OVOC server.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This parameter is mandatory.</li> <li>■ When you configure this parameter, an Upstream Group is automatically added (see <a href="#">Configuring Upstream Groups</a> on page 483).</li> <li>■ The NGINX directive for this parameter is "upstream ems { addr1, addr2 backup }" and "proxy_pass scheme://ems".</li> <li>■ The IP address version (IPv4 or IPv6) of the OVOC address and the IP Interface (see 'OVOC Listening Interface' field above) must be the same.</li> </ul>

## Troubleshooting NGINX Configuration

Troubleshooting may be necessary when configuring your HTTP or TCP/UDP proxy services with NGINX directives. Due to the large and complex dictionary of directives supported by NGINX and their complex grammatical structure, the device assists you by validating your configured directives. It does this only once you have applied them (i.e., clicked the **Apply** button) in the HTTP Directives table (see [Configuring HTTP Directives](#) on page 489).

In addition, the device generates the following NGINX configuration files:

- **nginx.conf:** This file contains the currently active configuration, which is valid.
- **temp\_nginx.conf:** This file is generated if you have invalid configuration (directive errors). It is a temporary file and contains your new configuration, which is invalid. It is applied only if the device is restarted.
- **nginx.errors:** This file is generated if you have invalid configuration (directive errors). This file contains all the error messages, indicating the line on which the error exists in the temp\_nginx.conf file.

If you have modified your configuration and errors occur, the device continues running with the previous, valid NGINX configuration, unless the device is restarted, in which case it applies and uses the modified configuration.

In addition, if an NGINX validation error exists during configuration or if the device restarts with an invalid NGINX configuration, the device indicates this by the following:

- Sends an alarm to the Active Alarms table ("NGINX configuration file is not valid")

- Sends the error to syslog, which is marked with "http\_app"

To send the NGINX files to a remote destination in tar file format (.tar), use the following CLI command:

```
# copy nginx-conf-files to <Protocol>://<Address>/<filename>.tar
```

To view the NGINX files in CLI, use the following command:

```
show network http-proxy conf active|errors|new
```

## Configuring a Public IP Address for NGINX NAT Traversal

When the device is located behind NAT, OVOC can only communicate with the device's embedded NGINX HTTP-based proxy using the device's public static NAT address. However, by default, the device sends its private address to OVOC. The device's address (private or public) appears in the proprietary X-AC-Proxy-URL header in HTTP requests that the device sends to OVOC.

### ➤ To configure a public IP address for HTTP Proxy:

1. Open the HTTP Proxy Settings page (**Setup** menu > **IP Network** tab > **HTTP Proxy** folder > **HTTP Proxy Settings**).
2. In the 'HTTP Proxy Global Address' [HttpProxyGlobalAddress] field, enter the public IP address:

HTTP Proxy Global Address

3. Click **Apply**.

## Configuring LDAP Authentication for NGINX HTTP Reverse Proxy

You can configure the device's HTTP Reverse Proxy to authenticate HTTP requests with an LDAP server. This is done using the device's integrated NGINX add-on module "nginx-auth-ldap-module".

### ➤ To configure LDAP authentication for HTTP Reverse Proxy:

1. Configure one or more LDAP servers in an HTTP Directive Set. Note that the declaration may include the optional "require group", "require valid\_user", or "require group" clauses.

```
ldap_server ad_1 {  
    # User search base  
    url "ldap://<YOUR LDAP
```

```

SERVER>:3268/,DC=company,DC=com?sAMAccountName?sub?
(objectClass=person)\";
# bind as
binddn \"CN=Operator,OU=Service Accounts,DC=company,DC=com\";
# bind pw
binddn_passwd <PUT Operator's PASSWORD HERE>;
# group attribute name which contains member object
group_attribute member;
# search for full DN in member object
group_attribute_is_dn on;
# matching algorithm (any / all)
satisfy any;
# optional list of allowed groups
require group \"CN=Admins,OU=My Security
Groups,DC=company,DC=com\";
require group \"CN=New York Users,OU=My Security
Groups,DC=company,DC=com\";

# optional list of allowed users
# require 'valid_user' cannot be used together with 'user' as valid user is a
superset
require valid_user;\"
# require user \"<YOUR LDAP QUERY>\";
}

```

2. Customize the url, DN password, and any other attributes of the query, as needed. Details of the syntax supported for the LDAP server declarations can be found [here](#).
3. Reference this new declaration in the “HTTP Context Directives”. For example, if in the previous step, you named the HTTP Directive Set “My LDAP Server”, then add the following line to the “HTTP Context Directives”:

```
<@Include My LDAP Server@>;
```

4. Activate LDAP authentication on the HTTP Servers and/or Locations:
  - a. Add the following lines to an HTTP Directive Set:

```

auth_ldap "Forbidden";
auth_ldap_servers ad_1;
# additional ldap servers as required...
# auth_ldap_servers ad_2;

```

- b. Set this HTTP Directive Set as the Additional Directive set for any HTTP servers or HTTP Locations for which you wish to authenticate using LDAP:

**HTTP Proxy Servers (1)**

## E9-1-1 Support for Microsoft Teams and Skype for Business

The Enhanced 9-1-1 (E9-1-1) service is becoming the mandatory emergency service required in many countries around the world. The E9-1-1 service, based on its predecessor 911, enables emergency operators to pinpoint the location (granular location) of callers who dial the 9-1-1 emergency telephone number.

Today, most companies implement an IP-based infrastructure providing a VoIP network with fixed and nomadic users, allowing connectivity anywhere with any device. This, together with an often deployed multi-line telephone system (MLTS) poses a challenge for E9-1-1 due to the difficulty in accurately locating the E9-1-1 caller.

This section describes the E9-1-1 solution provided by Microsoft Teams / Skype for Business and AudioCodes' device's ELIN interworking capabilities, which provides the SIP Trunk or ISDN (or CAMA) connectivity to the E9-1-1 emergency service provider. This section also describes the configuration of the device for interoperating between the Teams / Skype for Business environment and the E9-1-1 emergency provider.

- The ELIN feature for E9-1-1 is a license-based feature and is available only if it is included in the License Key installed on the device. For ordering the feature, please contact the sales representative of your purchased device. For installing a new License Key, see [License Key](#) on page 1362.
- The ELIN feature for E9-1-1 is applicable to the SBC application and the Gateway application (digital PSTN interfaces only).

## About E9-1-1 Services

E9-1-1 is a national emergency service for many countries, enabling E9-1-1 operators to automatically identify the geographical location and phone number of a 911 caller. In E9-1-1, the 911 caller is routed to the nearest E9-1-1 operator, termed *public safety answering point* (PSAP) based on the location of the caller. Automatic identification of the caller's location and phone number reduces the time spent on requesting this information from the 911 caller. Therefore, the E9-1-1 service enables the PSAP to quickly dispatch the relevant emergency services (for example, fire department or police) to the caller's location. Even if the call prematurely disconnects, the operator has sufficient information to call back the 911 caller.

The figure below illustrates the routing of an E9-1-1 call to the PSAP:

1. The VoIP user dials 9-1-1.
2. The AudioCodes' ELIN device sends the call to the emergency service provider over the PSTN or SIP Trunk (PSAP server).
3. The emergency service provider identifies the call is an emergency call and sends it to an E9-1-1 Selective Router in the Emergency Services provider's network.
4. The E9-1-1 Selective Router determines the geographical location of the caller by requesting this information from an Automatic Location Identification (ALI) database based on the phone number or Automatic Number Identifier (ANI) of the 911 caller. Exact location information is also supplied by the Master Street Address Guide (MSAG) database, which is a companion database to the ALI database. Phone companies and public safety agencies collaborate beforehand to create master maps that match phone numbers, addresses and cross streets to their corresponding PSAP. This MSAG is the official record of valid streets (with exact spelling), street number ranges, and other address elements with which the service providers are required to update their ALI databases.
5. The E9-1-1 Selective Router sends the call to the appropriate PSAP based on the retrieved location information from the ALI.

6. The PSAP operator dispatches the relevant emergency services to the E9-1-1 caller.

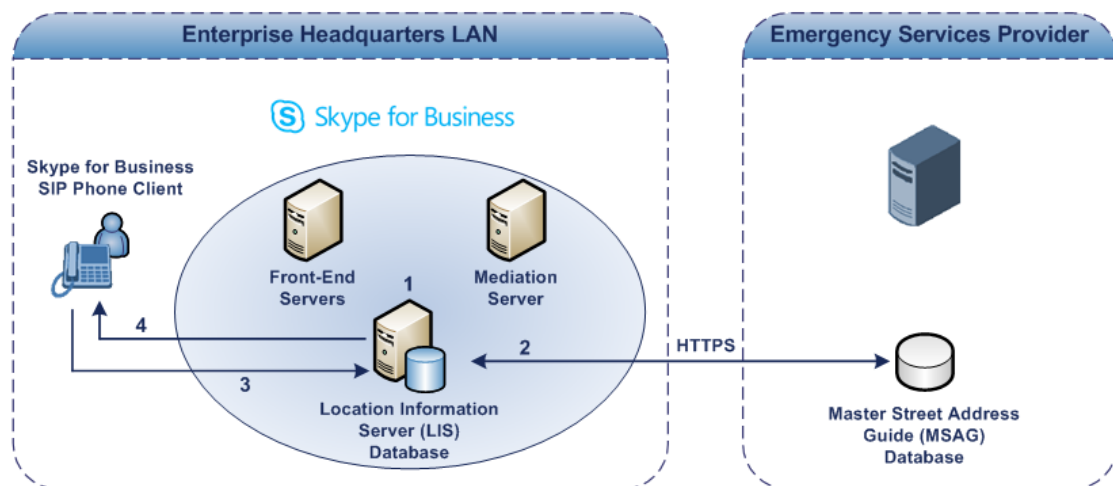

## Microsoft Skype for Business and E9-1-1

Microsoft Skype for Business enables Enterprise voice users to access its unified communications platform from virtually anywhere and through many different devices. This, together with a deployed MLTS, poses a challenge for E9-1-1 due to the difficulty in accurately locating the E9-1-1 caller. However, Skype for Business offers an innovative solution to solving Enterprises E9-1-1 location problems.

### Gathering Location Information of Skype for Business Clients for 911 Calls

When a Microsoft Skype for Business client is enabled for E9-1-1, the location data that is stored on the client is sent during an emergency call. This stored location information is acquired automatically from the Microsoft Location Information Server (LIS). The LIS stores the location of each network element in the enterprise. Immediately after the Skype for Business client registration process or when the operating system detects a network connection change, each Skype for Business client submits a request to the LIS for a location. If the LIS is able to resolve a location address for the client request, it returns the address in a location response. Each client then caches this information. When the Skype for Business client dials 9-1-1, this location information is then included as part of the emergency call and used by the emergency service provider to route the call to the correct PSAP.

The gathering of location information in the Skype for Business network is illustrated in the figure below:

1. The Administrator provisions the LIS database with the location of each network element in the Enterprise. The location is a civic address, which can include contextual in-building and company information. In other words, it associates a specific network entity (for example, a WAP) with a physical location in the Enterprise (for example, Floor 2, Wing A, and the Enterprise's street address). For more information on populating the LIS database, see [Adding ELINs to the Location Information Server](#) on page 502.

2. The Administrator validates addresses with the emergency service provider's MSAG—a companion database to the ALI database. This ensures that the civic address is valid as an official address (e.g., correct address spelling).
3. The Skype for Business client initiates a location request to the LIS under the following circumstances:

- Immediately after startup and registering the user with Skype for Business
- Approximately every four hours after initial registration
- Whenever a network connection change is detected (such as roaming to a new WAP)

The Skype for Business client includes in its location request the following known network connectivity information:

- Always included:
  - ◆ IPv4 subnet
  - ◆ Media Access Control (MAC) address
- Depends on network connectivity:
  - ◆ Wireless access point (WAP) Basic Service Set Identifier (BSSID)
  - ◆ Link Layer Discovery Protocol-Media Endpoint Discovery (LLDP-MED) chassis ID and port ID

For a Skype for Business client that moves inside the corporate network such as a soft phone on a laptop that connects wirelessly to the corporate network, Skype for Business can determine which subnet the phone belongs to or which WAP / SSID is currently serving the soft-client.

4. The LIS queries the published locations for a location and if a match is found, returns the location information to the client. The matching order is as follows:
  - WAP BSSID
  - LLDP switch / port
  - LLDP switch
  - Subnet
  - MAC address

This logic ensures that for any client that is connected by a wireless connection, a match is first attempted based on the hardware address of its connected access point. The logic is for the match to be based on the most detailed location. The subnet generally provides the least detail. If no match is found in the LIS for WAP BSSID, LLDP switch / port, LLDP switch, or subnet, the LIS proxies the MAC address to an integrated Simple Network Management Protocol (SNMP) scanning application. Using SNMP may benefit some organizations for the following reasons:

- LLDP is not supported by Skype for Business so this provides a mechanism for soft phones to acquire detailed location information.
- Installed Layer-2 switches may not support LLDP.

If there is no match and the LIS cannot determine the location, the user may be prompted to manually enter the location. For example, the client may be located in an undefined subnet, at home, in a coffee shop or anywhere else outside the network. When a user manually provides a location, the location is mapped based on the MAC address of the default gateway of the client's network and stored on the client. When the client returns to any previously stored location, the client is automatically set to that location. A user can also manually select any location stored in the local users table and manage existing entries.

### Adding ELINs to the Location Information Server

As mentioned in the previous section, the administrator needs to populate the Location Information Server (LIS) database with a network wire map, which maps the company's network elements to civic addresses. Once done, it can automatically locate clients within a network. You can add addresses individually to the LIS or in a batch using a comma-separated value (CSV) file containing the column formats for the network elements, as listed below:

#### ■ **Wireless access point:**

<BSSID>,<Description>,<Location>,<**CompanyName**>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>

#### ■ **Subnet:**

<Subnet>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>

#### ■ **Port:**

<ChassisID>,<PortIDSubType>,<PortID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>

#### ■ **Switch:**

<ChassisID>,<Description>,<Location>,<CompanyName>,<HouseNumber>,<HouseNumberSuffix>,<PreDirectional>,<StreetName>,<StreetSuffix>,<PostDirectional>,<City>,<State>,<PostalCode>,<Country>

For the ELIN number to be included in the SIP INVITE (XML-based PIDF-LO message) sent by the Mediation Server to the ELIN device, the administrator must add the ELIN number to the <CompanyName> column (shown in the table above in bold typeface). As the ELIN device supports up to five ELINs per PIDF-LO, the <CompanyName> column can be populated with up to this number of ELINs, each separated by a semicolon. The digits of each ELIN can be separated by hyphens (xxx-xxx-xxx) or they can be adjacent (xxxxxxxxx). When the ELIN device receives the SIP INVITE message, it extracts the ELINs from the ELIN field in the PIDF-LO (e.g., <ca:ELIN>1111-222-333; 1234567890 </ca:ELIN>), which corresponds to the <CompanyName> column of the LIS.

For backward compatibility, if the ELIN field doesn't appear in the PIDF-LO, the device extracts the ELINs from the NAM field.

If you do not populate the location database and the Skype for Business location policy, and Location Required is set to **Yes** or **Disclaimer**, the user is prompted to enter a location manually.

### Passing Location Information to the PSTN Emergency Provider

When a Skype for Business client, enabled for E9-1-1 emergency services, dials 9-1-1, the location data and callback information stored on the client is sent with the call through the Mediation Server to a SIP Trunk-based or PSTN-based emergency service provider. The emergency service provider then routes the call to the nearest and most appropriate PSAP based on the location information contained within the call.

Skype for Business passes the location information of the Skype for Business client in an IETF-standard format - Presence Information Data Format - Location Object (PIDF-LO)—in a SIP INVITE message. However, this content cannot be sent on the SIP Trunk or PSTN since they do not support such a content. To overcome this, Enterprises deploying the device can divide their office space into Emergency Response Locations (ERLs) and assign a dedicated Emergency Location Identification Number (ELIN) to each ERL (or zone). When Skype for Business sends a SIP INVITE message with the PIDF-LO to the device, it can parse the content and translate the calling number to an appropriate ELIN. The device then sends the call to the SIP Trunk or PSTN with the ELIN number as the calling number. The ELIN number is sent to the emergency service provider, which sends it on to the appropriate PSAP according to the ELIN address match in the ALI database lookup.

The ERL defines a specific location at a street address, for example, the floor number of the building at that address. The geographical size of an ERL is according to local or national regulations (for example, less than 7000 square feet per ERL). Typically, you would have an ERL for each floor of the building. The ELIN is used as the phone number for 911 callers within this ERL.

The figure below illustrates the use of ERLs and ELINs, with an E9-1-1 call from floor 2 at the branch office:

The table below shows an example of designating ERLs to physical areas (floors) in a building and associating each ERL with a unique ELIN.

**Table 16-31: Designating ERLs and Assigning to ELINs**

ERL Number	Physical Area	IP Address	ELIN
1	Floor 1	10.13.124.xxx	503 972-4410
2	Floor 2	10.15.xxx.xxx	503 972-4411
3	Floor 3	10.18.xxx.xxx	503 972-4412

In the table above, a unique IP subnet is associated per ERL. This is useful if you implement different subnets between floors. Therefore, IP phones, for example, on a specific floor are in the same subnet and therefore, use the same ELIN when dialing 9-1-1.

## AudioCodes ELIN Device for Teams / Skype for Business E9-1-1 Calls to PSTN

Microsoft Mediation Server sends the location information of the E9-1-1 caller in the XML-based PIDF-LO body contained in the SIP INVITE message. However, this content cannot be sent on the SIP Trunk or PSTN since they do not support such content. To solve this issue, Skype for Business requires a ELIN SBC or Gateway to send the E9-1-1 call to the SIP Trunk or PSTN. When Skype for Business sends the PIDF-LO to the ELIN device, it parses the content and translates

the calling number to an appropriate ELIN. This ensures that the call is routed to an appropriate PSAP based on ELIN-address match lookup in the emergency service provider's ALI database.

The figure below illustrates an AudioCodes ELIN device deployed in the Skype for Business environment for handling E9-1-1 calls between the company and the emergency service provider.

## Detecting and Handling E9-1-1 Calls

The ELIN device identifies E9-1-1 calls and translates their incoming E9-1-1 calling numbers into ELIN numbers, which are sent to the PSAP. The device handles the received E9-1-1 calls as follows:

1. The device identifies E9-1-1 calls if the incoming SIP INVITE message contains a PIDF-LO XML message body. This is indicated in the SIP *Content-Type* header, as shown below:

```
Content-Type: application/pdf+xml
```

2. The device extracts the ELIN number(s) from the ELIN field in the XML message. The ELIN field corresponds to the <CompanyName> column in the Location Information Server (LIS). The device supports up to five ELIN numbers per XML message. The ELINs are separated by a semicolon. The digits of the ELIN number can be separated by hyphens (xxx-xxx-xxx) or they can be adjacent (xxxxxxxx), as shown below:

```
<ca:ELIN>1111-222-333; 1234567890 </ca:ELIN>
```

For backward compatibility, if the ELIN field doesn't appear in the PIDF-LO, the device extracts the ELINs from the NAM field.

3. The device saves the From header value of the SIP INVITE message in its ELIN database table ('Call From' field). The ELIN table is used for PSAP callback, as discussed later in [PSAP Callback for Dropped E9-1-1 Calls](#) on page 508. The ELIN table also stores the following information:

- **ELIN:** ELIN number
- **Time:** Time at which the original E9-1-1 call was terminated with the PSAP
- **Count:** Number of E9-1-1 calls currently using the ELIN

An example of the ELIN database table is shown below:

ELIN	Time	Count	Index	Call From
4257275678	22:11:52	0	2	4258359333
4257275999	22:11:57	0	3	4258359444
4257275615	22:12:03	0	0	4258359555
4257275616	22:11:45	0	1	4258359777

The ELIN table stores this information for a user-defined period (see [Configuring the E9-1-1 Callback Timeout](#) on page 511), starting from when the E9-1-1 call, established with the PSAP, terminates. After this time expires, the table entry with its ELIN is disregarded and no longer used (for PSAP callback). Therefore, table entries of only the most recently terminated E9-1-1 callers are considered in the ELIN table. The maximum entries in the ELIN table is 100.

4. The device uses the ELIN number as the E9-1-1 calling number and sends it in the SIP INVITE or ISDN Setup message (as an ANI / Calling Party Number) to the SIP Trunk or PSTN.

An example of a SIP INVITE message received from an E9-1-1 caller is shown below. The SIP Content-Type header indicating the PIDF-LO and the ELIN field listing the ELINs are shown in **bold** typeface.

### Pre-empting Existing Calls for E9-1-1 Calls

If the ELIN device receives an E9-1-1 call from the IP network and there are unavailable channels (for example, all busy), the device immediately terminates one of the non-E9-1-1 calls (arbitrary) and accepts the E9-1-1 call on the freed-up channel:

- SBC application: Preemption is done only on a call belonging to the same source IP Group from which the E9-1-1 call is received, or the same destination IP Group (i.e., PSAP Server).
- Gateway application: Preemption is done only on a channel belonging to the same Trunk Group for which the E9-1-1 call was initially destined. For example, if an E9-1-1 call is destined for Trunk Group #2 and all the channels belonging to this group are busy, the device terminates one of the calls in this group to free a channel for accepting the E9-1-1 call.

This feature is initiated only if the received SIP INVITE message contains a Priority header set to "emergency", as shown below:

```
Priority: emergency
```

### PSAP Callback for Dropped E9-1-1 Calls

As the E9-1-1 service automatically provides all the contact information of the E9-1-1 caller to the PSAP, the PSAP operator can call back the E9-1-1 caller. This is especially useful in cases where the caller disconnects prematurely. However, as the Enterprise sends ELINs to the PSAP for E9-1-1 calls, a callback can only reach the original E9-1-1 caller using the device to translate the ELIN number back into the E9-1-1 caller's extension number.

In the ELIN table of the device, the temporarily stored *From* header value of the SIP INVITE message originally received from the E9-1-1 caller is used for PSAP callback. When the PSAP makes a callback to the E9-1-1 caller, the device translates the called number (i.e., ELIN) received from the PSAP to the corresponding E9-1-1 caller's extension number as matched in the ELIN table.

The handling of PSAP callbacks by the device is as follows:

1. When the device receives a call from the emergency service provider, it searches the ELIN table for an ELIN that corresponds to the received called party number in the incoming message.
2. If a match is found in the ELIN table, it routes the call to the Mediation Server by sending a SIP INVITE, where the values of the *To* and *Request-URI* are taken from the value of the original *From* header that is stored in the ELIN table (in the **Call From** column).
3. The device updates the 'Time' field in the ELIN table (the 'Count' field is not affected).

The PSAP callback can be done only within a user-defined period (see [Configuring the E9-1-1 Callback Timeout](#) on page 511), started from after the original E9-1-1 call, established with the PSAP is terminated. After this time expires, the table entry with its ELIN is disregarded and no longer used (for PSAP callback). Therefore, table entries of only the most recently terminated E9-1-1 callers are considered in the ELIN table. If the PSAP callback is done after this timeout expires, the device is unable to route the call to the E9-1-1 caller and instead, either sends it as a regular call or most likely, rejects it if there are no matching routing rules. However, if another E9-1-1 caller has subsequently been processed with the same ELIN number, the PSAP callback is routed to this new E9-1-1 caller.

In scenarios where the same ELIN number is used by multiple E9-1-1 callers, upon receipt of a PSAP callback, the device sends the call to the most recent E9-1-1 caller. For example, if the ELIN number "4257275678" is being used by three E9-1-1 callers, as shown in the table below, then when a PSAP callback is received, the device sends it to the E9-1-1 caller with phone number "4258359555".

**Table 16-32: Choosing Caller of ELIN**

ELIN	Time	Call From
4257275678	11:00	4258359333
4257275678	11:01	4258359444
4257275678	11:03	<b>4258359555</b>

### Selecting ELIN for Multiple Calls within Same ERL

The device supports the receipt of up to five ELIN numbers in the XML message of each incoming SIP INVITE message. As discussed in the preceding sections, the device sends the ELIN number as the E9-1-1 calling number to the emergency service provider. If the XML message contains more than one ELIN number, the device chooses the ELIN according to the following logic:

- If the first ELIN in the list is not being used by other active calls, it chooses this ELIN.
- If the first ELIN in the list is being used by another active call, the device skips to the next ELIN in the list, and so on until it finds an ELIN that is not being used and sends this ELIN.

- If all the ELINs in the list are in use by active calls, the device selects the ELIN number as follows:
  - a. The ELIN with the lowest count (i.e., lowest number of active calls currently using this ELIN).
  - b. If the count between ELINs is identical, the device selects the ELIN with the greatest amount of time passed since the original E9-1-1 call using this ELIN was terminated with the PSAP. For example, if E9-1-1 caller using ELIN 4257275678 was terminated at **11:01** and E9-1-1 caller using ELIN 4257275670 was terminated at **11:03**, then the device selects ELIN 4257275678.

In this scenario, multiple E9-1-1 calls are sent with the same ELIN.

### Location Based Emergency Routing

The device supports location-based emergency routing (E-911) in Teams / Skype for Business environments. This ensures that E-911 calls from remote branches are routed to emergency providers that are relevant to the geographical area in which the remote branch callers are physically located. To support this, the device enables routing and SIP header / number manipulation of such emergency calls based on the geographical location of the caller. The device manipulates the received destination number (i.e., 911) from the remote branch callers, into a destination number of an emergency provider that is relevant to the geographical area in which the remote branch office is located.

For an example on location-based emergency call routing, see [Configuring Location-Based Emergency Routing](#) on page 512.

Location-based emergency routing is applicable only to the Gateway application.

### Configuring AudioCodes ELIN Device

This section describes E9-1-1 configuration of the AudioCodes ELIN Gateway deployed in the Microsoft Teams / Skype for Business environment.

#### Enabling the E9-1-1 Feature

By default, the ELIN device feature for E9-1-1 emergency call handling in a Microsoft Teams / Skype for Business environment is disabled.

#### ➤ To enable ELIN feature for the SBC application:

- For the IP Group through which you want to communicate with the public-safety answering point (PSAP), configure the 'SBC PSAP Mode' parameter to **Enable**. For more information, see [Configuring IP Groups](#) on page 591.

➤ **To enable ELIN feature for the Gateway application:**

1. Open the Priority & Emergency page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Priority and Emergency**).
2. From the 'E911 Gateway' drop-down list (E911Gateway), select **NG911 Callback Gateway**.

E911 Gateway

NG911 Callback Gateway ▼

3. Click **Apply**.

### Configuring the E9-1-1 Callback Timeout

If the initial established call between the E9-1-1 caller and the PSAP is prematurely terminated, the PSAP can use the ELIN to call back the E9-1-1 caller within a user-defined time interval (in minutes) from when the call was terminated. By default, an ELIN can be used for PSAP callback within 30 minutes after the call terminates. You can change this to any value between 0 and 60. For more information on PSAP callback for dropped E9-1-1 calls, see [PSAP Callback for Dropped E9-1-1 Calls](#) on page 508.

➤ **To configure the E9-1-1 callback timeout**

1. Open the Priority & Emergency page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Priority and Emergency**).
2. In the 'E911 Callback Timeout' field (E911CallbackTimeout), enter the required callback timeout.

E911 Callback Timeout

30

3. Click **Apply**.

### Enabling SIP Release Cause Code Response for Failed E9-1-1 Calls

When a Teams client makes an emergency call, the call is routed through the Microsoft Mediation Server to the ELIN device, which sends it to the PSTN. In some scenarios, the call may not be established due to the destination (for example, busy or not found) or the ELIN device (for example, lack of resources or an internal error). In such a scenario, the Mediation Server requires that the ELIN device "reject" the call with a SIP release cause code 503 "Service Unavailable" (instead of the designated release call). Such a release cause code enables the Mediation Server to issue a failover to another entity (for example, another ELIN device), instead of retrying the call or returning the release call to the user.

To support this requirement, you can configure the ELIN device to send a 503 "Service Unavailable" release cause code instead of SIP 4xx if an emergency call cannot be established.

The feature is applicable only to the Gateway application and for digital interfaces.

➤ **To enable SIP response 503 upon failed E9-1-1:**

1. Open the Advanced Parameters page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway Advanced Parameters**).
2. Select the 'Emergency Special Release Cause' check box [EmergencySpecialReleaseCause]:

Emergency Special Release Cause ☒

3. Click **Apply**.

### Configuring SBC IP-to-IP Routing Rule for E9-1-1

To route incoming Teams / Skype for Business E9-1-1 calls to the emergency service provider's PSAP server, you need to configure routing rules in the IP-to-IP Routing table for routing between the emergency callers' IP Group and the PSAP server's IP Group. The only special configuration is to define the emergency number (e.g., 911) in the 'Destination Username Pattern' parameter of the IP Group belonging to the E9-1-1 callers. The following example shows IP-to-IP routing rules for E9-1-1:

INDEX	NAME	ROUTING POLICY	ALTERNATIVE ROUTE OPTIONS	SOURCE IP GROUP	REQUEST TYPE	SOURCE USERNAME PREFIX	DESTINATION USERNAME PREFIX	DESTINATION TYPE	DESTINATION IP GROUP
0	E911 > PSAP	Default_SBCRou	Route Row	LAN IP PBX	All	*	911	IP Group	PSAP Server
1	PSAP > E911	Default_SBCRou	Route Row	PSAP Server	All	*	*	IP Group	LAN IP PBX

This feature is applicable only to the SBC application.

### Configuring Location-Based Emergency Routing

The device identifies the geographical location of emergency callers by their ELIN numbers, which is present in the PIDF-LO XML body of received SIP INVITE messages. Therefore, you need to configure the device to route emergency calls to a destination (i.e., emergency center such as the police) that is appropriate to the caller's ELIN number. As the destination of incoming calls is the emergency number (e.g., 999), the device needs to manipulate the destination number to a number that represents the caller's **local** emergency center (e.g., +4420999 for London police).

Location-based emergency routing is applicable only to the Gateway application.

To add manipulation rules for location-based emergency routing, you need to use the Destination Phone Number Manipulation for IP-to-Tel Calls table. In this table, you need to use the ELIN number (e.g., 5000) as the source prefix, with the "ELIN" string value added in front of it (e.g., ELIN5000) which is used by the device to identify the number as an ELIN number (and **not** used for any other routing processes etc.). For each corresponding ELIN source number prefix entry, you need to configure the manipulation action required on the destination number so that the call is routed to the appropriate destination.

Following is an example of how to configure location-based emergency routing:

#### ■ Assumptions:

- Company with offices in different cities -- London and Manchester.
- Each city has its local police department.
- In an emergency, users need to dial 999.
- Company employs Microsoft Skype for Business for communication between employers, and between employers and the external telephone network (PSTN). In other words, all employers are seemingly (virtual) in the same location in respect to the IP network.
- ELIN numbers are used to identify the geographical location of emergency calls dialed by users:
  - ◆ London ELIN is 5000.
  - ◆ Manchester ELIN is 3000.

#### ■ Configuration Objectives:

- Emergency calls received from London office users are routed by the device to the London police department (+4420999).
- Emergency calls received from Manchester office users are routed by the device to the Manchester police department (+44161999).

The international code, +44 for England is used for IP routing considerations, but can be omitted depending on your specific deployment.

The above scenario is configured as follows:

1. Enable location-based emergency routing, by loading an ini file to the device with the following parameter setting:
  - a. Open the Gateway Advanced Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway Advanced Settings**).
  - b. From the 'E911 Gateway' drop-down list [E911Gateway], select **Location Based Manipulations**.

2. In the Destination Phone Number Manipulation for IP-to-Tel Calls table (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983), add the following two rules for manipulating the destination number of incoming emergency calls, based on ELIN numbers:

INDEX	NAME	SOURCE IP ADDRESS	DESTINATION PREFIX	STRIPPED DIGITS FROM LEFT	STRIPPED DIGITS FROM RIGHT	NUMBER OF DIGITS TO LEAVE	PREFIX TO ADD
0	Emergency London	*	*	0	0	255	+4420
1	Emergency Manchester	*	*	0	0	255	+44161

Index 0 manipulates the destination number for London emergency callers; Index 1 manipulates the destination number for Manchester emergency callers.

### Viewing the ELIN Table

To view the ELIN table:

- CLI:

```
# show voip e911
ELIN      Time    Count Index Call From
-----
4257275678 22:11:52 0 2 4258359333
4257275999 22:11:57 0 3 4258359444
257275615 22:12:03 0 0 4258359555
4257275616 22:11:45 0 1 4258359777
----- Current Time: 22:12:40
```

- Syslog, by invoking the following Web command shell:

```
SIP / GateWay / E911Dump
```

## Microsoft Skype for Business Presence of Third-Party Endpoints

Microsoft presence capability allows Skype for Business users to know the status (e.g., "Available" or "Do Not Disturb") of their contacts. Presence status of contacts is displayed on the user's Skype for Business endpoint. Presence information of Skype for Business endpoints (such as Skype for Business desktop client) is handled solely by the Skype for Business Server, without any intervention of the device. However, when third-party (non-Skype for Business) endpoint devices (e.g., mobile phone or PBX phone) are used by the Skype for Business users, presence status information can only be reported to the Skype for Business Server by the device. For example, if John and Alice are Skype for Business users and John makes or receives a call on a mobile device, Alice is able to see that John is in a call, even though the call is not on a native Skype for Business endpoint. Once the device reports the presence status, the Skype for Business Server sends this status change to the Skype for Business users in the network.

- Currently, the device reports the following presence status:
  - ✓ "On the Phone" - user is busy (in a call or doesn't want to be disturbed)
  - ✓ "Clear" - cancels the "On the Phone" status (returning the user's presence to its previous state)
- The feature supports Skype for Business Server 2015 and Lync Server version 5.0.8308.866 and later.
- The feature is applicable to the SBC application and the Gateway application (Tel-to-IP calls only).

The device notifies the Skype for Business Server of a user's presence status, by using SIP PUBLISH messages. The message transactions between the device and Skype for Business Server is as follows:

1. The device routes a call between two Skype for Business users and when connected, sends a PUBLISH message with the Event header set to "presence", Expires header set to "600", Content-Type header set to "application/pidf+xml", and where the XML body's "activity" is set to "on-the-phone", as shown in the following example for user John Doe:

```
PUBLISH sip:john.doe@sfb.example SIP/2.0
From: <sip:john.doe@sfb.example>;tag=1c537837102
To: <sip:john.doe@sfb.example>
CSeq: 1 PUBLISH
Event: presence
Expires: 600
Content-Type: application/pidf+xml
Content-Length: 489
```

```
<?xml version="1.0" encoding="utf-8"?>
<presence xmlns="urn:ietf:params:xml:ns:pidf"
xmlns:ep="urn:ietf:params:xml:ns:pidf:status:rp-id-status"
xmlns:et="urn:ietf:params:xml:ns:pidf:rp-id-tuple"
xmlns:ci="urn:ietf:params:xml:ns:pidf:cid"
entity="sip:john.doe@sfb.example">
  <tuple id="0">
    <status>
      <basic>open</basic>
      <ep:activities>
        <ep:activity>on-the-phone</ep:activity>
      </ep:activities>
    </status>
  </tuple>
  <ci:display-name>John Doe</ci:display-name>
</presence>
```

2. The Skype for Business Server responds to the device with a SIP 200 OK. The message is sent with a SIP-ETag header which identifies the entity (and Expires header set to 600 seconds), as shown in the following example:

```
SIP/2.0 200 OK
From: "John Doe"<sip:john.doe@sfb.example>;tag=1c537837102
To:
<sip:john.doe@sfb.example>;tag=0E4324A4B27040E4A167108D4FAD27E3
Call-ID: 1284896643279201635736@10.33.221.57
CSeq: 1 PUBLISH
Via: SIP/2.0/TLS 10.33.221.57:5061;alias;...received=10.33.221.57;ms-
received port=48093;ms-received-cid=4900
SIP-ETag: 2545777538-1-1
Expires: 600
Content-Length: 0
```

3. If the call lasts longer than 600 seconds, the device sends another PUBLISH message with the same SIP-ETag value and with an Expires header value of 600 seconds. The Skype for Business Server responds with another 200 OK, but with a new SIP-ETag value (and Expires header set to 600 seconds). This scenario occurs for each 600-second call interval.
4. When the call ends, the device sends a PUBLISH message to cancel the user's online presence status (and the user's previous presence state is restored). The message is sent with a SIP-If-Match header set to the matching entity tag (SIP-ETag) value (i.e., SIP-ETag value of last 200 OK) and Expires header value set to "0", as shown in the following example:

```
PUBLISH sip:john.doe@sfb.example SIP/2.0
From: <sip:john.doe@sfb.example>;tag=1c1654434948
To: <sip:john.doe@sfb.example>
CSeq: 1 PUBLISH
Contact: <sip:john.doe@10.33.221.57:5061;transport=tls>

Expires: 0
User-Agent: sur1-vg1.ecarecenters.net/v.7.20A.001.080
SIP-If-Match: 2545777538-1-1
Content-Length: 0
```

The following figure shows a basic illustration of the device's integration into Microsoft Skype for Business Presence feature for third-party endpoints.

## Configuring Skype for Business Server for Presence

On the Skype for Business Server side, you need to define the device in the Skype for Business Topology as a Trusted Application.

- Detailed configuration of Skype for Business Server is beyond the scope of this document.
- Before performing the below procedure, make sure that you have defined the device in the PSTN Gateway node of the Skype for Business Server Topology (using the Topology Builder).

Using the Skype for Business Server Management Shell, perform the following steps:

### 1. Obtain the Site ID

Run the following cmdlet to retrieve the SiteId property of the site:

```
Get-CsSite
```

### 2. Create a Trusted Application Pool

Run the following cmdlet to create a new pool to host the presence application:

```
New-CsTrustedApplicationPool -Identity <Pool FQDN> -Registrar <Registrar FQDN> -Site <Site Id>
```

where:

- *Identity* is the FQDN of the device, which sends the SIP PUBLISH messages with the presence status to Skype for Business Server
- *Registrar* is the FQDN of the Registrar service for the pool
- *Site* is the Site Id

For example:

```
New-CsTrustedApplicationPool -Identity sbcgw.example.com -Registrar  
skypepool.example.com -Site Portland
```

### 3. Add the Trusted Application (Presence) to the Pool

```
New-CsTrustedApplication-ApplicationId <String> -  
TrustedApplicationPoolFqdn <String> -Port <Port Number>
```

where:

- *ApplicationId* is the name of the application
- *TrustedApplicationPoolFqdn* is the FQDN of the trusted application pool
- *Port* is the port number on which the application will run (5061)

For example:

```
New-CsTrustedApplication -ApplicationId MSpresence -  
TrustedApplicationPoolFqdn sbcgw.example.com -Port 5061
```

Make sure the port number matches the port number configured on the device.

### 4. Enable and Publish the Skype for Business Server 2015 Topology

Run the following cmdlet to publish and enable your new topology:

```
Enable-CsTopology
```

## Configuring the Device for Microsoft Teams Presence

The following procedure describes how to configure the device for notifying Teams of presence status of Teams users when making and receiving calls using third-party, endpoint devices. To help you understand the configuration, the following lists in chronological order the main processing steps:

1. The device receives an incoming call.
2. The device uses a Call Setup Rule to perform LDAP queries on Microsoft Entra ID to retrieve Teams usernames (Request URIs) for the corresponding calling (source) and/or called (destination) number. For SBC calls, the Call Setup Rule is associated with the classified

source IP Group (in the IP Groups table). For Tel-to-IP Gateway calls, the Call Setup Rule is associated with the destination IP Group (in the Tel-to-IP Routing table).

3. The device routes the call to the required destination, according to the normal routing rules.
4. When the call is connected, the device sends a SIP PUBLISH message to Teams server, indicating that the users' presence status is now "On-the-Phone".
5. When the call ends, the device sends another SIP PUBLISH message to the Teams server, clearing the users' "On-the-Phone" status (the presence status changes to what it was before the call was connected).

➤ **To configure device for Teams presence:**

1. Configure a TLS Context (TLS certificate) for secured communication (mutual authentication) between the device and Teams (see [Configuring TLS Certificate Contexts](#) on page 227).
2. Configure a Proxy Set to define the address of the Teams (see [Configuring Proxy Sets](#) on page 632). Make sure you configure the following:
  - 'TLS Context Name': Assign the TLS Context that you configured in Step 2 (above).
  - 'Proxy Address': Configure the address (FQDN or IP address).
  - 'Transport Type': **TLS**
3. Configure an IP Group to represent Teams server (see [Configuring IP Groups](#) on page 591). Make sure that you assign it with the Proxy Set that you configured in Step 3 (above).
4. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**):
  - a. From the 'Presence Publish IP Group ID' drop-down list, select the IP Group of the Teams server that you configured (above) as the destination (presence gateway) to where the device sends the SIP PUBLISH messages.
  - b. Select the 'Microsoft Presence Status' check box to enable the Microsoft presence feature.

**MICROSOFT PRESENCE**

Presence Publish IP Group ID	• <div style="border: 1px solid #ccc; padding: 2px; display: inline-block;">#0 [Default_IPG]</div>	<a href="#">View</a>
Microsoft Presence Status	• <input checked="" type="checkbox"/>	

5. Configure the Teams' LDAP server (Entra ID) to query for the Teams users' SIP URIs (see [Configuring LDAP Servers](#) on page 385).
6. Configure Call Setup Rules to perform LDAP queries in Microsoft Entra ID for the SIP URI of the caller (source) and called (destination) parties (see [Configuring Call Setup Rules](#) on

page 809). The device first needs to search Entra ID for the caller or called number of the third-party endpoint device. For example, to search for a called mobile number, the searched LDAP Attribute would be "mobile" set to the value of the destination number (e.g., 'mobile=+' + param.call.dst.user). If the entry exists, the query searches for the Attribute (e.g., ipPhone) where the SIP URI is defined for the corresponding mobile user. If found, the query returns the Attribute's value (i.e., URI) to the device (instructed using the special 'Condition' string "presence.dst" or "presence.src"). This is the URI that the device uses as the Request-URI in the PUBLISH message that it sends to the Teams server. The configuration of the example used in this step is shown below:

Parameter	Rule 1	Rule 2
'Request Type'	<b>LDAP</b>	<b>LDAP</b>
'Request Key'	'mobile=+' + param.call.dst.user	'mobile=+' + param.call.src.user
'Attributes To Get'	ipPhone	ipPhone
'Condition'	ldap.attr.ipPhone exists	ldap.attr.ipPhone exists
'Action Subject'	presence.dst	presence.src
'Action Type'	<b>Add</b>	<b>Add</b>
'Action Value'	ldap.attr.ipPhone	ldap.attr.ipPhone

7. Configure routing rules to route the calls in the network.
8. (SBC application) Configure IP Groups to represent your call party entities, and assign them the group of Call Setup Rules (Set ID) that you configured in Step 7 (above). For configuring IP Groups, see [Configuring IP Groups](#) on page 591.
9. (Gateway application) Assign the group of Call Setup Rules (Set ID) that you configured in Step 7 (above) to your Tel-to-IP Routing rules (see [Configuring Tel-to-IP Routing Rules](#) on page 946).

## Microsoft Teams with Local Media Optimization

The device can be configured to support the Local Media Optimization feature when deployed in a Microsoft Teams environment. This feature is intended for complex environments consisting of a central SBC device (i.e., this device that you are configuring), which is referred to by Microsoft as the *Proxy SBC*, integrated in the Teams environment, and multiple remote SBCs or Gateways (referred to by Microsoft as *remote site SBCs*). In this environment, the central SBC determines the optimal path for connecting calls between the Teams clients, based on network connectivity (good or bad) and voice quality. The device path selection is based on supplementary information provided by Microsoft using their proprietary headers that are included in the SIP messages during call setup between Teams clients:

Microsoft SIP Header	Value	Description
X-MS-UserLocation	Internal or External	Indicates if the Teams client is located in the internal or external network with respect to the central SBC. Based on the header value, the device selects the Media Realm, using the IP Group's 'Internal Media Realm' or 'Media Realm' parameters, respectively.
X-MS-MediaPath	sbc1.contoso.com sbc2.contoso.com ...	Indicates the order of remote SBCs that should be used for the media path between the Teams clients. If the first address is the central SBC itself, the media traverses the device (non-direct media).
X-MS-UserSite	usersiteID	Indicates the name of the Teams site in which the Teams client is located.

Configuration of the device for Local Media Optimization is done on the IP Group of the Teams client, using the following IP Group table parameters:

- 'Teams Local Media Optimization Handling': Enables Local Media Optimization and defines how the device handles the Teams call based on the Microsoft proprietary SIP headers.
- 'Internal Media Realm': Assigns a Media Realm which is used if the X-MS-UserLocation header value is "Internal". If the header value is "External" (or not present), the Media Realm assigned by the 'Media Realm' parameter is used.
- 'Teams Local Media Optimization Initial Behavior': Defines how the central SBC device initially sends the received INVITE message with the SDP Offer to Teams.
- 'Teams Local Media Optimization Site' : Defines the name of the Teams site (e.g., "Singapore") to which the IP Group (Teams client) belongs. The Teams site is indicated in the SIP header, X-MS-UserSite of the incoming SIP message received from the Teams client. The device searches the Dial Plan, specified by the 'Regions Connectivity Dial Plan' parameter, to check if this IP Group's Teams site and the Teams site of the destination IP Group share a common group number. If they do share a group number, the device processes the call as a direct media (bypass) call. For more information, see [Using Dial Plans for Microsoft Local Media Optimization](#) on page 852.

For more information on the above parameters, see their descriptions in [Configuring IP Groups](#) on page 591.

For detailed technical information on deploying the device in a Microsoft Teams environment with Local Media Optimization, contact your AudioCodes sales representative.

- For detailed configuration of Microsoft Teams Direct Routing for enterprises with AudioCodes SBC, refer to [Connecting AudioCodes' SBC to Microsoft Teams Direct Routing Enterprise Model](#).
- This section is applicable only to the SBC application.

## 17 Quality of Experience

This chapter describes how to configure the Quality of Experience feature.

### Reporting Voice Quality of Experience to OVOC

The device can be configured to report voice (media) Quality of Experience (QoE) to AudioCodes' One Voice Operations Center (OVOC). The reports include real-time metrics of the quality of the call experience, which are then processed by OVOC.

OVOC is also a VoIP-quality monitoring and analysis tool. It provides comprehensive details on voice traffic quality, allowing system administrators to quickly identify, fix and prevent issues that could affect the voice calling experience in enterprise and service provider VoIP networks. IT and administrators can employ OVOC in their VoIP networks to guarantee effective utilization, smooth performance, reliable QoS levels, and SLA fulfillment.

- For information on OVOC, refer to the *OVOC User's Manual*.
- For configuring the SNMP connection between the device and OVOC, see [Configuring SNMP for OVOC Connectivity](#) on page 122.

### Reporting QoE to OVOC

The Quality of Experience Settings table lets you configure the address (and other connectivity parameters) of AudioCodes One Voice Operations Center (OVOC) server to where the device sends Quality of Experience (QoE) voice metric reports.

You can also configure the device to use a TLS connection with OVOC. Before you can do this, configure a TLS Context (certificate) in the TLS Contexts table (see [Configuring TLS Certificate Contexts](#) on page 227). If no TLS Context is specified, the device uses the default TLS Context (ID 0). You can also configure at what stage of the call the device sends the QoE report to OVOC. The report can be sent during the call or only at the end of the call. Reporting at the end of the call may be beneficial when there is network congestion as this reduces bandwidth usage over time.

You can configure at what stage (during or end) of the call to send the QoE report. You can also enable the filtering of the report, and then use the Logging Filters table to configure the actual filter (e.g., by a specific IP Group).

If a QoE traffic overflow occurs between OVOC and the device, the device sends the QoE data only at the end of the call, regardless of your settings.

The following procedure describes how to configure the OVOC server for QoE through the Web interface. You can also configure it through ini file [QOESettings] or CLI (`configure voip > qoe qoe-settings`).

➤ **To configure OVOC for QoE:**

1. Open the Quality of Experience Settings table (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Quality of Experience** > **Quality of Experience Settings**).

2. Configure the OVOC server according to the parameters described in the table below.
3. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

**Table 17-1: Quality of Experience Settings Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' tls [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Primary OVOC Address' server-name [ServerName]	Defines the address of the OVOC server to where the device sends the QoE reports. The valid value is an IP address (IPv4 or IPv6) or an FQDN (hostname). <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ The IP address version (IPv4 or IPv6) of the OVOC address and the IP Interface (see 'QoE Network Interface' parameter below) must be the same.</li> <li>■ If you are using a WebSocket tunnel connection between the device and OVOC, then configure the parameter to the IP address mentioned in <a href="#">Configuring WebSocket Tunnel with OVOC</a> on page 123.</li> </ul>
'Secondary OVOC Address'	<b>Note:</b> This parameter is currently not supported and

Parameter	Description
secondary-server-name [SecondaryServerName]	therefore, can be ignored.
'QoE Network Interface' interface [Interface]	<p>Assigns an IP network interface (IPv4 or IPv6) from which the device sends the QoE reports.</p> <p>The default is the IPv4 OAMP interface (<b>O+M+C</b>).</p> <p>To configure IP network interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ The IP address version (IPv4 or IPv6) of the IP Interface and the OVOC address (see 'Primary OVOC Address' field above) must be the same.</li> </ul>
'Keep Alive Time Interval' keep-alive-time [KeepAliveTime]	<p>Defines the interval (in seconds) between every consecutive keep-alive message that the device sends to the OVOC server. Keep-alive messages can be useful to keep the communication link between the device and OVOC open when there is no other traffic flow between them.</p> <p>The default is 1. A value of 0 disables the keep-alive feature.</p>
<b>TLS</b>	
'Use TLS' tls [EnableTls]	<p>Enables a TLS connection with the OVOC server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul>
'TLS Context' tls-context-name [ContextName]	<p>Assigns a TLS Context (certificate) for the TLS connection with the OVOC server.</p> <p>The default is the default TLS Context (ID 0).</p> <p><b>Note:</b> The parameter is applicable only if the 'Use TLS' parameter is configured to <b>Enable</b>.</p>
'Verify Certificate' verify-certificate [VerifyCertificate]	<p>Enables the verification of the TLS certificate that is used in the incoming connection request from the OVOC server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) No certificate verification is done.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = The device verifies the authentication of the certificate received from the OVOC server. The device authenticates the certificate against the trusted root certificate store associated with the assigned TLS Context and if ok, allows communication with OVOC. If authentication fails, the device denies communication (i.e., handshake fails). The device can also authenticate the certificate by querying with an Online Certificate Status Protocol (OCSP) server whether the certificate has been revoked. This is configured for the assigned TLS Context.</li> </ul> <p><b>Note:</b> The parameter is applicable only if the 'Use TLS' parameter is configured to <b>Enable</b>.</p>
'Verify Certificate Subject Name' verify-certificate-subject-name [VerifyCertificateSubjectName]	<p>Enables the verification of the TLS certificate subject name (Common Name / CN or Subject Alternative Name / SAN) that is used in the incoming connection request from the OVOC server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) No verification is done.</li> <li>■ [1] <b>Enable</b> = The device verifies the subject name of the certificate received from the OVOC server with the hostname or IP address configured for OVOC (in the 'Primary OVOC Address' above). If authentication fails, the device denies communication (i.e., handshake fails).</li> </ul> <p><b>Note:</b> The parameter is applicable only if the 'Use TLS' parameter is configured to <b>Enable</b>.</p>
<b>QoE Report</b>	
'QoE Report Mode' report-mode [ReportMode]	<p>Defines at what stage of the call the device sends the call's QoE data to the OVOC server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Report QoE During Call</b> (default)</li> <li>■ [1] <b>Report QoE at End of Call</b></li> </ul> <p><b>Note:</b> If a QoE traffic overflow between OVOC and the device occurs, the device sends the QoE data only at the end of the call, regardless of the parameter's settings.</p>

Parameter	Description
'Filter Reports' filter-reports [FilterReports]	<p>Enables the filtering (e.g., by IP Group #2) of the QoE reports that the device sends to OVOC.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>Log filtering is configured in the Logging Filters table (see <a href="#">Configuring Logging Filter Rules</a> on page 1602). When configuring a rule for QoE filtering, make sure that it also includes the following settings:</p> <ul style="list-style-type: none"> <li>■ 'Log Destination': <b>OVOC (QoE)</b></li> <li>■ 'Log Type': <b>CDR</b></li> </ul>

## Configuring Clock Synchronization between Device and OVOC

To ensure accurate call quality statistics and analysis by OVOC, you must configure the device and the OVOC server with the same clock source for clock synchronization. In other words, you need to configure them with the same NTP server (same address).

The NTP server can be one of the following:

- OVOC server (also acting as an NTP server)
- Third-party, external NTP server

To configure, the NTP server's address on the device, see [Synchronizing Date and Time through SNTP](#) on page 138.

## Configuring Firewall Rules for OVOC Traffic

To allow incoming traffic from OVOC, you need to configure the device's firewall (Firewall table) with additional "Allow" firewall rules, as described in [Configuring Firewall Rules to Allow Incoming OVOC Traffic](#) on page 261.

## Enabling RTCP XR Reporting to OVOC

For the device to be able to send voice metric reports to AudioCodes OVOC, you need to enable the RTP Control Protocol Extended Reports (RTCP XR) VoIP management protocol. RTCP XR defines a set of voice metrics that contain information for assessing VoIP call quality and diagnosing problems. Enabling RTCP XR means that the device can send RTCP XR messages, containing the call-quality metrics, to OVOC.

For enabling RTCP XR reporting, see [Configuring RTCP XR](#) on page 1506. To configure what to report to OVOC, see [Configuring Quality of Experience Profiles](#) on the next page.

## Configuring Interval for QoE Report Collection and Generation

By default, the device generates QoE reports based on 30-second collection intervals of voice metrics obtained from RTCP / RTCP-XR packets. However, as packets are typically sent and received every 5 seconds, the QoE report reflects an average of these multiple packet sampling intervals (i.e., typically 6 collection intervals). Therefore, you might want to shorten the device's QoE collection and generation interval to get the following benefits:

- More reports generated for the call.
- Faster initial reports - first report is available soon after the call starts, providing valuable insights even for short calls.
- Capturing subtle changes in call quality throughout the call.

To configure the QoE collection and generation interval, see the [\[\[QoEMediaStatisticTimer\]](#) on page 1913] ini file parameter.

## Configuring Quality of Experience Profiles

Quality of Experience Profiles enable you to effectively monitor the quality of voice calls traversing the device in your network. Quality of Experience Profiles define severity thresholds for voice metrics monitored by the device, which if crossed can result in various actions (discussed later in the section).

Quality of Experience is configured using two tables with parent-child relationship. The Quality of Experience Profile table is the parent, which defines the name of the Quality of Experience Profile. The Quality of Experience Color Rules table is the child, which defines severity thresholds per voice metric for the specific Quality of Experience Profile. You can configure up to 256 Quality of Experience Profiles and up to 256 Quality of Experience Color Rules.

Once configured, you can apply the Quality of Experience Profiles to specific calls (network links), by assigning them to any of the following configuration entities:

- IP Groups (see [Configuring IP Groups](#) on page 591)
- Media Realms (see [Configuring Media Realms](#) on page 548)
- Remote Media Subnets (see [Configuring Remote Media Subnets](#) on page 552)

The Quality of Experience Profile allows you to configure thresholds for the following monitored voice metrics:

- **Mean Opinion Score (MOS):** MOS is the average grade on a quality scale, expressed as a single number in the range of 1 to 5, where 1 is the lowest audio quality and 5 the highest audio quality.
- **Delay (or latency):** Time it takes for information to travel from source to destination (round-trip time).
- **Packet Loss:** Lost packets are RTP packets that are not received by the voice endpoint. Packet loss can result in choppy voice transmission.

- **Jitter:** Jitter can result from uneven delays between received voice packets. To space evenly, the device's jitter buffer adds delay. The higher the measurement, the greater the impact of the jitter buffer's delay on audio quality.
- **Residual Echo Return Loss (RERL):** An echo is a reflection of sound arriving at the listener at some time after the sound was initiated (often by the listener). Echo is typically caused by delay.

At any given time during a call, a voice metric can be in one of the following color-coded quality states (as displayed in OVOC):

- **Green:** Indicates good call quality
- **Yellow:** Indicates fair call quality
- **Red:** Indicates poor call quality

When the threshold of a voice metric is crossed, the device changes the alarm severity and corresponding color-coded quality state of the call:

- **Minor Threshold (Yellow):** Lower threshold that indicates changes from Green or Red to Yellow.
- **Major Threshold (Red):** Higher threshold that indicates changes from Green or Yellow to Red.

The device also uses hysteresis to determine whether the threshold has indeed been crossed. Hysteresis defines the amount of fluctuation from the threshold in order for the threshold to be considered as crossed (i.e., change in color state). Hysteresis is used to avoid false reports being sent by the device. Hysteresis is used only for threshold crossings toward a lesser severity (i.e., from Red to Yellow, Red to Green, or Yellow to Green).

The following example is used to explain how the device considers threshold crossings. The example is based on the MOS of a call, where the Major threshold is configured to 2, the Minor threshold to 4 and the hysteresis for both thresholds to 0.1:

**Table 17-2: Threshold Crossings based on Threshold and Hysteresis**

Threshold Crossing	Calculation	Threshold based on Example
Green to Yellow (Minor alarm)	The change occurs if the measured metric crosses the configured Minor threshold only (i.e., hysteresis is not used).	4
Green to Red (Major alarm)	The change occurs if the measured metric crosses the configured Major threshold only (i.e., hysteresis is not used).	2
Yellow to Red (Major alarm)	The change occurs if the measured metric crosses the configured Major threshold only (i.e., hysteresis is not used).	2
Red to Yellow (Minor alarm)	The change occurs if the measured metric crosses the configured Major threshold with hysteresis configured for the Major threshold.	2.1 (i.e., 2 + 0.1)
Red to Green (alarm cleared)	The change occurs if the measured metric crosses the configured Minor threshold with hysteresis configured for the Minor threshold.	4.1 (i.e., 4 + 0.1)
Yellow to Green (alarm cleared)	The change occurs if the measured metric crosses the configured Minor threshold with hysteresis configured for the Minor threshold.	4.1 (i.e., 4 + 0.1)

Each time a voice metric threshold is crossed (i.e., color changes), the device can do the following depending on configuration:

- Report the change in the measured metrics to AudioCodes' OVOC. OVOC displays this call quality status for the associated link (IP Group, Media Realm, or Remote Media Subnet). To configure the OVOC's address, see [Reporting QoE to OVOC](#) on page 523.
- Depending on the crossed threshold type, you can configure the device to reject calls to the destination IP Group or use an alternative IP Profile for the IP Group. For more information, see [Configuring Quality of Service Rules](#) on page 540.
- Alternative routing based on measured metrics. If a call is rejected because of a crossed threshold, the device generates a SIP 806 response. You can configure this SIP response

code as a reason for alternative routing (see [Configuring SIP Response Codes for Alternative Routing Reasons](#) on page 1214).

For your convenience, the device provides pre-configured Quality of Experience Profiles. One of these pre-configured profiles is the default Quality of Experience Profile, which is used if you do not configure a Quality of Experience Profile.

The following procedure describes how to configure Quality of Experience Profiles through the Web interface. You can also configure it through other management platforms:

- **Quality of Experience Profile table:** *ini* file [QoEProfile] or CLI (`configure voip > qoe qoe-profile`)
- **Quality of Experience Color Rules table:** *ini* file [QOECOLORRules] or CLI (`configure voip > qoe qoe-color-rules`)

➤ **To configure a QoE Profile:**

1. Open the Quality of Experience Profile table (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Quality of Experience** > **Quality of Experience Profile**).
2. Click **New**; the following dialog box appears:

3. Configure a QoE Profile according to the parameters described in the table below.
4. Click **Apply**.

**Table 17-3: Quality of Experience Profile Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Profile Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 20 characters.

Parameter	Description
	<b>Note:</b> The parameter value cannot contain a forward slash (/).
'Sensitivity Level' sensitivity-level [SensitivityLevel]	<p>Defines the pre-configured threshold profile to use.</p> <ul style="list-style-type: none"> <li>■ [0] <b>User Defined</b> = Need to define thresholds per monitored parameter in the Quality of Experience Color Rules table.</li> <li>■ [1] <b>Low</b> = Pre-configured low sensitivity thresholds.</li> <li>■ [2] <b>Medium</b> = (Default) Pre-configured medium sensitivity thresholds.</li> <li>■ [3] <b>High</b> = Pre-configured high sensitivity thresholds. Reporting is done for small fluctuations in parameter values.</li> </ul>

5. In the Quality of Experience Profile table, select the row for which you want to configure QoE thresholds, and then click the **Quality of Experience Color Rules** link located below the table; the Quality of Experience Color Rules table appears.
6. Click **New**; the following dialog box appears:

7. Configure a rule according to the parameters described in the table below.
8. Click **New**, and then save your settings to flash memory.

**Table 17-4: Quality of Experience Color Rules Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' index [QOECOLORRules_ ColorRuleIndex]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Monitored Parameter'	Defines the parameter to monitor and report.

Parameter	Description
monitored-parameter [QOECOLORRules_monitoredParam]	<ul style="list-style-type: none"> <li>■ [0] <b>MOS</b> (default)</li> <li>■ [1] <b>Delay</b></li> <li>■ [2] <b>Packet Loss</b></li> <li>■ [3] <b>Jitter</b></li> <li>■ [4] <b>RERL [Echo]</b></li> </ul>
'Direction' direction [QOECOLORRules_direction]	<p>Defines the monitoring direction.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Device Side</b> (default)</li> <li>■ [1] <b>Remote Side</b></li> </ul>
'Sensitivity Level' sensitivity-level [QOECOLORRules_profile]	<p>Defines the sensitivity level of the thresholds.</p> <ul style="list-style-type: none"> <li>■ [0] <b>User Defined</b> = Need to define the thresholds in the parameters described below.</li> <li>■ [1] <b>Low</b> = Pre-configured low sensitivity threshold values. Thus, reporting is done only if changes in parameters' values are significant.</li> <li>■ [2] <b>Medium</b> = (Default) Pre-configured medium sensitivity threshold values.</li> <li>■ [3] <b>High</b> = Pre-configured high sensitivity threshold values. Thus, reporting is done for small fluctuations in parameter values.</li> </ul>
Thresholds	
'Minor Threshold (Yellow)' minor-threshold-yellow [QOECOLORRules_MinorThreshold]	<p>Defines the Minor threshold value, which is the lower threshold located between the Yellow and Green states. To consider a threshold crossing:</p> <ul style="list-style-type: none"> <li>■ <b>Increase in severity (i.e., Green to Yellow):</b> Only this value is used.</li> <li>■ <b>Decrease in severity (Red to Green, or Yellow to Green):</b> This value is used with the hysteresis, configured by the 'Minor Hysteresis (Yellow)' parameter (see below).</li> </ul> <p>The valid threshold values are as follows:</p> <ul style="list-style-type: none"> <li>■ MOS values are in multiples of 10. For example, to denote a MOS of 3.2, the value 32 (i.e., 3.2*10) must be entered.</li> <li>■ Delay values are in msec.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Packet Loss values are in percentage (%).</li> <li>■ Jitter is in msec.</li> <li>■ Echo measures the Residual Echo Return Loss (RERL) in dB.</li> </ul>
'Minor Hysteresis (Yellow)' minor-hysteresis-yellow [QOECOLORRules_MinorHysteresis]	<p>Defines the amount of fluctuation (hysteresis) from the Minor threshold, configured by the 'Minor Threshold (Yellow)' parameter in order for the threshold to be considered as crossed. The hysteresis is used only to determine threshold crossings to Green (i.e., from Yellow to Green, or Red to Green). In other words, the device considers a threshold crossing to Green only if the measured voice metric crosses the Minor threshold and the hysteresis.</p> <p>For example, if you configure the 'Minor Threshold (Yellow)' parameter to 4 and the 'Minor Hysteresis (Yellow)' parameter to 0.1 (for MOS), the device considers a threshold crossing to Green only if the MOS crosses 4.1 (i.e., <math>4 + 0.1</math>).</p>
'Major Threshold (Red)' major-threshold-red [QOECOLORRules_MajorThreshold]	<p>Defines the Major threshold value, which is the upper threshold located between the Yellow and Red states. To consider a threshold crossing:</p> <ul style="list-style-type: none"> <li>■ <b>Increase in severity (i.e., Yellow to Red):</b> Only this value is used.</li> <li>■ <b>Decrease in severity (Red to Yellow):</b> This value is used with the hysteresis, configured by the 'Major Hysteresis (Red)' parameter (see below).</li> </ul> <p>The valid threshold values are as follows:</p> <ul style="list-style-type: none"> <li>■ MOS values are in multiples of 10. For example, to denote a MOS of 3.2, the value 32 (i.e., <math>3.2 \times 10</math>) must be entered.</li> <li>■ Delay values are in msec.</li> <li>■ Packet Loss values are in percentage (%).</li> <li>■ Jitter is in msec.</li> <li>■ Echo measures the Residual Echo Return Loss (RERL) in dB.</li> </ul>
'Major Hysteresis (Red)' major-hysteresis-red [QOECOLORRules_MajorHysteresis]	<p>Defines the amount of fluctuation (hysteresis) from the Major threshold, configured by the 'Major Threshold (Red)' parameter in order for the threshold to be considered as crossed. The hysteresis is used only to determine threshold crossings from Red to Yellow. In other words, the device considers a threshold crossing to Yellow only if the measured voice metric crosses the</p>

Parameter	Description
	<p>Major threshold and the hysteresis.</p> <p>For example, if you configure the 'Major Threshold (Red)' parameter to 2 and the 'Major Hysteresis (Red)' parameter to 0.1 (for MOS), the device considers a threshold crossing to Yellow only if the MOS crosses 2.1 (i.e., 2 + 0.1).</p>

## Configuring Bandwidth Profiles

The Bandwidth Profile table lets you configure up to 486 Bandwidth Profiles. A Bandwidth Profile defines bandwidth utilization thresholds for audio and video traffic (incoming and outgoing), which if crossed can result in various actions (discussed later in the section). Bandwidth Profiles enhance the device's monitoring of bandwidth utilization.

Once configured, you can apply Bandwidth Profiles to specific calls, by assigning them to any of the following configuration entities:

- IP Groups (see [Configuring IP Groups](#) on page 591)
- Media Realms (see [Configuring Media Realms](#) on page 548)
- Remote Media Subnets (see [Configuring Remote Media Subnets](#) on page 552)

Each time a configured bandwidth threshold is crossed, the device can do the following, depending on configuration:

- Reject calls destined to the IP Group or use an alternative IP Profile for the IP Group. For more information, see [Configuring Quality of Service Rules](#) on page 540.
- Use an alternative routing rule for alternative routing. If a call is rejected due to a crossed threshold, the device generates a SIP 806 response. You can configure the SIP response code as a reason for alternative routing (see [Configuring SIP Response Codes for Alternative Routing Reasons](#) on page 1214).
- Send an SNMP alarm (acMediaRealmBWThresholdAlarm). The device clears the alarm when bandwidth utilization returns to normal (Green).

AudioCodes One Voice Operations Center (OVOC) displays bandwidth utilization using color-coded states:

- **Green:** Indicates bandwidth utilization is within normal range.
- **Yellow:** Indicates bandwidth utilization is encroaching on "total" bandwidth, serving as a warning (or it could also mean that bandwidth utilization has dropped below the red state).
- **Red:** Indicates that bandwidth utilization has exceeded total bandwidth.

Bandwidth Profiles let you configure bandwidth thresholds, which when crossed changes the color-coded state for bandwidth utilization:

- **Green-Yellow (Minor) Threshold:** Lower threshold configured as a percentage of the configured major (total) bandwidth threshold. When bandwidth goes over the threshold, the device considers it a Yellow state (Minor alarm severity); when it goes below the threshold, it considers it a Green state (cleared alarm).
- **Yellow-Red (Major) Threshold:** Upper threshold configured by the major (total) bandwidth threshold. When bandwidth goes over the threshold, the device considers it a Red state (Major alarm severity); when it goes below the threshold, it considers it a Yellow state (Minor alarm severity).

The device also uses hysteresis to determine whether the threshold has indeed being crossed. Hysteresis defines the amount of fluctuation from the threshold in order for the threshold to be considered as crossed (i.e., change in color state). Hysteresis is used to avoid false reports being sent by the device. Hysteresis is used only for threshold crossings toward a lesser severity (i.e., from Red to Yellow, Red to Green, or Yellow to Green). Hysteresis is configured as a percentage of the configured major (total) bandwidth threshold.

The following example is used to explain how the device considers threshold crossings. The example is based on a setup where the Major (total) bandwidth threshold is configured to 64,000 Kbps, the Minor threshold to 50% (of the total) and the hysteresis to 10% (of the total):

**Table 17-5: Threshold Crossings based on Threshold and Hysteresis**

Threshold Crossing	Calculation	Threshold based on Example
Green to Yellow (Minor alarm)	The change occurs if the current bandwidth crosses the configured Minor threshold only (i.e., hysteresis is not used).	32,000 Kbps
Green to Red (Major alarm)	The change occurs if the current bandwidth crosses the configured Major threshold only (i.e., hysteresis is not used).	64,000 Kbps
Yellow to Red (Major alarm)	The change occurs if the current bandwidth crosses the	64,000 Kbps

Threshold Crossing	Calculation	Threshold based on Example
	configured Major threshold only (i.e., hysteresis is not used).	
Red to Yellow (Minor alarm)	The change occurs if the current bandwidth crosses the configured Major threshold with hysteresis.	57,600 Kbps [64,000 - (10% x 64,000)]
Yellow to Green (alarm cleared)	The change occurs if the current bandwidth crosses the configured Minor threshold with hysteresis.	25,600 Kbps [32,000 - (10% x 64,000)]
Red to Green (alarm cleared)	The change occurs if the current bandwidth crosses the configured Minor threshold with hysteresis.	25,600 Kbps [32,000 - (10% x 64,000)]

The following procedure describes how to configure Bandwidth Profiles through the Web interface. You can also configure it through ini file [BWProfile] or CLI (`configure voip > qoe bw-profile`).

➤ **To configure a Bandwidth Profile:**

1. Open the Bandwidth Profile table (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Quality of Experience** > **Bandwidth Profile**).
2. Click **New**; the following dialog box appears:

The screenshot shows a 'Bandwidth Profile' configuration window. It is divided into two main sections: 'GENERAL' and 'THRESHOLDS'.  
 In the 'GENERAL' section, there are input fields for:  
 - Index: 0  
 - Name: (empty)  
 - Egress Audio Bandwidth [Kbps]: (empty)  
 - Ingress Audio Bandwidth [Kbps]: (empty)  
 - Egress Video Bandwidth [Kbps]: (empty)  
 - Ingress Video Bandwidth [Kbps]: (empty)  
 - Total Egress Bandwidth [Kbps]: (empty)  
 - Total Ingress Bandwidth [Kbps]: (empty)  
 In the 'THRESHOLDS' section, there are:  
 - A 'Minor Threshold [%]' field set to 70.  
 - A 'Hysteresis [%]' field set to 5.  
 - A 'Generate Alarm' dropdown menu currently set to 'Disable'.

3. Configure a rule according to the parameters described in the table below.
4. Click **Apply**, and then restart the device with a save to flash memory.

**Table 17-6: Bandwidth Profile Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 20 characters. <b>Note:</b> The parameter value cannot contain a forward slash (/).
'Egress Audio Bandwidth' egress-audio-bandwidth [EgressAudioBandwidth]	Defines the major (total) threshold for outgoing audio traffic (in Kbps).
'Ingress Audio Bandwidth' ingress-audio-bandwidth [IngressAudioBandwidth]	Defines the major (total) threshold for incoming audio traffic (in Kbps).
'Egress Video Bandwidth' egress-video-bandwidth [EgressVideoBandwidth]	Defines the major (total) threshold for outgoing video traffic (in Kbps).
'Ingress Video Bandwidth' ingress-video-bandwidth [IngressVideoBandwidth]	Defines the major (total) threshold for incoming video traffic (in Kbps).
'Total Egress Bandwidth' total-egress-bandwidth [TotalEgressBandwidth]	Defines the major (total) threshold for video and audio outgoing bandwidth (in Kbps).
'Total Ingress Bandwidth' total-ingress-bandwidth [TotalIngressBandwidth]	Defines the major (total) threshold for video and audio incoming bandwidth (in Kbps).

Parameter	Description
<b>Thresholds</b>	
'Minor Threshold' minor-threshold [MinorThreshold]	<p>Defines the Minor threshold value, which is the lower threshold located between the Yellow and Green states. The parameter is configured as a percentage of the major (total) bandwidth threshold (configured by the above bandwidth parameters). For example, if you configure the parameter to 50 and the 'Egress Audio Bandwidth' parameter to 64,000, the Minor threshold for outgoing audio bandwidth is 32,000 (i.e., 50% of 64,000).</p> <p>To consider a threshold crossing:</p> <ul style="list-style-type: none"> <li>■ <b>Increase in severity (i.e., Green to Yellow):</b> Only this value is used.</li> <li>■ <b>Decrease in severity (Red to Green, or Yellow to Green):</b> This value is used with the hysteresis, configured by the 'Hysteresis' parameter (see below).</li> </ul> <p><b>Note:</b> The parameter applies to all your configured bandwidths.</p>
'Hysteresis' hysteresis [Hysteresis]	<p>Defines the amount of fluctuation (hysteresis) from the configured bandwidth threshold in order for the threshold to be considered as crossed (i.e., avoids false reports of threshold crossings). The hysteresis is used only to determine threshold crossings when severity is reduced (i.e., from Red to Yellow, Yellow to Green, or Red to Green). The parameter is configured as a percentage of the Major (total) bandwidth threshold.</p> <p>For example, if you configure the parameter to 10 and the 'Egress Audio Bandwidth' parameter to 64,000, the hysteresis is 6,400 (10% of 64,000) and threshold crossings are considered at the following bandwidths:</p> <ul style="list-style-type: none"> <li>■ Red-to-Yellow (Yellow-Minor alarm severity): 57,600 Kbps [64,000 - (10% x 64,000)]</li> <li>■ Yellow-to-Green (Green-alarm cleared): 25,600 Kbps [32,000 - (10% x 64,000)]</li> </ul>
'Generate Alarm' generate-alarms [GenerateAlarms]	<p>Enables the device to send an SNMP alarm if a bandwidth threshold is crossed.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul>

## Configuring Quality of Service Rules

The Quality of Service Rules table lets you configure up to 510 Quality of Service rules. A Quality of Service rule defines an action to perform when the threshold (major or minor) of a specific performance monitoring call metric is crossed for a specific IP Group. The call metric can be voice quality (i.e., MOS), bandwidth, Answer-seizure ratio (ASR), Network Effectiveness Ratio (NER), or Average Call Duration (ACD).

The section is applicable only to the SBC application.

Depending on the call metric, you can configure the following actions to be performed if the threshold is crossed:

- Reject calls to the IP Group for a user-defined duration. Rejection of calls can also trigger alternative routing. When the device rejects a call due to an ASR, NER or ACD threshold crossing, it generates the SIP response code 850 (Signaling Limits Exceeded). When the device rejects a call due to Voice Quality and Bandwidth threshold crossing, it generates the SIP response code 806 (Media Limits Exceeded). If you configure these SIP response codes for an Alternative Reasons Set (see [Configuring SIP Response Codes for Alternative Routing Reasons](#) on page 1214) that is assigned to the IP Group ('SBC Alternative Routing Reasons Set' parameter) and the device rejects a call, it searches in the IP-to-IP Routing table for an alternative routing rule.

When the device rejects calls to an IP Group based on a Quality of Service rule, it raises an SNMP alarm (acIpGroupNoRouteAlarm). The alarm is also raised upon a keep-alive failure with the IP Group. For more information, refer to the document [SBC-Gateway Series SNMP Alarm Reference Guide](#).

- Use a different IP Profile for the IP Group or current call. This action can be useful, for example, when poor quality occurs due to packet loss and the device can then switch to an IP Profile configured with a higher RTP redundancy level or lower bit-rate coder.

To learn more about which actions are supported per call metric, see the description of the 'Rule Action' parameter below.

To configure thresholds, see the following sections:

- Voice Quality (MOS) - [Configuring Quality of Experience Profiles](#) on page 528
- Bandwidth - [Configuring Bandwidth Profiles](#) on page 535
- ASR, ACD and NER - See Alarm Thresholds

The following procedure describes how to configure Quality of Service rules through the Web interface. You can also configure it through ini file [QualityOfServiceRules] or CLI (`configure voip > qoe quality-of-service-rules`).

➤ **To configure a Quality of Service rule:**

1. Open the Quality of Service Rules table (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Quality of Service Rules**).
2. Click **New**; the following dialog box appears:

3. Configure a rule according to the parameters described in the table below.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

**Table 17-7: Quality of Service Rules Table Parameter Descriptions**

Parameter	Description
Match	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'IP Group' ip-group-name [IPGroupName]	Assigns an IP Group. The rule applies to all calls belonging to the IP Group. <b>Note:</b> This parameter is mandatory.
'Rule Metric' rule-metric [RuleMetric]	Defines the performance monitoring call metric to which the rule applies if the metric's threshold is crossed. <ul style="list-style-type: none"> <li>■ [0] <b>Voice Quality</b> = (Default) The device calculates MOS of calls and if the threshold is crossed (i.e., poor quality), the configured action (see 'Rule Action' parameter below) is done for all <b>new</b> calls and for the <b>entire</b> IP Group.</li> <li>■ [1] <b>Bandwidth</b></li> <li>■ [2] <b>ACD</b></li> <li>■ [3] <b>ASR</b></li> <li>■ [4] <b>NER</b></li> <li>■ [5] <b>Poor InVoice Quality</b> = The device calculates MOS (and</li> </ul>

Parameter	Description
	<p>TMMBR) of the call and if the threshold is crossed (i.e., poor quality), the device uses a different IP Profile (see 'Rule Action' parameter below) for the <b>current call only</b> (not the entire IP Group). This option is also used for voice quality for unregistered users (see <a href="#">Configuring Voice Quality for Unregistered Users</a> on page 546).</p> <ul style="list-style-type: none"> <li>■ [6] <b>Registered User Voice Quality</b> = The device calculates the MOS of calls belonging to users that are registered with the device. For more information on this feature, see <a href="#">Configuring Voice Quality for Registered Users</a> on page 544.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>✓ When this option is selected, a User-type IP Group must be selected in the 'IP Group' parameter (above).</li> <li>✓ This option is applicable only to the SBC application.</li> </ul>
'Severity' severity [Severity]	<p>Defines the alarm severity level. When the configured severity occurs, the device performs the action of the rule.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Major</b> (Default)</li> <li>■ [1] <b>Minor</b></li> </ul> <p><b>Note:</b> If you configure the 'Rule Metric' parameter to <b>ACD</b>, <b>ASR</b> or <b>NER</b>, you must configure the parameter to <b>Major</b>. For all other 'Rule Metric' parameter values, you can configure the parameter to any value.</p>
Action	
'Rule Action' rule-action [RuleAction]	<p>Defines the action to be done if the rule is matched.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Reject Calls</b> = (Default) New calls destined to the specified IP Group are rejected for a user-defined duration. To configure the duration, use the 'Calls Reject Duration' parameter (see below).</li> <li>■ [1] <b>Alternative IP Profile</b> = A different IP Profile is used for the IP Group or call (depending on the 'Rule Metric' parameter). To specify the IP Profile, use the 'Alternative IP Profile Name' parameter (see below).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the 'Rule Metric' parameter to <b>ACD</b>, <b>ASR</b> or <b>NER</b>, you must configure the parameter to <b>Reject Calls</b>.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If you configure the 'Rule Metric' parameter to <b>Voice Quality</b> or <b>Bandwidth</b>: <ul style="list-style-type: none"> <li>✓ If you configure the 'Severity' parameter to <b>Minor</b>, you must configure the parameter to <b>Alternative IP Profile</b>.</li> <li>✓ If you configure the 'Severity' parameter to <b>Major</b>, you can configure the parameter to any option.</li> </ul> <p>When configured to <b>Alternative IP Profile</b> and the threshold is crossed, the device changes the IP Profile for the entire IP Group for all new calls.</p> </li> <li>■ If you configure the 'Rule Metric' parameter to <b>Poor InVoice Quality</b>, you must configure the parameter to <b>Alternative IP Profile</b>. If the threshold is crossed (i.e., poor call quality), the device changes the IP Profile for the specific call <b>only</b> (during the call).</li> <li>■ If you configure the 'Rule Metric' parameter to <b>Registered User Voice Quality</b>: <ul style="list-style-type: none"> <li>✓ If you configure the 'Severity' parameter to <b>Minor</b>, you must configure the parameter to <b>Alternative IP Profile</b>. If the threshold is crossed (i.e., poor MOS), the device changes the IP Profile (from the original IP Profile configured with the G.711 coder to the alternative IP Profile configured with the Opus coder)during the call. As soon as the device detects an improvement in the network (based on packet loss), it returns to the original IP Profile.</li> <li>✓ If you configure the 'Severity' parameter to <b>Major</b>, you can configure the parameter to any option.</li> <li>✓ If you configure the parameter to <b>Alternative IP Profile</b>, new calls will initially use the coder that was last used in the previous call (regardless of MOS).</li> <li>✓ If you configure the parameter to <b>Alternative IP Profile</b>, this feature is not supported for HA switchover (e.g., if coder changed to Opus before switchover, after switchover the call remains with Opus until it ends, regardless of MOS level).</li> <li>✓ If you configure the parameter to <b>Alternative IP Profile</b> and the device supports other media types (e.g., video) in addition to audio, at least one of the peers must</li> </ul> </li> </ul>

Parameter	Description
	support re-INVITE without SDP.
'Calls Reject Duration' calls-reject-duration [CallsRejectDuration]	<p>Defines the duration (in minutes) for which the device rejects calls to the IP Group if the rule is matched.</p> <p>The default is 5.</p> <p><b>Note:</b> The parameter is applicable only if the 'Rule Action' parameter is configured to <b>Reject Calls</b>.</p>
'Alternative IP Profile Name' alt-ip-profile-name [AltIPProfileName]	<p>Assigns a different IP Profile to the IP Group or call (depending on the 'Rule Metric' parameter) if the rule is matched.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The parameter is applicable only if the 'Rule Action' parameter is configured to <b>Alternative IP Profile</b>.</p>

## Configuring Voice Quality for Registered Users

You can configure the device to measure the mean opinion score (MOS) of calls belonging to users that are registered with the device.

During the call, the device measures MOS every 30 seconds. The device provides MOS measurements as values (MOS \* 10, i.e., 0 to 50), and colors (green, yellow, or red) according to your Quality of Experience Color rules (see [Configuring Quality of Experience Profiles](#) on page 528). Whenever a change in MOS color occurs, the device reports this to the registered user, by sending an out-of-dialog SIP NOTIFY message containing the proprietary SIP header 'x-VoiceQuality: <Value> <Color>', as shown in the following example (MOS 3.2 and red color):

```
x-VoiceQuality: 32 red
```

You can configure the device (see [Configuring Quality of Service Rules](#) on page 540) to take one of the following actions if it detects a low MOS level during a call:

- Reject new calls (destined to the IP Group) for a user-defined time.
- Change the IP Profile during the call. Using an alternative IP Profile is especially useful if you want to use a different voice coder that is more efficient (e.g., Opus) than the coder (e.g., G.711) currently used for the call. In this scenario, if the device measures low MOS, it immediately uses the alternative IP Profile, switching to the more efficient coder (e.g., Opus). If at any stage during the call, the device detects an improvement in the network (based on packet loss), it uses the original IP Profile, switching back to the original coder associated with this IP Profile (e.g., G.711).

- This feature is applicable only to the SBC application.
- When implementing the alternative IP Profile method for Quality of Service:
  - ✓ New calls will initially use the coder that was last used in the previous call (regardless of MOS).
  - ✓ This feature is not supported for HA switchover (e.g., if coder changed to Opus before switchover, after switchover the call remains with Opus until it ends, regardless of MOS level).
  - ✓ If the device supports other media types (e.g., video) in addition to audio, at least one of the peers must support re-INVITE without SDP.

In addition to real-time MOS measurements discussed above, the device performs average MOS calculations per registered user. The device measures MOS in an "observation window" that is comprised of 12 intervals, where each interval can be configured as one hour (i.e., total of 12 hours in the window) or two hours (total of 24 hours in the window). Based on these intervals, the device provides the following MOS measurements:

- Average MOS of the 12 intervals (i.e., average MOS is calculated per interval - this is the average of these 12 MOS average measurements)
- Minimum average MOS of the 12 intervals (i.e., lowest MOS average measured for an interval)

The average MOS of each interval is calculated by "weight" of call duration relative to total call duration in the interval. For example, If the observation interval is 1 hour and two calls occurred in an interval, one that lasted 10 minutes with MOS of 4.2 and another call that lasted 20 minutes with MOS of 3.7, the average MOS is calculated as follows:  $4.2 * 10 / 30 + 3.7 * 20 / 30 = 3.86$

You can view MOS measurements per registered user in the SBC Registered Users table (see [Viewing SBC Registered Users](#) on page 1485).

The device calculates MOS based on RTCP-XR reports received from the user. However, for WebRTC users, which typically don't send RTCP-XR reports, the device calculates MOS based on RTCP packets. For more information on WebRTC, see [WebRTC](#) on page 1269.

#### ➤ To configure MOS measurement of registered users:

1. Open the Registered User Voice Quality page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **Quality of Experience** > **Registered User Voice Quality**); the following appears:

Registered User MOS Observation Window (hours)	<input type="text" value="1"/>
MOS Stored Timeout For No Calls (min)	<input type="text" value="60"/>

2. Configure the following:

- In the 'Registered User MOS Observation Window' field, enter the duration (in hours) of each of the 12 intervals for measuring MOS.
  - In the 'MOS Stored Timeout For No Calls' field, enter the time (in minutes) of no calls for a registered user after which the MOS measurement for that user is deleted (reset to zero).
3. Configure a QoE Profile to define the severity-color thresholds for MOS (see [Configuring Quality of Experience Profiles](#) on page 528).
  4. (Optional) Configure a Quality of Service rule to define what action to take (reject future calls or use an alternative IP Profile) when a specific MOS severity level occurs (see [Configuring Quality of Service Rules](#) on page 540). Make sure that you configure the 'Rule Metric' parameter to **Registered User Voice Quality**.
  5. (See note below) In the IP Group of the registered user, configure the 'User Voice Quality Report' parameter to **Enable**:

User Voice Quality Report

Enable

If you configure a Quality of Service rule (in Step 4), it's unnecessary to enable the MOS calculation and reporting feature in the IP Groups table (Step 5). If you don't configure a Quality of Service rule, then you need to enable the feature in the IP Groups table.

## Configuring Voice Quality for Unregistered Users

You can configure the device to dynamically switch voice coders to improve voice quality during a call with an unregistered user.

If it detects poor voice quality (based on MOS), it switches coders from G.711 to Opus for the unregistered user side. If it subsequently detects an improvement in the network (based on packet loss) during the same call, it switches back to G.711. The device switches coders, by changing between two IP Profiles - one associated with G.711, and the other associated with Opus.

- This feature is applicable only to the SBC application.
- This feature is for **Server**-type IP Groups.
- When the device operates in HA mode, this feature is not supported for HA switchover (e.g., if coder changed to Opus before switchover, after switchover the call remains with Opus until it ends, even if voice quality improves).

### ➤ To configure voice quality for unregistered users:

1. Open the Allowed Audio Coders Group table (see [Configuring Allowed Audio Coder Groups](#) on page 669), and then add two groups - one with G.711 only and the other with Opus

only.

2. Open the IP Profiles table (see [Configuring IP Profiles](#) on page 674), and then add two IP Profiles:

- Main IP Profile:
  - ◆ 'Allowed Audio Coders': Assign the Allowed Audio Coders Group with G.711
  - ◆ 'Switch Coder Upon Voice Quality': **Enable**

Switch Coder Upon Voice Quality

Enable

- Alternative IP Profile:
    - ◆ 'Allowed Audio Coders': Assign the Allowed Audio Coders Group with Opus
3. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then make sure that you assign the IP Group (**Server-Type**) to which the user belongs, with the main IP Profile associated with G.711.
  4. Open the Quality of Experience Profile table (see [Configuring Quality of Experience Profiles](#) on page 528), and then configure a rule with severity-color thresholds for MOS.
  5. Open the Quality of Service Rules table (see [Configuring Quality of Service Rules](#) on page 540), and then configure a rule that changes the IP Profile upon poor voice quality:
    - 'IP Group': Assign the IP Group of the user (see Step 3)
    - 'Rule Metric': **Poor InVoice Quality**
    - 'Rule Action': **Alternate IP Profile**
    - 'Alternative IP Profile Name': Assign the alternative IP Profile that is associated with the Opus coder (see Step 2)

## 18 Core Entities

This section describes configuration of core SIP entities.

### Configuring Media Realms

The Media Realms table lets you configure a pool of up to 12 SIP media interfaces, termed *Media Realms*. Media Realms lets you divide a Media-type interface (configured in the IP Interfaces table) into several media realms, where each realm is specified by a UDP port range. Media Realms also define the maximum number of permitted media sessions.

Once configured, to apply Media Realms to specific calls, you need to assign them to any of the following configuration entities:

- IP Groups (see [Configuring IP Groups](#) on page 591)
- SIP Interfaces (see [Configuring SIP Interfaces](#) on page 570)

You can also apply the device's Quality of Experience feature to Media Realms:

- **Quality of Experience Profile:** Call quality monitoring based on thresholds for voice metrics (e.g., MOS) can be applied per Media Realm. For example, if MOS is considered poor, calls on this Media Realm can be rejected. To configure Quality of Experience Profiles, see [Configuring Quality of Experience Profiles](#) on page 528.
- **Bandwidth Profile:** Bandwidth utilization thresholds can be applied per Media Realm. For example, if bandwidth thresholds are crossed, the device can reject any new new calls on this Media Realm. To configure Bandwidth Profiles, see [Configuring Bandwidth Profiles](#) on page 535.

The Media Realms table provides the following "child" tables:

- Remote Media Subnets: Defines remote destination subnets per Media Realm and assigns each subnet a Quality of Experience Profile and Bandwidth Profile. For more information, see [Configuring Remote Media Subnets](#) on page 552.
- Media Realm Extensions: Defines port ranges for multiple Media-type interfaces per Media Realm. For more information, see [Configuring Media Realm Extensions](#) on page 555.

- The Media Realm assigned to an IP Group overrides any other Media Realm assigned to any other configuration entity associated with the call.
- If you modify a Media Realm that is currently being used by a call, the device doesn't perform Quality of Experience for the call.
- If you delete a Media Realm that is currently being used by a call, the device maintains the call until the call parties end the call.
- The device provides a default Media Realm ("DefaultRealm"), which you can modify or delete.

The following procedure describes how to configure Media Realms through the Web interface. You can also configure it through ini file [CpMediaRealm] or CLI (`configure voip > realm`).

➤ **To configure a Media Realm:**

1. Open the Media Realms table (**Setup** menu > **Signaling & Media** tab > **Core Entities** folder > **Media Realms**).
2. Click **New**; the following dialog box appears:

The screenshot shows a web-based configuration interface for Media Realms. It features two main sections: 'GENERAL' and 'QUALITY OF EXPERIENCE'. The 'GENERAL' section includes fields for 'Index', 'Name', 'Topology Location', 'IPv4 Interface Name', 'IPv6 Interface Name', 'UDP Port Range Start', 'Number Of Media Session Legs', 'UDP Port Range End', 'Default Media Realm', and 'Used By Routing Server'. The 'QUALITY OF EXPERIENCE' section includes 'QoE Profile' and 'Bandwidth Profile'. Each field has a 'View' link next to it.

3. Configure the Media Realm according to the parameters described in the table below.
4. Click **Apply**.

**Table 18-1: Media Realms Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [MediaRealmName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 39 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Topology Location'	Defines the display location of the Media Realm in the

Parameter	Description
<code>topology-location</code> [TopologyLocation]	<p>Topology view.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Down</b> = (Default) The Media Realm element is displayed on the lower border of the view.</li> <li>■ [1] <b>Up</b> = The Media Realm element is displayed on the upper border of the view.</li> </ul> <p>For more information on the Topology view, see <a href="#">Building and Viewing SIP Entities in Topology View</a> on page 654.</p>
'IPv4 Interface Name' <code>ipv4</code> [IPv4IF]	<p>Assigns an IPv4 interface to the Media Realm.</p> <p>By default, no value is defined.</p> <p>To configure IP network interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p>
'IPv6 Interface Name' <code>ipv6if</code> [IPv6IF]	<p>Assigns an IPv6 interface to the Media Realm.</p> <p>By default, no value is defined.</p> <p>To configure IP network interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p>
'UDP Port Range Start' <code>port-range-start</code> [PortRangeStart]	<p>Defines the starting port for the range of media interface UDP ports.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You must configure <b>all</b> your Media Realms with port ranges or all without; not some with and some without.</li> <li>■ The available UDP port range is according to the [BaseUDPport] parameter. For more information, see <a href="#">Configuring RTP Base UDP Port</a> on page 301.</li> <li>■ The port number <b>must</b> be different from ports configured for SIP traffic (i.e., ports configured for SIP Interfaces) that use the same IP Interface. For example, if the RTP port range is 6000 to 6999, the SIP port can be less than 6000 or greater than 6999.</li> <li>■ Media Realms associated with the same IP Interface must not have overlapping port ranges.</li> <li>■ Media Realms and Media Realm Extensions associated with the same IP Interface must not</li> </ul>

Parameter	Description
	have overlapping port ranges.
'Number of Media' Session Legs session-leg [MediaSessionLeg]	Defines the number of media sessions for the configured port range. By default, no value is defined.
'UDP Port Range End' port-range-end [PortRangeEnd]	<p>(Read-only field) Displays the ending port for the range of media interface UDP ports. The device automatically populates the parameter with a value, calculated by the summation of the 'UDP Port Range Start' parameter and 'Number of Media Session Legs' parameter (multiplied by the port chunk size) minus 1:</p> $\text{start port} + (\text{sessions} * \text{port spacing}) - 1$ <p>For example, a port starting at 6,000, 5 sessions and 10 port spacing:</p> $6,000 + (5 * 10) - 1 = 6,000 + (50) - 1 = 6,000 + 49 = 6,049$ <p>For more information on UDP port allocation and spacing, see <a href="#">Configuring RTP Base UDP Port</a> on page 301.</p>
'Default Media Realm' is-default [IsDefault]	<p>Defines the Media Realm as the default Media Realm. The default Media Realm is used for SIP Interfaces and IP Groups for which you have not assigned a Media Realm.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> (default)</li> <li>■ [1] <b>Yes</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure the parameter to <b>Yes</b> for only <b>one</b> Media Realm; all the other Media Realms must be configured to <b>No</b>.</li> <li>■ If you do not configure the parameter (i.e., the parameter is <b>No</b> for all Media Realms), the device uses the first Media Realm in the table as the default.</li> <li>■ If the table is not configured, the default Media Realm includes all configured media interfaces.</li> </ul>

Parameter	Description
'Used By Routing Server' used-by-routing-server [UsedByRoutingServer]	<p>Enables the Media Realm to be used by ARM for call routing decisions.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Used</b> (default)</li> <li>■ [1] <b>Used</b></li> </ul> <p>For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</p>
Quality of Experience	
'QoE Profile' qoe-profile [QoeProfile]	<p>Assigns a QoE Profile to the Media Realm.</p> <p>By default, no value is defined.</p> <p>To configure QoE Profiles, see <a href="#">Configuring Quality of Experience Profiles</a> on page 528.</p>
'BW Profile' bw-profile [BWProfile]	<p>Assigns a Bandwidth Profile to the Media Realm.</p> <p>By default, no value is defined.</p> <p>To configure Bandwidth Profiles, see <a href="#">Configuring Bandwidth Profiles</a> on page 535.</p>

## Configuring Remote Media Subnets

Remote Media Subnets define destination subnets for media (RTP/SRTP) traffic on a specific Media Realm. Each Remote Media Subnet can be assigned different call quality (Quality of Experience Profile) and bandwidth utilization (Bandwidth Profile) profiles. These profiles are configured in [Configuring Quality of Experience Profiles](#) on page 528 and [Configuring Bandwidth Profiles](#) on page 535, respectively. Thus, you can apply these profiles to remote media subnets instead of Media Realms or IP Groups. You can configure up to five Remote Media Subnets per Media Realm.

The figure below illustrates an example for implementing Remote Media Subnets. IP Group #2 represents a SIP Trunk which routes international (USA and India) and local calls. As international calls are typically more prone to higher delay than local calls, different Quality of Experience Profiles are assigned to them. This is done by creating Remote Media Subnets for each of these call destinations and assigning each Remote Media Subnet a different Quality of Experience Profile. A Quality of Experience Profile that defines a packet delay threshold is assigned to the international calls, which if crossed, a different IP Profile is used that defines higher traffic priority to voice over other traffic. In addition, IP Group #2 has a 10-Mbps bandwidth threshold and a "tighter" bandwidth limitation (e.g., 1 Mbps) is allocated to local calls. If this limit is exceeded, the device rejects new calls to this Remote Media Subnet.

The following procedure describes how to configure Remote Media Subnets through the Web interface. You can also configure it through ini file [RemoteMediaSubnet] or CLI (`configure voip > remote-media-subnet`).

➤ **To configure a Remote Media Subnet:**

1. Open the Media Realms table (see [Configuring Media Realms](#) on page 548).
2. Select the Media Realm row for which you want to add Remote Media Subnets, and then click the **Remote Media Subnet** link located below the table; the Remote Media Subnet table appears.
3. Click **New**; the following dialog box appears:

Remote Media Subnet
⌵ ⌵

GENERAL

Index	<input type="text" value="0"/>
Name	<input type="text"/>
Prefix Length	<input type="text" value="16"/>
Address Family	<input type="text" value="IPv4"/>
Destination IP	<input type="text" value="0.0.0.0"/>
QoE Profile	<input type="text" value="--"/> <span style="float: right;">View</span>
BW Profile	<input type="text" value="--"/> <span style="float: right;">View</span>

4. Configure the Remote Media Subnet according to the parameters described in the table below.

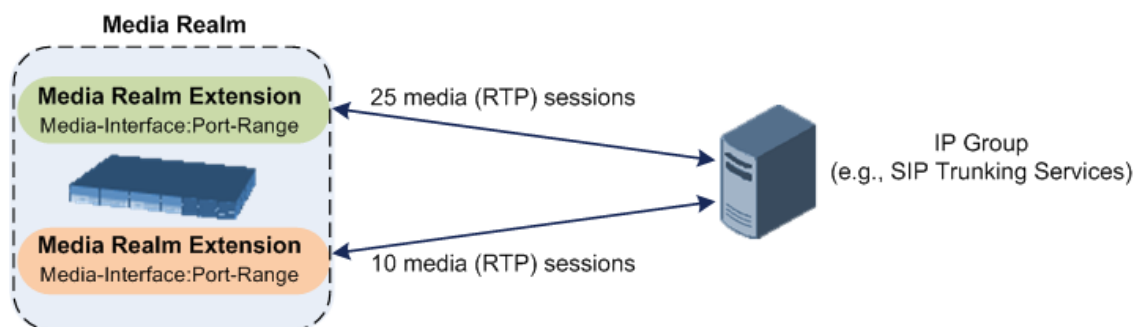

5. Click **Apply**.**Table 18-2: Remote Media Subnet Table Parameter Descriptions**

Parameter	Description
'Index' [RemoteMediaSubnet_ RemoteMediaSubnetIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [RemoteMediaSubnet_ RemoteMediaSubnetName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 20 characters. <b>Note:</b> Configure each row with a unique name.
'Prefix Length' prefix-length [RemoteMediaSubnet_ PrefixLength]	Defines the subnet mask in Classless Inter-Domain Routing (CIDR) notation. For example, 16 denotes 255.255.0.0. The default is 16.
'Address Family' address-family [RemoteMediaSubnet_ AddressFamily]	Defines the IP address protocol. <ul style="list-style-type: none"> <li>■ [2] <b>IPv4</b> (default)</li> <li>■ [10] <b>IPv6</b></li> </ul>
'Destination IP' dst-ip-address [RemoteMediaSubnet_ DstIPAddress]	Defines the IP address of the destination. The default is 0.0.0.0.
'QoE Profile' qoe-profile [RemoteMediaSubnet_ QOEProfileName]	Assigns a Quality of Experience Profile to the Remote Media Subnet. By default, no value is defined. To configure QoE Profiles, see <a href="#">Configuring Quality of Experience Profiles</a> on page 528.
'BW Profile' bw-profile [RemoteMediaSubnet_ BWProfileName]	Assigns a Bandwidth Profile to the Remote Media Subnet. By default, no value is defined. To configure Bandwidth Profiles, see <a href="#">Configuring Bandwidth Profiles</a> on page 535.

## Configuring Media Realm Extensions

The Media Realm Extension table lets you configure up to 24 Media Realm Extensions. A Media Realm Extension is associated with a specific Media Realm and defines a port range and the number of media sessions for a specific Media-type network interface (configured in the IP Interfaces table). Therefore, a Media Realm Extension enhances a Media Realm by allowing you to define different port ranges, media sessions, and network interface than is defined by the associated Media Realm (i.e., the Media Realm is distributed across multiple interfaces).

Media Realm Extensions can be useful, for example, to overcome limitations of the maximum number of media ports supported per interface. Instead of configuring only a single Media Realm in the Media Realms table (see [Configuring Media Realms](#) on page 548), you can also configure additional "Media Realms" in the Media Realm Extensions table associated with the single Media Realm. An IP Group that is associated with a Media Realm configured with Media Realm Extensions, allocates its media sessions / ports between the different interfaces, as configured by the Media Real and its associated Media Realm Extensions. For example, two Media Realm Extensions could be configured, whereby one allocates 25 media sessions on interface "LAN-1" and another, 10 sessions on interface "LAN-2". The Media Realm associated with these Media Realm Extensions would be assigned to the relevant IP Group.

The following procedure describes how to configure Media Realm Extensions through the Web interface. You can also configure it through ini file [MediaRealmExtension] or CLI (`configure voip > voip-network realm-extension`).

### ➤ To configure a Media Realm Extension:

1. Open the Media Realms table (see [Configuring Media Realms](#) on page 548).
2. Select the Media Realm for which you want to add Remote Media Extensions, and then click the **Media Realm Extension** link located below the table; the Media Realm Extension table appears.
3. Click **New**; the following dialog box appears:

4. Configure the Media Realm Extension according to the parameters described in the table below.
5. Click **Apply**.

**Table 18-3: Media Realm Extension Table Parameter Descriptions**

Parameter	Description
'Index' [MediaRealmExtension_ExtensionIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'IPv4 Interface Name' [MediaRealmExtension_IpV4IF]	Assigns an IPv4 network interface (configured in the IP Interfaces table) to the Media Realm Extension. By default, no value is defined. To configure IP network interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ You must configure the Media Realm Extension with an IP network interface that has the same IP version(s) as the Media Realm to which the Media Realm Extension is associated. If the associated Media Realm is assigned both an IPv4 and IPv6 network interface, you also need to assign the Media Realm Extension with both an IPv4 and IPv6 network interface. For example, if the associated Media Realm is assigned only an IPv4 network interface, you also need to assign the Media Realm Extension with an IPv4 network interface.</li> </ul>
'IPv6 Interface Name'	Assigns an IPv6 network interface (configured in the IP

Parameter	Description
[MediaRealmExtension_IpV6IF]	<p>Interfaces table) to the Media Realm Extension.</p> <p>By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is mandatory.</li> <li>You must configure the Media Realm Extension with an IP network interface that has the same IP version(s) as the Media Realm to which the Media Realm Extension is associated. If the associated Media Realm is assigned both an IPv4 and IPv6 network interface, you also need to assign the Media Realm Extension with both an IPv4 and IPv6 network interface. For example, if the associated Media Realm is assigned an IPv6 network interface, you also need to assign the Media Realm Extension with an IPv6 network interface.</li> </ul>
'Port Range Start' [MediaRealmExtension_PortRangeStart]	<p>Defines the first (lower) port in the range of media UDP ports for the Media Realm Extension.</p> <p>By default, no value is defined.</p> <p><b>Notes:</b></p> <ul style="list-style-type: none"> <li>You must either configure all your Media Realms with port ranges or all without; not some with and some without.</li> <li>The available UDP port range is according to the [BaseUDPport] parameter (see <a href="#">Configuring RTP Base UDP Port</a> on page 301).</li> <li>The port range must not overlap with any other media port range configured for other Media Realm Extensions, Media Realms, or SIP Interfaces that are associated with the same IP network interface.</li> </ul>
'Port Range End' [MediaRealmExtension_PortRangeEnd]	<p>Defines the last (upper) port in the range of media UDP ports for the Media Realm Extension.</p> <p><b>Note:</b> It is unnecessary to configure the parameter. The device automatically populates the parameter with a value, calculated by the summation of the 'Number of Media Session Legs' parameter (multiplied by the port chunk size) and the 'Port Range Start' parameter. After you have added the Media Realm Extension row to the table, the parameter is displayed with the calculated value.</p>

Parameter	Description
'Number Of Media Session Legs' [MediaRealmExtension_MediaSessionLeg]	<p>Defines the number of media sessions for the port range. For example, 100 ports correspond to 10 media sessions, since ports are allocated in chunks of 10.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The parameter is mandatory.</p>

## Configuring SRDs

The SRDs table lets you configure up to 20 signaling routing domains (SRD). The SRD is a logical representation of an entire SIP-based VoIP network (Layer 5) consisting of groups of SIP users and servers. The SRD is associated with all the configuration entities (e.g., SIP Interfaces and IP Groups) required for routing calls within the network. Typically, only a **single** SRD is required (recommended) for most deployments. Multiple SRDs are only required for multi-tenant deployments, where the physical device is "split" into multiple logical devices. For more information on multi-tenant architecture, see [Multiple SRDs for Multi-tenant Deployments](#) on page 566.

As the device is shipped with a default SRD ("DefaultSRD" at Index 0), if your deployment requires only one SRD, you can use the default SRD instead of creating a new one. When only one SRD is employed and you create other related configuration entities (e.g., SIP Interfaces), the default SRD is automatically assigned to the new configuration entity. Therefore, when employing a single-SRD configuration topology, there is no need to handle SRD configuration (i.e., transparent).

You can assign SRDs to the following configuration entities:

- SIP Interface (mandatory) - see [Configuring SIP Interfaces](#) on page 570
- IP Group (mandatory) - see [Configuring IP Groups](#) on page 591
- Proxy Set (mandatory) - see [Configuring Proxy Sets](#) on page 632
- (SBC application only) Classification rule - see [Configuring Classification Rules](#) on page 1171

As mentioned previously, if you use only a single SRD, the device automatically assigns it to the above-listed configuration entities.

As each SIP Interface defines a different Layer-3 network (see [Configuring SIP Interfaces](#) on page 570 for more information) on which to route or receive calls and as you can assign multiple SIP Interfaces to the same SRD, for most deployment scenarios (even for multiple Layer-3 network environments), you only need to employ a single SRD to represent your VoIP network (Layer 5). For example, if your VoIP deployment consists of an corporate IP PBX (LAN), a SIP Trunk (WAN), and far-end users (WAN), you would only need a single SRD. The single SRD would be assigned to three different SIP Interfaces, where each SIP Interface would represent a specific Layer-3 network (IP PBX, SIP Trunk, or far-end users) in your environment. The following figure provides an example of such a deployment:

- It is recommended to use a single-SRD configuration topology, unless you are deploying the device in a multi-tenant environment, in which case multiple SRDs are required.
- Each SIP Interface, Proxy Set, and IP Group can be associated with only one SRD.
- If you have upgraded your device to Version 7.0 and your device was configured with multiple SRDs but not operating in a multi-tenant environment, it is recommended to gradually change your configuration to a single SRD topology.
- If you upgrade the device from an earlier release to Version 7.0, your previous SRD configuration is fully preserved regarding functionality. The same number of SRDs is maintained, but the configuration elements are changed to reflect the configuration topology of Version 7.0. Below are the main changes in configuration topology when upgrading to Version 7.0:
  - ✓ The SIP Interface replaces the associated SRD in several tables (due to support for multiple SIP Interfaces per SRD).
  - ✓ Some fields in the SRDs table were duplicated or moved to the SIP Interfaces table.
  - ✓ Indices used for associating configuration entities in tables are changed to row pointers (using the entity's name).
  - ✓ Some tables are now associated (mandatory) with an SRD (SIP Interface, IP Group, Proxy Set, and Classification).
  - ✓ Some fields used for associating configuration entities in tables now have a value of **Any** to distinguish between **Any** and **None** (deleted entity or not associated).

The following procedure describes how to configure SRDs through the Web interface. You can also configure it through ini file [SRD] or CLI (`configure voip > srd`).

#### ➤ To configure an SRD:

1. Open the SRDs table (**Setup** menu > **Signaling & Media** tab > **Core Entities** folder > **SRDs**).

2. Click **New**; the following dialog box appears:

The screenshot shows a dialog box titled "SRDs" with two tabs: "GENERAL" and "REGISTRATION".

**GENERAL Tab:**

- Index: Text input field containing "1f".
- Name: Text input field.
- Sharing Policy: Dropdown menu set to "Shared".
- SBC Operation Mode: Dropdown menu set to "B2BUA".
- SBC Routing Policy: Dropdown menu set to "#0 [Default\_SBCRoutingPolicy]" with a "View" link.
- Used By Routing Server: Dropdown menu set to "Not Used".
- Dial Plan: Dropdown menu set to "--" with a "View" link.

**REGISTRATION Tab:**

- Max. Number of Registered Users: Text input field containing "-1".
- User Security Mode: Dropdown menu set to "Accept All".
- Enable Un-Authenticated Registrations: Dropdown menu set to "Enable".

3. Configure an SRD according to the parameters described in the table below.

4. Click **Apply**.

**Table 18-4: SRDs table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value can be a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>The parameter is mandatory.</li> <li>Configure each row with a unique name.</li> <li>The parameter value can't contain a forward slash (/).</li> <li>The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Sharing Policy' type [SharingPolicy]	Defines the sharing policy of the SRD, which determines whether the SRD shares its SIP resources (SIP Interfaces, Proxy Sets, and IP Groups) with all other SRDs (Shared and

Parameter	Description
	<p>Isolated).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Shared</b> = (Default) SRD shares its resources with other SRDs (Isolated and Shared) and calls can thus be routed between the SRD and other SRDs.</li> <li>■ [1] <b>Isolated</b> = SRD doesn't share its resources with other SRDs and calls cannot be routed between the SRD and other Isolated SRDs. However, calls can be routed between the SRD and other Shared SRDs.</li> </ul> <p>For more information on SRD Sharing Policy, see <a href="#">Multiple SRDs for Multi-tenant Deployments</a> on page 566.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'SBC Operation Mode'</p> <p><code>sbc-operation-mode</code></p> <p>[SBCOperationMode]</p>	<p>Defines the device's operational mode for the SRD.</p> <ul style="list-style-type: none"> <li>■ [0] <b>B2BUA</b> = (Default) Device operates as a back-to-back user agent (B2BUA), changing the call identifiers and headers between the inbound and outbound legs.</li> <li>■ [1] <b>Call Stateful Proxy</b> = Device operates as a Stateful Proxy, passing the SIP message transparently between inbound and outbound legs. In other words, the same SIP dialog identifiers (tags, Call-Id and CSeq) occur on both legs (as long as no other configuration disrupts the CSeq compatibility).</li> <li>■ [2] <b>Microsoft Server</b> = Operating mode for the One-Voice Resiliency feature, whereby the device is deployed together with Skype for Business-compatible IP Phones at small remote branch offices in a Microsoft® Skype for Business™ environment.</li> </ul> <p>For more information on B2BUA and Stateful Proxy modes, see <a href="#">B2BUA and Stateful Proxy Operating Modes</a> on page 1123.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The settings of the parameter also determines the default behavior of related parameters in the IP Profiles table (SBCRemoteRepresentationMode, SBCKeepVIAHeaders, SBCKeepUserAgentHeader, SBCKeepRoutingHeaders, SBCRemoteMultipleEarlyDialogs).</li> <li>■ If the 'SBC Operation Mode' parameter is configured in the IP Groups table, the 'SBC Operation Mode' parameter in the SRDs table is ignored.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'SBC Routing Policy'</p> <p>sbc-routing-policy-name</p> <p>[SBCRoutingPolicyName]</p>	<p>Assigns a Routing Policy to the SRD.</p> <p>By default, no value is defined if you have configured multiple Routing Policies. If you have configured only one Routing Policy, the device assigns it to the SRD by default.</p> <p>For more information on Routing Policies, see <a href="#">Configuring SBC Routing Policies</a> on page 1218.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you have assigned a Routing Policy to a Classification rule that is associated with the SRD, the Routing Policy assigned to the SRD is ignored.</li> <li>■ You can assign the same Routing Policy to multiple SRDs.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Used By Routing Server'</p> <p>used-by-routing-server</p> <p>[UsedByRoutingServer]</p>	<p>Enables the SRD to be used by ARM for call routing decisions.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Used</b> (default)</li> <li>■ [1] <b>Used</b></li> </ul> <p>For more information on routing by ARM, see</p>

Parameter	Description
	<a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.
'Dial Plan' sbc-dial-plan-name [SBCDialPlanName]	<p>Assigns a Dial Plan to the SRD. The device searches the Dial Plan for a dial plan rule that matches the source number and if not found, for a rule that matches the destination number. If a matching dial plan rule is found, the rule's tag is used in the routing and/or manipulation processes as source and/or destination tags.</p> <p>To configure Dial Plans, see <a href="#">Configuring Dial Plans</a> on page 825.</p>
'CAC Profile' cac-profile [AdmissionProfile]	<p>Assigns a Call Admission Control Profile (CAC rules) to the SRD.</p> <p>By default, no value is defined.</p> <p>To configure CAC Profiles, see <a href="#">Configuring Call Admission Control</a> on page 1164.</p>
Registration	
'Max. Number of Registered Users' max-reg-users [MaxNumOfRegUsers]	<p>Defines the maximum number of users belonging to the SRD that can register with the device.</p> <p>The default is -1, which means that the number of allowed user registrations is unlimited.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'User Security Mode' block-un-reg-users [BlockUnRegUsers]	<p>Defines the blocking (reject) policy for incoming SIP dialog-initiating requests (e.g., INVITE messages) from registered and unregistered users belonging to the SRD.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Accept All</b> = (Default) Accepts requests from registered and unregistered users.</li> <li>■ [1] <b>Accept Registered Users</b> = Accepts requests only from users registered with the device. Requests from users not registered are rejected.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ <b>[2] Accept Registered Users from Same Source</b> = Accepts requests only from registered users whose source address is the same as that registered with the device (during the REGISTER message process). All other requests are rejected. If the transport protocol is UDP, the verifies the IP address and port; otherwise, it verifies only the IP address. The verification is performed before any of the device's call handling processes (i.e., Classification, Manipulation and Routing).</li> <li><b>Note:</b></li> <li>■ The parameter is applicable only to calls belonging to User-type IP Groups.</li> <li>■ The feature is not applicable to REGISTER requests.</li> <li>■ The option, Accept Registered Users from Same Source [2] doesn't apply to registration refreshes. These requests are accepted even if the source address is different to that registered with the device.</li> <li>■ When the device rejects a call, it sends a SIP 500 "Server Internal Error" response to the user. In addition, it reports the rejection (Dialog establish failure - Classification failure) using the Intrusion Detection System (IDS) feature (see <a href="#">Configuring IDS Policies</a> on page 264), by sending an SNMP trap.</li> <li>■ When the corresponding parameter in the SIP Interfaces table ('User Security Mode') is configured to any value other than <b>Not Configured</b> for a SIP Interface that is associated with the SRD, the parameter in the SRDs table is ignored for calls belonging to the SIP Interface.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>

Parameter	Description
'Enable Un-Authenticated Registrations' enable-un-auth-registrs [EnableUnAuthenticatedRegistrations]	<p>Enables the device to accept REGISTER requests and register them in its registration database from new users that have not been authenticated by a proxy/registrar server (due to proxy down) and thus, re-routed to a User-type IP Group.</p> <p>In normal operation scenarios in which the proxy server is available, the device forwards the REGISTER request to the proxy and if authenticated by the proxy (i.e., device receives a success response), the device adds the user to its registration database. The routing to the proxy is according to the SBC IP-to-IP Routing table where the destination is the proxy's IP Group. However, when the proxy is unavailable (e.g., due to network connectivity loss), the device can accept REGISTER requests from new users if a matching alternative routing rule exists in the SBC IP-to-IP Routing table where the destination is the user's User-type IP Group (i.e., call survivability scenarios) and if the parameter is enabled.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = The device rejects REGISTER requests from new users that were not authenticated by a proxy server.</li> <li>■ [1] <b>Enable</b> = (Default) The device accepts REGISTER requests from new users even if they were not authenticated by a proxy server, and registers the user in its registration database.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Regardless of the parameter, the device always accepts registration refreshes from users that are already registered in its database.</li> <li>■ For a SIP Interface that is associated with the SRD, if the corresponding parameter in the SIP Interfaces table ('Enable Un-Authenticated Registrations') is configured</li> </ul>

Parameter	Description
	<p>to <b>Disable</b> or <b>Enable</b>, the parameter in the SRD is ignored for calls belonging to the SIP Interface.</p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> </ul>

## Multiple SRDs for Multi-tenant Deployments

The device can be deployed in a multi-tenant architecture, serving multiple customers (tenants) from a single, shared physical entity. The device's multi-tenant feature is fully scalable, offering almost “non-bleeding” partition per tenant, whereby users of one tenant can't infringe on the space of users of another tenant. The device provides per tenant configuration, monitoring, reporting, analytics, alarms and interfacing. The device is a real-time multi-tenant system that provides each tenant with optimal real-time performance, as each session received by the device is classified and processed only through the tenant's “orbit”.

While some enterprises are large enough to justify a dedicated standalone device, many enterprises require only a fraction of the device's capacity and capabilities. Service providers offering SIP Trunking services can funnel multiple enterprises into a single device and thereby, reap significant cost improvements over a device-per-customer model. Tenant size in a multi-tenant architecture can vary and therefore, the instance CPU, memory and interface allocations should be optimized so as not to waste resources for small-sized tenants on the one hand, and not to allocate too many instances for a single tenant/customer on the other. For example, it would be a waste to allocate a capacity of 100 concurrent sessions to a small tenant for which 10 concurrent sessions suffice.

In a multi-tenant deployment, each tenant is represented by a dedicated SRD. The different Layer-3 networks (e.g., LAN IP-PBX users, WAN SIP Trunk, and WAN far-end users) of the tenant are represented by SIP Interfaces, which are all associated with the tenant's SRD. As related configuration entities (SIP Interfaces, IP Groups, Proxy Sets, Classification rules, and IP-to-IP Routing rules) are associated with the specific SRD, each SRD has its own logically separated configuration tables (although configured in the same tables). Therefore, full logical separation (on the SIP application layer) between tenants is achieved by SRD.

To create a multi-tenant configuration topology that is as non-bleeding as possible, you can configure an SRD (tenant) as *Isolated* and *Shared*:

- **Isolated SRD:** An Isolated SRD has its own dedicated SIP resources (SIP Interfaces, Proxy Sets, and IP Groups). No other SRD can use the SIP resources of an Isolated SRD. Thus, call traffic of an Isolated SRD is kept separate from other SRDs (tenants), preventing any risk of traffic “leakage” with other SRDs.

Isolated SRDs are more relevant when each tenant needs its own separate (dedicated) routing “table” for non-bleeding topology. Separate routing tables are implemented using Routing Policies. In such a non-bleeding topology, routing between Isolated SRDs is not

possible. This enables accurate and precise routing per SRD, eliminating any possibility of erroneous call routing between SRDs, restricting routing to each tenant's (SRD's) sphere. Configuring only one Routing Policy that is shared between Isolated SRDs is not best practice for non-bleeding environments, since it allows routing between these SRDs.

- **Shared SRD:** Isolated SRDs have their own dedicated SIP resources (SIP Interfaces, Proxy Sets, and IP Groups). This may not be possible in some deployments. For example, in deployments where all tenants use the same SIP Trunking service, or use the same SIP Interface due to limited SIP interface resources (e.g., multiple IP addresses cannot be allocated and SIP port 5060 must be used). In contrast to Isolated SRDs, a Shared SRD can share its' SIP resources with all other SRDs (Shared and Isolated). This is typically required when tenants need to use common resources. In the SIP Trunk example, the SIP Trunk would be associated with a Shared SRD, enabling all tenants to route calls with the SIP Trunk.

Another configuration entity that can be used for multi-tenant deployments is the Routing Policy. Routing Policies allow each SRD (or tenant) to have its own routing rules, manipulation rules, Least Cost Routing (LCR) rules, and/or LDAP-based routing configuration. However, not all multi-tenant deployments need multiple Routing Policies and typically, their configuration is not required. Isolated SRDs are more relevant only when each tenant requires its own dedicated Routing Policy to create separate, dedicated routing "tables"; for all other scenarios, SRDs can be Shared. For more information on Routing Policies, see [Configuring SBC Routing Policies](#) on page 1218.

The figure below illustrates a multi-tenant architecture with Isolated SRD tenants ("A" and "B") and a Shared SRD tenant ("Data Center") serving as a SIP Trunk:

To facilitate multi-tenant configuration through CLI, you can access a specific tenant "view". Once in a specific tenant view, all configuration commands apply only to the currently viewed tenant. Only table rows (indexes) belonging to the viewed tenant can be modified. New table rows are automatically associated with the viewed tenant (i.e., SRD name). The display of tables and show running-configuration commands display only rows relevant to the viewed tenant (and shared tenants). The show commands display only information relevant to the viewed tenant. To support this CLI functionality, use the following commands:

- To access a specific tenant view:

```
# srd-view <SRD name>
```

Once accessed, the tenant's name (i.e., SRD name) forms part of the CLI prompt, for example:

```
# srd-view datacenter
(srd-datacenter)#
```

- To exit the tenant view:

```
# no srd-view
```

## Cloning SRDs

You can clone (duplicate) existing SRDs. This is especially useful when operating in a multi-tenant environment and you need to add new tenants (SRDs). The new tenants can quickly and easily be added by simply cloning one of the existing SRDs. Once cloned, all you need to do is tweak configuration entities associated with the SRD clone.

When an SRD is cloned, the device adds the new SRD clone to the next available index row in the SRDs table. The SRD clone is assigned a unique name in the following syntax format: <unique clone ID>\_<original SRD index>\_CopyOf\_<name, or index if no name, of original SRD>. For example, if you clone SRD "SIP-Trunk" at index 2, the new SRD clone is assigned the name, "36454371\_2\_CopyOf\_SIP-Trunk".

The SRD clone has identical settings as the original SRD. In addition, all configuration entities associated with the original SRD are also cloned and these clones are associated with the SRD clone. The naming convention of these entities is the same as the SRD clone (see above) and all have the same unique clone ID ("36454371" in the example above) as the cloned SRD. These configuration entities include IP Groups, SIP Interfaces, Proxy Sets (without addresses), Classification rules, and Call Admission Control profiles. If the Routing Policy associated with the original SRD is not associated with any other SRD, the Routing Policy is also cloned and its' clone is associated with the SRD clone. All configuration entities associated with the original Routing Policy are also cloned and these clones are associated with the Routing Policy clone. These configuration entities include IP-to-IP Routing rules, Inbound Manipulation rules, and Outbound Manipulation rules.

When any configuration entity is cloned (e.g., an IP-to-IP Routing rule) as a result of a cloned SRD, all fields of the entity's row which "point" to other entities (e.g., SIP Interface, Source IP Group, and Destination IP Group) are replaced by their corresponding clones.

For some cloned entities such as SIP Interfaces, some parameter values may change. This occurs in order to avoid the same parameter having the same value in more than one table row (index), which would result in invalid configuration. For example, a SIP Interface clone will have an empty Network Interface setting. After the clone process finishes, you thus need to update the Network Interface for valid configuration.

### ➤ To clone an SRD:

- Web interface: In the SRDs table, select an SRD to clone, and then click the **Clone** button.
- CLI:

```
(config-voip)# srd clone <SRD index that you want cloned>
```

## Color-Coding of SRDs in Web Interface

To easily identify your configured SRDs, the Web interface displays each SRD in a unique color. The color is automatically and randomly assigned to new SRDs and is displayed in a box alongside the name of the SRD in tables where the SRD is configured or assigned. This is applied throughout the Web interface. The following example shows SRDs assigned with unique color codes.

INDEX ↕	NAME
0	 DefaultSRD (#0)
1	 Comp-A (#1)
2	 Comp-B (#2)
3	 Comp-C (#3)

## Automatic Configuration based on SRD

To facilitate configuration and eliminate possible flaws in configuration due to invalid associations between configuration entities, the Web interface automatically configures configuration entities based on SRD:

- If you delete an SRD (in the SRDs table) that is associated with other configuration entities in other tables, the device automatically deletes the associated table rows. For example, if you delete an SRD that is associated with a Proxy Set, the device automatically deletes the Proxy Set.
- If you associate an SRD with a configuration entity in another table (i.e., other than the SRDs table), the device automatically configures certain parameters of the configuration entity according to the SRD or associated SRD. For example, if you add a rule in the IP-to-IP Routing table and you select a Routing Policy, the 'Source IP Group' and 'Destination IP Group' parameters list only IP Groups that re associated with the SRD to which the Routing Policy is assigned (and IP Groups belonging to a Shared SRD, if exists).
- If your configuration setup includes only a single SRD, the device automatically selects the SRD when adding related configuration entities. For example, when adding an IP Group, the single SRD is automatically selected in the Add Row dialog box.

## Configuring SIP Interfaces

The SIP Interfaces table lets you configure up to 80 SIP Interfaces. A SIP Interface represents a Layer-3 network in your deployment environment, by defining a local, listening port number and type (e.g., UDP), and assigning an IP network interface for SIP signaling traffic. For example, if your deployment consists of an IP PBX in the LAN, a SIP Trunk in the WAN, and remote far-end users in the WAN, you would need to configure a SIP Interface for each of these SIP entities. You can configure SIP Interfaces for the different types of applications (SBC and

Gateway). You can also configure various optional features for the SIP Interface such as assigning it a Media Realm, blocking calls received on the SIP Interface from users not registered with the device, and enabling direct media (media bypass).

Each SIP Interface can be associated with only one SRD. As the SRD configuration entity represents your VoIP deployment SIP network (Layer 5), you need to associate your SIP Interfaces with a specific SRD in order to represent your Layer-3 networks. For most deployments (except multi-tenant deployments), your SRD represents your entire network and thus, only one SRD is required. The device provides a default SRD and in such scenarios where only a single SRD is required, your SIP Interfaces are automatically assigned to the default SRD. Therefore, there is no need to even handle SRD configuration entity.

Once configured, you can apply SIP Interfaces to calls, by assigning them to the following configuration entities in their respective tables:

- (Mandatory) Proxy Set to specify the SIP Interface for communication with the proxy server (i.e., IP Group). For more information, see [Configuring Proxy Sets](#) on page 632.
- Intrusion Detection System (IDS) for applying the IDS policy to a specific SIP Interface. For more information, see [Configuring IDS Policies](#) on page 264.
- (SBC application only) IP-to-IP Routing rules for specifying the destination SIP Interface to where you want to route the call. For more information, see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186.
- (SBC application only) Classification rules for specifying the SIP Interface as a matching characteristic of the incoming call. This is especially useful for the single SRD-configuration topology, where each SIP Interface represents a Layer-3 network (SIP entity). Therefore, classification of calls to IP Groups (SIP entities) can be based on SIP Interface.

The SIP Interface can also be used for tag-based classification of incoming SIP dialogs if the SIP Interface is configured with a Call Setup Rule Set ID that determines the source tag. For more information, see [Configuring Classification Based on Tags](#) on page 1183.

For more information on classification, see [Configuring Classification Rules](#) on page 1171.

- (Gateway application only) Tel-to-IP Routing rules for specifying the destination SIP Interface to where you want to route Tel-to-IP calls. For more information, see [Configuring Tel-to-IP Routing Rules](#) on page 946.
- (Gateway application only) IP-to-Trunk Group Routing rules for specifying the SIP Interface as a matching characteristics for the incoming IP call.

The device terminates active calls associated with a SIP Interface if you do one of the following:

- Delete the associated SIP Interface.
- Edit any of the following fields of the associated SIP Interface: 'Application Type', 'UDP Port', 'TCP Port', 'TLS Port' or 'SRD' fields.
- Edit or delete a network interface in the IP Interfaces table that is associated with the SIP Interface.

The following procedure describes how to configure SIP interfaces through the Web interface. You can also configure it through ini file [SIPInterface] or CLI (`configure voip > sip-interface`).

➤ **To configure a SIP Interface:**

1. Open the SIP Interfaces table (**Setup** menu > **Signaling & Media** tab > **Core Entities** folder > **SIP Interfaces**).
2. Click **New**; the following dialog box appears:

3. Configure a SIP Interface according to the parameters described in the table below.
4. Click **Apply**.

**Table 18-5: SIP Interfaces table Parameter Descriptions**

Parameter	Description
'SRD' srd-name [SRDName]	<p>Assigns an SRD to the SIP Interface.</p> <p>If only one SRD is configured in the SRDs table, the SRD is assigned to the SIP Interface by default. If multiple SRDs are configured in the SRDs table, no value is defined and you must assign an SRD.</p> <p>To configure SRDs, see <a href="#">Configuring SRDs</a> on page 558.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ You can assign the same SRD to multiple SIP Interfaces (SBC and Gateway).</li> </ul>
<b>General</b>	
'Index' [Index]	<p>Defines an index for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>

Parameter	Description
<p>'Name'</p> <p>interface-name</p> <p>[InterfaceName]</p>	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, if you do not configure a name, the device automatically assigns the name "&lt;row index&gt;" (e.g., "SIPInterface_1" when added to Index 1).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
<p>'Topology Location'</p> <p>topology-location</p> <p>[TopologyLocation]</p>	<p>Defines the display location of the SIP Interface in the Topology view in the Web interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Down</b> = (Default) The SIP Interface element is displayed on the lower border of the view.</li> <li>■ [1] <b>Up</b> = The SIP Interface element is displayed on the upper border of the view.</li> </ul> <p>For more information on the Topology view, see <a href="#">Building and Viewing SIP Entities in Topology View</a> on page 654.</p>
<p>'Network Interface'</p> <p>network-interface</p> <p>[NetworkInterface]</p>	<p>Assigns an IP Interface to the SIP Interface. By default, no value is defined.</p> <p>To configure IP Interfaces, see <a href="#">Configuring IP Network Interfaces</a> on page 159.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ The 'Application Type' parameter of the assigned IP Interface must at least include "Control".</li> </ul>
<p>'Application Type'</p> <p>application-type</p>	<p>Defines the application for which the SIP Interface is used.</p>

Parameter	Description
[ApplicationType]	<ul style="list-style-type: none"> <li>■ [0] <b>GW</b> = (Default) Gateway application.</li> <li>■ [2] <b>SBC</b> = SBC application.</li> </ul>
'UDP Port' udp-port [UDPPort]	<p>Defines the device's listening and source port for SIP signaling traffic over UDP.</p> <p>The valid range is 1 to 65534. The default is 5060.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The port number <b>must</b> be different from ports configured for RTP traffic (i.e., ports configured for Media Realms and Media Realm Extensions) using the same IP network interface. For example, if the RTP port range is 6000 to 6999, the SIP port can either be less than 6000 or greater than 6999.</li> <li>■ Each SIP Interface must have a unique UDP signaling port within its underlying network interface (i.e., no port overlapping between such SIP Interfaces). For example:               <ul style="list-style-type: none"> <li>✓ Valid configuration:                   <ul style="list-style-type: none"> <li>● SIP Interface #0: 'UDP Port' = 6010; 'Network Interface' = #0</li> <li>● SIP Interface #1: 'UDP Port' = 6010; 'Network Interface' = #1</li> </ul> </li> <li>✓ Invalid configuration:                   <ul style="list-style-type: none"> <li>● SIP Interface #0: 'UDP Port' = 6010; 'Network Interface' = #0</li> <li>● SIP Interface #1: 'UDP Port' = 6010; 'Network Interface' = #0</li> </ul> </li> </ul> </li> </ul>
'TCP Port' tcp-port [TCPPort]	<p>Defines the device's listening port for SIP signaling traffic over TCP.</p> <p>The valid range is 1 to 65534. The default is 5060.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the specific SIP Interface, the TCP</li> </ul>

Parameter	Description
	<p>port number must be different from the TLS port number (configured by the 'TLS Port' parameter below).</p> <ul style="list-style-type: none"> <li>■ The port must be different from the TCP port configured for Media Realms and Media Realm Extensions that use the same IP Interface.</li> <li>■ The source ports used for outgoing TCP connections are not configurable and are dynamically determined by the device in the range of 32,768-61,000.</li> <li>■ Each SIP Interface must have a unique TCP signaling port within its underlying network interface (i.e., no port overlapping between such SIP Interfaces). For example: <ul style="list-style-type: none"> <li>✓ Valid configuration: <ul style="list-style-type: none"> <li>● SIP Interface #0: 'TCP Port' = 6010; 'Network Interface' = #0</li> <li>● SIP Interface #1: 'TCP Port' = 6010; 'Network Interface' = #1</li> </ul> </li> <li>✓ Invalid configuration: <ul style="list-style-type: none"> <li>● SIP Interface #0: 'TCP Port' = 6010; 'Network Interface' = #0</li> <li>● SIP Interface #1: 'TCP Port' = 6010; 'Network Interface' = #0</li> </ul> </li> </ul> </li> </ul>
'TLS Port' tls-port [TLSPort]	<p>Defines the device's listening port for SIP signaling traffic over TLS.</p> <p>The valid range is 1 to 65534. The default is 5061.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the specific SIP Interface, the TLS port number must be different from the TCP port number (configured by the 'TCP Port' parameter above).</li> <li>■ The port must be different from the TCP port configured for Media Realms and</li> </ul>

Parameter	Description
	<p>Media Realm Extensions that use the same IP Interface.</p> <ul style="list-style-type: none"> <li>■ The source ports used for outgoing TLS connections are not configurable and are dynamically determined by the device in the range of 32,768-61,000.</li> <li>■ Each SIP Interface must have a unique TLS signaling port within its underlying network interface (i.e., no port overlapping between such SIP Interfaces). For example: <ul style="list-style-type: none"> <li>✓ Valid configuration: <ul style="list-style-type: none"> <li>• SIP Interface #0: 'TLS Port' = 6020; 'Network Interface' = #0</li> <li>• SIP Interface #1: 'TLS Port' = 6020; 'Network Interface' = #1</li> </ul> </li> <li>✓ Invalid configuration: <ul style="list-style-type: none"> <li>• SIP Interface #0: 'TLS Port' = 6020; 'Network Interface' = #0</li> <li>• SIP Interface #1: 'TLS Port' = 6020; 'Network Interface' = #0</li> </ul> </li> </ul> </li> </ul>
'Additional UDP Ports' additional-udp-ports [AdditionalUDPPorts]	<p>Defines a port range for the device's local, listening and source ports for SIP signaling traffic over UDP. The parameter can be used for the following features:</p> <ul style="list-style-type: none"> <li>■ Assigning a unique port per registered user (User-type IP Group) on the leg interfacing with the proxy server (Server-type IP Group). For enabling this feature and for more information, see the 'User UDP Port Assignment' parameter in the IP Groups table.</li> <li>■ Assigning a specific local port to each SIP entity (e.g., PBX) communicating with a common SIP entity (e.g., proxy server). This is the port on the leg interfacing with the proxy server. In other words,</li> </ul>

Parameter	Description
	<p>the SIP Interface associated with the proxy server. For more information, see <a href="#">Configuring Specific UDP Ports using Tag-based Routing</a> on page 1208</p> <ul style="list-style-type: none"> <li>■ Assigning a unique port for each Account registering with the same Serving IP Group (registrar server). For more information, see <a href="#">Configuring Registration Accounts</a> on page 777.</li> </ul> <p>The valid range is 1,025 to 65535. The range is configured using the syntax x-y, where x is the starting port and y the ending port of the range (e.g., 6000-7000). By default, the parameter is not configured.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ To configure whether the device keeps the configured ports (sockets) open or opens them only when needed, use the SIP Interface's 'Additional UDP Ports Mode' parameter (below).</li> <li>■ The parameter's port range value must not overlap with the UDP port, which is configured by the 'UDP Port' parameter. For example, if the 'UDP Port' parameter is configured to 5070, you cannot configure the 'Additional UDP Ports' parameter with a range of 5060-6000.</li> <li>■ The parameter's port range value must not overlap with UDP port ranges of Media Realms and Media Realm Extensions that are configured on the same network interface. For example, if the RTP port range is 6000-6999, you must configure the 'Additional UDP Ports' parameter to a range that is less than 6000 or greater than 6999.</li> <li>■ The maximum number of ports in the</li> </ul>

Parameter	Description
	<p>range is limited to the maximum number of licensed registered SBC users as specified in the License Key installed on the device, or the maximum number of IP Groups that can be configured (see <a href="#">Configuring IP Groups</a> on page 591) - the higher of the two determines it. For example, if the License Key allows 20 users and the maximum IP Groups that can be configured is 10, then the maximum number of ports is 20.</p>
<p>'Additional UDP Ports Mode' additional-udp-ports-mode [AdditionalUDPPortsMode]</p>	<p>Enables the device to open sockets (ports) for signaling only when needed. The parameter applies to the Additional UDP Port feature with dynamic port allocation (see the 'Additional UDP Ports' parameter, above). This allows you to configure the additional UDP port range without having to make sure that the total number of configured ports are within the maximum, as defined by the device's License Key.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Always Open</b> = (Default) The device keeps the ports (sockets) that are configured in the SIP Interface's 'Additional UDP Ports' parameter, open all the time.</li> <li>■ [1] <b>Open When Used</b> = For the ports (sockets) that are configured in the SIP Interface's 'Additional UDP Ports' parameter, the device opens a port only when it is used. A port is needed when the device initiates registration with an external SIP entity for a SIP Account (sent to the Account's Serving IP Group), or forwards a registration request from a user (IP Group) to a proxy (Server-type IP Group). This option is applicable only to dynamic port allocation, where a port is allocated on the outgoing REGISTER message and closed when the</li> </ul>

Parameter	Description
	<p>registration expires. For HA systems, upon a switchover, all the ports used in the active device are also opened on the redundant device (now active), so that the SIP entity is reachable. Ports that are not configured by the SIP Interface's 'Additional UDP Ports' parameter are closed. The option is applicable only when the SIP Interface's 'Additional UDP Ports' parameter is configured and enabled for a Server-type IP Group (IP Group's 'User UDP Port Assignment' parameter) and/or SIP Account (Account's 'UDP Port Assignment' parameter).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ For static port allocation (i.e., using additional UDP ports feature for assigning a specific local port to each SIP entity), configure the parameter to <b>Always Open</b>.</li> </ul>
'Encapsulating Protocol' encapsulating-protocol [EncapsulatingProtocol]	<p>Defines the type of incoming traffic (SIP messages) expected on the SIP Interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No Encapsulation</b>= (Default) Regular (non-WebSocket) traffic.</li> <li>■ [1] <b>WebSocket</b> = Traffic received on the SIP Interface is identified by the device as WebSocket signaling traffic (encapsulated by WebSocket frames). For outgoing traffic, the device encapsulates the traffic using the WebSocket protocol (frames) on the TCP/TLS ports.</li> </ul> <p>For more information on SIP over WebSocket (and WebRTC), see <a href="#">SIP over WebSocket</a> on page 1272.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ WebSocket encapsulation is not supported for UDP ports.</li> <li>■ If you're using WebSocket tunneling, the IP address <b>169.254.0.1</b> must not be configured for any IP Interface in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159).</li> </ul>
'Enable TCP Keepalive' tcp-keepalive-enable [TCPKeepaliveEnable]	<p>Enables the TCP Keep-Alive mechanism with the IP entity on this SIP Interface. TCP keep-alive can be used, for example, to keep a NAT entry open for clients located behind a NAT server, or simply to check that the connection to the IP entity is available.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> To configure TCP keepalive, use the following parameters: [TCPKeepAliveTime], [TCPKeepAliveInterval], and [TCPKeepAliveRetry].</p>
'Used By Routing Server' used-by-routing-server [UsedByRoutingServer]	<p>Enables the SIP Interface to be used by ARM for call routing decisions.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Used</b> (default)</li> <li>■ [1] <b>Used</b></li> </ul> <p>For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</p>
'Pre-Parsing Manipulation Set' pre-parsing-man-set [PreParsingManSetName]	<p>Assigns a Pre-Parsing Manipulation Set to the SIP Interface. This lets you apply pre-parsing SIP message manipulation rules on any incoming SIP message received on this SIP Interface.</p> <p>By default, no Pre-Parsing Manipulation Set is assigned.</p> <p>To configure Pre-Parsing Manipulation Sets, see <a href="#">Configuring Pre-Parsing Manipulation Rules</a> on page 870.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Pre-Parsing Manipulation is done only on incoming calls.</li> <li>■ The device performs Pre-Parsing Manipulation before Pre-Classification Manipulation and Classification.</li> </ul>
<p>'CAC Profile'</p> <p>cac-profile</p> <p>[AdmissionProfile]</p>	<p>Assigns a Call Admission Control Profile (CAC rules) to the SIP Interface.</p> <p>By default, no value is defined.</p> <p>To configure CAC Profiles, see <a href="#">Configuring Call Admission Control</a> on page 1164.</p>
Classification	
<p>'Classification Failure Response Type'</p> <p>classification-fail-response-type</p> <p>[ClassificationFailureResponseType]</p>	<p>Defines the SIP response code that the device sends if a received SIP request (OPTIONS, REGISTER, or INVITE) fails the SBC Classification process.</p> <p>The valid value can be a SIP response code from 400 through 699, or it can be set to 0 to not send any response at all. The default response code is 500 (Server Internal Error).</p> <p>This feature is important for preventing Denial of Service (DoS) attacks, typically initiated from the WAN. Malicious attackers can use SIP scanners to detect ports used by SIP devices. These scanners scan devices by sending UDP packets containing a SIP request to a range of specified IP addresses, listing those that return a valid SIP response. Once the scanner finds a device that supports SIP, it extracts information from the response and identifies the type of device (IP address and name) and can execute DoS attacks. A way to defend the device against such attacks is to not send a SIP reject response to these unclassified "calls" so that the attacker assumes that no device exists at such an IP address and port.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the device to reject unclassified calls, which is done using the 'Unclassified Calls' parameter (see <a href="#">Configuring Classification Rules</a> on page 1171).</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Pre Classification Manipulation Set ID'</p> <p>preclassification-manset</p> <p>[PreClassificationManipulationSet]</p>	<p>Assigns a Message Manipulation Set ID to the SIP Interface. This lets you apply SIP message manipulation rules on incoming SIP initiating-dialog request messages (not in-dialog), received on this SIP Interface, prior to the Classification process.</p> <p>By default, no Message Manipulation Set ID is defined.</p> <p>To configure Message Manipulation rules, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The Message Manipulation Set assigned to a SIP Interface that is associated with an outgoing call, is ignored. Only the Message Manipulation Set assigned to the associated IP Group is applied to the outgoing call.</li> <li>■ If both the SIP Interface and IP Group associated with the incoming call are assigned a Message Manipulation Set, the one assigned to the SIP Interface is applied first.</li> <li>■ If Classification fails or the request is rejected prior to the Classification stage, then manipulation rules according to this parameter are applied to the reject response. In this case, the device adds a Reason header to the reject response. If routing fails, manipulation on the reject response is according to the 'Outbound Message Manipulation Set' parameter of</li> </ul>

Parameter	Description
	<p>the classified IP Group. When a Reason header is added to the reject response, its value is according to the type of failure:</p> <ul style="list-style-type: none"> <li>✓ Routing failure: "General Routing Failure"</li> <li>✓ Classification failure: "Classification Failure"</li> <li>✓ Pre-Classification rejection due to device overload: "Board In Overload"</li> <li>✓ Pre-Classification rejection due to locked device: "Board Is Locked"</li> <li>✓ Pre-Classification rejection due to too many SIP headers in the request: "Header Overflow"</li> <li>✓ Post-Classification failure of a REGISTER request when the source IP Group doesn't allow registers from the IP Group: "IPGroup Registration Mode Configuration"</li> </ul> <p>■ The parameter is applicable only to the SBC application.</p>
<p>'Call Setup Rules Set ID'</p> <p><code>call-setup-rules-set-id</code></p> <p>[CallSetupRulesSetId]</p>	<p>Assigns a Call Setup Rules Set ID to the SIP Interface. The Call Setup Rule is run before the Classification stage.</p> <p>By default, no Call Setup Rules Set ID is defined.</p> <p>To configure Call Setup Rules, see <a href="#">Configuring Call Setup Rules</a> on page 809.</p> <p>Call Setup Rules can be used for Classification of incoming calls to IP Groups based on tags (source), as described in <a href="#">Configuring Classification Based on Tags</a> on page 1183.</p> <p><b>Note:</b></p> <p>■ Call Setup Rules that are triggered from the SIP Interfaces table are done after</p>

Parameter	Description
	<p>identifying the incoming SIP Interface, but before classification, manipulation and routing. Call Setup Rules can run asynchronous queries for services such as LDAP, ENUM, and HTTP, as well as synchronous queries such as Dial Plan queries. For example, an asynchronous query can be sent to an external HTTP server (AudioCodes ARM) for a source tag, which can then be used to classify the incoming SIP INVITE request to a source IP Group.</p> <ul style="list-style-type: none"> <li>■ Call Setup Rules can be used to generated source and destination tags. For classification, only source tags are used.</li> <li>■ Using Call Setup Rules with the SIP Interface is suitable for actions that affect the source and the Classification of SIP dialog requests (such as modifying source tags or modifying the From header). It's not suitable for actions that affect the destination of the request and its routing (such as modifying the Request-URI header) because it might conflict with other features.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Classify By Registration DB' classify-by-reg-db [ClassifyByRegDB]	<p>Enables classification to IP Groups of incoming SIP dialog-initiating requests (e.g., INVITE) by the device's users registration database.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Disables classification of incoming dialog-initiating SIP requests by the users registration database. The device skips this classification stage and attempts to classify the SIP request by Proxy Set. If this classification stage fails, the device attempts classification by the Classification table (see <a href="#">Configuring</a></li> </ul>

Parameter	Description
	<p><a href="#">Classification Rules</a> on page 1171).</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = (Default) Enables classification of incoming dialog-initiating SIP requests by the users registration database.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
Media	
<p>'Media Realm'</p> <p>media-realm-name</p> <p>[MediaRealm]</p>	<p>Assigns a Media Realm to the SIP Interface. By default, no value is defined.</p> <p>To configure Media Realms, see <a href="#">Configuring Media Realms</a> on page 548.</p>
<p>'Direct Media'</p> <p>sbc-direct-media</p> <p>[SBCDirectMedia]</p>	<p>Enables direct media (RTP/SRTP) flow or media bypass (i.e., no Media Anchoring) between endpoints associated with the SIP Interface for SBC calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Media Anchoring is employed, whereby the media stream traverses the device (and each leg uses a different coder or coder parameters).</li> <li>■ [1] <b>Enable</b> = Direct Media is enabled (i.e., no Media Anchoring). Media stream flows directly between the endpoints (i.e., doesn't traverse the device).</li> <li>■ [2] <b>Enable when Same NAT</b> = Direct Media is enabled (i.e., no Media Anchoring). Media stream flows directly between the endpoints if they are located behind the same NAT.</li> </ul> <p>For more information on direct media, see <a href="#">Direct Media Calls</a> on page 1135.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is enabled for direct media and the two endpoints belong to the same SIP Interface, calls cannot be established if the following scenario exists:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ One of the endpoints is defined as a foreign user (for example, “follow me service”)</li> <li>✓ and one endpoint is located on the WAN and the other on the LAN.</li> </ul> <p>The reason for the above is that in direct media, the device doesn't interfere in the SIP signaling such as manipulation of IP addresses, which is necessary for calls between LAN and WAN.</p> <ul style="list-style-type: none"> <li>■ To enable direct media for all calls, use the global parameter [SBCDirectMedia]. If the global parameter is enabled but the SIP Interface is disabled for direct media, direct media is employed for calls belonging to the SIP Interface. If the global parameter is disabled and the SIP Interface is enabled for direct media, direct media is employed for calls belonging to the SIP Interface.</li> <li>■ If you enable direct media for the SIP Interface, make sure that your Media Realm provides sufficient ports, as media may traverse the device for mid-call services (e.g., call transfer).</li> <li>■ If you have configured a SIP Recording rule (see <a href="#">SIPREC SIP-based Media Recording</a> on page 339) for calls associated with this SIP Interface, the device automatically disables direct media for these calls (during their SIP signaling setup). This ensures that the media passes through the device so that it can be recorded and sent to the SRS. However, if you enable direct media using the [SBCDirectMedia] global parameter (i.e., for all calls), direct media is always enforced and calls will not be recorded.</li> <li>■ Regardless of this parameter's settings,</li> </ul>

Parameter	Description
	<p>the device always handles calls whose incoming SIP dialog-initiating request (e.g., INVITE message) contains the proprietary SIP header 'X-AC-Action' with the value 'direct-media' (i.e., 'X-AC-Action: direct-media'), as direct media calls. These calls remain as direct media calls until they end.</p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'MSRP TCP Port'</p> <p><code>msrp-tcp-port</code></p> <p>[MSRPTCPPort]</p>	<p>Defines the listening TCP port for MSRP sessions.</p> <p>The valid range is 4000 to 32768. The default is 0.</p> <p>The port number is used in the SDP's 'a=path' line.</p> <p>For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b> The port number must be unique for the SIP Interface (i.e., different to 'MSRP TLS Port', 'UDP Port', 'TCP Port' and 'TLS Port' parameters).</p>
<p>'MSRP TLS Port'</p> <p><code>msrp-tls-port</code></p> <p>[MSRPTLSPort]</p>	<p>Defines the listening TLS port for secured MSRP sessions (MSRPS).</p> <p>The valid range is 4000 to 32768. The default is 0.</p> <p>The port number is used in the SDP body's 'a=path' line.</p> <p>For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The port number must be unique for the SIP Interface (i.e., different to 'MSRP TCP Port', 'UDP Port', 'TCP Port' and 'TLS Port' parameters).</li> <li>■ For MSRPS, you also need to assign a TLS Context to the SIP Interface (see 'TLS</li> </ul>

Parameter	Description
	Context Name' parameter below).
Security	
'TLS Context Name' tls-context-name [TLSContext]	<p>Assigns a TLS Context (TLS configuration) to the SIP Interface.</p> <p>The default TLS Context ("default" at Index 0) is assigned to the SIP Interface by default.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For incoming calls: The assigned TLS Context is used if no TLS Context is configured for the Proxy Set associated with the call or classification to an IP Group based on Proxy Set fails.</li> <li>■ For outgoing calls: The assigned TLS Context is used if no TLS Context is configured for the Proxy Set associated with the call.</li> <li>■ To configure TLS Contexts, see <a href="#">TLS Certificates</a> on page 227.</li> </ul>
'TLS Mutual Authentication' tls-mutual-auth [TLSMutualAuthentication]	<p>Enables TLS mutual authentication for the SIP Interface (when the device acts as a server).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Device doesn't request the client certificate for TLS connection on the SIP Interface.</li> <li>■ [1] <b>Enable</b> = Device requires receipt and verification of the client certificate to establish the TLS connection on the SIP Interface.</li> </ul> <p>By default, no value is defined and the global 'TLS Mutual Authentication' parameter [SIPSRequireClientCertificate] is applied.</p>
'Message Policy' message-policy-name [MessagePolicyName]	<p>Assigns a SIP message policy to the SIP interface.</p> <p>To configure SIP Message Policy rules, see <a href="#">Configuring SIP Message Policy Rules</a> on page 867.</p>

Parameter	Description
'User Security Mode' block-un-reg-users [BlockUnRegUsers]	<p>Defines the blocking (reject) policy for incoming SIP dialog-initiating requests (e.g., INVITE messages) from registered and unregistered users belonging to the SIP Interface.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) The corresponding parameter in the SRDs table ('User Security Mode') of the SRD that is associated with the SIP Interface is applied.</li> <li>■ [0] <b>Accept All</b> = Accepts requests from registered and unregistered users.</li> <li>■ [1] <b>Accept Registered Users</b> = Accepts requests only from users registered with the device. Requests from users not registered are rejected.</li> <li>■ [2] <b>Accept Registered Users from Same Source</b> = Accepts requests only from registered users whose source address is the same as that registered with the device (during the REGISTER message process). All other requests are rejected. If the transport protocol is UDP, the device verifies the IP address and port; otherwise, it verifies only the IP address. The verification is performed before any of the device's call handling processes (i.e., Classification, Manipulation and Routing).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to calls belonging to User-type IP Groups.</li> <li>■ The feature is not applicable to REGISTER requests.</li> <li>■ The option, Accept Registered Users from Same Source [2] doesn't apply to registration refreshes. These requests are accepted even if the source address is different to that registered with the</li> </ul>

Parameter	Description
	<p>device.</p> <ul style="list-style-type: none"> <li>■ When the device rejects a call, it sends a SIP 500 "Server Internal Error" response to the user. In addition, it reports the rejection (Dialog establish failure - Classification failure) using the Intrusion Detection System (IDS) feature (see <a href="#">Configuring IDS Policies</a> on page 264), by sending an SNMP trap.</li> <li>■ If you configure the parameter to any value other than default [-1], it overrides the corresponding parameter in the SRDs table ('User Security Mode') for the SRD associated with the SIP Interface.</li> </ul>
<p>'Enable Un-Authenticated Registrations'</p> <p><code>enable-un-auth-registrs</code></p> <p>[EnableUnAuthenticatedRegistrations]</p>	<p>Enables the device to accept REGISTER requests and register them in its registration database from new users that have not been authenticated by a proxy/registrar server (due to proxy down) and thus, re-routed to a User-type IP Group.</p> <p>In normal operation scenarios in which the proxy server is available, the device forwards the REGISTER request to the proxy and if authenticated by the proxy (i.e., device receives a success response), the device adds the user to its registration database. The routing to the proxy is according to the SBC IP-to-IP Routing table where the destination is the proxy's IP Group. However, when the proxy is unavailable (e.g., due to network connectivity loss), the device can accept REGISTER requests from new users if a matching alternative routing rule exists in the SBC IP-to-IP Routing table where the destination is the user's User-type IP Group (i.e., call survivability scenarios) and if the parameter is enabled.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) The corresponding parameter in the SRDs table ('Enable Un-Authenticated</li> </ul>

Parameter	Description
	<p>Registrations') of the SRD associated with the SIP Interface is applied.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = The device rejects REGISTER requests from new users that were not authenticated by a proxy server.</li> <li>■ [1] <b>Enable</b> = The device accepts REGISTER requests from new users even if they were not authenticated by a proxy server, and registers the user in its registration database.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Regardless of the parameter, the device always accepts registration refreshes from users that are already registered in its database.</li> <li>■ If configured to Disable or Enable, the parameter overrides the 'Enable Un-Authenticated Registrations' parameter settings of the SRD (in the SRDs table) that is associated with the SIP Interface.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Max. Number of Registered Users'</p> <p>max-reg-users</p> <p>[MaxNumOfRegUsers]</p>	<p>Defines the maximum number of users belonging to the SIP Interface that can register with the device.</p> <p>By default, no value is defined (i.e., the number of allowed user registrations is unlimited).</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>

## Configuring IP Groups

The IP Groups table lets you configure up to 80 IP Groups. An IP Group represents a SIP entity in the network with which the device communicates. This can be a server (e.g., IP PBX or ITSP) or a group of users (e.g., LAN IP phones). For servers, the address of the IP Group is typically defined by associating it with a Proxy Set (see [Configuring Proxy Sets](#) on page 632).

You can use IP Groups for the following:

- (SBC Application ) Classifying incoming SIP dialog-initiating requests (e.g., INVITE messages) to IP Groups based on Proxy Set. If the source address of the incoming SIP dialog is defined for a Proxy Set, the device assigns ("bonds") the SIP dialog to the IP Group associated with the Proxy Set. The feature is configured using the IP Groups table's 'Classify by Proxy Set' parameter.
- (SBC Application ) Classifying incoming SIP dialog-initiating requests (e.g., INVITE messages) to IP Groups based on source tags of the incoming dialog. Tag-based classification occurs only if Classification based on user registration and on Proxy Set fail. For more information, see [Configuring Classification Based on Tags](#) on page 1183.
- (SBC Application) Representing the source and destination of calls in IP-to-IP Routing rules (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186).
- SIP dialog registration and authentication (digest user/password) of specific IP Groups (Served IP Group, e.g., corporate IP-PBX) with other IP Groups (Serving IP Group, e.g., ITSP). This is configured in the Accounts table (see [Configuring Registration Accounts](#) on page 777).
- (Gateway Application) Call routing rules:
  - Tel-to-IP calls: The IP Group is used as the destination of the outgoing IP call and is used in Tel-to-IP call routing rules (see [Configuring Tel-to-IP Routing Rules](#) on page 946).
  - IP-to-Tel calls: The IP Group identifies the source of the IP call and is used in IP-to-Tel call routing rules (see [Configuring IP-to-Tel Routing Rules](#) on page 960).
  - Number manipulation: The IP Group can be associated with a number manipulation rule (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983).
- Included in routing decisions by ARM. If necessary for routing, ARM can even create an IP Group. For more information, see [Centralized Routing by ARM \(AudioCodes Routing Manager\)](#) on page 451.

You can also apply the device's Quality of Experience feature to IP Groups:

- **Quality of Experience Profile:** Call quality monitoring based on thresholds for voice metrics (e.g., MOS) can be applied per IP Group. For example, if MOS is considered poor, calls belonging to this IP Group can be rejected. To configure Quality of Experience Profiles, see [Configuring Quality of Experience Profiles](#) on page 528.
- **Bandwidth Profile:** Bandwidth utilization thresholds can be applied per IP Group. For example, if bandwidth thresholds are crossed, the device can reject any new calls on this IP Group. To configure Bandwidth Profiles, see [Configuring Bandwidth Profiles](#) on page 535.

- For the Gateway application, regarding table row index #0:
  - ✓ it is recommended to **not** configure any IP Group in table row index #0. This index number entity is not supported by certain device functionality (e.g., not counted in performance monitoring).
  - ✓ IP Group in row index #0 cannot be associated with Proxy Set row index #0.
  - ✓ If no IP Group exists in the IP Groups table, the device rejects all Gateway calls. Even if you are not using IP Groups to route calls, IP Group row index #0 (default) must exist for the device to route calls.
- If you delete an IP Group or modify the 'Type' or 'SRD' parameters, the device immediately terminates currently active calls that are associated with the IP Group. In addition, all users belonging to the IP Group are removed from the device's users database.

The following procedure describes how to configure IP Groups through the Web interface. You can also configure it through ini file [IPGroup] or CLI (`configure voip > ip-group`).

➤ **To configure an IP Group:**

1. Open the IP Groups table (**Setup** menu > **Signaling & Media** tab > **Core Entities** folder > **IP Groups**).
2. Click **New**; the following dialog box appears:

3. Configure an IP Group according to the parameters described in the table below.
4. Click **Apply**.

**Table 18-6: IP Groups Table Parameter Descriptions**

Parameter	Description
'SRD' srd-name [SRDName]	<p>Assigns an SRD to the IP Group.</p> <p>If only one SRD is configured in the SRDs table, the SRD is assigned by default. If multiple SRDs are configured in the SRDs table, no value is assigned by default and you must assign one.</p> <p>To configure SRDs, see <a href="#">Configuring SRDs</a> on page 558.</p> <p><b>Note:</b> The parameter is mandatory.</p>

Parameter	Description
General	
'Index' [Index]	<p>Defines an index for the new table row.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the Gateway application, regarding table row index #0: <ul style="list-style-type: none"> <li>✓ It is recommended to <b>not</b> configure any IP Group in table row index #0 (even though it is considered valid configuration). This index number is not supported by certain device functionality (e.g., not counted in performance monitoring).</li> <li>✓ IP Group in row index #0 cannot be associated with Proxy Set row index #0.</li> <li>✓ If no IP Group exists in the IP Groups table, the device <b>rejects</b> all Gateway calls. Even if you are not using IP Groups to route calls, IP Group row index #0 (default) must exist for the device to route calls. However, if you have deleted all IP Groups, the device returns IP Group #0 after a device restart.</li> </ul> </li> <li>■ Each row must be configured with a unique index.</li> </ul>
'Name' name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Topology Location' topology-location [TopologyLocation]	<p>Defines the display location of the IP Group in the Topology view of the Web interface.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Down</b> = (Default) The IP Group element is displayed on the lower border of the view.</li> <li>■ [1] <b>Up</b> = The IP Group element is displayed on the upper border of the view.</li> </ul> <p>For more information on the Topology view, see <a href="#">Building and Viewing SIP Entities in Topology View</a> on page 654.</p>

Parameter	Description
'Type' type [Type]	<p>Defines the type of IP Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Server</b> = Applicable when the destination address of the IP Group (e.g., ITSP, Proxy, IP-PBX, or Application server) is known. The address is configured by the Proxy Set that is associated with the IP Group.</li> <li>■ [1] <b>User</b> = Represents a group of users such as IP phones and softphones where their location is dynamically obtained by the device when REGISTER requests and responses traverse (or are terminated) by the device. These users are considered remote (far-end).</li> </ul> <p>Typically, this IP Group is configured with a Serving IP Group that represents an IP-PBX, Application or Proxy server that serves this <b>User</b>-type IP Group. Each SIP request sent by a user of this IP Group is proxied to the Serving IP Group. For registrations, the device updates its registration database with the AOR and contacts of the users.</p> <p>Digest authentication using SIP 401/407 responses (if needed) is performed by the Serving IP Group. The device forwards these responses directly to the SIP users.</p> <p>To route a call to a registered user, a rule must be configured in the Tel-to-IP Routing table or SBC IP-to-IP Routing table. The device searches the dynamic database (by using the Request-URI) for an entry that matches a registered AOR or Contact. Once an entry is found, the IP destination is obtained from this entry and a SIP request is sent to the destination.</p> <p>The device also supports NAT traversal for the SIP clients located behind NAT. In this case, the device must be defined with a global IP address.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Gateway</b> = (Applicable only to the SBC application) In scenarios where the device receives requests to and from a gateway representing multiple users. This IP Group type is necessary for any of the following scenarios: <ul style="list-style-type: none"> <li>✓ The IP Group cannot be defined as a <b>Server</b>-type since its address is initially unknown and therefore, a Proxy Set cannot be configured for it.</li> </ul> </li> </ul>

Parameter	Description
	<p>✓ The IP Group cannot be defined as a <b>User</b>-type since the SIP Contact header of the incoming REGISTER doesn't represent a specific user. The Request-URI user part can change and therefore, the device is unable to identify an already registered user and therefore, adds an additional record to the database.</p> <p>The IP address of the Gateway-type IP Group is obtained dynamically from the host part of the Contact header in the REGISTER request received from the IP Group. Therefore, routing to this IP Group is possible only once a REGISTER request is received (i.e., IP Group is registered with the device). If a REGISTER refresh request arrives, the device updates the new location (i.e., IP address) of the IP Group. If the REGISTER fails, no update is performed. If an UN-REGISTER request arrives, the IP address associated with the IP Group is deleted and therefore, no routing to the IP Group is done.</p> <p>You can view the registration status of the Gateway-type IP Group in the 'GW Group Registered Status' field, and view the IP address of the IP Group in the 'GW Group Registered IP Address' field if it is registered with the device.</p>
<p>'Proxy Set'</p> <p>proxy-set-name</p> <p>[ProxySetName]</p>	<p>Assigns a Proxy Set to the IP Group. All INVITE messages destined to the IP Group are sent to the IP address configured for the Proxy Set.</p> <p>To configure Proxy Sets, see <a href="#">Configuring Proxy Sets</a> on page 632.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the Gateway application, IP Group ID 0 cannot be associated with Proxy Set ID 0.</li> <li>■ The Proxy Set must be associated with the same SRD as that assigned to the IP Group.</li> <li>■ You can assign the same Proxy Set to multiple IP Groups.</li> <li>■ For the SBC application: Proxy Sets are used for <b>Server</b>-type IP Groups, but may in certain scenarios also be used for <b>User</b>-type IP Groups. For example, this is</li> </ul>

Parameter	Description
	<p>required in deployments where the device mediates between an IP PBX and a SIP Trunk, and the SIP Trunk requires SIP registration for each user that requires service. In such a scenario, the device must register all the users to the SIP Trunk on behalf of the IP PBX. This is done by using the SBC User Information table, where each user is associated with the source IP Group (i.e., the IP PBX). To configure the SBC User Information table, see <a href="#">Configuring SBC User Information</a> on page 802.</p> <ul style="list-style-type: none"> <li>■ For the Gateway application, Proxy Sets are applicable only to Sever-type IP Groups.</li> </ul>
'IP Profile' ip-profile-name [ProfileName]	<p>Assigns an IP Profile to the IP Group.</p> <p>By default, no value is defined.</p> <p>To configure IP Profiles, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
'Media Realm' media-realm-name [MediaRealm]	<p>Assigns a Media Realm to the IP Group. The Media Realm determines the UDP port range and maximum sessions on a specific IP interface for media traffic associated with the IP Group.</p> <p>By default, no value is defined.</p> <p>To configure Media Realms, see <a href="#">Configuring Media Realms</a> on page 548.</p> <p><b>Note:</b> If you delete a Media Realm in the Media Realms table that is assigned to the IP Group, the parameter value reverts to undefined.</p>
'Internal Media Realm' internal-media-realm-name [InternalMediaRealm]	<p>Assigns an "internal" Media Realm to the IP Group. This is applicable when the device is deployed in a Microsoft Teams environment. The device selects this Media Realm (instead of the Media Realm assigned by the 'Media Realm' parameter above) if the value of the X-MS-UserLocation header in the incoming SIP message is "Internal" and the 'Teams Local Media Optimization Handling' parameter (see below) is configured to any value other than <b>None</b>.</p> <p>The Media Realm determines the UDP port range and maximum sessions on a specific IP interface for media traffic associated with the IP Group.</p> <p>By default, no value is defined.</p> <p>To configure Media Realms, see <a href="#">Configuring Media Realms</a></p>

Parameter	Description
	<p>on page 548.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you have configured the 'Teams Local Media Optimization Handling' parameter (see below) to any value other than <b>None</b>.</li> <li>■ If you delete a Media Realm in the Media Realms table that is assigned to the IP Group, the parameter value reverts to undefined.</li> <li>■ If you don't configure the parameter, the device uses the Media Realm that you assigned by the 'Media Realm' parameter.</li> </ul>
'Contact User' contact-user [ContactUser]	<p>Defines the user part of the From, To, and Contact headers of SIP REGISTER messages, and the user part of the Contact header of INVITE messages received from this IP Group and forwarded by the device to another IP Group.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to <b>Server</b>-type IP Groups.</li> <li>■ The parameter is overridden by the 'Contact User' parameter in the Accounts table (see <a href="#">Configuring Registration Accounts</a> on page 777).</li> </ul>
'SIP Group Name' sip-group-name [SIPGroupName]	<p>Defines the hostname (e.g., 194.90.179.0) which the device uses to overwrite the original host part of the URI in certain SIP headers. Therefore, the parameter allows you to implement topology hiding in SIP messages, by concealing the host part of the communicating UAs from each another.</p> <p>For the SBC application: The affected SIP headers depend on whether the IP Group is the destination or source of the call:</p> <ul style="list-style-type: none"> <li>■ <b>Destination IP Group:</b> The device overwrites the host part of the following SIP headers for messages sent (outgoing) to this IP Group:               <ul style="list-style-type: none"> <li>✓ For all requests: Request-URI header (if the destination of the request isn't a registered user or Trunk Group, and the URL in the Request-URI is not</li> </ul> </li> </ul>

Parameter	Description
	<p>GRUU) and P-Called-Party-ID header.</p> <ul style="list-style-type: none"> <li>✓ For all non-REGISTER requests (e.g., INVITE and SUBSCRIBE): To header and Remote-Party-ID header (only the first Remote-Party-ID header whose type is "called" in the message).</li> <li>✓ For INVITE requests only: If the 'Destination URI Input' parameter is configured for the source IP Group, the header type configured by the 'Destination URI Input' parameter is also modified according to the 'SIP Group Name' parameter of the destination IP Group.</li> </ul> <p>■ <b>Source IP Group:</b> The device overwrites the host part of the following SIP headers for messages received (incoming) from this IP Group.</p> <ul style="list-style-type: none"> <li>✓ For all types of requests: From header.</li> <li>✓ For REGISTER requests: To header.</li> <li>✓ For all non-REGISTER requests (e.g., INVITE and SUBSCRIBE): P-Preferred-Identity (only first P-Preferred-Identity header in message), P-Asserted-Identity (only first P-Asserted-Identity header in message), Remote-Party-ID (only the first Remote-Party-ID header whose type is "calling" in the message).</li> <li>✓ For INVITE requests only: If the 'Source URI Input' parameter is configured for the source IP Group, the header type configured by the 'Source URI Input' parameter is also overwritten according to the 'SIP Group Name' parameter of the source IP Group.</li> </ul> <p>The valid value is a string of up to 100 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the SBC application: When the IP Group is the source of the call, if you configure the destination IP Group's 'SIP Source Host Name' parameter (see below), the device ignores the 'SIP Group Name' parameter of the source IP Group. (The 'SIP Source Host Name' parameter also defines a URI host part to overwrite the original source host part, but it affects many more</li> </ul>

Parameter	Description
	<p>source-related SIP headers.)</p> <ul style="list-style-type: none"> <li>■ When the parameter is configured for the source or destination IP Group, it overrides Inbound Message Manipulation rules (assigned by the 'Inbound Message Manipulation Set' parameter to the source IP Group) that manipulate the host part in the Request-URI, To, and From SIP headers. If you configure the parameter and you want to manipulate the host part in any of these SIP headers, assign your Message Manipulation rules to the destination IP Group using the 'Outbound Message Manipulation Set' parameter.</li> <li>■ For the Gateway application: The parameter is not applicable when the IP Group is the source of the call. When the parameter is configured for the destination IP Group, the device uses the configured value to overwrite the host part in the Request-URI and To headers of INVITE requests, and the Request-URI of REGISTER requests sent (outgoing) to this IP Group.</li> <li>■ For the Gateway application: If the IP Group is of User type, the parameter is used internally as a host name in the Request-URI for Tel-to-IP initiated calls. For example, if an incoming call from the device's trunk is routed to a <b>User</b>-type IP Group, the device first creates the Request-URI (&lt;destination_number&gt;@&lt;SIP Group Name&gt;), and then it searches the registration database for a match.</li> </ul>
'Created By Routing Server' [CreatedByRoutingServer]	<p>(Read-only) Indicates if the IP Group was created by ARM:</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b></li> </ul> <p>For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</p>
'Used By Routing Server' used-by-routing-server [UsedByRoutingServer]	<p>Enables the IP Group to be used by ARM for call routing decisions.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Used</b> (default)</li> <li>■ [1] <b>Used</b></li> </ul> <p>For more information on routing by ARM, see <a href="#">Centralized</a></p>

Parameter	Description
	<a href="#">Routing by ARM (AudioCodes Routing Manager)</a> on page 451.
'Proxy Set Connectivity' show voip proxy sets status [ProxySetConnectivity]	<p>(Read-only field) Displays the connectivity status with <b>Server</b>-type IP Groups. As the Proxy Set defines the address of the IP Group, the connectivity check (keep-alive) by the device is done to this address.</p> <ul style="list-style-type: none"> <li>■ "NA": Functionality is not applicable due to one of the following:               <ul style="list-style-type: none"> <li>✓ <b>User</b>-type IP Group.</li> <li>✓ <b>Server</b>-type IP Group, but the keep-alive mechanism of its' associated Proxy Set is disabled.</li> </ul> </li> <li>■ "Not Connected": Keep-alive failure (i.e., no connectivity with the IP Group).</li> <li>■ "Connected": Keep-alive success (i.e., connectivity with the IP Group).</li> </ul> <p>The connectivity status is also displayed in the Topology View page (see <a href="#">Building and Viewing SIP Entities in Topology View</a> on page 654).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The feature is applicable only to <b>Server</b>-type IP Groups.</li> <li>■ To support the feature, you must enable the keep-alive mechanism of the Proxy Set that is associated with the IP Group (see <a href="#">Configuring Proxy Sets</a> on page 632).</li> <li>■ If the Proxy Set is configured with multiple proxies (addresses) and at least one of them is "alive", the displayed status is "Connected". To view the connected proxy server, see <a href="#">Viewing Proxy Set Status</a> on page 1488.</li> <li>■ The "Connected" status also applies to scenarios where the device rejects calls with the IP Group due to low QoE (e.g., low MOS), despite connectivity.</li> </ul>
SBC General	
'Classify By Proxy Set' classify-by-proxy- set [ClassifyByProxySet]	<p>Enables the classification of incoming SIP dialog messages to a <b>Server</b>-type IP Group based on Proxy Set.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = (Default) Enables classification by Proxy Set of all types of incoming SIP dialog messages (e.g., INVITE, OPTIONS, and REGISTER) to a <b>Server</b>-type IP Group.</li> </ul> <p>By default, the device checks if the <b>source IP address</b> (ISO Layer 3) of the incoming SIP dialog matches an IP address in the Proxy Set that is associated with the IP Group (see the 'Proxy Set' parameter). If the Proxy Set is configured with a hostname, the device checks if the source IP address matches one of the dynamically DNS-resolved IP addresses. If such a Proxy Set exists, the device classifies the SIP dialog to the IP Group associated with this Proxy Set.</p> <p>You can also configure classification by Proxy Set whereby the device checks if the IP address in the <b>SIP Contact header</b> of the incoming SIP dialog matches an IP address in the Proxy Set that is associated with the IP Group. If the header contains a SIP URI that has an IP address (not hostname) in the host part and it matches an IP address in the Proxy Set, the call is classified to the IP Group. This mode is useful, for example, when the source IP address is an internal address.</p> <p>To specify which IP address to use (source IP address or SIP Contact header's IP address) in the incoming SIP message for classification by Proxy Set, use the global parameter 'Classify By Proxy Set Mode' (<b>Setup</b> menu &gt; <b>Signaling &amp; Media</b> tab &gt; <b>SIP Definitions</b> folder &gt; <b>SIP Definitions General Settings</b>). When configured to <b>Both</b>, the device first checks if the source IP address matches an IP address in the Proxy Set. Only if there is no match, does it check if the IP address in the SIP Contact header matches an IP address in the Proxy Set.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Enable for OPTIONS</b> = Enables classification by Proxy Set of incoming SIP OPTIONS (only) messages to a <b>Server</b>-type IP Group. For a detailed description of this option, see the description of the <b>Enable</b> value (above).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to <b>Server</b>-type IP Groups.</li> <li>■ For security, it's recommended to classify SIP dialogs</li> </ul>

Parameter	Description
	<p>based on Proxy Set only if the IP address of the IP Group is unknown (i.e., if the Proxy Set associated with the IP Group is configured with an FQDN). In such cases, the device classifies incoming SIP dialogs to the IP Group based on the DNS-resolved IP address.</p> <p>If the IP address is known, it's recommended to use Classification rules instead (and disable the Classify by Proxy Set feature), where the rules are configured with not only the IP address, but also with SIP message characteristics to increase the strictness of the classification process (see <a href="#">Configuring Classification Rules</a> on page 1171).</p> <p>The reason for preferring classification based on Proxy Set when the IP address is unknown is that IP address forgery (commonly known as IP spoofing) is more difficult than malicious SIP message tampering and therefore, using a Classification rule without an IP address offers a weaker form of security. When classification is based on Proxy Set, the Classification table for the specific IP Group is ignored.</p> <ul style="list-style-type: none"> <li>■ If you have assigned the same Proxy Set to multiple IP Groups, disable the parameter and use Classification rules instead to classify incoming SIP dialogs to these IP Groups (see <a href="#">Configuring Classification Rules</a> on page 1171). If the parameter is enabled, the device is unable to correctly classify incoming INVITEs to their appropriate IP Groups.</li> <li>■ Classification by Proxy Set occurs only if classification based on the device's registration database fails (i.e., INVITE isn't from a registered user).</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Validate Source IP' validate-source-ip [ValidateSourceIP]	<p>Enables the device to validate the source IP address of incoming SIP dialog-initiating requests (e.g., INVITE messages) by checking that it matches an IP address (or DNS-resolved IP address) in the Proxy Set that is associated with the IP Group.</p> <p>The feature applies both to messages that were classified to IP Groups by Proxy Set (i.e., by configuring the IP Group's 'Classify By Proxy Set' parameter to <b>Enable</b>), as well as to messages classified by rules in the Classification table (see</p>

Parameter	Description
	<p><a href="#">Configuring Classification Rules</a> on page 1171).</p> <p>This feature is especially useful when you need to classify SIP dialogs originating from the same Proxy Set, into multiple IP Groups, where Classification table rules are necessary to produce the desired mapping to the different IP Groups.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Validation is done after Classification, but before Manipulation and Routing.</li> <li>■ Validation is done for the IP address only (not port, transport, or SIP Interface).</li> <li>■ Upon validation failure, the device rejects the incoming SIP dialog with a 500 SIP response (Reason header value is "Source IP doesn't match Proxy Set").</li> <li>■ Don't enable this parameter if the global 'Classify By Proxy Set Mode' parameter is configured to <b>Contact Header</b> or <b>Both</b>, as in most cases, the source IP address of the SIP message will not be a member of the Proxy Set.</li> <li>■ This feature is typically used for <b>Server</b>-type IP Groups. However, you can also use it for <b>User</b>-type IP Groups.</li> </ul>
<p>'SBC Operation Mode'</p> <p>sbc-operation-mode</p> <p>[SBCOperationMode]</p>	<p>Defines the device's operational mode for the IP Group.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default)</li> <li>■ [0] <b>B2BUA</b> = Device operates as a back-to-back user agent (B2BUA), changing the call identifiers and headers between the inbound and outbound legs.</li> <li>■ [1] <b>Call Stateful Proxy</b> = Device operates as a Stateful Proxy, passing the SIP message transparently between inbound and outbound legs. In other words, the same SIP dialog identifiers (tags, Call-Id and CSeq) occur on both legs (as long as no other configuration disrupts the CSeq compatibleness).</li> <li>■ [2] <b>Microsoft Server</b> = Operating mode for the One-Voice Resiliency feature, whereby the device is</li> </ul>

Parameter	Description
	<p>deployed together with Skype for Business-compatible IP Phones at small remote branch offices in a Microsoft® Skype for Business™ environment.</p> <p>For more information on B2BUA and Stateful Proxy modes, see <a href="#">B2BUA and Stateful Proxy Operating Modes</a> on page 1123.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If configured, the parameter overrides the 'SBC Operation Mode' parameter in the SRDs table.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'SBC Client Forking Mode'</p> <p>sbc-client-forking-mode</p> <p>[EnableSBCCClientForking]</p>	<p>Defines call forking of INVITE messages to up to five separate SIP outgoing legs for <b>User</b>-type IP Groups. This occurs if multiple contacts are registered under the same AOR in the device's registration database.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Sequential</b> = (Default) Sequentially sends the INVITE to each contact. If there is no answer from the first contact, it sends the INVITE to the second contact, and so on until a contact answers. If no contact answers, the call fails or is routed to an alternative destination, if configured.</li> <li>■ [1] <b>Parallel</b> = Sends the INVITE simultaneously to all contacts. The call is established with the first contact that answers.</li> <li>■ [2] <b>Sequential Available Only</b> = Sequentially sends the INVITE only to available contacts (i.e., not busy). If there is no answer from the first available contact, it sends the INVITE to the second contact, and so on until a contact answers. If no contact answers, the call fails or is routed to an alternative destination, if configured.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device can also fork INVITE messages received for a Request-URI of a specific contact (user) registered in the database to all other users located under the same AOR as the specific contact. This is configured by the [SBCSendInviteToAllContacts] parameter.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'CAC Profile'	Assigns a Call Admission Control Profile (CAC rules) to the IP

Parameter	Description
<code>cac-profile</code> [AdmissionProfile]	<p>Group.</p> <p>By default, no value is defined.</p> <p>To configure CAC Profiles, see <a href="#">Configuring Call Admission Control</a> on page 1164.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'SIP Source Host Name' <code>sip-source-host-name</code> [SIPSourceHostName]	<p>Defines a hostname, which the device uses to overwrite the hostname of the URI in certain SIP headers. The parameter allows you to implement topology hiding for the source of SIP messages, by concealing the hostname of the source UA.</p> <p>The valid value is a string of up to 100 characters. By default, no value is defined.</p> <p>When the device forwards a SIP message to this IP Group, the configured hostname overwrites the host part in SIP headers (see below) that are concerned with the source of the message:</p> <ul style="list-style-type: none"> <li>■ From, P-Asserted-Identity, P-Preferred-Identity, Referred-By, P-Charge-Info, Remote-Party-ID, P-Associated-URI, Diversion, and History-info headers.</li> <li>■ If you configure the global parameter 'SIP Topology Hiding Mode' parameter to <b>Fallback to IP Addresses</b> and the 'Remote REFER Mode' parameter to <b>Regular</b> (default), the host part in the Refer-To header is also overwritten.</li> <li>■ For REGISTER requests, the host part in the To header is also overwritten.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only when the IP Group is the destination of the call (not source).</li> <li>■ This parameter has higher priority than the 'SIP Group Name' parameter (see above) of the source IP Group. When this parameter is configured, the device ignores the value of the 'SIP Group Name' parameter that is configured for the source IP Group.</li> <li>■ The parameter is applicable only to SIP dialog-initiating requests and in-dialog REFER requests.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>

Parameter	Description
<b>Advanced</b>	
'Local Host Name' local-host-name [ContactName]	<p>Defines the host name (string) that the device uses in the SIP message's Via and Contact headers. This is typically used to define an FQDN as the host name. The device uses this string for Via and Contact headers in outgoing INVITE messages sent to a specific IP Group, and the Contact header in SIP 18x and 200 OK responses for incoming INVITE messages received from a specific IP Group. The IP-to-Tel Routing table can be used to identify the source IP Group from where the INVITE message was received.</p> <p>If the parameter is not configured, these headers are populated with the device's dotted-decimal IP address of the network interface on which the message is sent.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> To ensure proper device handling, the parameter should be a valid FQDN.</p>
'UUI Format' uui-format [UUIFormat]	<p>Enables the generation of the Avaya UCID value, adding it to the outgoing INVITE sent to this IP Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disabled</b> (default)</li> <li>■ [1] <b>Enabled</b></li> </ul> <p>This provides support for interworking with Avaya equipment by generating Avaya's UCID value in outgoing INVITE messages sent to Avaya's network. The device adds the UCID in the User-to-User SIP header.</p> <p>Avaya's UCID value has the following format (in hexadecimal): 00 + FA + 08 + node ID (2 bytes) + sequence number (2 bytes) + timestamp (4 bytes)</p> <p>This is interworked in to the SIP header as follows:</p> <p>User-to-User: 00FA080019001038F725B3;encoding=hex</p> <p><b>Note:</b> To define the Network Node Identifier of the device for Avaya UCID, use the 'Network Node ID' (NetworkNodeId) parameter.</p>
'Always Use Src Address' always-use-source-addr [AlwaysUseSourceAddr]	<p>Enables the device to always send SIP requests and responses, within a SIP dialog, to the source IP address received in the previous SIP message packet. This feature is especially useful in scenarios where the IP Group endpoints are located behind a NAT firewall (and the device is unable</p>

Parameter	Description
	<p>to identify this using its regular NAT mechanism).</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device sends SIP requests according to the settings of the global parameter, SIPNatDetection.</li> <li>■ [1] <b>Yes</b> = The device sends SIP requests and responses to the source IP address received in the previous SIP message packet.</li> </ul> <p>For more information on NAT traversal, see <a href="#">SIP User Agent Located behind NAT</a> on page 183.</p>
SBC Advanced	
'Source URI Input' src-uri-input [SourceUriInput]	<p>Defines the SIP header in the incoming INVITE that is used for call matching characteristics based on source URIs.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> (default)</li> <li>■ [0] <b>From</b></li> <li>■ [1] <b>To</b></li> <li>■ [2] <b>Request-URI</b></li> <li>■ [3] <b>P-Asserted - First Header</b></li> <li>■ [4] <b>P-Asserted - Second Header</b></li> <li>■ [5] <b>P-Preferred</b></li> <li>■ [6] <b>Route</b></li> <li>■ [7] <b>Diversion</b></li> <li>■ [8] <b>P-Associated-URI</b></li> <li>■ [9] <b>P-Called-Party-ID</b></li> <li>■ [10] <b>Contact</b></li> <li>■ [11] <b>Referred-by</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ The parameter is applicable only when classification is done according to the Classification table (see <a href="#">Configuring Classification Rules</a> on page 1171).</li> <li>■ Once classified, the device uses the URI of the selected header for the following SIP headers in the outgoing</li> </ul>

Parameter	Description
	<p>INVITE: From, P-Asserted (if exists), P-Preferred (if exists), and Remote-Party-ID (if exists).</p> <ul style="list-style-type: none"> <li>■ If the configured SIP header doesn't exist in the incoming INVITE message, the classification of the message to a source IP Group fails.</li> <li>■ If the device receives an INVITE as a result of a REFER request or a 3xx response, then the incoming INVITE is routed according to the Request-URI. The device identifies such INVITEs according to a specific prefix in the Request-URI header, configured by the SBCXferPrefix parameter. Therefore, in this scenario, the device ignores the parameter setting.</li> </ul>
'Destination URI Input' dst-uri-input [DestUriInput]	<p>Defines the SIP header in the incoming INVITE to use as a call matching characteristic based on destination URIs. The parameter is used for classification and routing purposes. The device first uses the parameter's settings as a matching characteristic (input) to classify the incoming INVITE to an IP Group (source IP Group) in the Classification table. Once classified, the device uses the parameter for routing the call. For example, if set to To, the URI in the To header of the incoming INVITE is used as a matching characteristic for classifying the call to an IP Group in the Classification table. Once classified, the device uses the URI in the To header as the destination.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> (default)</li> <li>■ [0] <b>From</b></li> <li>■ [1] <b>To</b></li> <li>■ [2] <b>Request-URI</b></li> <li>■ [3] <b>P-Asserted - First Header</b></li> <li>■ [4] <b>P-Asserted - Second Header</b></li> <li>■ [5] <b>P-Preferred</b></li> <li>■ [6] <b>Route</b></li> <li>■ [7] <b>Diversion</b></li> <li>■ [8] <b>P-Associated-URI</b></li> <li>■ [9] <b>P-Called-Party-ID</b></li> <li>■ [10] <b>Contact</b></li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ <b>[11] Referred-By</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ The parameter can be configured for an IP Group regardless of the way in which SIP requests are classified to the IP Group (by Classification table, by Proxy Set or by the Registration database).</li> <li>■ The Request-URI in the outbound side is modified according to the header selected by this parameter (if this parameter is configured), unless the Request-URI is overridden again by some other feature (e.g., Outbound Message Manipulations).</li> <li>■ If the configured SIP header doesn't exist in the incoming INVITE message, the classification of the message to a source IP Group fails.</li> <li>■ If the device receives an INVITE as a result of a REFER request or a 3xx response, the incoming INVITE is routed according to the Request-URI. The device identifies such INVITEs according to a specific prefix in the Request-URI header, configured by the SBCXferPrefix parameter. Therefore, in this scenario, the device ignores the parameter setting.</li> </ul>
'SIP Connect' sip-connect [SIPConnect]	<p>Defines the IP Group as representing multiple registering servers, each of which may use a single registration, yet represent multiple users. In addition, it defines how the device saves registration information for REGISTER messages received from the IP Group, in its registration database. For requests routed to the IP Group's users, the device replaces the Request-URI header with the incoming To header (which contains the remote phone number).</p> <ul style="list-style-type: none"> <li>■ <b>[0] No</b> = (Default) Disables the SIP Connect feature. No extra key based on source IP address is added to the registration database and registration is done by Contact and Address of Record (AoR).</li> <li>■ <b>[1] Yes</b> = Enables the SIP Connect feature. For initial registrations that are received from the IP Group, the device attempts to add two <i>keys</i> representing the user to its registration database:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Key 1: The first key contains the incoming REGISTER message's source IP address, port (only if UDP), and SIP Interface ID (e.g., "10.33.3.3:5010#1").</li> <li>✓ Key 2: The second key contains the incoming REGISTER message's URI (user@host) of the Contact header, source IP address, port (only if UDP), and SIP Interface ID (e.g., "user@host.com#10.33.3.3:5010#1").</li> </ul> <p>The device classifies incoming non-REGISTER SIP dialog requests (e.g., INVITEs) from this IP Group, by first using the regular user search method in the registration database by Contact-AoR pair matching. If unsuccessful, the device searches the registration database for a matching Key 2 (i.e., Contact URI, source IP address, and port if the transport type is UDP). If no matching Key 2 exists, the device then searches for a matching Key 1 (i.e., source IP address only and port if the transport type is UDP). If no key is found at all, the device continues with the next Classification stage (e.g., by Proxy Set).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to <b>User</b>-type IP Groups.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'SBC PSAP Mode' sbc-psap-mode [SBCPSAPMode]	<p>Enables E9-1-1 emergency call routing in a Microsoft Skype for Business environment.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information, see <a href="#">E9-1-1 Support for Microsoft Teams and Skype for Business</a> on page 498.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Route Using Request URI Port' use-requri-port [SBCRouteUsingRequestURI Port]	<p>Enables the device to use the port indicated in the Request-URI of the incoming message as the destination port when routing the message to the IP Group. The device uses the IP address (and not port) that is configured for the Proxy Set associated with the IP Group. The parameter thus allows the device to route calls to the same server (IP Group), but different port.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The port configured for the associated Proxy Set is used as the destination port.</li> <li>■ [1] <b>Enable</b> = The port indicated in the Request-URI of the incoming message is used as the destination port.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Media TLS Context' dtls-context [DTLSContext]	<p>Assigns a TLS Context (TLS configuration) to the IP Group that is used for secured media sessions (e.g., DTLS) with the IP Group.</p> <p>The default is the default TLS Context ("default" at Index 0). To configure TLS Contexts, see <a href="#">TLS Certificates</a> on page 227. For more information on DTLS, see <a href="#">SRTP using DTLS Protocol</a> on page 324.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Keep Original Call-ID' sbc-keep-call-id [SBCKeepOriginalCallID]	<p>Enables the device to use the same call identification (SIP Call-ID header value) received in incoming messages for the call identification in outgoing messages. The call identification value is contained in the SIP Call-ID header.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device creates a new Call-ID value for the outgoing message.</li> <li>■ [1] <b>Yes</b> = The device uses the same Call-ID value received in the incoming message for the Call-ID in the outgoing message.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ When the device sends an INVITE as a result of a REFER/3xx termination, the device always creates a new Call-ID value and ignores the parameter's settings.</li> </ul>
'Dial Plan' sbc-dial-plan-name [SBCDialPlanName]	<p>Assigns a Dial Plan to the IP Group.</p> <p>The device searches the Dial Plan for a dial plan rule that matches the prefix of the source number and if not found, it searches for a rule that matches the prefix of the destination number. If a matching Dial Plan rule is found, the rule's tag is used in the routing or manipulation processes as the source or destination tag.</p>

Parameter	Description
	<p>To configure Dial Plans, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ For destination tag-based routing (i.e., 'Destination Type' parameter of IP-to-IP Routing rules configured to <b>Destination Tag</b>): <ul style="list-style-type: none"> <li>✓ The parameter is applicable only to the source IP Group. The device searches the Dial Plan for a dial plan rule that matches the prefix of the destination number only.</li> <li>✓ If a destination tag is determined during the routing stage by a Call Setup Rule (i.e., Call Setup Rule Set assigned to the IP-to-IP Routing rule's 'Pre Route Call Setup Rules Set ID' parameter), the tag overrides any other determined tag (i.e., from the Dial Plan or Call Setup Rule Set of the SIP Interface).</li> <li>✓ For more information on tag-based routing, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</li> </ul> </li> </ul>
<p>'Call Setup Rules Set ID'</p> <p>call-setup-rules-set-id</p> <p>[CallSetupRulesSetId]</p>	<p>Assigns a Call Setup Rule Set ID to the IP Group. The device runs the Call Setup rule immediately before the routing stage (i.e., only after the classification and manipulation stages).</p> <p>By default, no value is assigned.</p> <p>To configure Call Setup Rules, see <a href="#">Configuring Call Setup Rules</a> on page 809.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Call Setup Rules that are triggered from the IP Groups table (incoming IP Group) are done after identifying the incoming SIP Interface and after classification and manipulation for identifying the incoming IP Group, but before the routing stage (IP-to-IP Routing table). This supports all types of queries (Dial Plan, LDAP, ENUM, and HTTP).</li> <li>■ For destination tag-based routing (i.e., 'Destination Type' parameter of IP-to-IP Routing rules configured to <b>Destination Tag</b>):</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ If a destination tag is determined during the routing stage by a Call Setup Rule (i.e., Call Setup Rule Set assigned to the IP-to-IP Routing rule's 'Pre Route Call Setup Rules Set ID' parameter), the tag overrides any other determined tag (i.e., from the Dial Plan or Call Setup Rule Set of the SIP Interface).</li> <li>✓ For more information on tag-based routing, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</li> </ul> <p>■ The parameter is applicable only to the SBC application.</p>
'Tags' tags [Tags]	<p>Defines tags (name=value or value only), which can be implemented in one of the following ways:</p> <ul style="list-style-type: none"> <li>■ <b>Classification based on source tags:</b> If the tag (name=value or value only) is the same tag as that of the incoming SIP dialog (obtained from the Call Setup Rule associated with the SIP Interface on which the dialog is received) and configured in the Classification table, then the incoming dialog is classified to this IP Group. For more information, see <a href="#">Configuring Classification Based on Tags</a> on page 1183.</li> <li>■ <b>Routing based on destination tags:</b> If this tag is matched, the device sends the incoming SIP dialog to this IP Group. The parameter is used when IP-to-IP Routing rules are configured for destinations-based on tags (i.e., 'Destination Type' parameter configured to <b>Destination Tag</b>). For more information on tag-based routing, see <a href="#">Using Destination Tags for Choosing Routing Destinations</a> on page 842.</li> </ul> <p>The valid value is:</p> <ul style="list-style-type: none"> <li>■ A string of up to 70 characters.</li> <li>■ Up to five tags, where each tag is separated by a semicolon (;).</li> <li>■ Up to four tags containing a name with a value (e.g., Country=Ireland).</li> <li>■ Only <b>one</b> tag containing a value only (e.g., Ireland).</li> <li>■ You can configure multiple tags with the same name (e.g., Country=Ireland;Country=Scotland).</li> </ul>

Parameter	Description
	<p>The following example configures the maximum number of tags (i.e., four name=value tags and one value-only tag): Country=Ireland;Country=Scotland;Country=RSA;Country=Canada;USA.</p> <p><b>Note:</b> For tag-based classification, if multiple IP Groups are configured with the same tag, the device classifies the incoming SIP dialog to the first matching IP Group.</p>
<p>'SBC Alternative Routing Reasons Set'</p> <p>sbc-alt-route-reasons-set</p> <p>[SBCAltRouteReasonsSetName]</p>	<p>Assigns an Alternative Reasons Set to the IP Group. This defines SIP response codes, which if received by the device from the IP Group, triggers alternative routing. Alternative routing could mean trying to send the SIP message to another online proxy (address) that is configured for the Proxy Set associated with the IP Group, or sending it to an alternative IP-to-IP Routing rule. For configuring Alternative Reasons Sets and for more information on how the device performs alternative routing, see <a href="#">Configuring SIP Response Codes for Alternative Routing Reasons</a> on page 1214.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Teams Local Media Optimization Handling'</p> <p>teams-local-media-optimization-handling</p> <p>[TeamsLocalMediaOptimization]</p>	<p>Enables and defines Local Media Optimization handling when the central SBC device (proxy SBC scenario) is deployed in a Microsoft Teams environment. Handling is based on supplementary information provided in the SIP message by Microsoft proprietary SIP headers, X-MS-UserLocation, X-MS-MediaPath and X-MS-UserSite.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) The device ignores the proprietary Microsoft headers for Teams in the SIP message and uses the "regular" Media Realm assigned by the IP Group's 'Media Realm' parameter for the call (i.e., regular call processing).</li> <li>■ [1] <b>Teams Decides</b> or [2] <b>SBC Decides</b> = The device's call handling depends on Teams headers and call direction: <ul style="list-style-type: none"> <li>✓ Inbound calls to Teams (PSTN-to-Teams): The device sends the initial INVITE message using the settings of the 'Teams Local Media Optimization Initial Behavior' parameter. When a SIP 200 OK is received in response, the device uses the X-MS-MediaPath header to determine if it's a direct</li> </ul> </li> </ul>

Parameter	Description
	<p>media call. For these calls, the device never uses the Dial Plan Region Connectivity feature (see <a href="#">Using Dial Plans for Microsoft Local Media Optimization</a> on page 852).</p> <p>✓ Outbound calls from Teams (Teams-to-PSTN): If the parameter is configured to <b>Teams Decides</b> and the call is the primary (initial) route, the device uses the X-MS-MediaPath header to determine if it is a direct media call. For secondary routes (e.g., 3xx, alternative route, call forking, or transfer) or if the parameter is configured to <b>SBC Decides</b>, the device uses the X-MS-UserLocation and X-MS-UserSite headers together with the 'Regions Connectivity Dial Plan' parameter to determine if it's a direct media call (see <a href="#">Using Dial Plans for Microsoft Local Media Optimization</a> on page 852).</p> <p>The X-MS-UserLocation and X-MS-MediaPath headers can change upon re-INVITE messages (such as for conference calls).</p> <p>If the call is a <b>non-primary</b> route (e.g., alternative route, 3xx, or forking), the device only uses the X-MS-UserLocation header in the incoming INVITE message, which it uses to select the appropriate Media Realm (as explained previously for primary routes). For non-primary routes, the media traverses the device (i.e., no direct media).</p> <p>For an overview of Microsoft Teams Local Media Optimization feature, see <a href="#">Microsoft Teams with Local Media Optimization</a> on page 520.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Teams Local Media Optimization Initial Behavior'</p> <p>teams-local-mo-initial-behavior</p> <p>[TeamsLocalMOInitialBehavior]</p>	<p>Defines how the central SBC device (proxy SBC scenario) initially sends the received INVITE message with the SDP Offer to Teams when the device is deployed in a Microsoft Teams environment for its Local Media Optimization feature. The parameter is applicable when the device receives the SDP Offer from a remote site SBC and the 'Teams Local Media Optimization Handling' parameter is configured to <b>Teams Decides</b> or <b>SBC Decides</b>.</p> <p>■ [0] <b>Direct Media</b> = (Default) The device sends the SDP</p>

Parameter	Description
	<p>Offer as is to Teams, indicating that the call is intended to be a direct media call (i.e., doesn't traverse the device).</p> <ul style="list-style-type: none"> <li>■ [1] <b>Internal</b> = The device sends the SDP Offer using the internal Media Realm (see the IP Group's 'Internal Media Realm' parameter) to Teams, indicating that the call is intended to be a non-direct media call (i.e., media traverses the central SBC device).</li> <li>■ [2] <b>External</b> = The device sends the SDP Offer using the external (regular) Media Realm (see the IP Group's 'Media Realm' parameter) to Teams, indicating that the call is intended to be a non-direct media call (i.e., media traverses the central SBC device).</li> </ul> <p>For an overview of Microsoft Teams Local Media Optimization feature, see <a href="#">Microsoft Teams with Local Media Optimization</a> on page 520.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Teams Local Media Optimization Site'</p> <p>teams-local-mo-site</p> <p>[TeamsLocalMOSite]</p>	<p>Defines the name of the Teams site (e.g., "Singapore") within which the Teams client is located, when the device is deployed in a Microsoft Teams environment for its Local Media Optimization feature. The Teams site is indicated in the Microsoft proprietary SIP header, X-MS-UserSite of the incoming SIP message received from the Teams client.</p> <p>The device searches the Dial Plan, specified by the 'Regions Connectivity Dial Plan' parameter, to check if this IP Group's Teams site and the Teams site of the destination IP Group share a common group number. If they do share a group number, it means that the path between them is good for high quality voice and the device considers the call as intended for direct media (bypass). For more information, see <a href="#">Using Dial Plans for Microsoft Local Media Optimization</a> on page 852.</p> <p>For an overview of Microsoft Teams Local Media Optimization feature, see <a href="#">Microsoft Teams with Local Media Optimization</a> on page 520.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to Teams-to-PSTN calls.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>The parameter is applicable only to the SBC application.</li> </ul>
'Teams Direct Routing Mode' teams-direct-routing-mode [TeamsDirectRoutingMode]	<p>Enables the device to include Microsoft's proprietary X-MS-SBC header in outgoing SIP INVITE and OPTIONS messages in a Microsoft Teams Direct Routing environment. The header is used by Microsoft Teams to identify vendor equipment (e.g., AudioCodes SBC).</p> <ul style="list-style-type: none"> <li>[0] <b>Disable</b> = (Default) The device doesn't include the header in the outgoing SIP message.</li> <li>[1] <b>Enable</b> = The device includes the header in the outgoing SIP message. The header's value is displayed in the format 'AudioCodes/&lt;model&gt;/&lt;firmware&gt;', where:               <ul style="list-style-type: none"> <li>✓ <i>model</i> is the product name of your AudioCodes device (valid values are listed by Microsoft at <a href="https://docs.microsoft.com/en-us/microsoftteams/direct-routing-border-controllers">https://docs.microsoft.com/en-us/microsoftteams/direct-routing-border-controllers</a>).</li> <li>✓ <i>firmware</i> is the software version running on the device.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>You can't modify or remove the header using Message Manipulation.</li> <li>The parameter is applicable only to the SBC application.</li> </ul>
'Metering Remote Type' metering-remote-type [MeteringRemoteType]	<p>Defines if the IP Group represents the VoiceAI Connect entity.</p> <ul style="list-style-type: none"> <li>[0] <b>Regular</b> = (Default) The IP Group represents a normal SIP proxy entity.</li> <li>[1] <b>VAIC</b> = The IP Group represents VoiceAI Connect.</li> </ul> <p><b>Note:</b> Leave the parameter at its default setting (i.e., <b>Regular</b>). The parameter is used only by AudioCodes support.</p>
Quality of Experience	
'QoE Profile' qoe-profile [QOEProfile]	<p>Assigns a Quality of Experience Profile rule.</p> <p>By default, no value is defined.</p> <p>To configure Quality of Experience Profiles, see <a href="#">Configuring Quality of Experience Profiles</a> on page 528.</p>

Parameter	Description
'Bandwidth Profile' bandwidth-profile [BWProfile]	<p>Assigns a Bandwidth Profile rule.</p> <p>By default, no value is defined.</p> <p>To configure Bandwidth Profiles, see <a href="#">Configuring Bandwidth Profiles</a> on page 535.</p>
'User Voice Quality Report' user-voice-quality-report [UserVoiceQualityReport]	<p>Enables MOS calculation and reporting of calls belonging to users that are registered with the device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (Default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information on this feature, see <a href="#">Configuring Voice Quality for Registered Users</a> on page 544.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This parameter is applicable only to <b>User</b>-type IP Groups.</li> <li>■ If you have configured a Quality of Service rule for rejecting calls or using an alternative IP Profile if MOS levels become low (see <a href="#">Configuring Quality of Service Rules</a> on page 540), it's unnecessary to enable this parameter because you need to select an IP Group when configuring the rule. If you don't configure a Quality of Service rule, then you need to enable this parameter.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
Message Manipulation	
'Inbound Message Manipulation Set' inbound-mesg-manipulation-set [InboundManSet]	<p>Assigns a Message Manipulation Set (rule) to the IP Group for SIP message manipulation on the inbound leg.</p> <p>By default, no value is defined.</p> <p>To configure Message Manipulation rules, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ The 'SIP Group Name' parameter overrides inbound message manipulation rules (assigned to the 'Inbound Message Manipulation Set' parameter) that manipulate the host name in Request-URI, To, and/or From SIP headers. If you want to manipulate the host name using message manipulation rules in any of these SIP headers,</li> </ul>

Parameter	Description
	you must apply your manipulation rule (Manipulation Set ID) to the IP Group as an Outbound Message Manipulation Set (see the 'Outbound Message Manipulation Set' parameter) when the IP Group is the destination of the call.
'Outbound Message Manipulation Set' outbound-mesg-manipulation-set [OutboundManSet]	<p>Assigns a Message Manipulation Set (rule) to the IP Group for SIP message manipulation on the outbound leg.</p> <p>By default, no value is defined.</p> <p>To configure Message Manipulation rules, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p> <p><b>Note:</b> If you assign a Message Manipulation Set ID that includes rules for manipulating the host name in the Request-URI, To, and/or From SIP headers, the parameter overrides the 'SIP Group Name' parameter.</p>
'Message Manipulation User-Defined String 1' msg-man-user-defined-string1 [MsgManUserDef1]	<p>Defines a value for the SIP user part that can be used in Message Manipulation rules configured in the Message Manipulations table. The Message Manipulation rule obtains this value from the IP Group, by using the following syntax:</p> <p><code>param.ipg.&lt;src dst&gt;.user-defined.&lt;0&gt;.</code></p> <p>The valid value is a string of up to 30 characters. By default, no value is defined.</p> <p>To configure Message Manipulation rules, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p>
'Message Manipulation User-Defined String 2' msg-man-user-defined-string2 [MsgManUserDef2]	<p>Defines a value for the SIP user part that can be used in Message Manipulation rules configured in the Message Manipulations table. The Message Manipulation rule obtains this value from the IP Group, by using the following syntax: <code>param.ipg.&lt;src dst&gt;.user-defined.&lt;1&gt;.</code></p> <p>The valid value is a string of up to 30 characters. By default, no value is defined.</p> <p>To configure Message Manipulation rules, see <a href="#">Configuring SIP Message Manipulation</a> on page 856.</p>
'Proxy Keep-Alive using IP Group Settings' proxy-keepalive-use-ipg [ProxyKeepAliveUsingIPG]	<p>Enables the device to apply certain IP Group settings to keep-alive SIP OPTIONS messages that are sent by the device to the proxy server. The parameter is applicable only if you have enabled proxy keep-alive for the Proxy Set that is associated with the IP Group (see <a href="#">Configuring Proxy Sets</a></p>

Parameter	Description
	<p>on page 632).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The IP Group's settings are not applied to the OPTIONS messages.</li> <li>■ [1] <b>Enable</b> = The following IP Group settings are applied (if configured) to the proxy keep-alive SIP OPTIONS messages: <ul style="list-style-type: none"> <li>✓ The IP Group's 'SIP Group Name' parameter (see above) value is used in the OPTIONS messages.</li> <li>✓ The IP Group's 'Outbound Message Manipulation Set' parameter (see above) is applied to the OPTIONS messages (instead of manipulations configured by the [GWOutboundManipulationSet] parameter). You can also use the manipulation syntax "param.ipg.dst" for denoting the IP Group's parameters.</li> <li>✓ When filtering logs (configured in the Logging Filters table), the OPTIONS messages are filtered by IP Group. For more information on log filtering, see <a href="#">Configuring Logging Filter Rules</a> on page 1602.</li> </ul> </li> </ul> <p><b>Note:</b> When multiple IP Groups are associated with the same Proxy Set, the parameter can be enabled only on <b>one</b> of them.</p>
SBC Registration and Authentication	
<p>'Max. Number of Registered Users'</p> <p>max-num-of-reg-users</p> <p>[MaxNumOfRegUsers]</p>	<p>Defines the maximum number of users in this IP Group that can register with the device.</p> <p>The default is -1, meaning that no limitation exists for registered users.</p> <p><b>Note:</b> The parameter is applicable only to <b>User</b>-type IP Groups.</p>
<p>'Registration Mode'</p> <p>registration-mode</p> <p>[RegistrationMode]</p>	<p>Defines the registration mode for the IP Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>User Initiates Registration</b> (default)</li> <li>■ [1] <b>SBC Initiates Registration</b> = Used when the device serves as a client (e.g., with an IP PBX). This functions only with the SBC User Information table (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803).</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>Registrations not Needed</b> = The device adds users to its database in active state.</li> </ul>
'Dedicated Connection Mode' dedicated-connection-mode [DedicatedConnectionMode]	<p>Enables the device to establish and use a dedicated TCP (TLS) connection with the SIP registrar server (proxy) for each user that is defined in the SBC User Information table. The dedicated connection is established when the device initially registers (SIP REGISTER) the user with the server. All subsequent SIP dialogs (e.g., INVITE) originating from the user are sent to the server over this dedicated connection. If you enable this feature and there is no valid dedicated connection when the user sends a SIP dialog-initiating request, the device rejects the SIP dialog. This also triggers the device to refresh registration with the server for the specific user.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The same connection may be used for all users, depending on the [EnableTCPConnectionReuse] parameter settings.</li> <li>■ [1] <b>Per User in SBC User Information Table</b> = The device establishes a dedicated connection per user.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to <b>User</b>-type IP Groups.</li> <li>■ To support this feature, you also need to do the following:               <ul style="list-style-type: none"> <li>✓ Configure the 'Registration Mode' parameter (above) to <b>SBC Initiates Registration</b> for this <b>User</b>-type IP Group.</li> <li>✓ Configure each relevant user in the SBC User Information table so that they are associated with this <b>User</b>-type IP Group (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803).</li> <li>✓ Configure the Proxy Set that is associated with the <b>Server</b>-type IP Group representing the registrar server, for TCP (or TLS) transport type (see <a href="#">Configuring Proxy Sets</a> on page 632).</li> <li>✓ Configure the associated IP-to-IP Routing rule (see</li> </ul> </li> </ul>

Parameter	Description
	<p><a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186) to send all SIP messages from the User-type IP Group to 'Destination Type' IP Group and the 'Destination IP Group' should be the Server-type IP Group (i.e., the registrar server).</p> <ul style="list-style-type: none"> <li>■ If you modify configuration relating to the user (e.g., IP-to-IP Routing rule) at any time after this feature has been configured, the device may no longer have a valid, dedicated connection until it's time to send a refresh REGISTER message for the user.</li> <li>■ This feature poses the following constraints: <ul style="list-style-type: none"> <li>✓ The maximum number of users that can have a dedicated TLS connection is less than the maximum number of rows (users) that you can configure in the SBC User Information table (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803).</li> <li>✓ When the device needs to open a new TLS connection for a user (SBC User Information entry), it only establishes the connection if the number of currently established TLS connections (incoming and outgoing) is less than the maximum number of supported TLS connections by the device. If the maximum is exceeded, it doesn't open the TLS connection and doesn't send a registration request to the proxy server for the user. For the maximum number of concurrent TLS connections supported by the device, refer to 'Capacity per Feature' in the <i>Release Notes</i>.</li> </ul> </li> </ul>
<p>'User Stickiness'</p> <p>sbc-user-stickiness</p> <p>[SBCUserStickiness]</p>	<p>Enables user "stickiness" (binding) to a specific registrar server. The registrar server is one of the IP addresses of the Proxy Set associated with this <b>Server</b>-type IP Group. This feature applies to users belonging to a <b>User</b>-type IP Group that are routed to this destination <b>Server</b>-type IP Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = After a successful initial registration of the user to a registrar, whenever the device receives a SIP request or registration refresh from the user, the device sends the request to whichever registrar (IP address of the Proxy Set) is currently active. In the case of proxy load-balancing, there is no certainty to which IP address</li> </ul>

Parameter	Description
	<p>the request is routed.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = The device always routes SIP requests (INVITEs, SUBSCRIBEs and REGISTER refreshes) received from the user to the same registrar server to which the last successful REGISTER request for that user was routed. In other words, once initial registration of the user to one of the IP addresses of the Proxy Set associated with this destination <b>Server</b>-type IP Group is successful (i.e., 200 OK), binding occurs to this specific address (registrar) and all future SIP requests from the user are routed (based on matched routing rule) only to this specific registrar.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to <b>Server</b>-type IP Groups</li> <li>■ The Proxy Set associated with the <b>Server</b>-type IP Group must be configured with multiple IP addresses (or an FQDN that resolves into multiple IP addresses).</li> <li>■ This feature is also applicable to IP Group Sets (see <a href="#">Configuring IP Group Sets</a> on page 1223). If a user is bound to a registrar associated with this <b>Server</b>-type IP Group which also belongs to an IP Group Set, IP Group Set logic of choosing an IP Group is ignored and instead, the device always routes requests from this user to this specific registrar.</li> <li>■ A user's "stickiness" to a specific registrar ends upon the following scenarios: <ul style="list-style-type: none"> <li>✓ If you modify the Proxy Set.</li> <li>✓ If the Proxy Set is configured with an FQDN and a DNS resolution refresh removes the IP address to which the user is bound.</li> <li>✓ User registration expires or the user initiates an unregister request.</li> </ul> </li> <li>■ The Proxy Set's Hot-Swap feature (for proxy redundancy) is not supported for users that are already bound to a registrar. However, you can achieve proxy "hot-swap" for failed initial (non-bounded) REGISTER requests. If the device receives a failure response for</li> </ul>

Parameter	Description
	<p>the initial REGISTER request and you have configured this response code for the Alternative Reasons Set associated (by the 'SBC Alternative Routing Reasons Set' parameter below) with the IP Group (see <a href="#">Configuring SIP Response Codes for Alternative Routing Reasons</a> on page 1214), "hot-swap" to the other IP addresses of the Proxy Set is done until a success response is received from one of the addresses. For failed REGISTER refresh requests from users that are already bound to a registrar, no "hot-swap" occurs for that request; only for subsequent refresh requests.</p> <ul style="list-style-type: none"> <li>■ When using the SBC User Information table (see <a href="#">Configuring SBC User Information</a> on page 802), registrar "stickiness" is supported only when the user initiates the REGISTER request. Therefore, you must configure the 'Registration Mode' parameter of the IP Group (<b>User-type</b>) to which the user belongs, to <b>User Initiates Registration</b>.</li> <li>■ This feature is also supported when the device operates in HA mode; registrar "stickiness" is retained even after an HA switchover.</li> </ul>
'User UDP Port Assignment' user-udp-port-assignment [UserUDPPortAssignment]	<p>Enables the device to assign a unique, local UDP port (for SIP signaling) per registered user (<b>User-type</b> IP Group) on the leg interfacing with the proxy server (<b>Server-type</b> IP Group). The port is used for incoming (from the proxy to the user) and outgoing (from the user to the proxy) SIP messages. Therefore, the parameter must be enabled for the IP Group of the proxy server.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device uses the same local UDP port for all the registered users. This single port is configured for the SIP Interface ('UDP Port' parameter) associated with the Proxy Set of the proxy server.</li> <li>■ [1] <b>Enable</b> = The device assigns each registered user a unique local port, chosen from a configured UDP port range. The port range is configured for the SIP Interface ('Additional UDP Ports' parameter) associated with the proxy server.</li> </ul> <p>The device assigns a unique port upon the first REGISTER request received from the user. Subsequent</p>

Parameter	Description
	<p>SIP messages other than REGISTER messages (e.g., INVITE) from the user are sent to the proxy server on this unique local port. The device rejects the SIP request if there is no available unique port for use (due to the number of registered users exceeding the configured port range). The same unique port is also used for registration refreshes. The device de-allocates the port for registration expiry. For SIP requests from the proxy server, the local port on which they are received is irrelevant (unique port or any other port); the device doesn't use this port to identify the registered user.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature doesn't apply to SIP requests received from non-registered users. For these users, the device sends all requests to the proxy server on the single port configured for the SIP Interface ('UDP Port' parameter).</li> <li>■ For HA systems, the unique port assigned to a registered user is also used after an HA switchover.</li> <li>■ This feature is applicable only if the user initiates registration (i.e., user sends the REGISTER request). In other words, the 'Registration Mode' parameter of the IP Group of the user must be configured to <b>User Initiates Registration</b>.</li> </ul>
<p>'Authentication Mode'</p> <p>authentication-mode</p> <p>[AuthenticationMode]</p>	<p>Defines the authentication mode.</p> <ul style="list-style-type: none"> <li>■ [0] <b>User Authenticates</b> = (Default) The device doesn't handle authentication, but simply forwards the authentication messages between the SIP user agents.</li> <li>■ [1] <b>SBC as Client</b> = The device authenticates as a client. When the device receives a SIP 401/407 response from the proxy requesting authentication for the outgoing SIP request, it sends the proxy its credentials (i.e., username and password), which it obtains from one of the following (listed in order of preference): <ul style="list-style-type: none"> <li>a. If an Account exists in the Accounts table (see <a href="#">Configuring Registration Accounts</a> on page 777) for the Served IP Group and the Serving IP Group (i.e., IP Group you are now configuring), the device obtains the credentials from the Account (only if authenticating a <b>Server</b>-type IP Group).</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li><b>b.</b> The device obtains the credentials from the SBC User Information table (see <a href="#">Configuring SBC User Information</a> on page 802).</li> <li><b>c.</b> The device obtains the credentials configured for this IP Group in the IP Groups table ('Username As Client' and 'Password As Client' parameters).</li> <li><b>d.</b> The device obtains the credentials from the global username and password parameters (only if authenticating a <b>Server</b>-type IP Group).</li> <li><b>e.</b> If no applicable credentials are found, the device forwards the SIP 401/407 response to the SIP UA.</li> </ul> <p>■ [2] <b>SBC as Server</b> = The device acts as an Authentication server:</p> <ul style="list-style-type: none"> <li>✓ Authenticates SIP clients: The device challenges (authenticates) incoming SIP requests from users belonging to this IP Group. When the 'SBC Server Authentication Type' parameter (see below) is configured to <b>Authentication is performed locally</b>, the device authenticates the users based on the username and password configured for this IP Group ('Username As Server' and 'Password As Server' parameters). However, if a user appears in the SBC User Information table and is configured with a username and password, the device authenticates the user with the credentials in the SBC User Information table (see <a href="#">Configuring SBC User Information</a> on page 802). If you have not configured a username and password, the device rejects the incoming SIP request.</li> <li>✓ Authenticates SIP servers (applicable only to <b>Server</b>-type IP Groups).</li> </ul> <p><b>Note:</b> Configure the SIP request (method) types (e.g., INVITE) that the device must challenge when acting as an authentication server, using the IP Group's 'Authentication Method List' parameter.</p> <p>■ [3] <b>SBC as Both Client and Server</b> = The device authenticates both as a client and an authentication server. For a description of each mode, see the optional values <b>SBC as Client</b> and <b>SBC as Server</b>.</p>

Parameter	Description
'Authentication Method List' authentication-method-list [MethodList]	<p>Defines SIP methods received from the IP Group that must be challenged by the device when the device acts as an Authentication server. If no methods are configured, the device doesn't challenge any methods.</p> <p>By default, no value is defined. To define multiple SIP methods, use the backslash (\) to separate each method (e.g., INVITE\REGISTER). To authenticate only setup INVITE requests (and not re-INVITE requests), configure the parameter to "setup-invite" (without quotation marks).</p> <p><b>Note:</b> The parameter is applicable only if you configure the device to act as an Authentication server (i.e., 'Authentication Mode' parameter is <b>SBC as Server</b> or <b>SBC as Both Client and Server</b>).</p>
'SBC Server Authentication Type' sbc-server-auth-type [TypeSBCServerAuthType]	<p>Defines the authentication method when the device, as an Authentication server, authenticates SIP requests from the IP Group.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Global Parameter</b> = (Default) Authentication is according to the [SBCServerAuthMode] parameter.</li> <li>■ [0] <b>Authentication is performed locally</b> = The device authenticates incoming SIP requests locally. For more information, see <a href="#">SIP Authentication Server Functionality</a> on page 1148.</li> <li>■ [2] <b>According to draft-sterman-aaa-sip-01</b> = The device authenticates incoming SIP requests using a remote RADIUS server, based on Internet Draft "draft-sterman-aaa-sip-01". For more information, see <a href="#">RADIUS-based Authentication of SIP User Agents</a> on page 1149.</li> <li>■ [3] <b>Authenticate with OAuth Server</b> = The device authenticates incoming SIP requests according to token-based authentication with an OAuth 2.0 authorization server (internal or external). The OAuth 2.0 server is configured as a Remote Web Service. The server is assigned to the IP Group using the IP Group's 'OAuth HTTP Service' parameter. For more information, see <a href="#">OAuth 2.0 Based SIP Message Authentication</a> on page 433.</li> <li>■ [4] <b>ARM Authentication</b> = The device authenticates incoming SIP requests (INVITE or REGISTER) from <b>User-</b></li> </ul>

Parameter	Description
	<p>type IP Groups, by first obtaining (REST-based API query) the user's password from ARM where the password is stored. Once the password is supplied, the device continues with the regular SIP digest authentication process (challenge) with the user. For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to any option except <b>Authentication is performed locally</b>, you also need to configure the device to act as an Authentication server (i.e., 'Authentication Mode' parameter is <b>SBC as Server</b> or <b>SBC as Both Client and Server</b>).</li> <li>■ If you configure the parameter to <b>ARM Authentication</b>, you also need to configure the IP Group's 'Authentication Method List' parameter to authenticate INVITE or REGISTER messages.</li> </ul>
'OAuth HTTP Service' oauth-http-service [OAuthHTTPService]	<p>Assigns a Remote Web Service to the IP Group. The Remote Web Service represents the OAuth 2.0 authorization server (internal or external), which the device uses to authenticate incoming SIP requests as a server. The device sends the OAuth token received from the client to the OAuth 2.0 server for authentication.</p> <p>To configure Remote Web Services, see <a href="#">Configuring Remote Web Services</a> on page 438. For more information on OAuth-based authentication, see <a href="#">OAuth 2.0 Based SIP Message Authentication</a> on page 433.</p> <p><b>Note:</b> The parameter is applicable only if the IP Group's 'SBC Server Authentication' parameter is configured to <b>Authenticate with OAuth Server</b>.</p>
'Username As Client' username-as-client [UsernameAsClient]	<p>Defines the username that is used when the device is challenged (SIP 401/407) by this IP Group for retrying the outgoing SIP request toward this IP Group.</p> <p>The valid value is a string of up to 60 characters. By default, no username is defined.</p> <p><b>Note:</b> The parameter is applicable only if you configure the device to authenticate as a client (i.e., 'Authentication Mode' parameter is <b>SBC as Client</b> or <b>SBC as Both Client and</b></p>

Parameter	Description
	<b>Server).</b>
'Password As Client' password-as-client [PasswordAsClient]	<p>Defines the password that is used when the device is challenged (SIP 401/407) by this IP Group for retrying the outgoing SIP request toward this IP Group.</p> <p>The valid value is a string of up to 64 characters. By default, no password is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the device to authenticate as a client (i.e., 'Authentication Mode' parameter is <b>SBC as Client</b> or <b>SBC as Both Client and Server</b>).</li> <li>■ The password cannot include wide characters.</li> </ul>
'Username As Server' username-as-server [UsernameAsServer]	<p>Defines the username that is used when the device challenges (authenticates) incoming SIP requests from users belonging to this IP Group (for <b>User</b>-type IP Groups), or challenges SIP servers (for <b>Server</b>-type IP Groups).</p> <p>The valid value is a string of up to 60 characters. By default, no username is defined.</p> <p><b>Note:</b> The parameter is applicable only if you configure the device to act as an Authentication server (i.e., 'Authentication Mode' parameter is <b>SBC as Server</b> or <b>SBC as Both Client and Server</b>).</p>
'Password As Server' password-as-server [PasswordAsServer]	<p>Defines the password that is used when the device challenges (authenticates) incoming SIP requests from users belonging to this IP Group (for <b>User</b>-type IP Groups), or challenges SIP servers (for <b>Server</b>-type IP Groups).</p> <p>The valid value is a string of up to 64 characters. By default, no password is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the device to act as an Authentication server (i.e., 'Authentication Mode' parameter is <b>SBC as Server</b> or <b>SBC as Both Client and Server</b>).</li> <li>■ The password cannot include wide characters.</li> </ul>
Gateway	
'SIP Re-routing Mode'	Defines the routing mode after a call redirection (i.e., a 3xx

Parameter	Description
re-routing-mode [SIPReRoutingMode]	<p>SIP response is received) or transfer (i.e., a SIP REFER request is received).</p> <ul style="list-style-type: none"> <li>■ [-1] = Not Configured (Default)</li> <li>■ [0] <b>Standard</b> = INVITE messages that are generated as a result of Transfer or Redirect are sent directly to the URI, according to the Refer-To header in the REFER message or Contact header in the 3xx response.</li> <li>■ [1] <b>Proxy</b> = Sends a new INVITE to the Proxy. This is applicable only if a Proxy server is used and the parameter [AlwaysSendtoProxy] is set to [0].</li> <li>■ [2] <b>Routing Table</b> = Uses the Routing table to locate the destination and then sends a new INVITE to this destination.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When the parameter is configured to [1] and the INVITE sent to the Proxy fails, the device re-routes the call according to the Standard mode [0].</li> <li>■ When the parameter is configured to [2] and the INVITE fails, the device re-routes the call according to the Standard mode [0]. If DNS resolution fails, the device attempts to route the call to the Proxy. If routing to the Proxy also fails, the Redirect / Transfer request is rejected.</li> <li>■ When the parameter is set to [2], the [XferPrefix] parameter can be used to define different routing rules for redirected calls.</li> <li>■ The parameter is ignored if the parameter [AlwaysSendToProxy] is set to [1].</li> </ul>
'Always Use Route Table' always-use-route-table [AlwaysUseRouteTable]	<p>Defines the Request-URI host name in outgoing INVITE messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> (default).</li> <li>■ [1] <b>Yes</b> = The device uses the IP address (or domain name) defined in the Tel-to-IP Routing table (see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946) as the Request-URI host name in outgoing INVITE messages, instead of the value configured in the 'SIP Group Name' field.</li> </ul>

Parameter	Description
	<b>Note:</b> The parameter is applicable only to <b>Server</b> -type IP Groups.
GW Group Status	
'GW Group Registered IP Address'	(Read-only field) Displays the IP address of the IP Group entity (gateway) if registered with the device; otherwise, the field is blank.  <b>Note:</b> The field is applicable only to <b>Gateway</b> -type IP Groups (i.e., the 'Type' parameter is configured to <b>Gateway</b> ). For <b>User</b> -type and <b>Server</b> -type IP Groups, the field displays "NA".
'GW Group Registered Status'	(Read-only field) Displays if the IP Group entity (gateway) is registered with the device ("Registered" or "Not Registered").  <b>Note:</b> The field is applicable only to <b>Gateway</b> -type IP Groups (i.e., the 'Type' parameter is configured to <b>Gateway</b> ). For <b>User</b> -type and <b>Server</b> -type IP Groups, the field displays "NA".

## Configuring Proxy Sets

The Proxy Sets table lets you configure up to 80 Proxy Sets. A Proxy Set defines the address (IP address or FQDN) and transport type (e.g., UDP or TCP) of a SIP server (e.g., SIP proxy and SIP registrar server). The Proxy Set represents the destination of the IP Group configuration entity.

- The maximum number of addresses that you can configure in the Proxy Address table ("child" of the Proxy Sets table) per Proxy Set is 10 . The address can be an IP address in dotted-decimal notation or a DNS hostname (FQDN).
- The maximum number of supported DNS-resolved IP addresses **per** Proxy Set is 15.
- The maximum number of supported DNS-resolved IP addresses for **all** Proxy Sets combined is 500. If the DNS resolution provides more than this number, it ignores the extra addresses.
- An SRV query sent by the device can return up to 50 hostnames. For each hostname, the subsequent DNS A-record query sent by the device can resolve into up to 50 IP addresses.

Multiple proxy servers enables you to implement proxy load balancing and redundancy. These features are supported by the device's proxy keep-alive feature, which when enabled, sends keep-alive messages (SIP OPTIONS) to all configured proxy servers to determine their connectivity status (offline or online). You can also configure the device to consider the proxy as offline if specific SIP response codes are received in response to the keep-alive messages. You

can configure the number of required consecutive successful keep-alive messages before the device considers a previously offline proxy as online. This mechanism avoids the scenario in which the device falsely detects a proxy as being online when it is actually offline, resulting in call routing failure.

You can assign each Proxy Set a specific TLS Context (TLS configuration), enabling you to use different TLS settings (including certificates) per SIP entity (IP Group).

You can also enable the device to classify incoming SBC SIP dialogs to IP Groups, based on Proxy Set. If the source address of the incoming SIP dialog is the same as the address of a Proxy Set, the device classifies the SIP dialog as belonging to the IP Group that is associated with the Proxy Set.

To use a configured Proxy Set, you need to assign it to an IP Group in the IP Groups table (see [Configuring IP Groups](#) on page 591). When the device sends INVITE messages to an IP Group, it sends it to the address configured for the Proxy Set. You can assign the same Proxy Set to multiple IP Groups (belonging to the same SRD).

- It is recommended to classify incoming SIP dialogs to IP Groups based on Classification rules (see [Configuring Classification Rules](#) on page 1171) instead of based on Proxy Sets.
- For the Gateway application, you can view the device's connectivity status with proxy servers in the Tel-to-IP Routing table for Tel-to-IP routing rules whose destination is an IP Group that is associated with a Proxy Set. The status is only displayed for Proxy Sets enabled with the Proxy Keep-Alive feature.
- To view connectivity status of Proxy Sets, see [Viewing Proxy Set Status](#) on page 1488.

The Proxy Set is configured using two tables with parent-child relationship:

- Proxy Sets table (parent): Defines the attributes of the Proxy Set such as associated SIP Interface and redundancy features - ini file parameter [ProxySet] or CLI command, `configure voip > proxy-set`
- Proxy Set Address table (child): Defines the addresses of the Proxy Set - table ini file parameter [ProxyIP] or CLI command, `configure voip > proxy-ip > proxy-set-id`

#### ➤ To configure a Proxy Set:

1. Open the Proxy Sets table (**Setup** menu > **Signaling & Media** tab > **Core Entities** folder > **Proxy Sets**).
2. Click **New**; the following dialog box appears (screenshot has been cropped due to page size):

3. From the 'SRD' drop-down list, select an SRD.
4. Configure a Proxy Set according to the parameters described in the table below.
5. Click **Apply**.
6. Configure proxy addresses for the Proxy Set:
  - a. Select the index row of the Proxy Set that you added, and then click the **Proxy Address** link located below the table; the Proxy Address table opens.
  - b. Click **New**; the following dialog box appears:

- c. Configure the address of the Proxy Set according to the parameters described in the table below.
- d. Click **Apply**.

**Table 18-7: Proxy Sets Table and Proxy Address Table Parameter Description**

Parameter	Description
'SRD'	Assigns an SRD to the Proxy Set.
voip-network proxy-set > srd- id [SRDName]	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory and must be configured first before you can configure the other parameters in the table.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ To configure SRDs, see <a href="#">Configuring SRDs</a> on page 558.</li> </ul>
General	
'Index' configure voip > voip-network proxy-set [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' proxy-name [ProxyName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Gateway IPv4 SIP Interface' gwipv4-sip-int-name [GWIPv4SIPInterfaceName]	Assigns an IPv4-based SIP Interface for Gateway calls to the Proxy Set. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter appears only if you have configured an IPv4 network interface in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159).</li> <li>■ At least one SIP Interface must be assigned to the Proxy Set.</li> <li>■ All SIP Interfaces assigned to the Proxy Set must be either IPv4 addresses or IPv6 addresses (not both).</li> <li>■ To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</li> </ul>
'SBC IPv4 SIP Interface' sbcipv4-sip-int-name [SBCIPv4SIPInterfaceName]	Assigns an IPv4-based SIP Interface for SBC calls to the Proxy Set. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter appears only if you have configured an IPv4 network interface in the IP Interfaces table (see <a href="#">Configuring IP Network Interfaces</a> on page 159).</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ At least one SIP Interface must be assigned to the Proxy Set.</li> <li>■ All SIP Interfaces assigned to the Proxy Set must be either IPv4 addresses or IPv6 addresses (not both).</li> <li>■ To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</li> </ul>
'Gateway IPv6 SIP Interface' gwipv6-sip-int-name [GWIPv6SIPInterfaceName]	Assigns an IPv6-based SIP Interface for Gateway calls to the Proxy Set. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter appears <b>only</b> if you have configured an IPv6 network interface in the IP Interfaces table.</li> <li>■ At least one SIP Interface must be assigned to the Proxy Set.</li> <li>■ All SIP Interfaces assigned to the Proxy Set must be either IPv4 addresses or IPv6 addresses (not both).</li> </ul>
'SBC IPv6 SIP Interface' sbcipv6-sip-int-name [SBCIPv6SIPInterfaceName]	Assigns an IPv6-based SIP Interface for SBC calls to the Proxy Set. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter appears only if you have configured an IPv6 network interface in the IP Interfaces table.</li> <li>■ At least one SIP Interface must be assigned to the Proxy Set.</li> <li>■ All SIP Interfaces assigned to the Proxy Set must be either IPv4 addresses or IPv6 addresses (not both).</li> </ul>
'TLS Context Name' tls-context-name [TLSContextName]	Assigns a TLS Context (TLS configuration) to the Proxy Set. By default, no TLS Context is assigned. If you assign a TLS Context, the TLS Context is used as follows: <ul style="list-style-type: none"> <li>■ Incoming calls: If the 'Transport Type' parameter (in this table) is set to <b>TLS</b> and the incoming call is successfully classified to an IP Group based on the Proxy Set, this TLS Context is used. If the 'Transport Type' parameter is set to <b>UDP</b> or classification to this Proxy Set fails, the TLS Context is not used. Instead, the device uses the TLS Context configured for the SIP Interface (see <a href="#">Configuring SIP Interfaces</a> on page 570) used for the call; otherwise, the default TLS Context (ID 0) is used.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Outgoing calls: If the 'Transport Type' parameter is set to <b>TLS</b> and the outgoing call is sent to an IP Group that is associated with this Proxy Set, this TLS Context is used. Instead, the device uses the TLS Context configured for the SIP Interface used for the call; otherwise, the default TLS Context (ID 0) is used. If the 'Transport Type' parameter is set to <b>UDP</b>, the device uses UDP to communicate with the proxy and no TLS Context is used.</li> </ul> <p>To configure TLS Contexts, see <a href="#">TLS Certificates</a> on page 227.</p>
Keep Alive	
'Proxy Keep-Alive' proxy-enable-keep-alive [EnableProxyKeepAlive]	<p>Enables the device's Proxy Keep-Alive feature, which checks connectivity with all the proxy servers of the Proxy Set, by sending keep-alive messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default).</li> <li>■ [1] <b>Using OPTIONS</b> = Enables the Proxy Keep-Alive feature using SIP OPTIONS messages. The device sends an OPTIONS message every user-defined interval, configured by the 'Proxy Keep-Alive Time' parameter (in this table). If the device receives a SIP response code that is configured in the 'Keep-Alive Failure Responses' parameter (in this table), the device considers the proxy as offline. You can also configure if the device uses its IP address, the proxy's IP address, or the device's name in the OPTIONS message, using the [UseGatewayNameForOptions] parameter.</li> <li>■ [2] <b>Using REGISTER</b> = Enables the Proxy Keep-Alive feature using SIP REGISTER messages. The device sends a REGISTER message every user-defined interval, configured by the [RegistrationTime] parameter (Gateway application) or [SBCProxyRegistrationTime] parameter (SBC application). Any SIP response from the proxy - success (200 OK) or failure (4xx response) - is considered as if the proxy is online. If the proxy doesn't respond to INVITE messages sent by the device, the proxy is considered as offline. The device sends keep-alive REGISTER messages only to one proxy. Only if the proxy fails to respond to the keep-alive, does the device send the keep-alive REGISTER message to the next proxy.</li> <li>■ [3] <b>Using OPTIONS on Active Server</b> = Enables the Proxy Keep-Alive feature using SIP OPTIONS messages (similar to</li> </ul>

Parameter	Description
	<p>the <b>Using OPTIONS</b> value), except that the proxy servers to which the keep-alive messages are sent depend on the settings of the Proxy Set's 'Redundancy Mode' parameter (see below):</p> <ul style="list-style-type: none"> <li>✓ <b>Parking:</b> The device sends keep-alive OPTIONS messages only to the currently active proxy server (to which it is connected and using).</li> <li>✓ <b>Homing:</b> The device sends keep-alive OPTIONS messages to the currently active proxy server and to all proxy servers with higher priority (according to the 'Proxy Priority' parameter in this table) than the active server. Once a higher priority server goes online, the device stops sending the keep-alive OPTIONS messages to the previously active server and connects to the higher priority server. The device now sends keep-alive messages to this newly active server and all other servers with higher priority.</li> <li>✓ If the 'Redundancy Mode' parameter is not configured (empty) and the Proxy Set's 'Proxy Load Balancing Method' parameter (in this table) is configured to any value other than <b>Disable</b>, the device sends the keep-alive OPTIONS messages to all proxy servers (same behavior as when you configure the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS</b>).</li> </ul> <p>■ [4] <b>Using Fake REGISTER</b> = Enables the Proxy Keep-Alive feature using SIP REGISTER messages. The device sends a REGISTER message every user-defined interval, configured by the 'Proxy Keep-Alive Time' parameter (in this table). The name in the Contact header of the REGISTER message is a fake name. Therefore, the REGISTER request is expected to fail and the device considers the proxy server as online if it receives a SIP 404 response. If the device receives a SIP response code that is configured in the 'Keep-Alive Failure Responses' parameter (in this table), the device considers the proxy as offline. You can also configure if the device uses its IP address, the proxy's IP address, or the device's name in the REGISTER message, using the [UseGatewayNameForOptions] parameter.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Proxy keep-alive using REGISTER messages (<b>Using</b></li> </ul>

Parameter	Description
	<p><b>REGISTER</b>) is applicable only to the Parking redundancy mode ('Redundancy Mode' parameter configured to <b>Parking</b>).</p> <ul style="list-style-type: none"> <li>■ If you enable the Proxy Keep-Alive feature, the device can operate with multiple proxy servers (addresses) for redundancy and load balancing (see the 'Proxy Load Balancing Method' parameter).</li> <li>■ For Survivability mode for User-type IP Groups, you must enable the Proxy Keep-Alive feature.</li> <li>■ If you enable the Proxy Keep-Alive feature and the proxy uses the TCP/TLS transport type, you can enable the CRLF Keep-Alive feature, using the [UsePingPongKeepAlive] parameter.</li> <li>■ If you enable proxy keep-alive using SIP OPTIONS messages (<b>Using OPTIONS</b> or <b>Using OPTIONS on Active Server</b>) or using fake REGISTER requests (<b>Using Fake REGISTER</b>), you can also enable the device to apply various settings (e.g., SIP message manipulation) of the IP Group that is associated with the Proxy Set, to these SIP messages. For more information, see the 'Proxy Keep-Alive using IP Group Settings' parameter in the IP Groups table.</li> <li>■ If you enable proxy keep-alive using SIP OPTIONS messages (<b>Using OPTIONS</b> or <b>Using OPTIONS on Active Server</b>) or using fake REGISTER requests (<b>Using Fake REGISTER</b>), you can also configure how long the device waits before re-sending a keep-alive OPTIONS message once the device considers the proxy as offline (i.e., after all retransmissions, configured by the 'Failure Detection Retransmissions' have failed). This feature is configured by the [FailedOptionsRetryTime] parameter.</li> </ul>
'Proxy Keep-Alive Time' proxy-keep-alive-time [ProxyKeepAliveTime]	<p>Defines the interval (in seconds) between keep-alive messages sent by the device when the Proxy Keep-Alive feature is enabled (see the 'Proxy Keep-Alive' parameter in this table). The valid range is 5 to 2,000,000. The default is 60.</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS</b>, <b>Using OPTIONS on Active Server</b> or <b>Using Fake REGISTER</b>.</p>
'Keep-Alive Failure Responses'	<p>Defines SIP response codes that if any is received in response to a keep-alive message using SIP OPTIONS (<b>Using OPTIONS</b> or</p>

Parameter	Description
<code>keepalive-fail-resp</code> <code>[KeepAliveFailureResp]</code>	<p><b>Using OPTIONS on Active Server</b>) or using fake REGISTER requests (<b>Using Fake REGISTER</b>), the device considers the proxy as offline.</p> <p>Up to three response codes can be configured, where each code is separated by a comma (e.g., 407,404). By default, no response code is defined. If no response code is configured, or if response codes received are not those configured, the proxy is considered online.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The SIP 200 response code is not supported for this feature.</li> <li>■ The parameter is applicable only if you configure the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS, Using OPTIONS on Active Server</b> or <b>Using Fake REGISTER</b>.</li> </ul>
<p>'Success Detection Retries'</p> <code>success-detect-retries</code> <code>[SuccessDetectionRetries]</code>	<p>Defines the minimum number of consecutive, successful keep-alive messages that the device sends to an offline proxy, before the device considers the proxy as online. The interval between the sending of each consecutive successful keep-alive is configured by the 'Success Detection Interval' parameter (see below). For an example of using this parameter, see the 'Success Detection Interval' parameter.</p> <p>The valid range is 1 to 100. The default is 1.</p> <p><b>Note:</b> The parameter is applicable only if you configure the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS, Using OPTIONS on Active Server</b> or <b>Using Fake REGISTER</b>.</p>
<p>'Success Detection Interval'</p> <code>success-detect-int</code> <code>[SuccessDetectionInterval]</code>	<p>Defines the interval (in seconds) between each successful keep-alive retries (as configured by the 'Success Detection Retries' parameter) that the device performs for offline proxies.</p> <p>The valid range is 1 to 200. The default is 10.</p> <p>For example, assume that the 'Success Detection Retries' parameter is configured to 3 and the 'Success Detection Interval' parameter to 5 (seconds). When connectivity is lost with the proxy, the device sends keep-alive messages to the proxy. If the device receives a successful response from the proxy, it sends another (1st) keep-alive after 5 seconds, and if successful, sends another (2nd) keep-alive after 5 seconds, and if successful, sends another (3rd) keep-alive after 5 seconds, and if successful, considers connectivity with the proxy as being restored.</p> <p><b>Note:</b> The parameter is applicable only if you configure the</p>

Parameter	Description
	'Proxy Keep-Alive' parameter to <b>Using OPTIONS, Using OPTIONS on Active Server</b> or <b>Using Fake REGISTER</b> .
'Failure Detection Retransmissions' fail-detect-rtx [FailureDetectionRetransmissions]	<p>Defines the maximum number of UDP retransmissions that the device sends to an offline proxy before the device considers the proxy as offline.</p> <p>The valid range is -1 to 255. The default is -1, which means that the setting of the global parameter [SIPMaxRtx] is applied.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS, Using OPTIONS on Active Server</b> or <b>Using Fake REGISTER</b>.</li> <li>■ If the device receives an ICMP error response (which indicates Host Unreachable or Network Unreachable) as opposed to a timeout, it may be desirable to abandon additional retries in favor of trying the next IP address (proxy) in the Proxy Set (typically required when Proxy Hot Swap is enabled). To enable this, configure the [AbortRetriesOnICMPError] parameter to 1.</li> </ul>
Redundancy	
'Redundancy Mode' proxy-redundancy-mode [ProxyRedundancyMode]	<p>Enables proxy redundancy.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured. Proxy redundancy method is according to the settings of the global parameter [ProxyRedundancyMode].</li> <li>■ [0] <b>Parking</b> = If the device operates with a proxy server that has the highest priority and the proxy goes offline, the device attempts to connect and operate with a different proxy that has the highest priority of all currently online proxies. However, once the device starts operating with this new proxy, it remains operating with it even if a previously offline proxy that has higher priority becomes online again.</li> <li>■ [1] <b>Homing</b> = The device always attempts to operate with the proxy that has the highest priority of all currently online proxies. For example, if the device is currently operating with proxy server 200.10.1.1 that has priority 4, and then a previously offline proxy 200.10.1.2 that has priority 0 (i.e., a higher priority) becomes online again, the device attempts to connect and operate with proxy 200.10.1.2.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For proxy redundancy, you also need to enable the proxy keep-alive feature (see the 'Proxy Keep-Alive' parameter, above). The <b>Homing</b> redundancy mode is applicable only to proxy keep-alive using SIP OPTIONS (i.e., 'Proxy Keep-Alive' parameter configured to <b>Using OPTIONS</b> or <b>Using OPTIONS on Active Server</b>) or using fake REGISTER requests (i.e., 'Proxy Keep-Alive' parameter configured to <b>Using Fake REGISTER</b>). The <b>Parking</b> redundancy mode is applicable to all proxy keep-alive methods (SIP OPTIONS and SIP REGISTER).</li> <li>■ From Version 7.20A.204, if you configure the parameter to <b>Parking</b> and the proxy keep-alive is done using REGISTER messages, when the proxy goes offline, the device arbitrarily chooses the next proxy to operate with.</li> <li>■ To configure proxy priority, see the 'Proxy Priority' parameter in the Proxy Address table (below).</li> </ul>
'Proxy Hot Swap Mode' is-proxy-hot-swap [IsProxyHotSwap]	<p>Enables the Proxy Hot-Swap feature, whereby if the device sends a SIP message (INVITE or REGISTER) to the proxy and the message fails, the device re-sends the same message to a redundant proxy in the Proxy Set. The redundant proxy is determined by your Proxy Set configuration (i.e., redundancy mode and load balancing).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Enable Only Before Alternative Routing</b> = If the device sends a SIP message (INVITE or REGISTER) to the proxy and the proxy rejects it or there is no response from the proxy for a user-defined number of re-transmissions (configured by the [SIPMaxRtx] parameter), the device doesn't attempt to connect to any other proxy in the Proxy Set, and the SIP message fails.</li> </ul> <p>However, if you've configured an SBC Alternative Routing Reasons Set for the IP Group (see <a href="#">Configuring SIP Response Codes for Alternative Routing Reasons</a> on page 1214), the device tries up to four online proxies in the Proxy Set. If it successfully connects to one of the redundant proxies, it re-sends the message to this proxy. This functionality doesn't apply to REGISTER requests initiated by the device (e.g., for Accounts).</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = If the device sends a SIP message (INVITE or</li> </ul>

Parameter	Description
	<p>REGISTER) to the proxy with which it is currently operating and any of the following occurs, the device re-sends the message to a redundant, online proxy:</p> <ul style="list-style-type: none"> <li>✓ No response is received from the proxy each time the device re-sends it. The number of retransmissions is configured by the [HotSwapRtx] parameter. In this scenario, the device sends itself the SIP response code 408 (Request Timeout).</li> <li>✓ (SBC Application) The proxy rejects the message with a SIP response code that you have configured for the Alternative Reasons Set that is assigned to the IP Group ('SBC Alternative Routing Reasons Set' parameter) associated with the Proxy Set (see <a href="#">Configuring SIP Response Codes for Alternative Routing Reasons</a> on page 1214).</li> <li>✓ (Gateway Application) The proxy rejects the message with a SIP response code that is configured in the Reasons for Tel-to-IP Alternative Routing table (see <a href="#">Alternative Tel-to-IP Routing Based on SIP Responses</a> on page 973).</li> </ul> <p><b>Note:</b>For the SBC application: You can employ alternative routing with this option. If no response is received from any of the redundant (online) proxies or the proxies reject the message with a SIP response code that you have configured for the Alternative Reasons Set that is assigned to the IP Group ('SBC Alternative Routing Reasons Set' parameter) associated with the Proxy Set, the device searches the IP-to-IP Routing table for an alternative routing rule and if found, sends the message to the rule's destination. For more information on the Proxy Hot Swap feature and alternative routing based on SIP response codes, see <a href="#">Configuring SIP Response Codes for Alternative Routing Reasons</a> on page 1214.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Disable</b> = (Default) Disables the Proxy Hot-Swap feature. If the device sends a SIP message (INVITE or REGISTER) to the proxy and the proxy rejects it or there is no response from the proxy for a user-defined number of re-transmissions (configured by the [SIPMaxRtx] parameter), the device doesn't attempt to connect to any other proxy in the Proxy Set, and the SIP message fails.</li> </ul>

Parameter	Description
'Proxy Load Balancing Method' proxy-load-balancing-method  [ProxyLoadBalancingMethod]	<p>Enables load balancing between proxy servers in the Proxy Set.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Disables proxy load balancing.</li> <li>■ [1] <b>Round Robin</b> = The device sends outgoing SIP messages to the online proxy servers of the Proxy Set in a round-robin fashion. The order of the round-robin is determined by the listed order of the IP addresses in the Proxy Address table and their priority. You can configure the priority for each IP address using the 'Proxy Priority' parameter (see below).</li> </ul> <p>For DNS-resolved IP addresses for proxy servers configured with an FQDN (including NAPTR and SRV, if configured), the priority is received from the DNS. The IP address list is refreshed every user-defined interval, configured by the [ProxyIPListRefreshTime] parameter. If a change in the order of the IP address entries in the list occurs, all load statistics are erased and balancing starts over again.</p> <p>For the Gateway application, REGISTER messages are also distributed in a round-robin fashion, unless you have configured a specific IP address of a registrar server (using the [RegistrarIP] parameter).</p> <ul style="list-style-type: none"> <li>■ [2] <b>Random Weights</b> = The outgoing requests are not distributed equally among the proxy servers. The distribution is determined by the weight of the proxy servers. You can configure the weight per proxy server, using the 'Proxy Random Weight' parameter in the Proxy Address table (see below).</li> </ul> <p>For proxy servers configured with an FQDN, the weight of each DNS-resolved IP address is received from the DNS server (using SRV records). However, if you have configured the weight for the FQDN in the 'Proxy Random Weight' parameter, this parameter's value overrides the weight from the DNS server. The device sends the requests in such a fashion that each proxy receives a percentage of the requests according to its' weight.</p>
'Min. Active Servers for Load Balancing' min-active-servers-lb  [MinActiveServersLB]	<p>Defines the minimum number of proxies in the Proxy Set that must be online for the device to consider the Proxy Set as online, when proxy load balancing is used.</p> <p>The valid value is 1 to 15. The default is 1.</p> <p><b>Note:</b> The parameter is applicable only if proxy load balancing is enabled (see the 'Proxy Load Balancing Method' parameter,</p>

Parameter	Description
	above).
Advanced	
'Classification Input' classification-input [ClassificationInput]	<p>Defines how the device classifies incoming IP calls to the Proxy Set.</p> <ul style="list-style-type: none"> <li>■ [0] <b>IP Address only</b> = (Default) Classifies calls to the Proxy Set according to IP address only.</li> <li>■ [1] <b>IP Address, Port &amp; Transport Type</b> = Classifies calls to the Proxy Set according to IP address, port, and transport type.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ The parameter is applicable only if the IP Groups table's parameter 'Classify by Proxy Set' is configured to <b>Enable</b> (see <a href="#">Configuring IP Groups</a> on page 591).</li> <li>■ If multiple Proxy Sets are configured with the same IP address and associated with the same SIP Interface, the device may classify the SIP dialog (based on Proxy Set) to an incorrect IP Group. In such a scenario, the device uses the Proxy Set with the lowest Index number (e.g., Proxy Set ID #1 over Proxy Set ID #4). A syslog warning message is generated in such scenarios. Therefore, it is recommended to configure each Proxy Set with a unique IP address.</li> </ul> <p>If multiple Proxy Sets are configured with the same IP address but associated with different SIP Interfaces, then classification based on Proxy Set can be correctly achieved.</p> <p>If multiple Proxy Sets are configured with the same IP address and SIP Interface, but with different ports (e.g., 10.1.1.1:5060 and 10.1.1.1:5070) and the parameter is configured to <b>IP Address, Port &amp; Transport Type</b>, classification to the correct IP Group is achieved. Therefore, when classification is by Proxy Set, pay attention to the configured IP addresses and this parameter. When multiple Proxy Sets are configured with the same IP address, the device selects the matching Proxy Set in the following order:</p> <ul style="list-style-type: none"> <li>✓ Selects the Proxy Set whose IP address, port, and transport type match the source of the incoming SIP request (regardless of the settings of this parameter).</li> </ul>

Parameter	Description															
	<div><div><div>✓</div><div>If no match is found for above, it selects the Proxy Set whose IP address and transport type match the source of the incoming SIP request (if the parameter is configured to <b>IP Address Only</b>).</div></div><div><div>✓</div><div>If no match is found for above, it selects the Proxy Set whose IP address match the source of the incoming SIP request (if the parameter is configured to <b>IP Address Only</b>).</div></div></div> <div>For example:</div> <table><tr><th>Index</th><th>Classification Input</th><th>Proxy Address (IP:Port;Transport Type)</th></tr><tr><td>1</td><td><b>IP Address, Port &amp; Transport Type</b></td><td>10.10.10.10:5060;UDP</td></tr><tr><td>2</td><td><b>IP Address only</b></td><td>10.10.10.10:5060;UDP</td></tr><tr><td>3</td><td><b>IP Address only</b></td><td>10.10.10.10:5070;UDP</td></tr><tr><td>4</td><td><b>IP Address only</b></td><td>10.10.10.10:5060;TCP</td></tr></table> <div><div>✓</div><div><b>Incoming SIP request from 10.10.10.10:5060;UDP:</b> Best match is #1 and #2 (same priority); second best match is #3 (due to transport type); third best match is #4.</div></div> <div><div>✓</div><div><b>Incoming SIP request from 10.10.10.10:5080;TLS:</b> Best match is #2, #3 and #4 (same priority).</div></div> <div><div>✓</div><div><b>Incoming SIP request from 10.10.10.10:5070;TCP:</b> Best match is #4 (due to transport type); second best match is #2 and #3 (same priority).</div></div>	Index	Classification Input	Proxy Address (IP:Port;Transport Type)	1	<b>IP Address, Port &amp; Transport Type</b>	10.10.10.10:5060;UDP	2	<b>IP Address only</b>	10.10.10.10:5060;UDP	3	<b>IP Address only</b>	10.10.10.10:5070;UDP	4	<b>IP Address only</b>	10.10.10.10:5060;TCP

<div>'DNS Resolve Method' dns-resolve-method [DNSResolveMethod]</div>	<div>Defines the DNS query record type for resolving the proxy server's hostname / domain name (FQDN) into an IP address (es).</div> <div><div>■</div><div>[-1] = Not configured. DNS resolution method is according to the settings of the global parameter [ProxyDNSQueryType].</div></div> <div><div>■</div><div>[0] <b>A-Record</b> = (Default) The device performs a DNS A-record query to resolve the FQDN into an IP address(es).</div></div> <div><div>■</div><div>[1] <b>SRV</b> = If the proxy address is configured with a domain name without a port (e.g., domain.com), the device performs an SRV query. The SRV query returns the host</div></div>															

Parameter	Description
	<p>names (and their weights). The device then performs DNS A-record queries per host name (according to the received weights). If the configured proxy address contains an FQDN with a port (e.g., domain.com:5080), the device performs a regular DNS A-record query.</p> <ul style="list-style-type: none"> <li>■ [2] <b>NAPTR</b> = The device performs a NAPTR query. If successful, the device sends an SRV query according to the information received in the NAPTR response (in preference order). The SRV response is resolved to obtain one or more FQDNs, which are then resolved with A-record queries. If no online servers are found, the resolution process returns to the next SRV record in the NAPTR response, and so on. If the NAPTR query fails, the device performs a SRV query according to the configured transport type. If the configured proxy address contains an domain name with a port (e.g., domain.com:5080), the device performs a regular DNS A-record query. If the transport type is configured for the proxy address, a NAPTR query is not performed.</li> <li>■ [3] <b>Microsoft Skype for Business</b> = The device performs an SRV query as required by Microsoft when the device is deployed in a Microsoft Skype for Business environment. The device sends a special SRV query to the DNS server according to the transport protocol configured in the 'Transport Type' parameter (described later in this section): <ul style="list-style-type: none"> <li>✓ <b>TLS</b></li> <li>✓ <b>TCP:</b> "_sipinternal._tcp.&lt;domain&gt;" and "_sip_tcp.&lt;domain&gt;".</li> <li>✓ <b>Undefined:</b> "_sipinternaltls_tcp.&lt;domain&gt;", "_sipinternal_tcp.&lt;domain&gt;", "_sip_tls.&lt;domain&gt;" and "_sip_tcp.&lt;domain&gt;".</li> </ul> </li> </ul> <p>The SRV query returns the host names (and their weights). The device then performs DNS A-record queries per host name (according to the received weights) to resolve into IP addresses.</p> <p><b>Note:</b> The device caches the DNS-resolved IP addresses of the last successful DNS query of a Proxy Set. The device uses the cache if the DNS server goes offline. This functionality occurs regardless of the setting of the [DNSCache] parameter.</p>
'Accept DHCP Proxy List'	Enables the device to obtain the Proxy Set's address(es) from a

Parameter	Description
accept-dhcp-proxy-list [AcceptDHCPProxyList]	<p>DHCP server. When enabled, it sends a DHCP request with Option 120 (SIP server address) to a DHCP server. This occurs upon a DHCP refresh (lease renewal). When the device receives the list of IP addresses (or DNS) from the server, it adds them to the Proxy Set (replaces any existing IP addresses or DNS).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> When enabled, the device uses UDP and port 5060.</p>
'TLS Remote Subject Name' tls-remote-subject-name [TLSRemoteSubjectName]	<p>Defines the Subject Name of the TLS certificate received from the remote side when establishing a TLS connection with the Proxy Set.</p> <p>When the device receives a certificate from the remote side, it validates the certificate by comparing the certificate's Subject Alternative Names (SAN) with the Proxy Set's addresses (IP address and FQDN) and the parameter's value. If a SAN matches an address or the parameter's value, the device considers the certificate as valid and establishes the TLS connection and allows the call.</p> <p>If there is no match and the SAN is marked as "critical", the device doesn't establish a TLS connection and rejects the call. If there is no match and the SAN isn't marked as "critical", the device compares the Proxy Set's addresses (IP address and FQDN) and the parameter's value with the certificate's Common Name (CN). If any of them match, the device establishes a TLS connection and allows the call; otherwise, it doesn't establish a TLS connection and rejects the call.</p> <p>The valid value is a string of up to 100 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the Proxy Set's parameter 'Peer Host Name Verification Mode' (or global parameter [PeerHostNameVerificationMode]) to <b>Server Only</b> or <b>Server &amp; Client</b>.</li> <li>■ If you configure the parameter, it overrides the global parameter [TLSRemoteSubjectName].</li> <li>■ For incoming messages, the 'TLS Mutual Authentication' parameter (global or per SIP Interface) must be enabled.</li> <li>■ For outgoing messages, either the 'TLS Mutual</li> </ul>

Parameter	Description
	<p>Authentication' parameter (global or per SIP Interface) or the 'TLS Client Verify Server Certificate' parameter must be enabled.</p> <ul style="list-style-type: none"> <li>■ A certificate may include multiple SAN types (e.g., Email, DNS, URI, and IP). The only SAN types that the device compares for matching are DNS and IP.</li> </ul>
<p>'Peer Host Name Verification Mode'</p> <p>peer-host-name-verification-mode</p> <p>[PeerHostNameVerificationMode]</p>	<p>Enables the device to verify the Subject Name of the TLS certificate received from the remote side for authentication and establishing a TLS connection.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Use Global Settings</b> = (Default) The settings of the global parameter [<a href="#">'Peer Host Name Verification Mode'</a> on page 1812] is applied.</li> <li>■ [0] <b>Disable</b> = No certificate verification is done.</li> <li>■ [1] <b>Server Only</b> = The device verifies the certificate's Subject Name only when it acts as a client for the TLS connection.</li> <li>■ [2] <b>Server &amp; Client</b> = The device verifies the certificate's Subject Name when it acts as a server or client for the TLS connection.</li> </ul> <p>If the device receives a certificate from a SIP entity (IP Group) and the parameter is configured to <b>Server Only</b> or <b>Server &amp; Client</b> (or global parameter is used and configured to one of these options), it attempts to authenticate the certificate based on the certificate's address:</p> <ol style="list-style-type: none"> <li>1. If the connection was classified to a Proxy Set, the device compares the certificate's Subject Alternative Names (SANs) with the Proxy Set's addresses (IP address or FQDN) and the 'TLS Remote Subject Name' parameter's value. The device checks the FQDN itself and not the DNS-resolved IP addresses.</li> <li>2. If a SAN matches an address or the 'TLS Remote Subject Name' parameter's value, the device considers the certificate as valid and establishes the TLS connection and allows the call.</li> <li>3. If there is no match and the SAN is marked as "critical", the device doesn't establish a TLS connection and rejects the call. If there is no match and the SAN isn't marked as "critical", the device compares the Proxy Set's addresses (IP</li> </ol>

Parameter	Description
	<p>address or FQDN) and the 'TLS Remote Subject Name' parameter's value with the certificate's Common Name (CN). If any of them match, the device establishes a TLS connection and allows the call; otherwise, the device doesn't establish a TLS connection and rejects the call.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>Server &amp; Client</b>, enable the global 'TLS Mutual Authentication' parameter [SIPSRequireClientCertificate].</li> <li>■ If you configure the parameter to <b>Server Only</b>, enable the 'TLS Client Verify Server Certificate' [VerifyServerCertificate] global parameter.</li> <li>■ For FQDN, the certificate may use wildcards (*) to replace parts of the domain name.</li> </ul>
<p>'TCP/TLS Connection Reuse'</p> <p>connection-reuse</p> <p>[ConnectionReuse]</p>	<p>Enables the reuse of the initially established TCP or TLS connection between the device and the proxy server for all subsequent SIP requests sent to the proxy server. New out-of-dialog requests (e.g., INVITE or REGISTER) use the same secured connection. One of the benefits of enabling the parameter is that it may improve performance by eliminating the need for additional TCP/TLS handshakes with the proxy, allowing sessions to be established rapidly.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = The device establishes a new TCP or TLS connection with the proxy for each SIP request.</li> <li>■ [1] <b>Enable</b> = The device uses the same TCP or TLS connection for all SIP requests with the proxy.</li> <li>■ [2] <b>Use Global Settings</b> = (Default) This feature is according to the global parameter ['TCP/TLS Connection Reuse' on page 1859].</li> </ul> <p><b>Note:</b> For SIP responses, the device always uses the TCP/TLS connection of the corresponding incoming SIP request, regardless of the parameter's setting.</p>
<p>'In-Call Route Mode'</p> <p>in-call-route-mode</p> <p>[InCallRouteMode]</p>	<p>Enables the device to send in-call SIP messages (e.g., re-INVITE and BYE) to the currently active proxy if the proxy to which the dialog-initiating INVITE message was sent is currently offline. This is applicable when the Proxy Set has multiple proxies (IP addresses). This feature occurs even if the currently active proxy was offline when the call was established.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device sends in-call SIP messages to the currently active proxy if it was online upon call establishment. If it was offline upon call establishment, the device sends the in-dialog message to a different proxy in the Proxy Set. If no additional proxies exist, the device doesn't send the message.</li> <li>■ [1] <b>Enable</b> = The device sends in-call SIP messages to the currently active proxy, regardless of its state (i.e., online or offline) when the call was established.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When enabling this feature, it's recommended to configure the Proxy Set's 'Proxy Keep-Alive' parameter to <b>Enable</b>.</li> <li>■ When enabling this feature, make sure to configure all proxies in the Proxy Set with the same transport type (e.g., all TCP). Otherwise, unexpected behavior (even call failure) may occur.</li> <li>■ The device's generated CDR displays only the proxy used for the dialog-initiating INVITE message.</li> </ul>
Proxy Address Table	
'Index' proxy-ip-index [ProxyIp_ProxyIpIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Proxy Address' proxy-address [ProxyIp_IpAddress]	Defines the address of the proxy server (Proxy Set). The address can be defined as an IP address in dotted-decimal notation (e.g., 201.10.8.1) or FQDN. You can also specify the port using the following format: <ul style="list-style-type: none"> <li>■ IPv4 address: &lt;IP address&gt;:&lt;port&gt; (e.g., 201.10.8.1:5060)</li> <li>■ IPv6 address: &lt;[IPV6 address]&gt;:&lt;port&gt; (e.g., [2000::1:200:200:86:14]:5060)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When configured with an FQDN:               <ul style="list-style-type: none"> <li>✓ You can configure the periodic interval at which the device performs DNS queries to resolve the FQDN into IP addresses. For more information, see the [ProxyIPListRefreshTime] parameter.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ The device caches the DNS-resolved IP addresses of the last successful DNS query of a Proxy Set, which is used if the DNS server goes offline. This functionality occurs regardless of the setting of the [DNSCache] parameter.</li> <li>✓ You can configure the method (e.g., A-record) for resolving the domain name into an IP address, using the 'DNS Resolve Method' parameter in this table (see above).</li> <li>■ For the SBC application: You can configure the device to use the port indicated in the Request-URI of the incoming message, instead of the port configured for the parameter. To enable this, use the 'Route Using Request URI Port' parameter for the IP Group that is associated with the Proxy Set (<a href="#">Configuring IP Groups</a> on page 591).</li> <li>■ If you are configuring the Proxy Sets with IP addresses, it is highly recommended to configure each Proxy Set with a unique IP address. Configuring multiple Proxy Sets with the same IP address can cause problems classifying incoming SIP requests to source IP Groups based on Proxy Set. If you have configured multiple Proxy Sets with the same IP address, the device uses the Proxy Set with lowest Index number. For example, if you have configured Proxy Set ID #1 and Proxy Set ID #4 with the same IP address, the device uses Proxy Set ID #1 to classify the incoming SIP request to an IP Group.</li> </ul> <p>However, configuring multiple Proxy Sets with the same IP address, but with different SIP Interfaces is acceptable for classifying incoming SIP requests to source IP Groups based on Proxy Set.</p> <p>For more information on determining the Proxy Set, see the 'Classification Input' parameter (above) parameter .</p>
'Transport Type' transport-type [ProxyIp_ TransportType]	<p>Defines the transport type for communicating with the proxy.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured. The transport type is according to the settings of the global parameter [SIPTransportType].</li> <li>■ [0] <b>UDP</b></li> <li>■ [1] <b>TCP</b></li> <li>■ [2] <b>TLS</b></li> </ul>

Parameter	Description
'Proxy Priority' priority [ProxyIp_Priority]	<p>Defines the priority of the proxy. When a proxy server goes offline, the device attempts to connect to an online proxy server that has the highest priority.</p> <p>The valid value is 0 to 65535, where 0 is the highest priority and 65535 the lowest. The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You must configure both priority and weight (or none of them). In other words, if you configure this parameter, you must also configure the 'Proxy Random Weight' parameter. If you don't configure this parameter, you must also not configure the 'Proxy Random Weight' parameter.</li> <li>■ If weight and priority are not configured for any of the proxy servers of the Proxy Set, the order in which the addresses (IP addresses and FQDNs) are listed in the table determine their priority (i.e., top-listed address has the highest priority).</li> <li>■ For FQDNs, weight and priority of DNS-resolved IP addresses are determined by the DNS server. However, this parameter's value overrides the priority received from the DNS.</li> <li>■ If you have configured at least one of the proxy servers of the Proxy Set with weight and priority, the device prioritizes all the configured proxy servers according to weight and priority. In this case, proxy servers that are not configured with priority (i.e., 0) are considered as proxy servers with the highest priority.</li> <li>■ The parameter is applicable to load balancing (see the 'Proxy Load Balancing Method' parameter), and homing and parking redundancy (see the 'Redundancy Mode' parameter).</li> </ul>
'Proxy Random Weight' weight [ProxyIp_Weight]	<p>Defines the weight of the proxy.</p> <p>The valid value is 0 to 65535, where 0 is the highest weight and 65535 the lowest. The default is 0.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you configure the 'Proxy Load Balancing Method' parameter to <b>Random Weights</b>. For more information on weights, see this parameter.</li> <li>■ You must configure both priority and weight (or none of</li> </ul>

Parameter	Description
	<p>them). In other words, if you configure this parameter, you must also configure the 'Proxy Priority' parameter. If you don't configure this parameter, you must also not configure the 'Proxy Priority' parameter.</p> <ul style="list-style-type: none"> <li>■ For proxy servers configured with FQDNs, this parameter's value overrides the weight received for DNS-resolved IP addresses from the DNS server.</li> </ul>

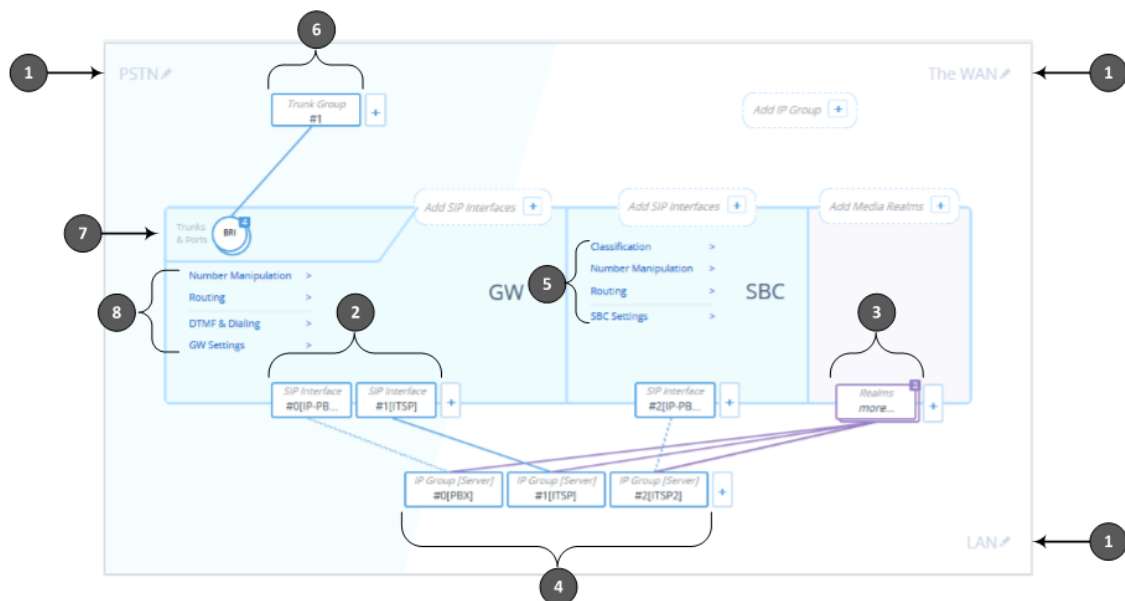

## Building and Viewing SIP Entities in Topology View

The Topology view lets you easily build and view your main SIP entities, including trunks and ports, Trunk Groups, IP Groups, SIP Interfaces, and Media Realms. The Topology view graphically displays these entities and the associations between them, giving you a better understanding of your SIP topology and configuration. The Topology view also lets you configure additional SIP settings that are important to your deployment such as routing and manipulation. You can use the Topology view as an alternative to configuring the entities in their respective Web pages or you can use it in combination.

To access the Topology view, do one of the following:

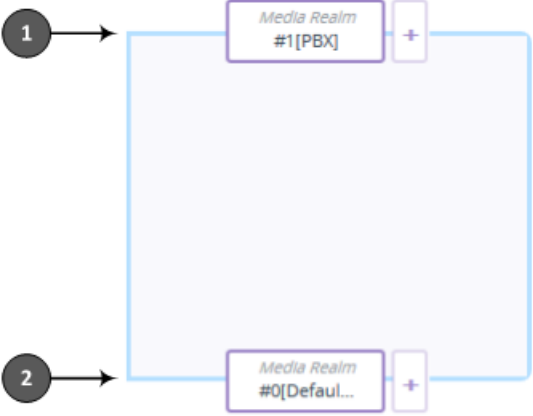

- Click the Topology View home  icon (**Setup** menu > **Signaling & Media** tab > **Topology View**).
- Click the logo, which is located in the top-left corner of the Web interface.

The main areas of the Topology view is shown below and described in the subsequent table.

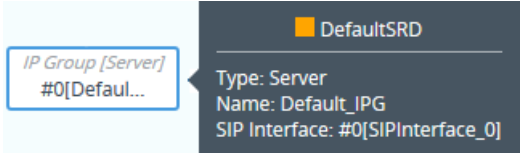

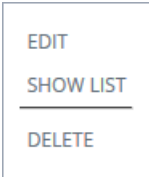

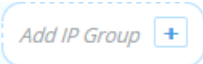

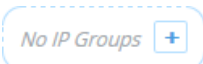

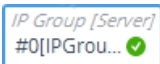

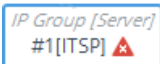

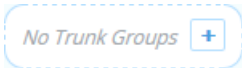

**Table 18-8: Description of Topology View**

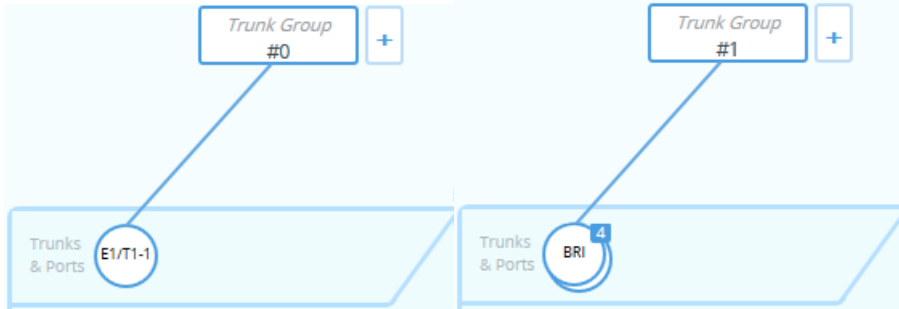

Item #	Description
1	<p>Demarcation area of the topology. By default, the Topology view displays the following names to represent the different demarcations of your voice configuration:</p> <ul style="list-style-type: none"> <li>■ "PSTN": Indicates the PSTN side</li> <li>■ "WAN": Indicates the external network side</li> <li>■ "LAN": Indicates the internal network (e.g., inside the company)</li> </ul> <p>To modify a demarcation name, do the following:</p> <ol style="list-style-type: none"> <li>1. Click the demarcation name; the name becomes editable in a text box, as shown in the example below:</li> </ol>  <ol style="list-style-type: none"> <li>2. Type a name as desired, and then click anywhere outside of the text box to apply the name.</li> </ol> <p>You can use demarcation to visually separate your voice network to provide a clearer understanding of your topology. This is especially useful for IP Groups, SIP Interfaces, and Media Realms, where you can display them on the top or bottom border of the Topology view (as shown in the figure below for callouts #1 and #2, respectively). For example, on the top border you can position all entities relating to WAN, and on the bottom border all entities relating to LAN.</p>  <p>By default, configuration entities are displayed on the bottom border. To define the position, use the 'Topology Location' parameter when configuring the entity, where <b>Down</b> is the bottom border and <b>Up</b> the top border:</p> <p>Topology Location <input type="text" value="Down"/></p>
2	<p>Configured SIP Interfaces. Each SIP Interface is displayed using the following "SIP Interface"-titled icon, which includes the name and row index number:</p>

Item #	Description
	<div data-bbox="839 282 986 344" data-label="Image"> </div> <p data-bbox="440 367 1394 439">If you hover your mouse over the icon, a pop-up appears displaying the following basic information (example):</p> <div data-bbox="817 450 1010 736" data-label="Image"> </div> <p data-bbox="440 759 1394 792">If you click the icon, a drop-down menu appears listing the following commands:</p> <div data-bbox="836 804 986 978" data-label="Image"> </div> <ul data-bbox="432 1014 1362 1240" style="list-style-type: none"> <li>■ <b>Edit:</b> Opens a dialog box in the SIP Interfaces table to modify the SIP Interface.</li> <li>■ <b>Show List:</b> Opens the SIP Interfaces table.</li> <li>■ <b>Delete:</b> Opens the SIP Interfaces table where you are prompted to confirm deletion of the SIP Interface.</li> </ul> <p data-bbox="440 1265 908 1299">To add a SIP Interface, do the following:</p> <ol data-bbox="432 1328 1394 1749" style="list-style-type: none"> <li>1. Click the <b>Add SIP Interface</b>  plus icon. The icon appears next to existing SIP Interfaces, or as  when no SIP Interfaces exist on a topology border, or as  when there are no SIP Interfaces at all. The SIP Interfaces table opens with a new dialog box for adding a SIP Interface to the next available index row.</li> <li>2. Configure the SIP Interface as desired, and then click <b>Apply</b>; the SIP Interfaces table closes and you are returned to the Topology View, displaying the new SIP Interface.</li> </ol> <p data-bbox="440 1780 1276 1852">For more information on configuring SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</p>
3	Configured Media Realms. Each Media Realm is displayed using the following "Media Realm"-titled icon, which includes the name and row index number:

Item #	Description
	<div data-bbox="831 277 992 342" data-label="Image"> </div> <p data-bbox="438 367 1396 439">If you hover your mouse over the icon, a pop-up appears displaying the following basic information (example):</p> <div data-bbox="775 448 1046 640" data-label="Image"> </div> <p data-bbox="438 663 1396 694">If you click the icon, a drop-down menu appears listing the following commands:</p> <div data-bbox="836 705 986 882" data-label="Image"> </div> <ul data-bbox="432 916 1370 1142" style="list-style-type: none"> <li>■ <b>Edit:</b> Opens a dialog box in the Media Realms table to modify the Media Realm.</li> <li>■ <b>Show List:</b> Opens the Media Realms table.</li> <li>■ <b>Delete:</b> Opens the Media Realms table where you are prompted to confirm deletion of the Media Realm.</li> </ul> <p data-bbox="438 1171 916 1202">To add a Media Realm, do the following:</p> <ol data-bbox="432 1227 1388 1695" style="list-style-type: none"> <li>1. Click the <b>Add Media Realm</b>  plus icon. The icon appears next to existing Media Realms, or as  when no Media Realms exist on a topology border, or as  when there are no Media Realms at all. The Media Realms table opens with a new dialog box for adding a Media Realm to the next available index row.</li> <li>2. Configure the Media Realm as desired, and then click <b>Apply</b>; the Media Realms table closes and you are returned to the Topology View, displaying the new Media Realm.</li> </ol> <p data-bbox="438 1722 1324 1794">For more information on configuring Media Realms, see <a href="#">Configuring Media Realms</a> on page 548.</p>
4	<p>Configured IP Groups. Each IP Group is displayed using the following "IP Group [Server]" or "IP Group [User]" titled icon (depending on whether it's a Server- or User-type IP Group respectively), which includes the name and row index number (example of a Server-type):</p>

Item #	Description
	<p></p> <p>If you hover your mouse over the icon, a pop-up appears displaying the following basic information (example):</p> <p></p> <p>If you click the icon, a drop-down menu appears listing the following commands:</p> <p></p> <ul style="list-style-type: none"> <li>■ <b>Edit:</b> Opens a dialog box in the IP Groups table to modify the IP Group.</li> <li>■ <b>Show List:</b> Opens the IP Groups table.</li> <li>■ <b>Delete:</b> Opens the IP Groups table where you are prompted to confirm deletion of the IP Group.</li> </ul> <p>To add an IP Group, do the following:</p> <ol style="list-style-type: none"> <li>1. Click the <b>Add IP Group</b>  plus icon. The icon appears next to existing IP Groups, or as  when no IP Groups exist on a topology border, or as  when there are no IP Groups at all.</li> </ol> <p>The IP Groups table opens with a new dialog box for adding a IP Group to the next available index row.</p> <ol style="list-style-type: none"> <li>2. Configure the IP Group as desired, and then click <b>Apply</b>; the IP Groups table closes and you are returned to the Topology View, displaying the new IP Group.</li> </ol> <p>For more information on configuring IP Groups, see <a href="#">Configuring IP Groups</a> on page 591.</p> <p>IP Group icons also display connectivity status with Server-type IP Groups:</p> <ul style="list-style-type: none"> <li>■  (Green with check mark): Keep-alive is successful and connectivity exists with IP Group.</li> <li>■  (Red with "x"): Keep-alive has failed and there is a loss of connectivity with the IP Group.</li> </ul>

Item #	Description
	<p>The line type connecting between an IP Group and a SIP Interface indicates whether a routing rule has been configured for the IP Group. A solid line indicates that you have configured a routing rule for the IP Group; a dashed line indicates that you have yet to configure a routing rule.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can also view connectivity status in the IP Groups table.</li> <li>■ To support the connectivity status feature, you must enable the keep-alive mechanism for the Proxy Set that is associated with the IP Group (see <a href="#">Configuring Proxy Sets</a> on page 632).</li> <li>■ The green-color state also applies to scenarios where the device rejects calls with the IP Group due to low QoE (e.g., low MOS), despite connectivity.</li> </ul>
5	<p>Links to Web pages relating to commonly required SBC configuration:</p> <ul style="list-style-type: none"> <li>■ Classification: Opens the Classification table where you can configure Classification rules (see <a href="#">Configuring Classification Rules</a> on page 1171).</li> <li>■ Number Manipulation: Opens the Outbound Manipulations table where you can configure manipulation rules on SIP Request-URI user parts (source or destination) or calling names in outbound SIP dialog requests (see <a href="#">Configuring IP-to-IP Outbound Manipulations</a> on page 1236).</li> <li>■ Routing: Opens the IP-to-IP Routing table where you can configure IP-to-IP routing rules (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186).</li> <li>■ SBC Settings: Opens the SBC General Settings page where you can configure miscellaneous settings.</li> </ul>
6	<p>Configured Trunk Groups. Each Trunk Group is displayed using the following "Trunk Group"-titled icon, which includes the row index number:</p> <div data-bbox="828 1435 991 1496" data-label="Image"> </div> <p>To edit or delete the Trunk Group, click the icon, and then from the drop-down menu, choose <b>Show List</b> to open the Trunk Groups table.</p> <p>To add a Trunk Group, do the following:</p> <ol style="list-style-type: none"> <li>1. Click the <b>Add Trunk Group</b>  plus icon. The icon appears next to existing Trunk Groups or as  when there are no Trunk Groups. The Trunk Groups table opens, allowing you to configure a Trunk Group.</li> <li>2. Configure the Trunk Group as desired, and then click <b>Apply</b>; the Trunk Groups table closes and you are returned to the Topology View, displaying the new Trunk Group and a line connecting it to the associated port, as</li> </ol>

Item #	Description
	<p>shown in the example below:</p>  <p>For more information on configuring Trunk Groups, see <a href="#">Configuring Trunk Groups</a> on page 934.</p>
7	<p>Displays the device's hardware configuration concerning telephony (Tel/PSTN) trunks and ports. It also displays the number of ports. The ports are displayed as round icons, as shown in Item #6 above.</p> <p>To configure a digital trunk, do the following:</p> <ol style="list-style-type: none"> <li>1. Click the icon, and then from the drop-down menu, choose <b>Trunk Settings</b>; the Trunk Settings page appears.</li> <li>2. Configure the trunk as desired.</li> </ol> <p>For more information on configuring trunk settings, see <a href="#">Configuring Trunk Settings</a> on page 878.</p>
8	<p>Links to Web pages relating to commonly required Gateway configuration:</p> <ul style="list-style-type: none"> <li>■ <b>Number Manipulation:</b> Opens the Destination Phone Number Manipulation for IP-to-Tel Calls table where you can configure destination phone number manipulation rules for IP-to-Tel calls (see <a href="#">Configuring Source-Destination Number Manipulation Rules</a> on page 983).</li> <li>■ <b>Routing:</b> Opens the IP-to-Tel Routing table where you can configure IP-to-Tel routing rules (see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960).</li> <li>■ <b>DTMF &amp; Dialing:</b> Opens the DTMF &amp; Dialing page where you can configure DTMF and dialing related settings.</li> <li>■ <b>GW Settings:</b> Opens the Gateway General Settings page where you can configure general gateway related settings.</li> </ul>

## 19 Coders and Profiles

This section describes configuration of coders and SIP profiles.

### Configuring Coders Groups

The Coders Groups table lets you configure Coders Groups, which determines the audio (voice) coders used for calls.

Coders Groups are configured using two tables with parent-child relationship:

- **Coders Groups table (parent):** This table defines the name of the Coders Group. You can configure up to 11 Coders Groups.
- **Coders table (child):** This table defines the coders of the selected Coders Group. You can configure up to 10 coders per Coders Group. Each coder can be configured with a packetization time (ptime), bit rate, payload type, and silence suppression. The first coder listed in the Coders table has the highest priority and is used by the device whenever possible. If the remote side cannot use the first coder, the device attempts to use the next coder in the list, and so on.

The Coders Groups table provides a default Coder Group called "AudioCodersGroups\_0" (index 0), which includes the G.711 A-law coder. If you don't configure any other Coder Groups, the device uses this default Coder Group (which you can modify) for all calls.

If you want to use specific coders or coder settings (e.g., packetization time) for specific calls (IP Groups), you can configure different Coders Groups and then assign them to the Tel Profiles (see [Configuring Tel Profile](#) on page 755) or IP Profiles (see [Configuring IP Profiles](#) on page 674) associated with the IP Groups. If an IP Group isn't associated with a Coders Group, the default Coders Group is used for the IP Group.

You can also use Coder Groups for audio coder transcoding of SBC calls. If two SIP entities need to communicate, but one doesn't support a coder that is required by the other, the device can add the required coder to the SDP offer. The added coder is referred to as an *extension* coder. For more information, see [Coder Transcoding](#) on page 1139.

To use a Coder Group for transcoding:

1. Configure a Coder Group.
2. In the IP Profile associated with the relevant SIP entity (see [Configuring IP Profiles](#) on page 674):
  - Assign the Coder Group, using the 'Extension Coders Group' parameter.
  - Enable the use of the Coder Group for transcoding, by configuring the 'Allowed Coders Mode' parameter to **Restriction** or **Restriction and Preference**.

- For supported audio coders, see [Supported Audio Coders](#) on page 665.
- Some coders are license-based and are available only if included in the device's License Key. For more information, contact the sales representative of your purchased device.
- Only the packetization time of the first coder listed in the Coder Group is declared in INVITE/200 OK SDP even if multiple coders are configured. The device always uses the packetization time requested by the remote side for sending RTP packets. If not specified, the packetization time is assigned the default value.
- The value of some fields is hard-coded according to common standards (e.g., payload type of G.711 U-law is always 0).
- The G.722 coder provides Packet Loss Concealment (PLC) capabilities, which ensures higher voice quality.
- Opus coder:
  - ✓ For SBC calls: If one leg uses a narrowband coder (e.g., G.711) and the other leg uses the Opus coder, the device maintains the narrowband coder flavor by using the narrowband Opus coder. Alternatively, if one leg uses a wideband coder (e.g., G.722) and the other leg uses the Opus coder, the device maintains the wideband coder flavor by using the wideband Opus coder.
  - ✓ Gateway calls always use the narrowband Opus coder.
- For more information on V.152 and implementation of T.38 and VBD coders, see [V.152 Support](#) on page 295.
- The G.729 coder refers to G.729A if silence suppression is disabled, or to G.729AB if silence suppression is enabled.

The following procedure describes how to configure Coders Groups through the Web interface. You can also configure them through other management platforms:

- **Coders Groups table (parent):** ini file [AudioCodersGroups] or CLI (`configure voip > coders-and-profiles audio-coders-groups`)
- **Coders table (child):** ini file [AudioCoders] or CLI (`configure voip > coders-and-profiles audio-coders-groups > audio-coders`)

#### ➤ To configure a Coders Group:

1. Open the Coders Groups table (**Setup** menu > **Signaling & Media** tab > **Coders & Profiles** folder > **Coders Groups**).
2. Click **New**; the following dialog box appears:

GENERAL	
Index	2
Name	

3. Configure a name for the Coders Group according to the parameters described in the table below.

4. Click **Apply**.**Table 19-1: Coders Groups Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' coders- group-name [Name]	Defines a descriptive name for the Coder Group, which is used when associating the row in other tables. The valid value is a string of up to 40 characters.

5. Select the Coders Group that you configured, and then click the **Coders Table** link located below the table; the Coders table appears.6. Click **New**; the following dialog box appears:

*Coders Table [99]* - x

GENERAL

Index	<input type="text" value="1"/>
Name	• G.723.1 ▼
pTime	30 ▼
Rate	5.3 ▼
Payload Type	4
Silence Suppression	Disable ▼
Coder Specific	<input type="text"/>

## 7. Configure a coder for the Coders Group according to the parameters described in the table below.

8. Click **Apply**, and then save your settings to flash memory.**Table 19-2: Coders Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines the coder type. For supported coders, see <a href="#">Supported Audio Coders</a> on page 665. <b>Note:</b> Each coder type (e.g., G.729) can be configured only once per Coder Group.
'pTime'	Defines the packetization time (in msec) of the coder.

Parameter	Description
p-time [pTime]	The packetization time determines how many coder payloads are combined into a single RTP packet. For ptime, see <a href="#">Supported Audio Coders</a> on the next page.
'Rate' rate [rate]	Defines the bit rate (in kbps) of the coder. For rates, see <a href="#">Supported Audio Coders</a> on the next page.
'Payload Type' payload-type [PayloadType]	Defines the payload type if the payload type (i.e., format of the RTP payload) of the coder is dynamic. For payload types, see <a href="#">Supported Audio Coders</a> on the next page.
'Silence Suppression' silence-suppression [Sce]	<p>Enables silence suppression for the coder.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (Default)</li> <li>■ [1] <b>Enable</b></li> <li>■ [2] <b>Enable No-Adaptation</b> = Enables silence suppression using the proprietary noise adaptation mechanism. This is applicable only when the call uses one of the following coders: <ul style="list-style-type: none"> <li>✓ G.711: The device sends only one SID packet during periods of silence.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you disable silence suppression for G.729, the device includes 'annexb=no' in the SDP of the relevant SIP messages. If you enable silence suppression, 'annexb=yes' is included. For the Gateway application, an exception is when the remote gateway is Cisco equipment (IsCiscoSCEMode).</li> </ul>
'Coder Specific' coder-specific [CoderSpecific]	<p>Defines additional settings specific to the AMR coder.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = Bandwidth Efficient</li> <li>■ [1] <b>1</b> = Octet Aligned (default)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the AMR coder and configures the payload format type.</li> <li>■ The AMR payload type can be configured globally using the [AmrOctetAlignedEnable] parameter.</li> </ul>

Parameter	Description
	Coders Group configuration overrides the global parameter.

## Supported Audio Coders

The table below lists the coders supported by the device.

**Table 19-3: Supported Audio Coders**

Coder Name	Packetization Time (msec) [1] 10, [2] 20, [3] 30, [4] 40, [5] 50, [6] 60, [8] 80, [9] 90, [10] 100, [12] 120	Rate (kbps)	Payload Type	Silence Suppression
<b>AMR</b> amr [14]	20 (default)	<input type="checkbox"/> [4] 4.75 <input type="checkbox"/> [6] 5.15 <input type="checkbox"/> [9] 5.90 <input type="checkbox"/> [14] 6.70 <input type="checkbox"/> [16] 7.40 <input type="checkbox"/> [18] 7.95 <input type="checkbox"/> [27] 10.2 <input type="checkbox"/> [30] 12.2 (default)	Dynamic	<input type="checkbox"/> [0] <b>Disable</b> <input type="checkbox"/> [1] <b>Enable</b>
<b>AMR-WB</b> amr-wb [15]	20 (default)	<input type="checkbox"/> [13] 6.6 <input type="checkbox"/> [21] 8.85 <input type="checkbox"/> [32] 12.65 <input type="checkbox"/> [37] 14.25 <input type="checkbox"/> [41] 15.85 <input type="checkbox"/> [48] 18.25 <input type="checkbox"/> [49] 19.85 <input type="checkbox"/> [53] 23.05 <input type="checkbox"/> [55] 23.8 (default)	Dynamic	<input type="checkbox"/> [0] <b>Disable</b> <input type="checkbox"/> [1] <b>Enable</b>

Coder Name	Packetization Time (msec) [1] 10, [2] 20, [3] 30, [4] 40, [5] 50, [6] 60, [8] 80, [9] 90, [10] 100, [12] 120	Rate (kbps)	Payload Type	Silence Suppression
<b>G.711A-law</b> g711-alaw [1]	10, 20 (default), 30, 40, 50, 60, 80, 100, 120	[90] 64	8	<input type="checkbox"/> [0] Disable (default) <input type="checkbox"/> [1] Enable
<b>G.711A-law_VBD</b> g711a-law-vbd [23]	10, 20 (default), 30, 40, 50, 60, 80, 100, 120	[90] 64	8 or Dynamic (default 118)	n/a (Disabled)
<b>G.711U-law</b> g711-ulaw [2]	10, 20 (default), 30, 40, 50, 60, 80, 100, 120	[90] 64	0	<input type="checkbox"/> [0] Disable (default) <input type="checkbox"/> [1] Enable
<b>G.711U-law_VBD</b> g711u-law-vbd [24]	10, 20 (default), 30, 40, 50, 60, 80, 100, 120	[90] 64	0 or Dynamic (default 110)	n/a (Disabled)
<b>G.723.1</b> g723-1 [0]	30 (default), 60, 90, 120, 150	<input type="checkbox"/> [7] 5.3 (default) <input type="checkbox"/> [11] 6.3	4	<input type="checkbox"/> [0] Disable (default) <input type="checkbox"/> [1] Enable
<b>G.726</b> g726 [5]	10, 20 (default), 30, 40, 50, 60, 80	<input type="checkbox"/> [43] 16 <input type="checkbox"/> [57] 24 <input type="checkbox"/> [64] 32 (default) <input type="checkbox"/> [70] 40	Dynamic (default 2)	<input type="checkbox"/> [0] Disable (default) <input type="checkbox"/> [1] Enable

Coder Name	Packetization Time (msec) [1] 10, [2] 20, [3] 30, [4] 40, [5] 50, [6] 60, [8] 80, [9] 90, [10] 100, [12] 120	Rate (kbps)	Payload Type	Silence Suppression

	30 (default), 60, 90, 120	[34] 13		

## Configuring Various Codec Attributes

The following procedure describes how to configure various coder attributes such as bit rate.

### ➤ To configure codec attributes:

1. Open the Coder Settings page (**Setup** menu > **Signaling & Media** tab > **Coders & Profiles** folder > **Coder Settings**).
2. Configure the following parameters:
  - AMR coder:
    - ◆ 'AMR Payload Format' (AmrOctetAlignedEnable): Defines the AMR payload format type:

AMR CODER

AMR Payload Format

Octet Aligned

- SILK coder (Skype's default audio codec):

- ◆ 'SILK Tx Inband FEC': Enables forward error correction (FEC) for the SILK coder.
- ◆ 'SILK Max Average Bit Rate': Defines the maximum average bit rate for the SILK coder.

SILK CODER	
SILK Tx Inband FEC	<input type="text" value="Disable"/>
SILK Max Average Bit Rate	<input type="text" value="50000"/>

- Opus coder:
  - ◆ 'Opus Max Average Bitrate' (OpusMaxAverageBitRate): Defines the maximum average bit rate (in bps) for the Opus coder.

OPUS CODER	
Opus Max Average Bit Rate [bps]	<input type="text" value="50000"/>

3. Click **Apply**.

## Configuring Allowed Audio Coder Groups

The Allowed Audio Coders Groups table lets you configure up to 10 Allowed Audio Coders Groups for SBC calls. For each Allowed Audio Coders Group, you can configure up to 10 audio coders. The coders can include pre-defined coders and user-defined (string) coders for non-standard or unknown coders.

Allowed Audio Coders Groups restrict coders for SIP entities. Only coders listed in the Allowed Audio Coders Group (i.e., allowed coders) that is associated with the SIP entity can be used. If the coders in the SDP offer ('a=rtpmap' field) of the incoming SIP message are not listed in the Allowed Audio Coders Group, the device rejects the calls, unless transcoding is configured, whereby "extension" coders are added to the SDP, as described in [Coder Transcoding](#) on page 1139. If the SDP offer contains some coders that are listed in the Allowed Audio Coders Group, the device manipulates the SDP offer by removing the coders that are not listed in the Allowed Audio Coders Group, before routing the SIP message to its destination. Thus, only coders that are common between the coders in the SDP offer and the coders in the Allowed Audio Coders Group are used. For more information on coder restriction, see [Restricting Audio Coders](#) on page 1138.

For example, assume the following:

- The SDP offer in the incoming SIP message contains the G.729, G.711, and G.723 coders.
- The allowed coders configured for the SIP entity include G.711 and G.729.

The device removes the G.723 coder from the SDP offer, re-orders the coder list so that G.711 is listed first, and sends the SIP message containing only the G.711 and G.729 coders in the SDP.

To apply an Allowed Audio Coders Group for restricting coders to a SIP entity:

1. Configure an Allowed Audio Coders Group in the Allowed Audio Coders Groups table (see description below).
2. In the IP Profile associated with the SIP entity (see [Configuring IP Profiles](#) on page 674):
  - Assign the Allowed Audio Coders Group, using the 'Allowed Audio Coders' parameter.
  - Enable the use of Allowed Audio Coders Groups, by configuring the 'Allowed Coders Mode' parameter to **Restriction** or **Restriction and Preference**.

The device also re-orders (prioritizes) the coder list in the SDP according to the order of appearance of the coders listed in the Allowed Audio Coders Group. The first listed coder has the highest priority and the last coder has the lowest priority. For more information, see [Prioritizing Coder List in SDP Offer](#) on page 1143.

- The Allowed Audio Coders Groups table is applicable only to the SBC application.
- The Allowed Audio Coders Group for coder restriction takes precedence over the Coder Group for extension coders. In other words, if an extension coder is not listed as an allowed coder, the device doesn't add the extension coder to the SDP offer.
- To configure "extension" coders for adding to the SDP offer for audio transcoding, use the Coders Groups table (see [Configuring Coders Groups](#) on page 661).

The following procedure describes how to configure Allowed Audio Coders Groups through the Web interface. You can also configure it through ini file [AllowedAudioCodersGroups] and [AllowedAudioCoders] or CLI (`configure voip > coders-and-profiles allowed-audio-coders-groups; configure voip > coders-and-profiles allowed-audio-coders < group index/coder index>`).

➤ **To configure an Allowed Audio Coders Group:**

1. Open the Allowed Audio Coders Groups table (**Setup** menu > **Signaling & Media** tab > **Coders & Profiles** folder > **Allowed Audio Coders Groups**).
2. Click **New**; the following dialog box appears:

3. Configure a name for the Allowed Audio Coders Group according to the parameters described in the table below.

4. Click **Apply**.
5. Select the new row that you configured, and then click the **Allowed Audio Coders** link located below the table; the Allowed Audio Coders table opens.
6. Click **New**; the following dialog box appears:

7. Configure coders for the Allowed Audio Coders Group according to the parameters described in the table below.
8. Click **Apply**.

**Table 19-4: Allowed Audio Coders Groups and Allowed Audio Coders Tables Parameter Descriptions**

Parameter	Description
<b>Allowed Audio Coders Groups Table</b>	
'Index' allowed-audio-coders-groups <index> [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' coders-group-name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
<b>Allowed Audio Coders Table</b>	
'Index' allowed-audio-coders <group index > coder index>	Defines an index number for the new table row. For a list of supported coders, see <b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
[AllowedAudioCodersIndex]	
'Coder' coder [CoderID]	Defines a coder from the list of coders. <b>Note:</b> Each coder can be configured only once per Allowed Audio Coders Group.
'User-defined Coder' user-define-coder [UserDefineCoder]	Defines a user-defined coder. The valid value is a string of up to 24 characters (case-insensitive). For example, "HD.123" (without quotation marks). <b>Note:</b> Each coder can be configured only once per Allowed Audio Coders Group.

## Configuring Allowed Video Coder Groups

The Allowed Video Coders Groups table lets you configure up to five Allowed Video Coders Groups for SBC calls. Each Allowed Video Coders Group can be configured with up to 10 user-defined (string) video coders. An Allowed Video Coders Group defines a list of video coders that can be used when forwarding video streams to a specific SIP entity.

Allowed Video Coders Groups are assigned to SIP entities, using IP Profiles (see [Configuring IP Profiles](#) on page 674). The video coders appear in the SDP media type "video" ('m=video' line). Coders that are not listed in the Allowed Video Coders Group are removed from the SDP offer that is sent to the SIP entity. Only coders that are common between the coders in the SDP offer and the coders listed in the Allowed Video Coders Group are used. Thus, Allowed Video Coders Groups enable you to enforce the use of only specified coders. For more information, see [Restricting Audio Coders](#) on page 1138.

The order of appearance of the coders listed in the Allowed Video Coders Group determines the priority (preference) of the coders in the SDP offer. The device arranges the SDP offer's coder list according to their order in the Allowed Video Coders Group. The priority is in descending order, whereby the first coder in the list is given the highest priority and the last coder, the lowest priority. For more information, see [Prioritizing Coder List in SDP Offer](#) on page 1143.

The Allowed Audio Coders Groups table is applicable only to the SBC application.

The following procedure describes how to configure Allowed Video Coders Groups through the Web interface. You can also configure it through ini file [AllowedVideoCodersGroups] and [AllowedVideoCoders] or CLI (configure voip > coders-and-profiles allowed-video-coders-groups; configure voip > coders-and-profiles allowed-video-coders < group index/coder index>).

➤ **To configure an Allowed Video Coders Group:**

1. Open the Allowed Video Coders Groups table (**Setup** menu > **Signaling & Media** tab > **Coders & Profiles** folder > **Allowed Video Coders Groups**).
2. Click **New**; the following dialog box appears:

3. Configure a name for the Allowed Video Coders Group according to the parameters described in the table below.
4. Click **Apply**.
5. Select the new row that you configured, and then click the **Allowed Video Coders** link located below the table; the Allowed Video Coders table opens.
6. Click **New**; the following dialog box appears:

7. Configure coders for the Allowed Video Coders Group according to the parameters described in the table below.
8. Click **Apply**.

**Table 19-5: Allowed Video Coders Groups and Allowed Video Coders Tables Parameter Descriptions**

Parameter	Description
<b>Allowed Video Coders Groups Table</b>	
'Index' allowed-video-coders-groups <index>	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
[Index]	
'Name' coders-group-name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
<b>Allowed Video Coders Table</b>	
'Index' allowed-video-coders <group index > coder index> [AllowedVideoCodersIndex]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'User Define Coder' user-define-coder [UserDefineCoder]	<p>Defines a user-defined coder.</p> <p>The valid value is a string of up to 24 characters (case-insensitive). For example, "HD.123" (without quotation marks).</p> <p><b>Note:</b> Each coder can be configured only once per Allowed Video Coders Group.</p>

## Configuring IP Profiles

The IP Profiles table lets you configure up to 20 IP Profiles. An IP Profile is a set of parameters with user-defined settings relating to signaling (e.g., SIP message terminations such as REFER) and media (e.g., coder type). An IP Profile can later be assigned to specific IP calls (inbound and/or outbound). Thus, IP Profiles provide high-level adaptation when the device interworks between different SIP user agents (UA), each of which may require different handling by the device. This can include, for example, transcoding or even transrating (of packetization time). For example, if a specific SIP UA uses the G.711 coder only, you can configure an IP Profile with G.711 for this UA.

Many parameters in the IP Profiles table have a corresponding "global" parameter, whose settings apply to all calls that are not associated with an IP Profile. The default value of these IP Profile parameters is the same as the default value of their corresponding global parameters. However, if you change a global parameter from its default value, the value of its corresponding IP Profile parameter inherits its value for all subsequently created (new) IP Profiles. For example, the IP Profile parameter for configuring maximum call duration is 'Max Call Duration'.

Its corresponding global parameter is [SBCMaxCallDuration]. The default of the global parameter is "0" and therefore, the default of this IP Profile parameter is also "0". However, if you configure the global parameter to "10", the value of this IP Profile parameter for all subsequently created (new) IP Profiles is also "10".

To use your IP Profile for specific calls, you need to assign it to any of the following:

- IP Groups - see [Configuring IP Groups](#) on page 591
- (Gateway application only) Tel-to-IP routing rules (see [Configuring Tel-to-IP Routing Rules](#) on page 946)
- (Gateway application only) IP-to-Tel routing rules (see [Configuring IP-to-Tel Routing Rules](#) on page 960)

For the Gateway application, the device selects the IP Profile as follows:

- If you assign different IP Profiles (not default) to the same specific calls in all of the above-mentioned tables, the device uses the IP Profile that has the highest preference level (as set in the 'Profile Preference' parameter). If these IP Profiles have the same preference level, the device uses the IP Profile that you assigned in the IP Groups table.
- If you assign different IP Profiles to all of the above-mentioned tables and one table is set to the default IP Profile, the device uses the IP Profile that is not the default.

You can also use IP Profiles when using a Proxy server (when the AlwaysUseRouteTable parameter is set to 1).

The following procedure describes how to configure IP Profiles through the Web interface. You can also configure it through ini file [IPProfile] or CLI (`configure voip > coders-and-profiles ip-profile`).

### ➤ To configure an IP Profile:

1. Open the IP Profiles table (**Setup** menu > **Signaling & Media** tab > **Coders & Profiles** folder > **IP Profiles**).
2. Click **New**; the following dialog box appears:

3. Configure an IP Profile according to the parameters described in the table below.

4. Click **Apply**.**Table 19-6: IP Profiles Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' profile-name [ProfileName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Created By Routing Server' created-by-routing-server [CreatedByRoutingServer]	(Read-only) Indicates whether the IP Profile was created by ARM: <ul style="list-style-type: none"> <li>■ [0] <b>No</b></li> <li>■ [1] <b>Yes</b></li> </ul> For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.
'Used By Routing Server' used-by-routing-server [UsedByRoutingServer]	Enables the IP Profile to be used by ARM for call routing decisions. <ul style="list-style-type: none"> <li>■ [0] <b>Not Used</b> (default)</li> <li>■ [1] <b>Used</b></li> </ul> For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.
<b>Media Security</b>	
'SBC Media Security Mode' sbc-media-security-behaviour [SBCMediaSecurityBehaviour]	Defines the handling of RTP/SRTP, and MSRP/MSRPS for the SIP UA associated with the IP Profile. <ul style="list-style-type: none"> <li>■ [0] <b>As is</b> = (Default) No special handling for RTP/SRTP and MSRP/MSRPS is done.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Secured</b> = SBC legs negotiate only SRTP/MSRPS media lines, and RTP/MSRP media lines are removed from the incoming SDP offer-answer.</li> <li>■ [2] <b>Not Secured</b> = SBC legs negotiate only RTP/MSRP media lines, and SRTP/MSRPS media lines are removed from the incoming offer-answer.</li> <li>■ [3] <b>Both</b> = Each offer-answer is extended (if not already) to two media lines - one RTP/MSRP and the other SRTP/MSRPS.</li> <li>■ [4] <b>Offer Both - Answer Prefer Secured</b> = The device prefers secured media on the outgoing SDP answer. If the incoming SDP offer contains secured media, the device sends the outgoing SDP answer with secured media, regardless of the incoming SDP answer (media secured or not). The device's handling for secured media on the SDP offer side is the same as the <b>Both</b> option.</li> </ul> <p>If two SBC legs (after offer-answer negotiation) use different security types (i.e., one RTP/MSRP and the other SRTP/MSRPS), the device performs RTP-SRTP/MSRP-MSRPS transcoding. For such transcoding, the following prerequisites must be met:</p> <ul style="list-style-type: none"> <li>■ At least one supported SDP "crypto" attribute and parameters.</li> <li>■ The [EnableMediaSecurity] parameter must be configured to [1]. (This prerequisite is not applicable to WebRTC calls.)</li> </ul> <p>If one of the above prerequisites is not met, then:</p> <ul style="list-style-type: none"> <li>■ any value other than <b>As is</b> is discarded.</li> <li>■ if the incoming offer is SRTP/MSRPS, forced transcoding, coder transcoding, and DTMF extensions are not applied.</li> </ul> <p><b>Note:</b> For secured MSRP (MSRPS), configure the parameter to <b>Secured</b> or <b>Both</b>. For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p>
'Gateway Media Security Mode'	Defines the handling of SRTP for the SIP UA associated with the IP Profile.

Parameter	Description
media-security-behaviour [MediaSecurityBehaviour]	<ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = Applies the settings of the corresponding global parameter [MediaSecurityBehaviour].</li> <li>■ [0] <b>Preferable</b> = (Default) The device initiates encrypted calls to this SIP UA. However, if negotiation of the cipher suite fails, an unencrypted call is established. The device accepts incoming calls received from the SIP UA that don't include encryption information.</li> <li>■ [1] <b>Mandatory</b> = The device initiates encrypted calls to this SIP UA, but if negotiation of the cipher suite fails, the call is terminated. The device rejects incoming calls received from the SIP UA that don't include encryption information.</li> <li>■ [2] <b>Disable</b> = This SIP UA doesn't support encrypted calls (i.e., SRTP).</li> <li>■ [3] <b>Preferable - Single Media</b> = The device sends SDP with a single media ('m=') line only (e.g., m=audio 6000 RTP/AVP 4 0 70 96) with RTP/AVP and crypto keys. The SIP UA can respond with SRTP or RTP parameters: <ul style="list-style-type: none"> <li>✓ If the SIP UA doesn't support SRTP, it uses RTP and ignores the crypto lines.</li> <li>✓ If the device receives an SDP offer with a single media (as shown above) from the SIP UA, it responds with SRTP (RTP/SAVP) if you configure the [EnableMediaSecurity] parameter to [1]. If SRTP is not supported (i.e., [EnableMediaSecurity] is configured to [0]), it responds with RTP.</li> <li>✓ If two 'm=' lines are received in the SDP offer, the device prefers the SAVP (secure audio video profile), regardless of the order in the SDP.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application.</li> <li>■ The parameter is applicable only if you configure the [EnableMediaSecurity] parameter to [1].</li> <li>■ The corresponding global parameter is</li> </ul>

Parameter	Description
	[MediaSecurityBehaviour].
'Symmetric MKI' enable-symmetric-mki  [EnableSymmetricMKI]	<p>Enables symmetric MKI negotiation.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device includes the MKI in its SIP 200 OK response according to the [SRTPTxPacketMKISize] parameter (if set to 0, it is not included; if set to any other value, it is included with this value).</li> <li>■ [1] <b>Enable</b> = The answer crypto line contains (or excludes) an MKI value according to the selected crypto line in the offer. For example, assume that the device receives an INVITE containing the following two crypto lines in SDP:               <pre>a=crypto:2 AES_CM_128_HMAC_SHA1_80 inline:TAaxNnQt8/qLQMnDuG4vxYfWl6K7eBK/ ufk04pR4 2^31 1:1 a=crypto:3 AES_CM_128_HMAC_SHA1_80 inline:bnuYZnMxSfUiGitviWJZmzr7OF3AiRO0 15Vnh0kH 2^31</pre> <p>The first crypto line includes the MKI parameter "1:1". In the 200 OK response, the device selects one of the crypto lines (i.e., '2' or '3'). Typically, it selects the first line that supports the crypto suite. However, for SRTP-to-SRTP in SBC sessions, it can be determined by the remote side on the outgoing leg. If the device selects crypto line '2', it includes the MKI parameter in its answer SDP, for example:</p> <pre>a=crypto:2 AES_CM_128_HMAC_SHA1_80 inline:R1VyAlxV/qwBjkEkl4kSJyl3wCtYeZL q1/QFuxw 2^31 1:1</pre> <p>If the device selects a crypto line that doesn't contain the MKI parameter, then the MKI parameter is not included in the crypto line in the SDP answer (even if the [SRTPTxPacketMKISize] parameter is set to any value other than 0).</p> <p><b>Note:</b> The corresponding global parameter is [EnableSymmetricMKI].</p> </li> </ul>
'MKI Size' mki-size [MKISize]	<p>Defines the size (in bytes) of the Master Key Identifier (MKI) in SRTP Tx packets.</p> <p>The valid value is 0 to 4. The default is 0 (i.e., new keys</p>

Parameter	Description
	<p>are generated without MKI).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Gateway application: The device only initiates the MKI size.</li> <li>■ SBC application: The device can forward MKI size as is for SRTP-to-SRTP flows or override the MKI size during negotiation. This can be done on the inbound or outbound leg.</li> <li>■ The corresponding global parameter is SRTPTxPacketMKISize.</li> </ul>
<p>'SBC Enforce MKI Size'</p> <p>sbc-enforce-mki-size</p> <p>[SBCEnforceMKISize]</p>	<p>Enables negotiation of the Master Key Identifier (MKI) length for SRTP-to-SRTP flows between SIP networks (i.e., IP Groups). This includes the capability of modifying the MKI length on the inbound or outbound SBC call leg for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Don't enforce</b> = (Default) Device forwards the MKI size as is.</li> <li>■ [1] <b>Enforce</b> = Device changes the MKI length according to the settings of the IP Profile parameter, MKISize.</li> </ul>
<p>'SBC Media Security Method'</p> <p>sbc-media-security-method</p> <p>[SBCMediaSecurityMethod]</p>	<p>Defines the media security protocol for SRTP, for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>SDES</b> = (Default) The device secures RTP using the Session Description Protocol Security Descriptions (SDES) protocol to negotiate the cryptographic keys (RFC 4568). The keys are sent in the SDP body ('a=crypto') of the SIP message and are typically secured using SIP over TLS (SIPS). The encryption of the keys is in plain text in the SDP. SDES implements TLS over TCP.</li> <li>■ [1] <b>DTLS</b> = The device uses Datagram Transport Layer Security (DTLS) protocol to secure UDP-based media streams (RFCs 5763 and 5764). For more information on DTLS, see <a href="#">SRTP using DTLS Protocol</a> on page 324.</li> <li>■ [2] <b>Both</b> = SDES and DTLS protocols are supported.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To support DTLS, you must also configure the</li> </ul>

Parameter	Description
	<p>following for the SIP UA:</p> <ul style="list-style-type: none"> <li>✓ TLS Context for DTLS (see <a href="#">Configuring TLS Certificate Contexts</a> on page 227). The server cipher ('Cipher Server') must be configured to All.</li> <li>✓ 'SBC Media Security Mode' parameter to <b>Secured</b> or <b>Both</b>.</li> <li>✓ 'RTCP Mux' parameter to <b>Supported</b>. The setting is required as the DTLS handshake is done for the port used for RTP. Therefore, RTCP and RTP should be multiplexed over the same port.</li> <li>■ The device doesn't support forwarding of DTLS transparently between SIP UAs.</li> <li>■ As DTLS has been defined by the WebRTC standard as mandatory for encrypting media channels for SRTP key exchange, the support is important for deployments implementing WebRTC. For more information on WebRTC, see <a href="#">WebRTC</a> on page 1269.</li> </ul>
<p>'Reset SRTP Upon Re-key'</p> <pre>configure voip &gt; media security &gt; reset-srtp-upon- re-key</pre> <p>[ResetSRTPStateUponRekey]</p>	<p>Enables synchronization of the SRTP state between the device and a server when a new SRTP key is generated upon a SIP session expire. This feature ensures that the roll-over counter (ROC), one of the parameters used in the SRTP encryption/decryption process of the SRTP packets is synchronized on both sides for transmit and receive packets.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) ROC is not reset on the device side.</li> <li>■ [1] <b>Enable</b> = If the session expires causing a session refresh through a re-INVITE, the device or server generates a new key and the device resets the ROC index (and other SRTP fields) as done by the server, resulting in a synchronized SRTP.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If this feature is disabled and the server resets the ROC upon a re-key generation, one-way voice may occur.</li> <li>■ The corresponding global parameter is [ResetSRTPStateUponRekey].</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter resets the SRTP stream on both legs. If you want the device to reset the SRTP stream only with the leg (call party) that changed the crypto key, enable this parameter and the global parameter <a href="#">[configure voip &gt; media security &gt; srtp-reset-tx-rx-separately</a> on page 1811].</li> </ul>
'Generate SRTP Keys Mode' generate-srtp-keys [GenerateSRTPKeys]	<p>Enables the device to generate (or not) a new SRTP key upon receipt of a re-INVITE from the SIP UA associated with the IP Profile. The key appears in the SDP's 'a=crypto' line.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Only If Required</b> = (Default) The device generates an SRTP key only if necessary.</li> <li>■ [1] <b>Always</b> = The device always generates a new SRTP key.</li> <li>■ [2] <b>Keep Original</b> = The device doesn't generate a new key, but preserves (uses) the original SRTP key from the SIP dialog-initiating INVITE message for the dialog's transactions.</li> </ul>
'SBC Remove Crypto Lifetime in SDP' sbc-sdp-remove-crypto-lifetime [SBCRemoveCryptoLifetimeInSDP]	<p>Defines the handling of the lifetime field in the 'a=crypto' attribute of the SDP for the SIP UA associated with the IP Profile. The SDP field defines the lifetime of the master key as measured in maximum number of SRTP or SRTCP packets using the master key.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device retains the lifetime field (if present) in the SDP.</li> <li>■ [1] <b>Yes</b> = The device removes the lifetime field from the 'a=crypto' attribute.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>Yes</b>, the following IP Profile parameters must be configured as follows:               <ul style="list-style-type: none"> <li>✓ 'Symmetric MKI' to <b>Enable</b>.</li> <li>✓ 'MKI Size' to 0.</li> <li>✓ 'SBC Enforce MKI Size' to <b>Enforce</b>.</li> </ul> </li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>

Parameter	Description
'SBC Remove Unknown Crypto' sbc-remove-unknown-crypto [SBCRemoveUnKnownCrypto]	<p>Defines whether the device keeps or removes unknown cryptographic suites (encryption and authentication algorithms) that are present in the SDP 'a=crypto' attribute in the incoming SIP message, before forwarding the message to the SIP UA associated with this IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device keeps all unknown cryptographic suites that are in the SDP's 'a=crypto' attribute.</li> <li>■ [1] <b>Yes</b> = The device removes all unknown cryptographic suites that are in the SDP's 'a=crypto' attribute.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The feature is applicable only to SRTP-to-SRTP calls and calls that do not require transcoding.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Crypto Suites Group' crypto-suites-group [SBCCryptoGroupName]	<p>Assigns an SBC Crypto Suite Group to the IP Profile, which defines the supported SRTP crypto suites.</p> <p>By default, the parameter is undefined and the crypto suite used by the IP Profile is according to the global parameter [SRTPOfferedSuites].</p> <p>For configuring SBC Crypto Suite Groups, see <a href="#">Configuring SRTP Crypto Suite Groups</a> on page 322.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Encryption on RTCP Packets' rtcp-encryption [RTCPEncryption]	<p>Defines the encryption of RTCP packets (i.e., SRTP).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Active</b> =               <ul style="list-style-type: none"> <li>✓ Incoming leg (SRTP-SRTP / SRTP-RTP calls): SRTP cryptos in the incoming SDP offer with the UNENCRYPTED_SRTP flag are rejected.</li> <li>✓ Outgoing leg (SRTP-SRTP / RTP-SRTP calls): The device removes the UNENCRYPTED_SRTP from all cryptos in the outgoing SDP offer.</li> </ul> </li> <li>■ [1] <b>InActive</b> =               <ul style="list-style-type: none"> <li>✓ Incoming leg (SRTP-SRTP / SRTP-RTP calls): SRTP cryptos in the incoming SDP offer without the</li> </ul> </li> </ul>

Parameter	Description
	<p>UNENCRYPTED_SRTCP flag are rejected.</p> <ul style="list-style-type: none"> <li>✓ Outgoing leg (SRTP-SRTP / RTP-SRTP calls): The device adds the UNENCRYPTED_SRTCP to all cryptos in the outgoing SDP offer.</li> <li>■ [2] <b>As Is</b> = (Default)</li> <li>✓ Incoming leg (SRTP-SRTP / SRTP-RTP calls): The device does nothing.</li> <li>✓ Outgoing leg: Cryptos that are received in the incoming leg are not modified. For new cryptos generated by device the encryption flag is set according to the global parameter [RTCPEncryptionDisableTx].</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>SBC Early Media</b>	
'Remote Early Media' sbc-rmt-early-media-sup [SBCRemoteEarlyMediaSupport]	<p>Defines whether the remote side can accept early media or not.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = Early media is not supported.</li> <li>■ [1] <b>Supported</b> = (Default) Early media is supported.</li> </ul>
'Remote Multiple 18x' sbc-rmt-mltple-18x-sup [SBCRemoteMultiple18xSupport]	<p>Defines whether multiple 18x responses including 180 Ringing, 181 Call is Being Forwarded, 182 Call Queued, and 183 Session Progress are forwarded to the caller, for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = Only the first 18x response is forwarded to the caller.</li> <li>■ [1] <b>Supported</b> = (Default) Multiple 18x responses are forwarded to the caller.</li> </ul>
'Remote Early Media Response Type' sbc-rmt-early-media-resp [SBCRemoteEarlyMediaResponseType]	<p>Defines the SIP provisional response type - 180 or 183 - for forwarding early media to the caller, for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) All early media response types are supported; the device forwards all responses as is (unchanged).</li> <li>■ [1] <b>180</b> = Early media is sent as 180 response only.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>183</b> = Early media is sent as 183 response only.</li> </ul>
'Remote Multiple Early Dialogs' sbc-multi-early-dialogs [SBCRemoteMultipleEarlyDialogs]	<p>Defines the device's handling of To-header tags in call forking responses (i.e., multiple SDP answers) sent to the SIP UA associated with the IP Profile.</p> <p>When the SIP UA initiates an INVITE that is subsequently forked (for example, by a proxy server) to multiple UAs, the endpoints respond with a SIP 183 containing an SDP answer. Typically, each endpoint's response has a different To-header tag. For example, a call initiated by the SIP UA (100@A) is forked and two endpoints respond with ringing, each with a different tag:</p> <ul style="list-style-type: none"> <li>■ Endpoint "tag 2":               <pre>SIP/2.0 180 Ringing From: &lt;sip:100@A&gt;;tag=tag1 To: sip:200@B;tag=tag2 Call-ID: c2</pre> </li> <li>■ Endpoint "tag 3":               <pre>SIP/2.0 180 Ringing From: &lt;sip:100@A&gt;;tag=tag1 To: sip:200@B;tag=tag3 Call-ID: c2</pre> </li> </ul> <p>In non-standard behavior (when the parameter is configured to Disable), the device forwards all the SDP answers with the same tag. In the example, endpoint "tag 3" is sent with the same tag as endpoint "tag 2" (i.e., To: sip:200@B;tag=tag2).</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Operation Mode</b> = (Default)                Depends on the setting of the 'Operation Mode' parameter in the IP Group or SRDs table:               <ul style="list-style-type: none"> <li>✓ B2BUA: Device operates as if the parameter is set to Disable [0].</li> <li>✓ Call State-full Proxy: Device operates as if the parameter is set to Enable [1]. In addition, the device preserves the From tags and Call-IDs of the endpoints in the SDP answer sent to the SIP UA.</li> </ul> </li> <li>■ [0] <b>Disable</b> = Device sends the multiple SDP answers with the same To-header tag, to the SIP UA. In other words, this option is relevant if the SIP UA doesn't</li> </ul>

Parameter	Description
	<p>support multiple dialogs (and multiple tags). However, non-standard, multiple answer support may still be configured by the <code>SBCRemoteMultipleAnswersMode</code> parameter.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = Device sends the multiple SDP answers with different To-header tags, to the SIP UA. In other words, the SIP UA supports standard multiple SDP answers (with different To-header tags). In this case, the <code>SBCRemoteMultipleAnswersMode</code> parameter is ignored.</li> </ul> <p><b>Note:</b> If the parameter and the <code>SBCRemoteMultipleAnswersMode</code> parameter are disabled, multiple SDP answers are not reflected to the SIP UA (i.e., the device sends the same SDP answer in multiple 18x and 200 responses).</p>
<p>'Remote Multiple Answers Mode'</p> <p><code>sbc-multi-answers</code></p> <p>[<code>SBCRemoteMultipleAnswersMode</code>]</p>	<p>Enables interworking multiple SDP answers within the same SIP dialog (non-standard). The parameter enables the device to forward multiple answers to the SIP UA associated with the IP Profile. The parameter is applicable only when the 'Remote Multiple Early Dialogs' parameter is disabled.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Device always sends the same SDP answer, which is based on the first received answer that it sent to the SIP UA, for all forked responses (even if the 'Forking Handling Mode' parameter is <b>Sequential</b>), and thus, may result in transcoding.</li> <li>■ [1] <b>Enable</b> = If the 'Forking Handling Mode' parameter is configured to <b>Sequential</b>, the device sends multiple SDP answers.</li> </ul>
<p>'Remote Early Media RTP Detection Mode'</p> <p><code>sbc-rmt-early-media-rtp</code></p> <p>[<code>SBCRemoteEarlyMediaRTP</code>]</p>	<p>Defines whether the destination UA sends RTP immediately after it sends a 18x response.</p> <ul style="list-style-type: none"> <li>■ [0] <b>By Signaling</b> = (Default) Remote client sends RTP immediately after it sends 18x response with early media. The device forwards 18x and RTP as is.</li> <li>■ [1] <b>By Media</b> = After sending 18x response, the remote client waits before sending RTP (e.g., Microsoft Skype for Business environment). For the</li> </ul>

Parameter	Description
	device's handling of this remote UA support, see <a href="#">Interworking SIP Early Media</a> on page 1155.
'Remote RFC 3960 Support' sbc-rmt-rfc3960-supp  [SBCRemoteSupportsRFC3960]	<p>Defines whether the destination UA is capable of receiving 18x messages with delayed RTP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = (Default) UA doesn't support receipt of 18x messages with delayed RTP. For the device's handling of this remote UA support, see <a href="#">Interworking SIP Early Media</a> on page 1155.</li> <li>■ [1] <b>Supported</b> = UA is capable of receiving 18x messages with delayed RTP.</li> </ul>
'Remote Can Play Ringback' sbc-rmt-can-play-ringback  [SBCRemoteCanPlayRingback]	<p>Defines whether the destination UA can play a local ringback tone.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = UA doesn't support local ringback tone. The device sends 18x with delayed SDP to the UA.</li> <li>■ [1] <b>Yes</b> = (Default) UA supports local ringback tone. For the device's handling of this remote UA support, see <a href="#">Interworking SIP Early Media</a> on page 1155.</li> </ul>
'Generate RTP' sbc-generate-rtp  [SBCGenerateRTP]	<p>Enables the device to generate "silence" RTP packets to the SIP UA until it detects audio RTP packets from the SIP UA. The parameter provides support for interworking with SIP entities that wait for the first incoming packets before sending RTP (e.g., early media used for ringback tone or IVR) during media negotiation.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) Silence packets are not generated.</li> <li>■ [1] <b>Until RTP Detected</b> = The device generates silence RTP packets to the SIP UA upon receipt of a SIP response (183 with SDP) from the SIP UA. In other words, these packets serve as the first incoming packets for the SIP UA. The device stops sending silence packets when it receives RTP packets from the peer side (which it then forwards to the SIP UA).</li> </ul> <p><b>Note:</b> To generate silence packets, DSP resources are required (except for calls using the G.711 coder).</p>
<b>SBC Media</b>	
'SDP Subsequent Responses'	Defines which incoming SIP responses to SIP dialog-

Parameter	Description
<b>Mode'</b> sdp-origin-same-session-ver [SDPSubsequentResponses]	<p>initiating INVITE requests are SDPs processed (handled) by the device.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Handle All</b> = (Default) The device processes the SDPs of all subsequent SIP responses.</li> <li>■ [1] <b>Handle Only First</b> = The device processes only the SDP in the first SIP response to the initial INVITE message, ignoring the SDPs in all the other subsequent SIP responses.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>'Mediation Mode'</b> transcoding-mode [TranscodingMode]	<p>Defines the transcoding mode (media negotiation) for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>RTP Mediation</b> = (Default) Transcoding is done only if required. If not required, many of the media settings (such as gain control) are not applied to the voice stream. The device forwards the RTP packets transparently (i.e., RTP-to-RTP) without processing the data; only the RTP headers are re-constructed.</li> <li>■ [1] <b>Force Transcoding</b> = This enables the device to receive capabilities that are not negotiated between the SIP entities, by implementing DSP transcoding. For example, it can enforce gain control to use voice transcoding even though both legs have negotiated without the device's intervention (such as Extension coders).</li> <li>■ [2] <b>RTP Forwarding</b> = If transcoding is not required and both legs are configured with RTP forwarding, then RTP packets are forwarded transparently without any processing. This mode is needed when the call parties pass invalid RTP packets on the RTP port. If you use this option, you may also need to configure the global parameters 'Forward Unknown RTP Payload Types' to <b>Handle as Valid Packet</b>, and 'Forward Invalid RTP Packets' to <b>Forward Packets</b>.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For transcoding, make sure that the device's License Key includes a license for the number of DSP resources ('DSP Channels') and a license for the</li> </ul>

Parameter	Description
	<p>number of transcoding sessions ('Transcoding Sessions'). For more information on the License Key, see <a href="#">License Key</a> on page 1362.</p> <ul style="list-style-type: none"> <li>■ Each transcoding session uses two DSP resources.</li> <li>■ The corresponding global parameter is [TranscodingMode].</li> </ul>
<p>'Extension Coders Group'</p> <p>sbc-ext-coders-group-name</p> <p>[SBCExtensionCodersGroupName]</p>	<p>Assigns a Coder Group for extension coders, which are added to the SDP offer in the outgoing leg for the SIP UA associated with the IP Profile. This is used when transcoding is required between two IP entities (i.e., the SDP answer from one doesn't include any coder included in the offer previously sent by the other).</p> <p>For more information on extension coders and transcoding, see <a href="#">Coder Transcoding</a> on page 1139. To configure Coder Groups, see <a href="#">Configuring Coders Groups</a> on page 661.</p>
<p>'Allowed Audio Coders'</p> <p>allowed-audio-coders-group-name</p> <p>[SBCAllowedAudioCodersGroupName]</p>	<p>Assigns an Allowed Audio Coders Group, which defines audio (voice) coders that can be used for the SIP UA associated with the IP Profile.</p> <p>To configure Allowed Audio Coders Groups, see <a href="#">Configuring Allowed Audio Coder Groups</a> on page 669. For a description of the Allowed Coders feature, see <a href="#">Restricting Audio Coders</a> on page 1138.</p>
<p>'Allowed Coders Mode'</p> <p>sbc-allowed-coders-mode</p> <p>[SBCAllowedCodersMode]</p>	<p>Defines the mode of the Allowed Coders feature for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Restriction</b> = In the incoming SDP offer, the device uses only Allowed coders; the rest are removed from the SDP offer (i.e., only coders common between those in the received SDP offer and the Allowed coders are used). If an Extension Coders Group is also assigned (using the 'Extension Coders Group' parameter, above), these coders are added to the SDP offer if they also appear in Allowed coders.</li> <li>■ [1] <b>Preference</b> = The device re-arranges the priority (order) of the coders in the incoming SDP offer according to their order of appearance in the Allowed Audio Coders Group or Allowed Video Coders Group. The coders in the original SDP offer are listed after the</li> </ul>

Parameter	Description
	<p>Allowed coders.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Restriction and Preference</b> = Performs both Restriction and Preference.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if Allowed coders are assigned to the IP Profile (see the 'Allowed Audio Coders' or 'Allowed Video Coders' parameters).</li> <li>■ For more information on the Allowed Coders feature, see <a href="#">Restricting Audio Coders</a> on page 1138.</li> </ul>
<p>'Allowed Video Coders'</p> <p>allowed-video-coders-group-name</p> <p>[SBCAllowedVideoCodersGroupPName]</p>	<p>Assigns an Allowed Video Coders Group. This defines permitted video coders when forwarding video streams to the SIP UA associated with the IP Profile. The video coders are listed in the "video" media type in the SDP (i.e., 'm=video' line). For this SIP UA, the device uses only video coders that appear in both the SDP offer and the Allowed Video Coders Group.</p> <p>By default, no Allowed Video Coders Group is assigned (i.e., all video coders are allowed).</p> <p>To configure Allowed Video Coders Groups, see <a href="#">Configuring Allowed Video Coder Groups</a> on page 672.</p>
<p>'Allowed Media Types'</p> <p>sbc-allowed-media-types</p> <p>[SBCAllowedMediaTypes]</p>	<p>Defines media types permitted for the SIP UA associated with the IP Profile. The media type appears in the SDP 'm=' line (e.g., 'm=audio'). The device permits only media types that appear in both the SDP offer and this configured list. If no common media types exist between the SDP offer and this list, the device drops the call.</p> <p>The valid value is a string of up to 64 characters. To configure multiple media types, separate the strings with a comma, e.g., " audio, text" (without quotation marks). By default, no media types are configured (i.e., all media types are permitted).</p>
<p>'Direct Media Tag'</p> <p>sbc-dm-tag</p> <p>[SBCDirectMediaTag]</p>	<p>Defines an identification tag for enabling direct media or media bypass (i.e., no Media Anchoring) of SBC calls for the SIP UA associated with the IP Profile. Direct media occurs between all UAs whose IP Profiles have the same tag value (non-empty value). For example, if you configure the parameter to "direct-rtp" for two IP Profiles "IP-PBX-1" and "IP-PBX-2", the device employs direct</p>

Parameter	Description
	<p>media for calls of UAs associated with IP Profile "IP-PBX-1", for calls of UAs associated with IP Profile "IP-PBX-2", and for calls between UAs associated with IP Profile "IP-PBX-1" and IP Profile "IP-PBX-2".</p> <p>The valid value is a string of up to 16 characters. By default, no value is defined.</p> <p>For more information on direct media, see <a href="#">Direct Media Calls</a> on page 1135.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you enable direct media for the IP Profile, make sure that your Media Realm provides enough ports, as media may traverse the device for mid-call services (e.g., call transfer).</li> <li>■ If you have configured a SIP Recording rule (see <a href="#">SIPREC SIP-based Media Recording</a> on page 339) for calls associated with this IP Profile, the device automatically disables direct media for these calls (during their SIP signaling setup). This ensures that the media passes through the device so that it can be recorded and sent to the SRS. However, if you enable direct media using the [SBCDirectMedia] global parameter (i.e., for all calls), direct media is always enforced and calls will not be recorded.</li> <li>■ Regardless of this parameter's settings, the device always handles calls whose incoming SIP dialog-initiating request (e.g., INVITE message) contains the proprietary SIP header 'X-AC-Action' with the value 'direct-media' (i.e., 'X-AC-Action: direct-media'), as direct media calls. These calls remain as direct media calls until they end.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'RFC 2833 Mode'</p> <p>sbc-rfc2833-behavior</p> <p>[SBCRFC2833Behavior]</p>	<p>Defines the handling of RFC 2833 SDP offer-answer negotiation for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>As is</b> = (Default) The device doesn't intervene in the RFC 2833 negotiation.</li> <li>■ [1] <b>Extend</b> = Each outgoing offer-answer includes RFC 2833 in the offered SDP. The device adds RFC 2833 only if the incoming offer doesn't include RFC 2833.</li> </ul>

Parameter	Description
	<p>■ [2] <b>Disallow</b> = The device removes RFC 2833 from the incoming offer.</p> <p><b>Note:</b> If the device interworks between different DTMF methods and one of the methods is in-band DTMF packets (in RTP), detection and generation of DTMF methods requires DSP resources. However, RFC 2833 to SIP INFO doesn't require DSP resources.</p>
<p>'RFC 2833 DTMF Payload Type'</p> <p>sbc-2833dtmf-payload</p> <p>[SBC2833DTMFPayloadType]</p>	<p>Defines the payload type of DTMF digits for the SIP UA associated with the IP Profile. The parameter enables the interworking of the DTMF payload type for RFC 2833 between different SBC call legs. For example, if two entities require different DTMF payload types, the SDP offer received by the device from one UA is forwarded to the destination UA with its payload type replaced with the configured payload type, and vice versa.</p> <p>The value range is 0 to 200. The default is 0 (i.e., the device forwards the received payload type as is).</p> <p>■ <b>For non-terminated calls:</b></p> <ul style="list-style-type: none"> <li>✓ Outgoing SDP offer: The payload type configured for the parameter is used. If not configured, the device uses the payload type of the incoming offer.</li> <li>✓ Outgoing SDP answer: If the payload type is configured for one of the IP Profiles, the payload type of the SDP offer is used. Otherwise, the payload type of the incoming SDP answer is used.</li> </ul> <p>■ <b>For terminated calls:</b></p> <ul style="list-style-type: none"> <li>✓ Outgoing SDP offer: The payload type configured for the parameter is used. If not configured and there is a peer leg, the payload of the SDP created by the peer leg is used. Otherwise, the device uses a default payload type.</li> <li>✓ Outgoing SDP answer: If the payload type is configured for one of the IP Profiles, the payload type of the SDP offer is used. Otherwise, the payload type of the peer incoming stream is used.</li> </ul>
<p>'Alternative DTMF Method'</p> <p>sbc-alternative-</p>	<p>The device's first priority for DTMF method at each leg is RFC 2833. Thus, if the device successfully negotiates RFC</p>

Parameter	Description
dtmf-method [SBCAlternativeDTMFMethod]	<p>2833 for the SIP UA associated with the IP Profile, the chosen DTMF method for this leg is RFC 2833. When RFC 2833 negotiation fails, the device uses the DTMF method configured by this parameter for the leg.</p> <ul style="list-style-type: none"> <li>■ [0] <b>As Is</b> = (Default) The device doesn't attempt to interwork any special DTMF method.</li> <li>■ [1] <b>In Band</b></li> <li>■ [2] <b>INFO - Cisco</b></li> <li>■ [3] <b>INFO - Nortel</b></li> <li>■ [4] <b>INFO - Lucent = INFO, Korea</b></li> <li>■ [5] <b>HTTP</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the device interworks between different DTMF methods and one of the methods is in-band DTMF packets (in RTP), detection and generation of DTMF methods requires DSP resources. However, RFC 2833 to SIP INFO doesn't require DSP resources.</li> <li>■ The <b>HTTP</b> option is for internal use and applicable only when the device is deployed with AudioCodes VoiceAI Connect solution.</li> </ul>
'Send Multiple DTMF Methods' sbc-send-multiple-dtmf-methods [SBCSupportMultipleDTMFMethods]	<p>Enables the device to send DTMF digits out-of-band (not with audio stream) using both the SIP INFO and RFC 2833 methods for the same call on the leg to which this IP Profile is associated. The RFC 2833 method sends out-of-band DTMF digits using the RTP protocol while the SIP INFO method sends the digits using the SIP protocol.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device sends DTMF digits using only one method (either SIP INFO, RFC 2833, or in-band).</li> <li>■ [1] <b>Enable</b> = The device sends DTMF digits using both methods - SIP INFO and RFC 2833.</li> </ul> <p>If you have enabled the parameter, you can also configure the device to stop sending DTMF digits using the SIP INFO method if the device receives a SIP re-INVITE (or UPDATE) from the SIP UA to where the SIP INFO is being sent (and keep sending the DTMF digits using the</p>

Parameter	Description
	<p>RFC 2833 method). This is done using the AudioCodes proprietary SIP header X-AC-Action and a Message Manipulation rule (inbound) to instruct the device to switch to a different IP Profile that is configured to disable the sending of DTMF digits using both methods (i.e., 'Send Multiple DTMF Methods' is configured to Disable):</p> <pre>X-AC-Action: 'switch-profile;profile-name=&lt;IP Profile Name&gt;'</pre> <p>If the IP Profile name contains one or more spaces, you must enclose the name in double quotation marks, for example:</p> <pre>X-AC-Action: 'switch-profile;profile-name="My IP Profile"'</pre> <p>The Message Manipulation rule adds the proprietary header with the value of the new IP Profile to the incoming re-INVITE or UPDATE message and as a result, the device uses the new IP Profile for the SIP UA and stops sending it SIP INFO messages. You can also configure an additional Message Manipulation rule to re-start the sending of the SIP INFO. For example, you can configure two Message Manipulation rules where the sending of both SIP INFO and RFC 2833 depends on the negotiated media port -- the device stops sending SIP INFO if the SDP of the re-INVITE or UPDATE message contains port 7550 and re-starts sending if the port is 8660. The rule that re-starts the SIP INFO switches the IP Profile back to the initial IP Profile that enables the sending of DTMF digits using both methods (i.e., 'Send Multiple DTMF Methods' is configured to Enable). The configured Message Manipulation rules for this example are shown below:</p> <ul style="list-style-type: none"> <li>■ Index 1 <ul style="list-style-type: none"> <li>✓ Message Type: reinvite.request</li> <li>✓ Condition: body.sdp regex (.*)(m=audio 7550 RTP/AVP)(.*)</li> <li>✓ Action Subject: header.X-AC-Action</li> <li>✓ Action Type: Add</li> <li>✓ Action Value: 'switch-profile;profile-name=ITSP-Profile-2'</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Index 2</li> <li>✓ Message Type: reinvite.request</li> <li>✓ Condition: body.sdp regex (.*)(m=audio 8660 RTP/AVP)(.*)</li> <li>✓ Action Subject: header.X-AC-Action</li> <li>✓ Action Type: Add</li> <li>✓ Action Value: 'switch-profile;profile-name=ITSP-Profile-1'</li> </ul> <p>The Message Manipulation rules must be assigned to the SIP UA's IP Group, using the 'Inbound Message Manipulation Set' parameter.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To send DTMF digits using both methods (i.e., when the parameter is enabled), you need to also configure the following: <ul style="list-style-type: none"> <li>✓ Configure the 'Alternative DTMF Method' parameter to one of the SIP INFO options (<b>INFO – Cisco</b>, <b>INFO – Nortel</b>, or <b>INFO – Lucent</b>).</li> <li>✓ Enable the sending of DTMF digits using the RFC 2833 method, by configuring the 'RFC 2833 Mode' parameter to <b>As Is</b> or <b>Extend</b>.</li> </ul> </li> <li>■ When using the X-AC-Action header to switch IP Profiles, it is recommended that the settings of the switched IP Profile are identical (except for the 'Send Multiple DTMF Methods' parameter) to the initial IP Profile in order to avoid any possible call handling errors.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Receive Multiple DTMF Methods' sbc-receive-multiple-dtmf-methods [ReceiveMultipleDTMFMethods]	<p>Enables the device to receive DTMF digits out-of-band (not with audio stream) using both the SIP INFO and RFC 2833 methods, but forwards the DTMF only using RFC 2833.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device receives DTMF digits only by the RFC 2833 method, if negotiated. Otherwise, the device uses the DTMF method</li> </ul>

Parameter	Description
	<p>according to the IP Profile's 'Alternative DTMF Method' parameter (see above). In other words, it receives DTMF digits using only one method only.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = The device receives DTMF digits using the SIP INFO message method even if both sides successfully negotiated the RFC 2833 method. In other words, both SIP INFO and RFC 2833 are used to detect DTMF digits by the device. However, the device forwards the DTMF using RFC 2833 only.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Adapt RFC2833 BW to Voice coder BW'</p> <p>sbc-adapt-rfc2833-bw-voice-bw</p> <p>[SBCAdaptRFC2833BWToVoiceCoderBW]</p>	<p>Defines the 'telephone-event' type (8000 or 16000) in the SDP that the device sends in the outgoing SIP 200 OK message for DTMF payload negotiation (sampling rate).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The device always sends the 'telephone-event' as 8000 in the outgoing SIP 200 OK, even if the SDP of the incoming INVITE contains multiple telephone-event types (e.g., 8000 and 16000).</li> <li>■ [1] <b>Enable</b> = The type of 'telephone-event' that the device sends in the outgoing SIP 200 OK message is according to the coder type (narrowband or wideband). If narrowband, it sends the 'telephone-event' as 8000; if wideband, it sends it as 16000.</li> </ul> <p>An example when the parameter is configured to <b>Enable</b> is shown below, whereby the 'telephone-event' is "16000" in the outgoing message due to the wideband coder:</p> <p><b>SDP in incoming INVITE:</b></p> <pre>a=rtpmap:97 AMR-WB/16000/1 a=fmtp:97 mode-change-capability=2 a=rtpmap:98 AMR-WB/16000/1 a=fmtp:98 octet-align=1; mode-change-capability=2 a=rtpmap:100 AMR/8000/1 a=fmtp:100 mode-change- capability=2 a=rtpmap:99 telephone- event/16000/1 a=fmtp:99 0-15 a=rtpmap:102 telephone-event/8000/1 a=fmtp:102 0-15</pre> <p><b>SDP in outgoing 200 OK:</b></p>

Parameter	Description
	<pre>m=audio 6370 RTP/AVP 97 99 a=rtpmap:99 telephone-event/16000/1 a=fmtp:99 0-15 a=sendrecv a=ptime:20 a=maxptime:120 a=rtpmap:97 AMR-WB/16000 a=fmtp:97 mode-change- capability=2;mode-set=0,1,2,3,4,5,6,7,</pre> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'SDP Ptime Answer' sbc-sdp-ptime-ans [SBCSDPPtimeAnswer]	<p>Defines the packetization time (ptime) of the coder in RTP packets for the SIP UA associated with the IP Profile. This is useful when implementing transrating.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Remote Answer</b> = (Default) Use ptime according to SDP answer.</li> <li>■ [1] <b>Original Offer</b> = Use ptime according to SDP offer.</li> <li>■ [2] <b>Preferred Value</b> = Use the ptime according to the 'Preferred Ptime' parameter (see below) if it is configured to a non-zero value.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Regardless of the settings of this parameter, if a non-zero value is configured for the 'Preferred Ptime' parameter (see below), it is used as the ptime in the SDP offer.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Preferred Ptime' sbc-preferred-ptime [SBCPreferredPTime]	<p>Defines the packetization time (ptime) in msec for the SIP UA associated with the IP Profile, in the outgoing SDP offer.</p> <p>If the 'SDP Ptime Answer' parameter (see above) is configured to Preferred Value [2] and the 'Preferred Ptime' parameter is configured to a non-zero value, the configured ptime is used (enabling ptime transrating if the other side uses a different ptime).</p> <p>If the 'SDP Ptime Answer' parameter is configured to Remote Answer [0] or Original Offer [1] and the 'Preferred Ptime' parameter is configured to a non-zero</p>

Parameter	Description
	<p>value, the configured value is used as the ptime in the SDP offer.</p> <p>The valid range is 0 to 200. The default is 0 (i.e., a preferred ptime is not used).</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Use Silence Suppression' sbc-use-silence-supp  [SBCUseSilenceSupp]	<p>Defines silence suppression support for the SIP UA associated with the IP Profile</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) Forward as is.</li> <li>■ [1] <b>Add</b> = Enable silence suppression for each relevant coder listed in the SDP.</li> <li>■ [2] <b>Remove</b> = Disable silence suppression for each relevant coder listed in the SDP.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature requires DSP resources.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'RTP Redundancy Mode' sbc-rtmp-red-behav [SBCRTPRedundancyBehavior]	<p>Enables interworking RTP redundancy negotiation support between SIP entities in the SDP offer-answer exchange (according to RFC 2198). The parameter defines the device's handling of RTP redundancy for the SIP UA associated with the IP Profile. According to the RTP redundancy SDP offer/answer negotiation, the device uses or discards the RTP redundancy packets. The parameter enables asymmetric RTP redundancy, whereby the device can transmit and receive RTP redundancy packets to and from a specific SIP UA, while transmitting and receiving regular RTP packets (no redundancy) for the other SIP UA involved in the voice path.</p> <p>The device can identify the RTP redundancy payload type in the SDP for indicating that the RTP packet stream includes redundant packets. RTP redundancy is indicated in SDP using the "red" coder type, for example:</p> <pre>a=rtpmap:&lt;payload type&gt; red/8000/1</pre> <p>RTP redundancy is useful when there is packet loss; the missing information may be reconstructed at the receiver side from the redundant packets.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>As Is</b> = (Default) The device doesn't interfere in the RTP redundancy negotiation and forwards the SDP offer/answer (incoming and outgoing calls) as is without interfering in the RTP redundancy negotiation.</li> <li>■ [1] <b>Enable</b> = The device always adds RTP redundancy capabilities in the outgoing SDP offer sent to the SIP UA. Whether RTP redundancy is implemented depends on the subsequent incoming SDP answer from the SIP UA. The device doesn't modify the incoming SDP offer received from the SIP UA, but if RTP redundancy is offered, it will support it in the outgoing SDP answer. Select the option if the SIP UA requires RTP redundancy.</li> <li>■ [2] <b>Disable</b> = The device removes the RTP redundancy payload (if present) from the SDP offer/answer for calls received from or sent to the SIP UA. Select the option if the SIP UA doesn't support RTP redundancy.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable the device to generate RFC 2198 redundant packets, use the 'RTP Redundancy Depth' parameter.</li> <li>■ To configure the payload type in the SDP offer for RTP redundancy, use the [RFC2198PayloadType] parameter.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'RTCP Mode' sbc-rtcp-mode [SBCRTCPMode]	<p>Defines how the device handles RTCP packets during call sessions for the SIP UA associated with the IP Profile. This is useful for interworking RTCP between SIP entities. For example, this may be necessary when incoming RTCP is not compatible with the destination SIP UA's (this IP Profile) RTCP support. In such a scenario, the device can generate the RTCP and send it to the SIP UA.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) RTCP is forwarded as is (unless transcoding is done, in which case, the device generates RTCP on both legs).</li> <li>■ [1] <b>Generate Always</b> = Generates RTCP packets during active and inactive (e.g., during call hold) RTP periods</li> </ul>

Parameter	Description
	<p>(i.e., media is 'a=recvonly' or 'a=inactive' in the INVITE SDP).</p> <ul style="list-style-type: none"> <li>■ [2] <b>Generate only if RTP Active</b> = Generates RTCP packets only during active RTP periods. In other words, the device doesn't generate RTCP when there is no RTP traffic (such as when a call is on hold).</li> </ul> <p><b>Note:</b> The corresponding global parameter is [SBCRTCPMode].</p>
'Jitter Compensation' sbc-jitter-compensation [SBCJitterCompensation]	<p>Enables the on-demand jitter buffer for SBC calls. The jitter buffer can be used when other functionality such as voice transcoding are not done on the call. The jitter buffer is useful when incoming packets are received at inconsistent intervals (i.e., packet delay variation). The jitter buffer stores the packets and sends them out at a constant rate (according to the coder's settings).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The jitter buffer parameters, 'Dynamic Jitter Buffer Minimum Delay' (DJBufMinDelay) and 'Dynamic Jitter Buffer Optimization Factor' (DJBufOptFactor) can be used to configure minimum packet delay only when transcoding is employed.</li> <li>■ This feature may require DSP resources. For more information, contact the sales representative of your purchased device.</li> </ul>
'ICE Mode' ice-mode [SBCIceMode]	<p>Enables Interactive Connectivity Establishment (ICE) for the SIP UA associated with the IP Profile. ICE is a methodology for NAT traversal, employing the Session Traversal Utilities for NAT (STUN) and Traversal Using Relays around NAT (TURN) protocols to provide a peer with a public IP address and port that can be used to connect to a remote peer. The device supports ICE-Full and ICE-Lite, but ICE-Lite is a limited implementation where the device can't initiate the ICE process.</p> <p>ICE is typically required, for example, when the device operates in a Microsoft Teams Direct Routing (media bypass) environment.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Lite</b> = Enables ICE-Lite.</li> <li>■ [2] <b>Full</b> = Enables ICE-Full.</li> </ul> <p>For more information on ICE , see <a href="#">Implementing ICE for Media Sessions</a> on page 186.</p> <p><b>Note:</b> As ICE has been defined by the WebRTC standard as mandatory, the support is important for deployments implementing WebRTC. For more information on WebRTC, see <a href="#">WebRTC</a> on page 1269.</p>
'SDP Handle RTCP' sbc-sdp-handle-rtcp [SBCSDPHandleRTCPAttribute]	<p>Enables the interworking of the RTCP attribute, 'a=rtcp' (RTCP) in the SDP, for the SIP UA associated with the IP Profile. The RTCP attribute is used to indicate the RTCP port for media when that port is not the next higher port number following the RTP port specified in the media line ('m=').</p> <p>The parameter is useful for SIP entities that either require the attribute or do not support the attribute. For example, Google Chrome and Web RTC do not accept calls without the RTCP attribute in the SDP. In Web RTC, Chrome (SDES) generates the SDP with 'a=rtcp', for example:</p> <pre>m=audio 49170 RTP/AVP 0 a=rtcp:53020 IN IP6 2001:2345:6789:ABCD:EF01:2345:6789:ABCD</pre> <ul style="list-style-type: none"> <li>■ [0] <b>Don't Care</b> = (Default) The device forwards the SDP as is without interfering in the RTCP attribute (regardless if present or not).</li> <li>■ [1] <b>Add</b> = The device adds the 'a=rtcp' attribute to the outgoing SDP offer sent to the SIP UA if the attribute was not present in the original incoming SDP offer.</li> <li>■ [2] <b>Remove</b> = The device removes the 'a=rtcp' attribute, if present in the incoming SDP offer received from the other SIP UA, before sending the outgoing SDP offer to the SIP UA.</li> </ul> <p><b>Note:</b> As the RTCP attribute has been defined by the WebRTC standard as mandatory, the support is important for deployments implementing WebRTC. For more</p>

Parameter	Description
	information on WebRTC, see <a href="#">WebRTC</a> on page 1269.
'RTCP Mux' sbc-rtcp-mux [SBCRTCPMux]	<p>Enables interworking of multiplexing of RTP and RTCP onto a single local port, between SIP entities. The parameter enables multiplexing of RTP and RTCP traffic onto a single local port, for the SIP UA associated with the IP Profile.</p> <p>Multiplexing of RTP data packets and RTCP packets onto a single local UDP port is done for each RTP session (according to RFC 5761). If multiplexing is not enabled, the device uses different (but adjacent) ports for RTP and RTCP packets.</p> <p>With the increased use of NAT and firewalls, maintaining multiple NAT bindings can be costly and also complicate firewall administration since multiple ports must be opened to allow RTP traffic. To reduce these costs and session setup times, support for multiplexing RTP data packets and RTCP packets onto a single port is advantageous.</p> <p>For multiplexing, the initial SDP offer must include the "a=rtcp-mux" attribute to request multiplexing of RTP and RTCP onto a single port. If the SDP answer wishes to multiplex RTP and RTCP, it must also include the "a=rtcp-mux" attribute. If the answer doesn't include the attribute, the offerer must not multiplex RTP and RTCP packets. If both ICE and multiplexed RTP-RTCP are used, the initial SDP offer must also include the "a=candidate:" attribute for both RTP and RTCP along with the "a=rtcp:" attribute, indicating a fallback port for RTCP in case the answerer doesn't support RTP and RTCP multiplexing.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = (Default) RTP and RTCP packets use different ports.</li> <li>■ [1] <b>Supported</b> = Device multiplexes RTP and RTCP packets onto a single port.</li> </ul> <p><b>Note:</b> As RTP multiplexing has been defined by the WebRTC standard as mandatory, the support is important for deployments implementing WebRTC. For more information on WebRTC, see <a href="#">WebRTC</a> on page 1269.</p>
'RTCP Feedback' sbc-rtcp-feedback	Enables RTCP-based feedback indication in outgoing SDPs sent to the SIP UA associated with the IP Profile.

Parameter	Description
[SBCRTCPFeedback]	<p>The parameter supports indication of RTCP-based feedback, according to RFC 5124, during RTP profile negotiation between two communicating SIP entities. RFC 5124 defines an RTP profile (S)AVPF for (secure) real-time communications to provide timely feedback from the receivers to a sender. For more information on RFC 5124, see <a href="http://tools.ietf.org/html/rfc5124">http://tools.ietf.org/html/rfc5124</a>.</p> <p>Some SIP entities may require RTP secure-profile feedback negotiation (AVPF/SAVPF) in the SDP offer/answer exchange, while other SIP entities may not support it. The device indicates whether or not feedback is supported on behalf of the SIP UA. It does this by adding an "F" or removing the "F" from the SDP media line ('m=') for AVP and SAVP. For example, the following shows "AVP" appended with an "F", indicating that the SIP UA is capable of receiving feedback</p> <pre>m=audio 49170 RTP/SAVPF 0 96</pre> <ul style="list-style-type: none"> <li>■ [0] <b>Feedback Off</b> = (Default) The device doesn't send the feedback flag ("F") in SDP offers/answers that are sent to the SIP UA. If the SDP 'm=' attribute of an incoming message that is destined to the SIP UA includes the feedback flag, the device removes it before sending the message to the SIP UA.</li> <li>■ [1] <b>Feedback On</b> = The device includes the feedback flag ("F") in the SDP offer sent to the SIP UA. The device includes the feedback flag in the SDP answer sent to the SIP UA only if it was present in the SDP offer received from the other SIP UA.</li> <li>■ [2] <b>As Is</b> = The device doesn't involve itself in the feedback, but simply forwards any feedback indication as is.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ As RTCP-based feedback has been defined by the WebRTC standard as mandatory, the support is important for deployments implementing WebRTC. For more information on WebRTC, see <a href="#">WebRTC</a> on page 1269.</li> <li>■ RTCP-based feedback is required for the VoIPerfect feature (see <a href="#">VoIPerfect</a> on page 1292).</li> </ul>

Parameter	Description
'Re-number MID' sbc-renumber-mid [SBCRenumberMID]	<p>Enables the device to change the value of the 'a=mid:n' attribute (where <i>n</i> is a unique value) in the outgoing SDP offer so that in the first media ('m=' line) the value will be 0, the next media the value will be 1, and so on. This is done only if the 'a=mid' attribute is present in the incoming SDP offer.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ For deployments implementing WebRTC (see <a href="#">WebRTC</a> on page 1269), it's recommended that you configure the parameter to <b>Enable</b>.</li> </ul>
'Voice Quality Enhancement' sbc-voice-quality-enhancement [SBCVoiceQualityEnhancement]	<p>Enables the device to detect speech and network quality (packet loss and bandwidth reduction) and triggers the device to overcome the adverse conditions to ensure high call quality.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to the VoIPerfect feature (see <a href="#">VoIPerfect</a> on page 1292).</p>
'Switch Coder Upon Voice Quality' switch-coder-upon-voice-quality [SwitchCoderUponVoiceQuality]	<p>Enables the device to detect poor voice quality during a call for an unregistered user, and then to change IP Profiles so that the coder switches between G.711 and Opus.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information, see <a href="#">Configuring Voice Quality for Unregistered Users</a> on page 546.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Max Opus Bandwidth' sbc-max-opus-bandwidth	<p>Defines the VoIPerfect mode of operation, which is based on the Opus coder.</p> <ul style="list-style-type: none"> <li>■ <b>0</b> = (Default) Managed Opus</li> </ul>

Parameter	Description
[SBCMaxOpusBW]	<ul style="list-style-type: none"> <li>■ <b>80000</b> = Smart Transcoding</li> </ul> <p><b>Note:</b> The parameter is applicable only to the VoIPerfect feature (see <a href="#">VoIPerfect</a> on page 1292).</p>
'Generate No-Op Packets' sbc-generate-noop [SBCGenerateNoOp]	<p>Enables the device to send RTP or T.38 No-Op packets during RTP or T.38 silence periods.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information on No-Op packets, see <a href="#">No-Op Packets</a> on page 185.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For configuring the Tx payload type for No-Op packets, use the [RTPNoOpPayloadType] parameter.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'SBC Multiple Coders' configure voip > coders-and-profiles ip-profile > sbc- multiple-coders [SBCMultipleCoders]	<p>Defines if the UA associated with this IP Profile supports multiple coders in the SDP answer that is received from the peer side.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = (Default) If multiple coders ('m=' line) are present in the SDP answer received from the peer side, the device uses only the first supported coder in the list for the RTP media.</li> <li>■ [1] <b>Supported</b> = If multiple coders ('m=' line) are present in the SDP answer received from the peer side, the device does one of the following, depending on whether DSP resources are required (e.g., for DTMF transcoding): <ul style="list-style-type: none"> <li>✓ DSP resources required: Upon receipt of the SDP answer, the device sends a re-INVITE message with only a single coder (first supported coder in the list) to the UA associated with this IP Profile. In other words, the device “forces” the UAs to negotiate only a single coder for the RTP media.</li> <li>✓ DSP resources not required: The device supports multiple coders in the SDP answer, allowing the RTP media to use any one of the listed coders (doesn't send a re-INVITE).</li> </ul> </li> </ul>

Parameter	Description
	<p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'SBC Allow Only Negotiated PT'</p> <pre>configure voip &gt; coders-and-profiles ip-profile &gt; sbc- allow-only- negotiated-pt</pre> <p>[SBCAllowOnlyNegotiatedPT]</p>	<p>Enables the device to allow only media (RTP) packets, from the UA associated with this IP Profile, using the single coder (payload type) that was negotiated during the SDP offer/answer exchange (e.g., 'm=audio 53456 RTP/AVP 0' for G.711). The device drops all other packets from the UA using any other coder.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> =(Default) The device allows packets with multiple negotiated coders.</li> <li>■ [1] <b>Enable</b> = The device allows only packets with the single negotiated coder.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Remove CSRC'</p> <pre>sbc-remove-csrc</pre> <p>[SBCRemoveCSRC]</p>	<p>Enables the device to remove the contributing source (CSRC) identifiers (CC field) from the RTP header in RTP packets sent to the UA associated with this IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (Default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'SBC Precondition'</p> <pre>sbc-precondition</pre> <p>[SBCPrecondition]</p>	<p>Defines if the UA associated with this IP Profile supports SIP session preconditions according to RFC 3312.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = (Default) If the Require header in the incoming SIP message contains the value 'precondition', the device rejects the message (420 Bad Extension response). The device never adds the value 'precondition' to the Supported header (or Require header) in outgoing messages.</li> <li>■ [1] <b>Supported</b> = The device always adds the value 'precondition' to the Supported header in the outgoing SIP message (unless it has to add it to the Require header according to RFC 3312).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For this functionality, you must also do the following:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Configure the IP Profile's 'Remote Can Play Ringback' parameter to <b>No</b> because according to the RFC, the 'precondition' must be done during the early media stage.</li> <li>✓ Configure the IP Profile's 'SIP UPDATE Support' parameter to <b>Supported</b> because using the SIP UPDATE message is mandatory according to the RFC.</li> <li>■ The device doesn't initiate precondition attributes in the SDP.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'BFCP IP from Audio Media' bfcip-ip-from-audio [SBCBFCPNatFromAudio]	<p>Enables the handling of calls with voice and Binary Floor Control Protocol (BFCP) media streams that are received from behind a NAT. The device latches onto the first incoming voice packet to determine the IP address and applies it to the BFCP stream. This allows the device to forward the BFCP packets to the remote side.</p> <p>The BFCP, as defined in RFC 8855, manages access to shared resources in multiparty conferencing environments. BFCP allows users to share presentations or desktops within an ongoing video conversation. The desktop sharing video stream runs in addition to the actual call which already has audio and video streams.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Global Parameter</b> = (Default) According to the settings of the global parameter [BFCPNatFromAudio].</li> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature assumes that both the voice and BFCP streams originate from the <b>same</b> source.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Remove EXTMAP' sbc-remove-extmap [SBCRemoveEXTMAP]	<p>Enables the device to remove the 'a=extmap' SDP line in outgoing SIP-initiating INVITE requests.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> </ul>

Parameter	Description
	<p>■ [1] <b>Enable</b></p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>Quality of Service</b>	
'RTP IP DiffServ' rtp-ip-diffserv [IPDiffServ]	<p>Defines the DiffServ value for Premium Media class of service (CoS) content.</p> <p>The valid range is 0 to 63. The default is 46.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The corresponding global parameter is [PremiumServiceClassMediaDiffServ].</li> <li>■ In addition to audio, the parameter applies to video media if the 'RTP Video DiffServ' is configured to -1 (default).</li> </ul>
'RTP Video DiffServ' rtp-video-diffserv [VideoDiffServ]	<p>Defines the DiffServ value for video media.</p> <p>The valid range is -1, or 0 to 63. The default is -1, which means the DiffServ value for video is according to the 'RTP IP DiffServ' parameter.</p>
'Signaling DiffServ' signaling-diffserv [SigIPDiffServ]	<p>Defines the DiffServ value for Premium Control CoS content (Call Control applications).</p> <p>The valid range is 0 to 63. The default is 40.</p> <p><b>Note:</b> The corresponding global parameter is [PremiumServiceClassControlDiffServ].</p>
'Data DiffServ' data-diffserv [DataDiffServ]	<p>Defines the DiffServ value of MSRP traffic in the IP header's DSCP field.</p> <p>The valid range is 0 to 63. The default is 0.</p> <p>For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>Jitter Buffer</b>	
'Dynamic Jitter Buffer Minimum Delay' jitter-buffer-minimum-delay	<p>Defines the minimum delay (in msec) of the device's dynamic Jitter Buffer.</p> <p>The valid range is 0 to 150. The default delay is 10.</p> <p>For more information on Jitter Buffer, see <a href="#">Configuring the</a></p>

Parameter	Description
[JitterBufMinDelay]	<p><a href="#">Dynamic Jitter Buffer</a> on page 296.</p> <p><b>Note:</b> The corresponding global parameter is [DJBufMinDelay].</p>
'Dynamic Jitter Buffer Optimization Factor' jitter-buffer-optimization-factor [JitterBufOptFactor]	<p>Defines the Dynamic Jitter Buffer frame error/delay optimization factor.</p> <p>The valid range is 0 to 12. The default factor is 10.</p> <p>For more information on Jitter Buffer, see <a href="#">Configuring the Dynamic Jitter Buffer</a> on page 296.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For data (fax and modem) calls, set the parameter to 12.</li> <li>■ The corresponding global parameter is [DJBufOptFactor].</li> </ul>
'Jitter Buffer Max Delay' jitter-buffer-max-delay [JitterBufMaxDelay]	<p>Defines the maximum delay and length (in msec) of the Jitter Buffer.</p> <p>The valid range is 150 to 2,000. The default is 250.</p>
<b>Voice</b>	
'Echo Canceled' echo-canceller [EnableEchoCanceller]	<p>Enables the device's Echo Cancellation feature (i.e., echo from voice calls is removed).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Line</b> (default)</li> <li>■ [2] <b>Acoustic</b></li> </ul> <p>For a detailed description of the Echo Cancellation feature, see <a href="#">Configuring Echo Cancellation</a> on page 278.</p> <p><b>Note:</b> The corresponding global parameter is [EnableEchoCanceller].</p>
'Input Gain' input-gain [InputGain]	<p>Defines the pulse-code modulation (PCM) input gain control (in decibels). For the Gateway application:</p> <p>Defines the level of the received signal for Tel-to-IP calls.</p> <p>The valid range is -32 to 31 dB. The default is 0 dB.</p> <p><b>Note:</b> The corresponding global parameter is [InputGain].</p>
'Voice Volume'	Defines the voice gain control (in decibels). For the

Parameter	Description
voice-volume [VoiceVolume]	<p>Gateway application: Defines the level of the transmitted signal for IP-to-Tel calls.</p> <p>The valid range is -32 to 31 dB. The default is 0 dB.</p> <p><b>Note:</b> The corresponding global parameter is [VoiceVolume].</p>
<b>SBC Signaling</b>	
'PRACK Mode' sbc-prack-mode [SbcPrackMode]	<p>Defines the device's handling of SIP PRACK messages for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disabled</b> = The device doesn't allow PRACK: <ul style="list-style-type: none"> <li>✓ For SIP requests (INVITE) and responses (18x), the device removes the '100rel' option from the SIP Supported header (if present). In other words, the device disables PRACK with this SIP UA.</li> <li>✓ If the device receives an INVITE message containing the header and value 'Require: 100rel', it rejects the message (with a SIP 420 response).</li> <li>✓ If the device receives a SIP 18x response containing the RSeq header and the '100rel' option, it sends a CANCEL message to cancel the SIP dialog.</li> </ul> </li> <li>■ [1] <b>Optional</b> = PRACK is optional. If required, the device performs the PRACK process on behalf of the SIP UA.</li> <li>■ [2] <b>Mandatory</b> = PRACK is required for this SIP UA. Calls from UAs that do not support PRACK are rejected. Calls destined to these UAs are also required to support PRACK.</li> <li>■ [3] <b>Transparent</b> = (Default) The device doesn't intervene with the PRACK process and forwards the request as is.</li> <li>■ [4] <b>Optional With Adaptations</b> = This option may be useful, for example, to prevent PRACK congestion caused by the flooding of the device with 18x messages without body. <ul style="list-style-type: none"> <li>✓ Outgoing INVITE messages (sent to SIP UA): <ul style="list-style-type: none"> <li>- The device adds the header 'Supported: 100rel' to the INVITE message. If the message included</li> </ul> </li> </ul> </li> </ul>

Parameter	Description
	<p>the header and value 'Require: 100rel', it removes the '100rel' option.</p> <ul style="list-style-type: none"> <li>- If the device adds the '100rel' option, it terminates and fully handles PRACK; otherwise, the device forwards the message transparently.</li> </ul> <p>✓ Incoming INVITE messages (from SIP UA):</p> <ul style="list-style-type: none"> <li>- If the message doesn't contain the '100rel' option, the device doesn't handle PRACK.</li> <li>- If the message contains the header and value 'Require: 100rel', the device processes PRACK as described for the <b>Mandatory</b> optional value above (and terminates PRACK, if necessary).</li> <li>- If the message contains the header and value 'Supported: 100rel', the device activates PRACK Extensions as follows: <ul style="list-style-type: none"> <li>&gt;&gt; If the device sends an outgoing 18x responses with body (e.g., SDP), the device processes PRACK as described for the <b>Mandatory</b> optional value above (and terminates PRACK, if necessary).</li> <li>&gt;&gt; If the device sends an outgoing 18x responses without body, the device removes the '100rel' option and the RSeq header (if present). If the RSeq header was present, the device sends a terminated PRACK to the incoming leg without Optional With Adaptations outgoing leg involvement.</li> </ul> </li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'P-Asserted-Identity Header Mode'</p> <p>sbc-assert-identity</p> <p>[SBCAssertIdentity]</p>	<p>Defines the device's handling of the SIP P-Asserted-Identity header for the SIP UA associated with the IP Profile. This header indicates how the outgoing SIP message asserts identity.</p> <ul style="list-style-type: none"> <li>■ [0] <b>As Is</b> = (Default) P-Asserted Identity header is not affected and the device uses the same P-Asserted-Identity header (if present) in the incoming message for the outgoing message.</li> <li>■ [1] <b>Add</b> = Adds a P-Asserted-Identity header. The header's values are taken from the source URL.</li> <li>■ [2] <b>Remove</b> = Removes the P-Asserted-Identity header.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter affects only initial INVITE requests.</li> <li>■ The corresponding global parameter is [SBCAssertIdentity].</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Diversion Header Mode' sbc-diversion-mode [SBCDiversionMode]	<p>Defines the device's handling of the SIP Diversion header for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>As Is</b> = (Default) Diversion header is not handled.</li> <li>■ [1] <b>Add</b> = History-Info header is converted to a Diversion header.</li> <li>■ [2] <b>Remove</b> = Removes the Diversion header and the conversion to the History-Info header depends on the SBCHistoryInfoMode parameter.</li> </ul> <p>For more information on interworking of the History-Info and Diversion headers, see <a href="#">Interworking SIP Diversion and History-Info Headers</a> on page 1152.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the Diversion header is used, you can specify the URI type (e.g., "tel:") to use in the header, using the [SBCDiversionUriType] parameter.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'History-Info Header Mode' sbc-history-info-mode [SBCHistoryInfoMode]	<p>Defines the device's handling of the SIP History-Info header for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>As Is</b> = (Default) History-Info header is not handled.</li> <li>■ [1] <b>Add</b> = Diversion header is converted to a History-Info header.</li> <li>■ [2] <b>Remove</b> = History-Info header is removed from the SIP dialog and the conversion to the Diversion header depends on the SBCDiversionMode parameter.</li> </ul> <p>For more information on interworking of the History-Info and Diversion headers, see <a href="#">Interworking SIP Diversion</a></p>

Parameter	Description
	<p><a href="#">and History-Info Headers</a> on page 1152.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Session Expires Mode'</p> <p>sbc-session-expires-mode</p> <p>[SBCSessionExpiresMode]</p>	<p>Defines the required session expires mode for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) The device doesn't interfere with the session expires negotiation.</li> <li>■ [1] <b>Observer</b> = If the SIP Session-Expires header is present, the device doesn't interfere, but maintains an independent timer for each leg to monitor the session. However, if the session is not refreshed on time, the device disconnects the call. The timer duration is configured by the global parameter [SipSessionExpiresObserverMode].</li> <li>■ [2] <b>Not Supported</b> = The device doesn't allow a session timer with this SIP UA.</li> <li>■ [3] <b>Supported</b> = The device enables the session timer with this SIP UA. If the incoming SIP message doesn't include any session timers, the device adds the session timer information to the sent message. You can configure the value of the Session-Expires and Min-SE headers, using the [SBCSessionExpires] and [SBCMinSE] parameters, respectively.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'SIP UPDATE Support'</p> <p>sbc-rmt-update-supp</p> <p>[SBCRemoteUpdateSupport]</p>	<p>Defines if the SIP UA associated with this IP Profile supports the receipt of SIP UPDATE messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = The UA doesn't support the receipt of UPDATE messages.</li> <li>■ [1] <b>Supported Only After Connect</b> = The UA supports the receipt of UPDATE messages, but only after the call is connected.</li> <li>■ [2] <b>Supported</b> = (Default) The UA supports the receipt of UPDATE messages during call setup and after call establishment.</li> <li>■ [3] <b>According Remote Allow</b> = The UA support for SIP UPDATE messages depends on the presence of the</li> </ul>

Parameter	Description
	<p>"update" capability in the Allow header in the last SIP message received from the UA. When the UA indicates UPDATE support:</p> <ul style="list-style-type: none"> <li>✓ If session refresh is used, the device sends session refreshes to the UA using UPDATE messages.</li> <li>✓ If an UPDATE message is received from a peer UA, the device forwards the UPDATE message to this supporting UA.</li> <li>✓ If a re-INVITE message containing an SDP is received from a peer UA, the device sends it as an UPDATE message to the supporting UA. If an INVITE message without an SDP is received from a peer UA, the device forwards the INVITE message to the supporting UA.</li> </ul> <p>If the Allow header doesn't indicate UPDATE support, the device sends INVITE messages instead of UPDATE messages to the UA.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Remote re-INVITE'</p> <p>sbc-rmt-re-invite-supp</p> <p>[SBCRemoteReinviteSupport]</p>	<p>Defines if the SIP UA associated with this IP Profile supports the receipt of SIP re-INVITE messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = The UA doesn't support the receipt of re-INVITE messages. If the device receives a re-INVITE from another UA that is destined to this UA, the device "terminates" the re-INVITE and sends a SIP response to the UA that sent it, which can be a success or a failure, depending on whether the device can bridge the media between the UAs.</li> <li>■ [1] <b>Supported only with SDP</b> = The UA supports the receipt of re-INVITE messages, but only if they contain an SDP body. If the incoming re-INVITE from another UA doesn't contain SDP, the device creates and adds an SDP body to the re-INVITE that it forwards to the UA.</li> <li>■ [2] <b>Supported</b> = (Default) The UA supports the receipt of re-INVITE messages with or without SDP.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>

Parameter	Description
<p>'Remote Delayed Offer Support'</p> <p>sbc-rmt-delayed-offer</p> <p>[SBCRemoteDelayedOfferSupport]</p>	<p>Defines if the remote UA supports delayed offer (i.e., initial INVITE requests without an SDP offer).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b></li> <li>■ [1] <b>Supported</b> (default)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the parameter to function, you need to assign extension coders to the IP Profile of the SIP UA that doesn't support delayed offer (using the 'Extension Coders Group' parameter).</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'MSRP re-INVITE/UPDATE'</p> <p>sbc-msrp-re-invite-update-supp</p> <p>[SBCMSRPReinviteUpdateSupport]</p>	<p>Defines if the SIP UA (MSRP endpoint) associated with this IP Profile supports the receipt of re-INVITE and UPDATE SIP messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = The device doesn't send re-INVITE or UPDATE messages to the UA. If the device receives any of these messages from the peer UA, the device "terminates" the messages, and then sends a SIP response to the peer UA on behalf of the UA associated with this IP Profile.</li> <li>■ [1] <b>Supported</b> (default)</li> </ul> <p>For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'MSRP Offer Setup Role'</p> <p>sbc-msrp-offer-setup-role</p> <p>[SBCMSRPOfferSetupRole]</p>	<p>Defines the device's preferred MSRP role, which is indicated in the initial SDP offer that it sends to the destination MSRP endpoint ('a=setup' line) associated with this IP Profile. However, this is only a preferred role; the actual role that the device takes on depends on the destination MSRP endpoint's desired role, which is indicated in the SDP answer in its reply to the device:</p> <ul style="list-style-type: none"> <li>■ If 'a=setup:active', the device takes the passive role.</li> <li>■ If 'a=setup:passive', the device takes the active role.</li> <li>■ If 'a=setup' (i.e., empty) or no 'a=setup', the device takes the active role.</li> </ul>

Parameter	Description
	<p>The possible values include:</p> <ul style="list-style-type: none"> <li>■ [0] <b>Active</b> = The device prefers the active role and includes 'a=setup:active' in the outgoing SDP offer sent to the endpoint associated with the IP Profile.</li> <li>■ [1] <b>Passive</b> = The device prefers the passive role and includes 'a=setup:passive' in the outgoing SDP offer sent to the endpoint associated with the IP Profile.</li> <li>■ [2] <b>ActPass</b> = (Default) The device has no role preference and includes 'a=setup:actpass' in the outgoing SDP offer sent to the endpoint associated with the IP Profile</li> </ul> <p>For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'MSRP Empty Message Format'</p> <p>sbc-msrp-empty-message-format</p> <p>[SBCMSRPEmpMsg]</p>	<p>On an active MSRP leg, enables the device to add the Content-Type header to the first empty (i.e., no body) MSRP message that is used to initiate the MSRP connection.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Default</b> = (Default) Sends the empty message with regular headers, according to the RFC for MSRP.</li> <li>■ [1] <b>With Content Type</b> = Adds the Content-Type header to the empty message (in addition to the regular headers according to the RFC for MSRP).</li> </ul> <p>For more information on MSRP, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Remote Representation Mode'</p> <p>sbc-rmt-rprnsntation</p> <p>[SBCRemoteRepresentationMode]</p>	<p>Enables interworking SIP in-dialog, Contact and Record-Route headers between SIP entities. The parameter defines the device's handling of in-dialog, Contact and Record-Route headers for messages sent to the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Operation Mode</b> = (Default) Depends on the setting of the 'Operation Mode' parameter in the IP Groups or SRDs table: <ul style="list-style-type: none"> <li>✓ B2BUA: Device operates as if the parameter is set</li> </ul> </li> </ul>

Parameter	Description
	<p>to Replace Contact [0].</p> <ul style="list-style-type: none"> <li>✓ Call State-full Proxy: Device operates as if the parameter is set to Add Routing Headers [1].</li> <li>■ [0] <b>Replace Contact</b> = The URI host part in the Contact header of the received message (from the other side) is replaced with the device's address or with the value of the 'SIP Group Name' parameter (configured in the IP Groups table) in the outgoing message sent to the SIP UA.</li> <li>■ [1] <b>Add Routing Headers</b> = Device adds a Record-Route header for itself to outgoing messages (requests\responses) sent to the SIP UA in dialog-setup transactions. The Contact header remains unchanged.</li> <li>■ [2] <b>Transparent</b> = Device doesn't change the Contact header and doesn't add a Record-Route header for itself. Instead, it relies on its' own inherent mechanism to remain in the route of future requests in the dialog (for example, relying on the way the endpoints are set up or on TLS as the transport type).</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Keep Incoming Via Headers'</p> <p>sbc-keep-via-headers</p> <p>[SBCKeepVIAHeaders]</p>	<p>Enables interworking SIP Via headers between SIP entities. The parameter defines the device's handling of Via headers for messages sent to the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Operation Mode</b> = Depends on the setting of the 'Operation Mode' parameter in the IP Groups table or SRDs table: <ul style="list-style-type: none"> <li>✓ B2BUA: Device operates as if the parameter is set to Disable [0].</li> <li>✓ Call State-full Proxy: Device operates as if the parameter is set to Enable [1].</li> </ul> </li> <li>■ [0] <b>Disable</b> = Device removes all Via headers received in the incoming SIP request from the other leg and adds a Via header identifying only itself, in the outgoing message sent to the SIP UA.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = Device retains the Via headers received in the incoming SIP request and adds itself as the top-most listed Via header in the outgoing message sent to the SIP UA.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Keep Incoming Routing Headers' sbc-keep-routing-headers [SBCKeepRoutingHeaders]	<p>Enables interworking SIP Record-Route headers between SIP entities. The parameter defines the device's handling of Record-Route headers for request/response messages sent to the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Operation Mode</b> = (Default) Depends on the setting of the 'Operation Mode' in the IP Group or SRDs table:               <ul style="list-style-type: none"> <li>✓ B2BUA: Device operates as if the parameter is set to Disable [0].</li> <li>✓ Call State-full Proxy: Device operates as if the parameter is set to Enable [1].</li> </ul> </li> <li>■ [0] <b>Disable</b> = Device removes the Record-Route headers received in requests and responses from the other side, in the outgoing SIP message sent to the SIP UA. The device creates a route set for that side of the dialog based on these headers, but doesn't send them to the SIP UA.</li> <li>■ [1] <b>Enable</b> = Device retains the incoming Record-Route headers received in requests and non-failure responses from the other side, in the following scenarios:               <ul style="list-style-type: none"> <li>✓ The message is part of a SIP dialog-setup transaction.</li> <li>✓ The messages in the setup and previous transaction didn't include the Record-Route header, and therefore hadn't set the route set.</li> </ul> </li> </ul> <p><b>Note:</b> Record-Routes are kept only for SIP INVITE, UPDATE, SUBSCRIBE and REFER messages.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Keep User-Agent Header'	Enables interworking SIP User-Agent headers between

Parameter	Description
sbc-keep-user-agent [SBCKeepUserAgentHeader]	<p>SIP entities. The parameter defines the device's handling of User-Agent headers for response/request messages sent to the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>According to Operation Mode</b> = (Default) Depends on the setting of the 'Operation Mode' parameter in the IP Group or SRDs table:               <ul style="list-style-type: none"> <li>✓ B2BUA: Device operates as if this parameter is set to Disable [0].</li> <li>✓ Call State-full Proxy: Device operates as if this parameter is set to Enable [1].</li> </ul> </li> <li>■ [0] <b>Disable</b> = Device removes the User-Agent/Server headers received in the incoming message from the other side, and adds its' own User-Agent header in the outgoing message sent to the SIP UA.</li> <li>■ [1] <b>Enable</b> = Device retains the User-Agent/Server headers received in the incoming message and sends the headers as is in the outgoing message to the SIP UA.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Use Initial Incoming INVITE for re-INVITE' use-initial-incoming-invite-for-reinvite [KeepInitialIncomingINVITE]	<p>Enables the device to use the initial (first) incoming SIP INVITE message of the dialog session, for creating a re-INVITE message. For example, if the device receives a REFER message (call transfer), it terminates the message locally, creates a re-INVITE based on the initial INVITE, and then sends it to the peer side. This may be useful if the initial incoming SIP INVITE includes customized headers or bodies that you want to preserve for the outgoing INVITE.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ This parameter doesn't apply to outgoing re-INVITE messages that are initiated by the SIP session-expires mechanism.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Enabling this parameter may reduce the device's performance by up to 10%.</li> </ul>
'Handle X-Detect' sbc-handle-xdetect [SBCHandleXDetect]	<p>Enables the detection and notification of events (AMD, CPT, and fax), using the X-Detect SIP header.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> (default)</li> <li>■ [1] <b>Yes</b></li> </ul> <p>For more information, see <a href="#">Event Detection and Notification using X-Detect Header</a> on page 303.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'ISUP Body Handling' sbc-isup-body-handling [SBCISUPBodyHandling]	<p>Defines the handling of ISUP data for interworking SIP and SIP-I endpoints.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) ISUP data is passed transparently (as is) between endpoints (SIP-I to SIP-I calls).</li> <li>■ [1] <b>Remove</b> = ISUP body is removed from INVITE messages.</li> <li>■ [2] <b>Create</b> = ISUP body is added to outgoing INVITE messages.</li> <li>■ [3] <b>Create If Not Exists</b> = ISUP body is added to outgoing INVITE messages if it doesn't exist in the incoming leg. If it exists, unknown fields and messages by the device are passed transparently, while known fields can be manipulated using Message Manipulation rules. For known fields, some values that are "reserved for national use" may be changed to default.</li> </ul> <p>For more information on interworking SIP and SIP-I, see <a href="#">Enabling Interworking of SIP and SIP-I Endpoints</a> on page 1262.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'ISUP Variant' sbc-isup-variant [SBCISUPVariant]	<p>Defines the ISUP variant for interworking SIP and SIP-I endpoints.</p> <ul style="list-style-type: none"> <li>■ [0] <b>itu92</b> = (Default) ITU 92 variant</li> <li>■ [1] <b>Spirou</b> = SPIROU (ISUP France)</li> </ul>

Parameter	Description
	<p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Max Call Duration'</p> <p>sbc-max-call-duration</p> <p>[SBCMaxCallDuration]</p>	<p>Defines the maximum duration (in minutes) per SBC call that is associated with the IP Profile. If the duration is reached, the device ends the call.</p> <p>The valid range is 0 to 35,791, where 0 means unlimited call duration. The default is the value configured for the global parameter [SBCMaxCallDuration].</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ You can also configure maximum call duration, using Message Manipulation rules with the call variables <code>Var.Call.Dst.MaxDuration</code> or <code>Var.Call.Src.MaxDuration</code>. For more information, refer to the document <i>SIP Message Manipulation Syntax Reference Guide</i>, by clicking <a href="#">here</a>.</li> </ul>
<p>'Disconnect In-Dialog Subscribe Failure'</p> <p>disconnect-in-dialog-subscribe-failure</p> <p>[DisconnectInDialogSubscribeFailure]</p>	<p>Defines if the device disconnects the call if a subscription request (SIP SUBSCRIBE) sent during the call (in-dialog) fails. Maintaining the call (by disabling this parameter) may be useful, for example, to preserve active 911 emergency calls even if in-dialog subscription requests fail.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = If an in-dialog SUBSCRIBE request fails, the device maintains the call.</li> <li>■ [1] <b>Enable</b> = (Default) If an in-dialog SUBSCRIBE request fails, the device disconnects the call.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When enabled, this feature applies to the IP Group (to which the IP Profile is assigned) that initiated the in-dialog subscription request (regardless of whether it's the inbound or outbound leg).</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Broken Signaling Connection Mode'</p>	<p>Defines the handling of established calls when the device detects a disconnection in the associated SIP signaling</p>

Parameter	Description
disconnect-on-broken-signaling-connection [DisconnectOnBrokenSignalingConnection]	<p>path (socket).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Ignore</b> = (Default) The device maintains the call despite loss in SIP signaling path (and ends the call when signaling ends it by a SIP BYE message). The device will try to re-establish a signaling connection when the next SIP signaling message needs to be sent.</li> <li>■ [1] <b>Disconnect</b> = The device immediately ends the call.</li> <li>■ [2] <b>Reroute</b> = The device immediately ends the call and then searches the IP-to-IP Routing table (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186) for a matching rule. If found, the device sends a new SIP INVITE message to the new destination. You can also configure a main routing rule whose matching characteristics is explicitly for calls that have broken SIP signaling connections. You do this by configuring the 'Call Trigger' parameter in the IP-to-IP Routing table to <b>Broken Connection</b>.</li> <li>■ [3] <b>Reroute with Original SIP Headers</b> = The device immediately ends the call and then searches the IP-to-IP Routing table (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186) for a matching rule. If found, the device sends a new SIP INVITE message to the new destination, but with the original SIP headers and non-SDP bodies (XML only of multipart SDP bodies). The SDP body is not copied but re-generated by the device. You can also configure a main routing rule whose matching characteristics is explicitly for calls that have broken SIP signaling connections. You do this by configuring the 'Call Trigger' parameter in the IP-to-IP Routing table to <b>Broken Connection</b>.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only for calls whose SIP signaling is over TCP.</li> <li>■ The optional values <b>Reroute</b> and <b>Reroute with Original SIP Headers</b> are applicable only to the outgoing leg. If you've configured one of these options for the incoming leg, the device handles the call according to the <b>Disconnect</b> option.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If during a call, the source IP address (from where the packets are received by the device) is changed without notifying the device, the device rejects the packets. To overcome this, configure the parameter to <b>Ignore</b>. With this configuration, the device doesn't detect packets arriving from the original source IP address and switches (after 300 msec) to the packets arriving from the new source IP address.</li> </ul>
<b>SBC Registration</b>	
'User Registration Time' sbc-usr-reg-time [SBCUserRegistrationTime]	<p>Defines the registration time (in seconds) that the device responds to SIP REGISTER requests from users belonging to the SIP UA associated with the IP Profile. The registration time is inserted in the Expires header in the outgoing response sent to the user.</p> <p>The Expires header determines the lifespan of the registration. For example, a value of 3600 means that the registration will timeout in one hour and at that point, the user will not be able to make or receive calls.</p> <p>The valid range is 0 to 2,000,000. The default is 0. If configured to 0, the Expires header's value received in the user's REGISTER request remains unchanged. If no Expires header is received in the REGISTER message and the parameter is set to 0, the Expires header's value is set to 180 seconds, by default.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The corresponding global parameter is [SBCUserRegistrationTime].</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'NAT UDP Registration Time' sbc-usr-udp-nat-reg-time [SBCUserBehindUdpNATRegistrationTime]	<p>Defines the registration time (in seconds) that the device includes in register responses, in response to SIP REGISTER requests from users belonging to the SIP UA associated with the IP Profile.</p> <p>The parameter applies only to users that are located behind NAT and whose communication type is UDP. The registration time is inserted in the Expires header in the outgoing response sent to the user.</p> <p>The Expires header determines the lifespan of the registration. For example, a value of 3600 means that the</p>

Parameter	Description
	<p>registration will timeout in one hour, unless the user sends a refresh REGISTER before the timeout. Upon timeout, the device removes the user's details from the registration database, and the user will not be able to make or receive calls through the device.</p> <p>The valid value is 0 to 2,000,000. If configured to 0, the Expires header's value received in the user's REGISTER request remains unchanged. By default, no value is defined (-1).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is not configured, the registration time is according to the global parameter [SBCUserRegistrationTime] or IP Profile parameter 'User Registration Time'.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'NAT TCP Registration Time'</p> <p>sbc-usr-tcp-nat-reg-time</p> <p>[SBCUserBehindTcpNATRegistrationTime]</p>	<p>Defines the registration time (in seconds) that the device includes in register responses, in response to SIP REGISTER requests from users belonging to the SIP UA associated with the IP Profile.</p> <p>The parameter applies only to users that are located behind NAT and whose communication type is TCP. The registration time is inserted in the Expires header in the outgoing response sent to the user.</p> <p>The Expires header determines the lifespan of the registration. For example, a value of 3600 means that the registration will timeout in one hour, unless the user sends a refresh REGISTER before the timeout. Upon timeout, the device removes the user's details from the registration database, and the user will not be able to make or receive calls through the device.</p> <p>The valid value is 0 to 2,000,000. If configured to 0, the Expires header's value received in the user's REGISTER request remains unchanged. By default, no value is defined (-1).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is not configured, the registration time is according to the global parameter [SBCUserRegistrationTime] or IP Profile parameter 'User Registration Time'.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<b>SBC Forward and Transfer</b>	
'Remote REFER Mode' sbc-rmt-refer-behavior [SBCRemoteReferBehavior]	<p>Defines the device's handling of SIP REFER requests for the SIP UA (transferee - call party that is transferred to the transfer target) associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Regular</b> = (Default) SIP Refer-To header value is unchanged and the device forwards the REFER message as is. However, if you configure the 'Remote Replaces Mode' parameter (see below) to any value other than <b>Keep as is</b>, the device may modify the URI of the Refer-To header to reflect the call identifiers of the leg.</li> <li>■ [1] <b>Database URL</b> = SIP Refer-To header value is changed so that the re-routed INVITE is sent through the device:               <ol style="list-style-type: none"> <li>Before forwarding the REFER request, the device changes the host part to the device's IP address and adds the prefix "T~&amp;R_" to the Contact user part.</li> <li>The incoming INVITE is identified as a REFER-resultant INVITE according to this special prefix.</li> <li>The device replaces the host part in the Request-URI with the host from the REFER contact. The special prefix remains in the user part for regular classification, manipulation, and routing. The special prefix can also be used for specific routing rules for REFER-resultant INVITES.</li> <li>The special prefix is removed before the resultant INVITE is sent to the destination (transfer target).</li> </ol> </li> <li>■ [2] <b>IP Group Name</b> = Changes the host part in the REFER message to the value that you configured for the 'SIP Group Name' parameter in the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591).</li> <li>■ [3] <b>Handle Locally</b> = Handles the incoming REFER request itself without forwarding the REFER. The device generates a new INVITE to the alternative destination (transfer target) according to the rules in</li> </ul>

Parameter	Description
	<p>the IP-to-IP Routing table (the 'Call Trigger' parameter must be set to <b>REFER</b>).</p> <ul style="list-style-type: none"> <li>■ [4] <b>Local Host</b> = In the REFER message received from the transferor, the device replaces the Refer-To header value (URL) with the IP address of the device or with the 'Local Host Name' parameter value configured for the IP Group (transferee) to where the device forwards the REFER message. This ensures that the transferee sends the re-routed INVITE back to the device which then sends the call to the transfer target.</li> <li>■ [5] <b>Keep URI (user@host)</b> = The device forwards the REFER message without changing the URI (user@host) in the SIP Refer-To header. If you configure the 'Remote Replaces Mode' parameter (see below) to any value other than <b>Keep as is</b>, the device may modify the 'replaces' parameter of the Refer-To header to reflect the call identifiers of the leg. This applies to all types of call transfers (e.g., blind and attendant transfer).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can override the parameter's settings using Message Manipulation rules configured with the AudioCodes proprietary SIP header, X-AC-Action. For more information, see <a href="#">Using Proprietary SIP X-AC-Action Header</a> on page 1244.</li> <li>■ The corresponding global parameter is [SBCReferBehavior].</li> <li>■ For MSRP sessions, the <b>Handle Locally</b> option is not applicable. For more information on MSRP sessions, see <a href="#">Configuring Message Session Relay Protocol</a> on page 1251.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Remote Replaces Mode' sbc-rmt-replaces-behavior [SBCRemoteReplacesBehavior]	<p>Enables the device to handle incoming INVITEs containing the Replaces header for the SIP UA (which doesn't support the header) associated with the IP Profile. The Replaces header is used to replace an existing SIP dialog with a new dialog such as in call transfer or call pickup.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Standard</b> = (Default) The SIP UA supports INVITE messages containing Replaces headers. The device forwards the INVITE message containing the Replaces header to the SIP UA. The device may change the value of the Replaces header to reflect the call identifiers of the leg.</li> <li>■ [1] <b>Handle Locally</b> = The SIP UA doesn't support INVITE messages containing Replaces headers. The device terminates the received INVITE containing the Replaces header and establishes a new call between the SIP UA and the new call party. It then disconnects the call with the initial call party, by sending it a SIP BYE request.</li> <li>■ [2] <b>Keep as is</b> = The SIP UA supports INVITE messages containing Replaces headers. The device forwards the Replaces header as is in incoming REFER and outgoing INVITE messages from/to the SIP UA (i.e., Replaces header's value is unchanged).</li> </ul> <p>For example, assume that the device establishes a call between A and B. If B initiates a call transfer to C, the device receives an INVITE with the Replaces header from C. If A supports the Replaces header, the device simply forwards the INVITE as is to A; a new call is established between A and C and the call between A and B is disconnected. However, if A doesn't support the Replaces header, the device uses this feature to terminate the INVITE with Replaces header and handles the transfer for A. The device does this by connecting A to C, and disconnecting the call between A and B, by sending a SIP BYE request to B. Note that if media transcoding is required, the device sends an INVITE to C on behalf of A with a new SDP offer.</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'Play RBT To Transferee' sbc-play-rbt-to-xferee [SBCPlayRBToTransferee]	<p>Enables the device to play a ringback tone to the transferred party (transferee) during a blind call transfer, for the SIP UA associated with the IP Profile (which doesn't support such a tone generation during call transfer). The ringback tone indicates to the transferee of the ringing of the transfer target (to where the transferee is being transferred).</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>No</b> (Default)</li> <li>■ [1] <b>Yes</b></li> </ul> <p>Typically, the transferee hears a ringback tone only if the transfer target sends it early media. However, if the transferee is put on-hold before being transferred, no ringback tone is heard.</p> <p>When this feature is enabled, the device generates a ringback tone to the transferee during call transfer in the following scenarios:</p> <ul style="list-style-type: none"> <li>■ Transfer target sends a SIP 180 (Ringing) to the device.</li> <li>■ For non-blind transfer, if the call is transferred while the transfer target is ringing and no early media occurs.</li> <li>■ The 'Remote Early Media RTP Behavior' parameter is set to Delayed (used in the Skype for Business environment), and transfer target sends a 183 Session Progress with SDP offer. If early media from the transfer target has already been detected, the transferee receives RTP stream from the transfer target. If it has not been detected, the device generates a ringback tone to the transferee and stops the tone generation once RTP has been detected from the transfer target.</li> </ul> <p>For any of these scenarios, if the transferee is put on-hold by the transferor, the device retrieves the transferee from hold, sends a re-INVITE if necessary, and then plays the ringback tone.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For the device to play the ringback tone, it must be loaded with a Prerecorded Tones (PRT) file. For more information, see <a href="#">Uploading a Prerecorded Tones File</a> on page 1357.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Remote 3xx Mode' sbc-rmt-3xx-behavior	Defines the device's handling of SIP 3xx redirect responses for the SIP UA associated with the IP Profile. By default, the device's handling of SIP 3xx responses is to

Parameter	Description
[SBCRemote3xxBehavior]	<p>send the Contact header unchanged. However, some SIP entities may support different versions of the SIP 3xx standard while others may not even support SIP 3xx. When enabled, the device handles SIP redirections between different subnets (e.g., between LAN and WAN sides). This is required when the new address provided by the redirector (Redirect sever) may not be reachable by the far-end user (FEU) located in another subnet. For example, a far-end user (FEU) in the WAN sends a SIP request via the device to a Redirect server in the LAN, and the Redirect server replies with a SIP 3xx response to a PBX in the LAN in the Contact header. If the device sends this response as is (i.e., with the original Contact header), the FEU is unable to reach the new destination.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) The device forwards the received SIP 3xx response as is, without changing the Contact header (i.e., transparent handling).</li> <li>■ [1] <b>Database URL</b> = The device changes the Contact header so that the re-route request is sent through the device. The device changes the URI in the Contact header of the received SIP 3xx response to its own URI and adds a special user prefix ("T~&amp;R_"), which is then sent to the FEU. The FEU then sends a new INVITE to the device, which the device then sends to the correct destination.</li> <li>■ [2] <b>Handle Locally</b> = The device handles SIP 3xx responses on behalf of the dialog-initiating UA and retries the request (e.g., INVITE) using one or more alternative URIs included in the 3xx response. The device sends the new request to the alternative destination according to the IP-to-IP Routing table (the 'Call Trigger' field must be set to <b>3xx</b>).</li> <li>■ [3] <b>IP Group Name</b> = If the 'SIP Group Name' parameter of the IP Group of the dialog-initiating UA is configured with a non-empty value, the device changes the host part of the Contact header in the 3xx response to this value, before forwarding the 3xx response to the dialog-initiating UA.</li> <li>■ [4] <b>Local Host</b> = The device changes the host part of the Contact header in the 3xx response before</li> </ul>

Parameter	Description
	<p>forwarding the 3xx response to the dialog-initiating UA. If the 'Local Host Name' parameter of the IP Group of the dialog-initiating UA is configured with a non-empty value, the device changes the host part of the Contact header to this value. If the 'Local Host Name' is empty, the device changes the host part to the device's IP address (the same IP address used in the SIP Via and Contact headers of messages sent to the IP Group).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When the parameter is changed from <b>Database URL</b> to <b>Transparent</b>, new 3xx Contact headers remain unchanged. However, requests with the special prefix continue using the device's database to locate the new destination.</li> <li>■ Optional values <b>IP Group Name</b> and <b>Local Host</b> are applicable only to 3xx responses received due to INVITE messages.</li> <li>■ Only one database entry is supported for the same host, port, and transport combination. For example, the following URLs cannot be distinguished by the device: <ul style="list-style-type: none"> <li>✓ sip:10.10.10.10:5060;transport=tcp;param=a</li> <li>✓ sip:10.10.10.10:5060;transport=tcp;param=b</li> </ul> </li> <li>■ The database entry expires two hours after the last use.</li> <li>■ The maximum number of destinations (i.e., database entries) is 50.</li> <li>■ The corresponding global parameter is [SBC3xxBehavior].</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
'Send Header for Transfer' header-for-transfer [HeaderForTransfer]	<p>Enables the device to notify a change in the remote party (calling or called) after a call transfer (locally handled by the device).</p> <p>The updated information is provided by adding a Remote-Party-ID header to the outgoing message (INVITE,</p>

Parameter	Description
	<p>UPDATE, or 200 OK). As the From header in the SIP dialogs throughout the call transfer process contains the URI of the initial call, the inclusion of the Remote-Party-ID header resolves the problem for identifying the new party.</p> <p>The device also sets the fields in the Remote-Party-ID header to 'party=calling;privacy=off;screen=yes'. However, if a Remote-Party-ID header with 'party=calling' is already present in the incoming request or response, the device only updates the URI. If a Remote-Party-ID header is present in the incoming request or response, but with a different value for the 'party' parameter (e.g. 'party=called'), the device adds an additional Remote-Party-ID header as described above.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) The device doesn't add the Remote-Party-ID header (as explained above).</li> <li>■ [1] <b>Remote-Party-ID</b> = The device adds the Remote-Party-ID header (as explained above).</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<b>SBC Hold</b>	
'Remote Hold Format' remote-hold-Format [SBCRemoteHoldFormat]	<p>Defines the format of the SDP in the SIP re-INVITE (or UPDATE) for call hold that the device sends to the held party.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) Device forwards SDP as is.</li> <li>■ [1] <b>Send Only</b> = Device sends SDP with 'a=sendonly'.</li> <li>■ [2] <b>Send Only Zero Ip</b> = Device sends SDP with 'a=sendonly' and 'c=0.0.0.0'.</li> <li>■ [3] <b>Inactive</b> = Device sends SDP with 'a=inactive'.</li> <li>■ [4] <b>Inactive Zero Ip</b> = Device sends SDP with 'a=inactive' and 'c=0.0.0.0'.</li> <li>■ [5] <b>Not Supported</b> = This option can be used when the remote side doesn't support call hold. The device terminates call hold requests received on the leg interfacing with the initiator of the call hold, and replies to this initiator with a SIP 200 OK response. However, call retrieve (resume) requests received</li> </ul>

Parameter	Description
	<p>from the initiator are forwarded to the remote side. The device can play a held tone to the held party if the 'Play Held Tone' parameter is set to <b>Internal</b>.</p> <ul style="list-style-type: none"> <li>■ [6] <b>Hold and Retrieve Not Supported</b> = This option can be used when the remote side doesn't support call hold and retrieve (resume). The device terminates call hold and call retrieve requests received on the leg interfacing with the initiator of the call hold/retrieve, and replies to this initiator with a SIP 200 OK response. Therefore, the device doesn't forward call hold and/or retrieve requests to the remote side.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
<p>'Reliable Held Tone Source' reliable-heldtone-source [ReliableHoldToneSource]</p>	<p>Enables the device to consider the received call-hold request (re-INVITE/UPDATE) with SDP containing 'a=sendonly', as genuine.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) Even if the received SDP contains 'a=sendonly', the device plays a held tone to the held party. This is useful in cases where the initiator of the call hold doesn't support the generation of held tones.</li> <li>■ [1] <b>Yes</b> = If the received SDP contains 'a=sendonly', the device doesn't play a held tone to the held party (and assumes that the initiator of the call hold plays the held tone).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The device plays a held tone only if the 'Play Held Tone' parameter is set to <b>Internal</b> or <b>External</b>.</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<p>'Play Held Tone' play-held-tone [SBCPlayHeldTone]</p>	<p>Enables the device to play Music-on-Hold (MoH) to call parties that are placed on hold. This is useful if the held party doesn't support the play of a local hold tone, or for IP entities initiating call hold that do not support the generation of hold tones.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device doesn't play any tone to held call parties.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] Internal = Plays the local default hold tone or a tone defined in the PRT file (if installed).</li> <li>■ [2] External = Plays MoH audio streams that originate from an external media source. For more information, see <a href="#">Configuring SBC MoH from External Media Source</a> on page 1264</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you configure the parameter to <b>Internal</b>, the device plays the tone only if the 'SBC Remote Hold Format' parameter is configured to one of the following: send-only, send only 0.0.0.0, not supported, or transparent (when the incoming SDP is 'sendonly').</li> <li>■ The parameter is applicable only to the SBC application.</li> </ul>
<b>SBC Fax</b>	
'Fax Coders Group' sbc-fax-coders-group-name [SBCFaxCodersGroupName]	Assigns a Coder Group which defines the supported fax coders for fax negotiation for the SIP UA associated with the IP Profile. To configure Coder Groups, see <a href="#">Configuring Coders Groups</a> on page 661.  <b>Note:</b> The parameter is applicable only if you configure the 'Fax Mode' parameter to a value other than <b>As Is</b> .
'Fax Mode' sbc-fax-behavior [SBCFaxBehavior]	Enables the device to handle fax offer-answer negotiations for the SIP UA associated with the IP Profile.  <ul style="list-style-type: none"> <li>■ [0] <b>As Is</b> = (Default) Device forwards fax transparently, without interference.</li> <li>■ [1] <b>Handle always</b> = Handle fax according to fax settings in the IP Profile for all offer-answer transactions (including the initial INVITE).</li> <li>■ [2] <b>Handle on re-INVITE</b> = Handle fax according to fax settings in the IP Profile for all re-INVITE offer-answer transactions (except for initial INVITE).</li> </ul> <p><b>Note:</b> The fax settings in the IP Profile include 'Fax Coders Group', 'Fax Offer Mode', and 'Fax Answer Mode'.</p>
'Fax Offer Mode' sbc-fax-offer-mode [SBCFaxOfferMode]	Defines the coders included in the outgoing SDP offer (sent to the called "fax") for the SIP UA associated with the IP Profile.

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>All coders</b> = (Default) Use only (and all) the coders of the selected Coder Group, configured by the 'Fax Coders Group' IP Profile parameter.</li> <li>■ [1] <b>Single coder</b> = Use only one coder. If a coder in the incoming offer (from the calling "fax") matches a coder configured by the 'Fax Coders Group' IP Profile parameter, the device uses this coder. If no match exists, the device uses the first coder listed in the 'Fax Coders Group' IP Profile parameter.</li> </ul> <p><b>Note:</b> The parameter is applicable only if you configure the 'Fax Mode' parameter to a value other than <b>As Is</b>.</p>
'Fax Answer Mode' sbc-fax-answer-mode [SBCFaxAnswerMode]	<p>Defines the coders included in the outgoing SDP answer (sent to the calling "fax") for the SIP UA associated with the IP Profile.</p> <ul style="list-style-type: none"> <li>■ [0] <b>All coders</b> = Use matched coders between the incoming offer coders (from the calling "fax") and the coders of the selected Coder Group (configured by the 'Fax Coders Group' IP Profile parameter).</li> <li>■ [1] <b>Single coder</b> = (Default) Use only one coder. If the incoming answer (from the called "fax") includes a coder that matches a coder match between the incoming offer coders (from the calling "fax") and the coders of the selected Coder Group ('Fax Coders Group' IP Profile parameter), then the device uses this coder. If no match exists, the device uses the first listed coder of the matched coders between the incoming offer coders (from the calling "fax") and the coders of the selected Coder Group.</li> </ul> <p><b>Note:</b> The parameter is applicable only if you configure the 'Fax Mode' parameter to a value other than <b>As Is</b>.</p>
'Remote Renegotiate on Fax Detection' sbc-rmt-renegotiate-on-fax-detect [SBCRemoteRenegotiateOnFaxDetection]	<p>Enables local handling of fax detection and negotiation by the device on behalf of the SIP UA associated with the IP Profile. This applies to faxes sent immediately upon the establishment of a voice channel (i.e., after 200 OK).</p> <p>The device attempts to detect the fax (CNG tone) from the originating SIP UA within a user-defined interval (see the SBCFaxDetectionTimeout parameter) immediately after the voice call is established.</p>

Parameter	Description
	<p>Once fax is detected, the device can handle the subsequent fax negotiation by sending re-INVITE messages to both SIP entities. The device also negotiates the fax coders between the two SIP entities. The negotiated coders are according to the list of fax coders assigned to each SIP UA, using the IP Profile parameter 'Fax Coders Group'.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Transparent</b> = (Default) Device doesn't interfere in the fax transaction and assumes that the SIP UA fully supports fax renegotiation upon fax detection.</li> <li>■ [1] <b>Only on Answer Side</b> = The SIP UA supports fax renegotiation upon fax detection only if it is the terminating (answering) fax, and doesn't support renegotiation if it is the originating fax.</li> <li>■ [2] <b>No</b> = The SIP UA doesn't support fax re-negotiation upon fax detection when it is the originating or terminating fax.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ This feature is applicable only when both SIP entities do not fully support fax detection (receive or send) and negotiation: one SIP UA must be assigned an IP Profile where the parameter is set to [1] or [2], while the peer SIP UA must be assigned an IP Profile where the parameter is set to [2].</li> <li>■ This feature is supported only if at least one of the SIP entities use the G.711 coder.</li> <li>■ This feature requires DSP resources. If there are insufficient resources, the fax transaction fails.</li> </ul>
<p>'Fax Rerouting Mode' sbc-fax-rerouting-mode [SBCFaxReroutingMode]</p>	<p>Enables the rerouting of incoming SBC calls that are identified as fax calls to a new IP destination.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Rerouting without delay</b></li> </ul> <p>For more information, see <a href="#">Configuring Rerouting of Calls to Fax Destinations</a> on page 1206.</p> <p><b>Note:</b> Configure the parameter for the IP leg that is interfacing with the fax termination.</p>

Parameter	Description
<b>Media</b>	
'Broken Connection Mode' disconnect-on- broken-connection [DisconnectOnBrokenConnect ion]	<p>Defines the handling of calls when RTP or MSRP packets (media) are not received within a timeout.</p> <p>You can configure the timeout for the following call stages:</p> <ul style="list-style-type: none"> <li>■ For RTP: <ul style="list-style-type: none"> <li>✓ During call setup: Configure this timeout using the [NoRTPDetectionTimeout] global parameter.</li> <li>✓ During an established call when packet flow suddenly stops: Configure this timeout using the 'Broken Connection Timeout' global parameter.</li> </ul> </li> <li>■ For MSRP: <ul style="list-style-type: none"> <li>✓ During call setup: Configure this timeout using the 'Timeout to Establish MSRP Connection' global parameter.</li> <li>✓ During an established call when the MSRP socket is closed (no timeout configuration).</li> </ul> </li> </ul> <p>Possible values:</p> <ul style="list-style-type: none"> <li>■ [0] <b>Ignore</b> = The device maintains the call despite no media and ends the call when signaling ends it (i.e., SIP BYE).</li> <li>■ [1] <b>Disconnect</b> = (Default) The device ends the call when the timeout expires.</li> <li>■ [2] <b>Reroute</b> = (SBC application only) The device ends the call and then searches the IP-to-IP Routing table (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186) for a matching rule. If found, the device generates a new INVITE to the new destination. You can also configure a main routing rule whose matching characteristics is explicitly for calls that have broken RTP or MSRP connections. You do this by configuring the 'Call Trigger' parameter in the IP-to-IP Routing table to <b>Broken Connection</b>.</li> <li>■ [3] <b>Reroute with Original SIP Headers</b> = (SBC application only) The device ends the call and then searches the IP-to-IP Routing table (see <a href="#">Configuring</a></li> </ul>

Parameter	Description
	<p><a href="#">SBC IP-to-IP Routing Rules</a> on page 1186) for a matching rule. If found, the device generates a new INVITE, but with the original SIP headers and non-SDP bodies (XML only of multipart SDP bodies) to the new destination. The SDP body is not copied but re-generated by the device. You can also configure a main routing rule whose matching characteristics is explicitly for calls that have broken RTP or MSRP connections. You do this by configuring the 'Call Trigger' parameter in the IP-to-IP Routing table to <b>Broken Connection</b>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The optional values <b>Reroute</b> and <b>Reroute with Original SIP Headers</b> are applicable only to the outgoing leg. If you've configured one of these options for the incoming leg, the device handles the call according to the <b>Disconnect</b> option.</li> <li>■ The device can only detect a broken RTP or MSRP connection if silence compression is disabled for the session.</li> <li>■ If during a call, the source IP address (from where the packets are received by the device) is changed without notifying the device, the device rejects the packets. To overcome this, configure the parameter to <b>Ignore</b>. With this configuration, the device doesn't detect packets arriving from the original source IP address and switches (after 300 msec) to the packets arriving from the new source IP address.</li> <li>■ The corresponding global parameter is [DisconnectOnBrokenConnection].</li> </ul>
<p>'No RTP Mode' no-rtsp-mode [NoRTPMode]</p>	<p>Defines the handling of calls when RTP packets (media) are not detected / received within a timeout during early media or upon call connect (i.e., never was RTP). The timeout is configured by the [NoRTPDetectionTimeout] parameter.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Disconnect</b> = (Default) The device ends the call.</li> <li>■ [2] <b>Reroute</b> = The device ends the call and then searches the IP-to-IP Routing table (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186) for a</li> </ul>

Parameter	Description
	<p>matching rule. If found, the device generates a new INVITE to the new destination. You can also configure a main routing rule whose matching characteristics is explicitly for calls that have no RTP. To do this, configure the 'Call Trigger' parameter in the IP-to-IP Routing table to <b>Broken Connection</b>.</p> <ul style="list-style-type: none"> <li>■ [3] <b>Reroute with Original SIP Headers</b> = The device ends the call and then searches the IP-to-IP Routing table (see <a href="#">Configuring SBC IP-to-IP Routing Rules</a> on page 1186) for a matching rule. If found, the device generates a new INVITE, but with the original SIP headers and non-SDP bodies (XML only of multipart SDP bodies) to the new destination. The SDP body is not copied, but re-generated by the device. You can also configure a main routing rule whose matching characteristics is explicitly for calls that have broken RTP connections. This is done by configuring the 'Call Trigger' parameter in the IP-to-IP Routing table to <b>Broken Connection</b>.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The optional values <b>Reroute</b> and <b>Reroute with Original SIP Headers</b> are applicable only to the outgoing leg. If you've configured one of these options for the incoming leg, the device handles the call according to the <b>Disconnect</b> option.</li> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ The device can only detect no RTP if silence compression is disabled for the session.</li> <li>■ The parameter is not applicable to MSRP sessions.</li> <li>■ The corresponding global parameter is [NoRTPMode].</li> </ul>
'Media IP Version Preference' media-ip-version-preference [MediaIPVersionPreference]	<p>Defines the preferred RTP media IP addressing version for outgoing SIP calls (according to RFC 4091 and RFC 4092). The RFCs concern Alternative Network Address Types (ANAT) semantics in the SDP to offer groups of network addresses (IPv4 and IPv6) and the IP address version preference to establish the media stream. The IP address is indicated in the "c=" field (Connection) of the SDP.</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [0] <b>Only IPv4</b> = (Default) SDP offer includes only IPv4 media IP addresses.</li> <li>■ [1] <b>Only IPv6</b> = SDP offer includes only IPv6 media IP addresses.</li> <li>■ [2] <b>Prefer IPv4</b> = SDP offer includes IPv4 and IPv6 media IP addresses, but the first (preferred) media is IPv4.</li> <li>■ [3] <b>Prefer IPv6</b> = SDP offer includes IPv4 and IPv6 media IP addresses, but the first (preferred) media is IPv6.</li> </ul> <p>To indicate ANAT support, the device uses the SIP Allow header or to enforce ANAT it uses the Require header:</p> <pre>Require: sdp-anat</pre> <p>In the outgoing SDP, each 'm=' field is associated with an ANAT group. This is done using the 'a=mid:' and 'a=group:ANAT' fields. Each 'm=' field appears under a unique 'a=mid:' number, for example:</p> <pre>a=mid:1 m=audio 63288 RTP/AVP 0 8 18 101 c=IN IP6 3000::290:8fff:fe40:3e21</pre> <p>The 'a=group:ANAT' field shows the 'm=' fields belonging to it, using the number of the 'a=mid:' field. In addition, the ANAT group with the preferred 'm=' fields appears first. For example, the preferred group includes 'm=' fields under 'a=mid:1' and 'a=mid:3':</p> <pre>a=group:ANAT 1 3 a=group:ANAT 2 4</pre> <p>If you configure the parameter to a "prefer" option, the outgoing SDP offer contains two medias which are the same except for the "c=" field. The first media is the preferred address type (and this type is also on the session level "c=" field), while the second media has its "c=" field with the other address type. Both medias are grouped by ANAT. For example, if the incoming SDP contains two medias, one secured and the other non-secured, the device sends the outgoing SDP with four medias:</p> <ul style="list-style-type: none"> <li>■ Two secured medias grouped in the first ANAT group, one with IPv4 and the other with IPv6. The first is the preferred type.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>Two non-secured medias grouped in the second ANAT group, one with IPv4 and the other with IPv6. The first is the preferred type.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only when the device offers an SDP.</li> <li>The IP addressing version is determined according to the first SDP "m=" field.</li> <li>The feature is applicable to any type of media (e.g., audio and video) that has an IP address.</li> <li>The corresponding global parameter is [MediaIPVersionPreference].</li> </ul>
'RTP Redundancy Depth' rtp-redundancy-depth  [RTPRedundancyDepth]	<p>Enables the device to generate RFC 2198 redundant packets. This can be used for packet loss where the missing information (audio) can be reconstructed at the receiver's end from the redundant data that arrives in subsequent packets. This is required, for example, in wireless networks where a high percentage (up to 50%) of packet loss can be experienced.</p> <ul style="list-style-type: none"> <li>[0] 0 = (Default) Disable.</li> <li>[1] 1 = Enable - previous voice payload packet is added to current packet.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>When enabled, you can configure the payload type, using the [RFC2198PayloadType] parameter.</li> <li>For the Gateway application, the RTP redundancy dynamic payload type can be included in the SDP, by using the [EnableRTPRedundancyNegotiation] parameter.</li> <li>The corresponding global parameter is [RTPRedundancyDepth].</li> </ul>
<b>Gateway</b> <b>Note:</b> These parameters are applicable only to the Gateway application.	
'Early Media' early-media	<p>Enables the Early Media feature for sending media (e.g., ringing) before the call is established.</p>

Parameter	Description
[EnableEarlyMedia]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> <ul style="list-style-type: none"> <li>✓ Digital: The device sends a SIP 18x response with SDP, allowing the media stream to be established before the call is answered.</li> <li>✓ Analog: The device sends a SIP 183 Session Progress response with SDP instead of a 180 Ringing, allowing the media stream to be established before the call is answered.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Digital: The inclusion of the SDP in the 18x response depends on the ISDN Progress Indicator (PI). The SDP is sent only if PI is set to 1 or 8 in the received Proceeding, Alerting, or Progress messages. See also the [ProgressIndicator2IP] parameter, which if set to 1 or 8, the device behaves as if it received the ISDN messages with the PI.</li> <li>✓ CAS: See the [ProgressIndicator2IP] parameter.</li> <li>✓ ISDN: Sending a 183 response depends on the ISDN PI. It is sent only if PI is set to 1 or 8 in the received Proceeding or Alerting messages. Sending 183 response also depends on the [ReleaseIP2ISDNCallOnProgressWithCause] parameter, which must be set to any value other than 2.</li> <li>■ See also the [IgnoreAlertAfterEarlyMedia] parameter. The parameter allows, for example, to interwork Alert with PI to SIP 183 with SDP instead of 180 with SDP.</li> <li>■ You can also configure early SIP 183 response immediately upon the receipt of an INVITE, using the [EnableEarly183] parameter.</li> <li>■ Analog: To send a 183 response, you must also set the [ProgressIndicator2IP] parameter to [1]. If set to [0], a 180 Ringing response is sent.</li> <li>■ The corresponding global parameter is [EnableEarlyMedia].</li> </ul>
'Early 183'	Enables the device to send SIP 183 responses with SDP to

Parameter	Description
enable-early-183 [EnableEarly183]	<p>the IP upon receipt of INVITE messages.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = By sending the 183 response, the device opens an RTP channel before receiving the "progress" tone from the ISDN side. The device sends RTP packets immediately upon receipt of an ISDN Progress, Alerting with Progress indicator, or Connect message according to the initial negotiation without sending the 183 response again, thereby saving response time and avoiding early media clipping.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ This parameter is applicable only to IP-to-Tel ISDN calls and applies to all calls.</li> <li>■ To enable this feature, set the [EnableEarlyMedia] parameter to [1].</li> <li>■ When the [BChannelNegotiation] parameter is set to Preferred or Any, the [EnableEarly183] parameter is ignored and a SIP 183 is not sent upon receipt of an INVITE. In such a case, you can set the [ProgressIndicator2IP] parameter to [1] (PI = 1) for the device to send a SIP 183 upon receipt of an ISDN Call Proceeding message.</li> <li>■ The corresponding global parameter is [EnableEarly183].</li> </ul>
'Early Answer Timeout' early-answer-timeout [EarlyAnswerTimeout]	<p>Defines the duration (in seconds) that the device waits for an ISDN Connect message from the called party (Tel side), started from when it sends a Setup message. If this timer expires, the call is answered by sending a SIP 200 OK message (to the IP side).</p> <p>The valid range is 0 to 2400. The default is 0 (i.e., disabled).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ The corresponding global parameter is [EarlyAnswerTimeout].</li> </ul>

Parameter	Description
'Profile Preference' ip-preference [IpPreference]	<p>Defines the priority of the IP Profile, where 20 is the highest priority and 1 the lowest priority.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If an IP Profile and a Tel Profile apply to the same call, the coders and other common parameters of the profile with the highest preference are applied to the call. If the preference of the profiles is identical, the Tel Profile parameters are applied.</li> <li>■ If the coder lists of both an IP Profile and a Tel Profile apply to the same call, only the coders common to both are used. The order of the coders is determined by the preference.</li> </ul>
'Coders Group' coders-group [CodersGroupName]	<p>Assigns a Coder Group, which defines audio coders supported by the SIP UA associated with the IP Profile. The default value is the default Coder Group ("AudioCodersGroups_0").</p> <p>To configure Coder Groups, see <a href="#">Configuring Coders Groups</a> on page 661.</p>
'Play RB Tone to IP' play-rbt-to-ip [PlayRBTone2IP]	<p>Enables the device to play a ringback tone to the IP side for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (Default)</li> <li>■ [1] <b>Enable</b> = Plays a ringback tone after a SIP 183 session progress response is sent.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To enable the device to send a 183/180+SDP responses, set the [EnableEarlyMedia] parameter to 1.</li> <li>■ If the [EnableDigitDelivery] parameter is set to 1, the device doesn't play a ringback tone to IP and doesn't send 183 or 180+SDP responses.</li> <li>■ Digital interfaces: If the parameter is enabled and [EnableEarlyMedia] is set to 1, the device plays a ringback tone according to the following: <ul style="list-style-type: none"> <li>✓ CAS: The device opens a voice channel, sends a 183+SDP response, and then plays a ringback tone to IP.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ ISDN: If a Progress or an Alerting message with PI (1 or 8) is received from the ISDN, the device opens a voice channel, sends a 183+SDP or 180+SDP response, but doesn't play a ringback tone to IP. If PI (1 or 8) is received from the ISDN, the device assumes that ringback tone is played by the ISDN switch; otherwise, the device plays a ringback tone to IP after receiving an Alerting message from the ISDN. It sends a 180+SDP response, signaling to the calling party to open a voice channel to hear the played ringback tone.</li> <li>■ The corresponding global parameter is [PlayRBTone2IP].</li> </ul>
'Progress Indicator to IP' prog-ind-to-ip [ProgressIndicator2IP]	Defines the Progress Indicator (PI) sent to the IP. <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured:               <ul style="list-style-type: none"> <li>✓ Analog: Default values are used (1 for FXO interfaces and 0 for FXS interfaces).</li> <li>✓ Digital ISDN: The PI received in ISDN Proceeding, Progress, and Alerting messages is used, as described in the options below.</li> </ul> </li> <li>■ [0] <b>No PI</b> =               <ul style="list-style-type: none"> <li>✓ Analog: For IP-to-Tel calls, the device sends a 180 Ringing response to IP after placing a call to a phone (FXS) or PBX (FXO).</li> <li>✓ Digital: For IP-to-Tel calls, the device sends 180 Ringing response to the IP after receiving an ISDN Alerting, or for CAS after placing a call to the PBX/PSTN.</li> </ul> </li> <li>■ [1] <b>PI = 1</b>:               <ul style="list-style-type: none"> <li>✓ Analog: For IP-to-Tel calls, if the EnableEarlyMedia parameter is set to 1, the device sends a 183 Session Progress message with SDP immediately after a call is placed to the analog line. This is used to cut-through the voice path before the remote party answers the call. This allows the originating party to listen to network call progress tones such as ringback tone or other network announcements.</li> </ul> </li> </ul>

Parameter	Description
	<p>✓ Digital: For IP-to-Tel calls, if the parameter EnableEarlyMedia is set to 1, the device sends 180 Ringing with SDP in response to an ISDN Alerting or it sends a 183 Session Progress message with SDP in response to only the first received ISDN Proceeding or Progress message after a call is placed to PBX/PSTN over the trunk.</p> <p>■ [8] <b>PI = 8: same as PI = 1.</b></p> <p><b>Note:</b> The corresponding global parameter is [ProgressIndicator2IP].</p>
'Hold' enable-hold [EnableHold]	<p>Analog: Enables the Call Hold feature, which allows users, connected to the device, to place a call on hold (or remove from hold), using the phone's Hook Flash button.</p> <p>Digital: Enables the interworking of the Hold/Retrieve supplementary service from ISDN to SIP .</p> <p>■ [0] <b>Disable</b></p> <p>■ [1] <b>Enable</b> (default)</p> <p><b>Note:</b></p> <p>■ Digital interfaces: To interwork the Hold/Retrieve supplementary service from SIP to ISDN (QSIG and Euro ISDN), set the [EnableHold2ISDN] parameter to 1.</p> <p>■ Analog interfaces: To use the call hold service, the devices at both ends must support this option.</p> <p>■ The corresponding global parameter is [EnableHold].</p>
'Add IE In Setup' add-ie-in-setup [AddIEInSetup]	<p>Defines an optional Information Element (IE) data (in hex format) which is added to ISDN Setup messages. For example, to add IE '0x20,0x02,0x00,0xe1', enter the value "200200e1".</p> <p><b>Note:</b></p> <p>■ The parameter is applicable only to digital interfaces.</p> <p>■ The IE is sent from the Trunk Group IDs configured by the [SendIEonTG] parameter.</p> <p>■ You can configure different IE data for Trunk Groups by configuring the parameter for different IP Profiles and then assigning the required IP Profile in the IP-to-</p>

Parameter	Description
	<p>Tel Routing table (PSTNPrefix).</p> <ul style="list-style-type: none"> <li>■ The feature is similar to that of the [EnableISDNTunnelingIP2Tel] parameter. If both parameters are configured, the [EnableISDNTunnelingIP2Tel] parameter takes precedence.</li> <li>■ The corresponding global parameter is [AddIEinSetup].</li> </ul>
'QSIG Tunneling' enable-qsig-tunneling [EnableQSIGTunneling]	<p>Enables QSIG tunneling-over-SIP for this SIP UA. This is according to IETF Internet-Draft draft-elwell-sipping-qsig-tunnel-03 and ECMA-355 and ETSI TS 102 345.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default).</li> <li>■ [1] <b>Enable</b> = Enables QSIG tunneling from QSIG to SIP, and vice versa. All QSIG messages are sent as raw data in corresponding SIP messages using a dedicated message body.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ QSIG tunneling must be enabled on originating and terminating devices.</li> <li>■ To enable this function, configure the [ISDNDuplicateQ931BuffMode] parameter to 128 (i.e., duplicate all messages).</li> <li>■ To define the format of encapsulated QSIG messages, use the [QSIGTunnelingMode] parameter.</li> <li>■ Tunneling according to ECMA-355 is applicable to all ISDN variants (in addition to the QSIG protocol).</li> <li>■ For more information on QSIG tunneling, see <a href="#">QSIG Tunneling</a> on page 925.</li> <li>■ The corresponding global parameter is [EnableQSIGTunneling].</li> </ul>
'Copy Destination Number to Redirect Number' copy-dst-to-redirect-number [CopyDest2RedirectNumber]	<p>Enables the device to copy the called number, received in the SIP INVITE message, to the redirect number in the outgoing Q.931 Setup message, for IP-to-Tel calls. Thus, even if there is no SIP Diversion or History header in the incoming INVITE message, the outgoing Q.931 Setup</p>

Parameter	Description
	<p>message will contain a redirect number.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default).</li> <li>■ [1] <b>After Manipulation</b> = Copies the called number after manipulation. The device first performs IP-to-Tel destination phone number manipulation, and only then copies the manipulated called number to the redirect number sent in the Q.931 Setup message to the Tel. Thus, the called and redirect numbers are the same.</li> <li>■ [2] <b>Before Manipulation</b> = Copies the called number before manipulation. The device first copies the original called number to the SIP Diversion header, and then performs IP-to-Tel destination phone number manipulation. Thus, the called (i.e., SIP To header) and redirect (i.e., SIP Diversion header) numbers are different.</li> </ul> <p><b>Note:</b> The corresponding global parameter is [CopyDest2RedirectNumber].</p>
'Number of Calls Limit' call-limit [CallLimit]	<p>Defines the maximum number of concurrent calls (incoming and outgoing) for the SIP UA associated with the IP Profile. If the number of concurrent calls reaches this limit, the device rejects any new incoming and outgoing calls belonging to this IP Profile.</p> <p>The parameter can also be set to the following:</p> <ul style="list-style-type: none"> <li>■ [-1] <b>-1</b> = (Default) Unlimited calls.</li> <li>■ [0] <b>0</b> = All calls are rejected.</li> </ul>
<b>Gateway DTMF</b>	
'Is DTMF Used' [IsDTMFUsed]	<p>Enables DTMF signaling.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul>
'First Tx DTMF Option' first-tx-dtmf-option [FirstTxDtmfOption]	<p>Defines the first preferred transmit DTMF negotiation method.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b> = No negotiation - DTMF digits are sent according to the parameters [DTMFTransportType] and [RFC2833PayloadType] for</li> </ul>

Parameter	Description
	<p>transmit and receive.</p> <ul style="list-style-type: none"> <li>■ [1] <b>INFO (Nortel)</b> = Sends DTMF digits according to IETF Internet-Draft draft-choudhuri-sip-info-digit-00.</li> <li>■ [2] <b>NOTIFY</b> = Sends DTMF digits according to IETF Internet-Draft draft-mahy-sipping-signaled-digits-01.</li> <li>■ [3] <b>INFO (Cisco)</b> = Sends DTMF digits according to the Cisco format.</li> <li>■ [4] <b>RFC 2833</b> = (Default) The device: <ul style="list-style-type: none"> <li>✓ negotiates RFC 2833 payload type using local and remote SDPs.</li> <li>✓ sends DTMF packets using RFC 2833 payload type according to the payload type in the received SDP.</li> <li>✓ expects to receive RFC 2833 packets with the same payload type as configured by the parameter [RFC2833PayloadType].</li> <li>✓ removes DTMF digits in transparent mode (as part of the voice stream).</li> </ul> </li> <li>■ [5] <b>INFO (Korea)</b> = Sends DTMF digits according to the Korea Telecom format.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When out-of-band DTMF transfer is used ([1], [2], [3], or [5]), the [DTMFTransportType] parameter is automatically set to 0 (DTMF digits are removed from the RTP stream).</li> <li>■ Digital interfaces: If an ISDN phone user presses digits (e.g., for interactive voice response / IVR applications such as retrieving voice mail messages), ISDN Information messages received by the device for each digit are sent in the voice channel to the IP network as DTMF signals, according to the settings of the parameter.</li> <li>■ The corresponding global parameter is [FirstTxDTMFOption].</li> </ul>
'Second Tx DTMF Option' second-tx-dtmf-	Defines the second preferred transmit DTMF negotiation method. For a description of the parameter, see the IP

Parameter	Description
option [SecondTxDtmfOption]	Profile's 'First Tx DTMF Option' parameter. <b>Note:</b> The corresponding global parameter is [SecondTxDTMFOption].
'Rx DTMF Option' rx-dtmf-option [RxDTMFOption]	<p>Enables the device to declare the RFC 2833 'telephony-event' parameter in the SDP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Supported</b></li> <li>■ [3] <b>Supported</b> (default)</li> </ul> <p>The device is always receptive to RFC 2833 DTMF relay packets. Thus, it is always correct to include the 'telephony-event' parameter by default in the SDP. However, some devices use the absence of the 'telephony-event' in the SDP to decide to send DTMF digits in-band using G.711 coder. If this is the case, set the parameter to 0.</p> <p><b>Note:</b> The corresponding global parameter is [RxDTMFOption].</p>
<b>Gateway Fax and Modem</b>	
'Fax Signaling Method' fax-sig-method [IsFaxUsed]	<p>Defines the SIP signaling method for establishing and transmitting a fax session when the device detects a fax.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No Fax</b> = (Default) No fax negotiation using SIP signaling. The fax transport method is according to the [FaxTransportMode] parameter</li> <li>■ [1] <b>T.38 Relay</b> = Initiates T.38 fax relay.</li> <li>■ [2] <b>G.711 Transport</b> = Initiates fax/modem using the coder G.711 A-law/Mu-law with adaptations (see note below).</li> <li>■ [3] <b>Fax Fallback</b> = Initiates T.38 fax relay. If the T.38 negotiation fails, the device re-initiates a fax session using the coder G.711 A-law/Mu-law with adaptations (see the Note below).</li> <li>■ [4] <b>G.711 Reject T.38</b> = Initiates fax/modem using the coder G.711 A-law/Mu-law with adaptations (see Note below), but if the incoming media is of type image ('m=image'), the device rejects the re-INVITE message for T.38.</li> </ul> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ Fax adaptations (for options 2 and 3):               <ul style="list-style-type: none"> <li>✓ Echo Celler = On</li> <li>✓ Silence Compression = Off</li> <li>✓ Echo Celler Non-Linear Processor Mode = Off</li> <li>✓ Dynamic Jitter Buffer Minimum Delay = 40</li> <li>✓ Dynamic Jitter Buffer Optimization Factor = 13</li> </ul> </li> <li>■ If the device initiates a fax session using G.711 (option 2 or 3), a 'gpmd' attribute is added to the SDP in the following format:               <ul style="list-style-type: none"> <li>✓ For A-law: 'a=gpmd:8 vbd=yes;ecan=on'</li> <li>✓ For Mu-law: 'a=gpmd:0 vbd=yes;ecan=on'</li> </ul> </li> <li>■ When the parameter is set to 1, 2, or 3, the parameter [FaxTransportMode] is ignored.</li> <li>■ When the parameter is set to 0, T.38 might still be used without the control protocol's involvement. To completely disable T.38, set [FaxTransportMode] to a value other than 1.</li> <li>■ For more information on fax transport methods, see <a href="#">Fax and Modem Transport Modes</a> on page 281.</li> <li>■ The corresponding global parameter is [IsFaxUsed].</li> </ul>
'CNG Detector Mode' cng-mode [CNGmode]	<p>Enables the detection of the fax calling tone (CNG) and defines the detection method.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) The originating fax doesn't detect CNG; the device passes the CNG signal transparently to the remote side.</li> <li>■ [1] <b>Relay</b> = The originating fax detects CNG. The device sends CNG packets to the remote side according to T.38 (if IsFaxUsed is set to 1) and the fax session is started. A SIP Re-INVITE message is not sent and the fax session starts by the terminating fax. This option is useful, for example, when the originating fax is located behind a firewall that blocks incoming T.38 packets on ports that have not yet received T.38 packets from the internal network (i.e., originating fax). To also send a Re-INVITE message upon detection of a fax CNG tone in this mode, set the</li> </ul>

Parameter	Description
	<p>parameter FaxCNGMode to 1 or 2.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Event Only</b> = The originating fax detects CNG and a fax session is started by the originating fax, using the Re-INVITE message. Typically, T.38 fax session starts when the preamble signal is detected by the answering fax. Some SIP devices do not support the detection of this fax signal on the answering fax and thus, in these cases, it is possible to configure the device to start the T.38 fax session when the CNG tone is detected by the originating fax. However, this mode is not recommended.</li> </ul> <p><b>Note:</b> The corresponding global parameter is [CNGDetectorMode].</p>
<p>'Vxx Modem Transport Type'</p> <p>vxx-transport-type</p> <p>[VxxTransportType]</p>	<p>Defines the modem transport type.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Not Configured) The settings of the global parameters are used: <ul style="list-style-type: none"> <li>✓ V21ModemTransportType</li> <li>✓ V22ModemTransportType</li> <li>✓ V23ModemTransportType</li> <li>✓ V32ModemTransportType</li> <li>✓ V34ModemTransportType</li> </ul> </li> <li>■ [0] <b>Disable</b> = Transparent.</li> <li>■ [2] <b>Enable Bypass</b> (Default)</li> <li>■ [3] <b>Events Only</b> = Transparent with Events.</li> </ul> <p>For a detailed description of the parameter per modem type, see the relevant global parameter (listed above).</p>
<p>'NSE Mode'</p> <p>nse-mode</p> <p>[NSEMode]</p>	<p>Enables Cisco's compatible fax and modem bypass mode, Named Signaling Event (NSE) packets.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>In NSE bypass mode, the device starts using G.711 A-Law (default) or G.711Mu-Law according to the [FaxModemBypassCoderType] parameter settings. The payload type of these G.711 coders is standard (8 for</p>

Parameter	Description
	<p>G.711 A-Law; 0 for G.711Mu-Law). The [FaxBypassPayloadType] and [ModemBypassPayloadType] parameters that configure the payload type for the "old" bypass mode are not used with NSE Bypass. The bypass packet interval is configured by the [FaxModemBypassBasicRtpPacketInterval] parameter.</p> <p>The SDP contains the following line:  <code>a=rtpmap:100 X-NSE/8000</code></p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When enabled, the following conditions must also be met: <ul style="list-style-type: none"> <li>✓ The Cisco gateway must include the following definition:  'modem passthrough nse payload-type 100 codec g711alaw'.</li> <li>✓ Configure the modem transport type to Bypass mode ([VxxModemTransportType] is 2) for all modems.</li> <li>✓ Configure the [NSEPayloadType] parameter to 100.</li> </ul> </li> <li>■ The corresponding global parameter is [NSEMode].</li> </ul>
<b>Answer Machine Detection</b>	
<p>'AMD Mode'</p> <p><code>amd-mode</code></p> <p>[AmdMode]</p>	<p>Enables the device to disconnect an IP-to-Tel call upon detection of an answering machine on the Tel side.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Don't Disconnect</b> = (Default) Device doesn't disconnect call upon detection of an answering machine.</li> <li>■ [1] <b>Disconnect on AMD</b> = Device disconnects call upon detection of an answering machine. It disconnects the call only after receipt of an ISDN Connect from the Tel side. In such a scenario, the device sends a SIP BYE message upon AMD.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Gateway application (digital interfaces).</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ When configured to <b>Disconnect on AMD</b>, the feature can only function if you configure the [EnableEarlyAMD] parameter to any value other than [1].</li> <li>■ This feature doesn't need the receipt of the SIP X-Detect header in the incoming INVITE to activate the AMD.</li> <li>■ The corresponding global parameter is [AMDmode].</li> </ul>
<p>'AMD Sensitivity Parameter Suite'</p> <p>amd-sensitivity-parameter-suite</p> <p>[AMDSensitivityParameterSuite]</p>	<p>Defines the AMD Parameter Suite to use for the Answering Machine Detection (AMD) feature.</p> <ul style="list-style-type: none"> <li>■ [0] <b>0</b> = (Default) Parameter Suite 0 based on North American English with standard detection sensitivity resolution (8 sensitivity levels, from 0 to 7). This AMD Parameter Suite is provided by the AMD Sensitivity file, which is shipped pre-installed on the device.</li> <li>■ [1] <b>1</b> = Parameter Suite based 1 on North American English with high detection sensitivity resolution (16 sensitivity levels, from 0 to 15). This AMD Parameter Suite is provided by the AMD Sensitivity file, which is shipped pre-installed on the device.</li> <li>■ [2-7] <b>2 to 7</b> = Optional Parameter Suites that you can create based on any language (16 sensitivity levels, from 0 to 15). This requires a customized AMD Sensitivity file that needs to be installed on the device. For more information, contact the sales representative of your purchased device.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To configure the detection sensitivity level, use the 'AMD Sensitivity Level' parameter.</li> <li>■ For more information on the AMD feature, see <a href="#">Answering Machine Detection (AMD)</a> on page 311.</li> <li>■ The corresponding global parameter is [AMDSensitivityParameterSuite].</li> </ul>
<p>'AMD Sensitivity Level'</p> <p>amd-sensitivity-level</p> <p>[AMDSensitivityLevel]</p>	<p>Defines the AMD sensitivity level, of the selected AMD Parameter Suite, for detecting an answering machine versus a live call (configured by the 'AMD Sensitivity Parameter Suite' parameter, above).</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For Parameter Suite 0: The valid range is 0 to 7 (default is 0). The higher the value, the better the detection for live calls over answering machines. In other words, 0 is best detection of an answering machine; 7 is best detection of a live call.</li> <li>■ For any Parameter Suite other than 0, the valid range is 0 to 15 (default is 8). The higher the value, the better the detection for live calls over answering machines. In other words, 0 is best detection of an answering machine; 15 is best detection of a live call.</li> </ul> <p><b>Note:</b> The corresponding global parameter is [AMDSensitivityLevel].</p>
'AMD Max Greeting Time' amd-max-greeting-time [AMDMaxGreetingTime]	<p>Defines the maximum duration (in 5-msec units) that the device can take to detect a greeting message. The valid range value is 0 to 51132767. The default is 300.</p> <p><b>Note:</b> The corresponding global parameter is [AMDMaxGreetingTime].</p>
'AMD Max Post Silence Greeting Time' amd-max-post-silence-greeting-time [AMDMaxPostSilenceGreetingTime]	<p>Defines the maximum duration (in 5-msec units) of silence from after the greeting time is over, configured by [AMDMaxGreetingTime], until the device's AMD decision. The valid value is 0 to 32767. The default is 400.</p> <p><b>Note:</b> The corresponding global parameter is [AMDMaxPostGreetingSilenceTime].</p>
<b>Local Tones</b>	
'Local Ringback Tone Index' local-ringback-tone-index [LocalRingbackTone]	<p>Defines the ringback tone that you want to play from the PRT file.</p> <p>To associate a user-defined tone, configure the parameter with the tone's index number (1-80) as appears in the PRT file. By default (value of -1), the device plays the default ringback tone.</p> <p>To play user-defined tones, you need to record your tones and then install them on the device using a loadable Prerecorded Tones (PRT) file, which is created using AudioCodes DConvert utility. When you create the PRT file, each recorded tone file must be added to the PRT file with the tone type "acUserDefineTone&lt;Index&gt;".</p>

Parameter	Description
	When you want to specify the ringback tone for this parameter, use the index number. For more information, see <a href="#">Uploading a Prerecorded Tones File</a> on page 1357.
'Local Held Tone Index' local-held-tone-index [LocalHeldTone]	<p>Defines the held tone that you want to play from the PRT file.</p> <p>To associate a user-defined tone, configure the parameter with the tone's index number (1-80) as appears in the PRT file. By default (value of -1), the device plays the default held tone.</p> <p>To play user-defined tones, you need to record your tones and then install them on the device using a loadable Prerecorded Tones (PRT) file, which is created using AudioCodes DConvert utility. When you create the PRT file, each recorded tone file must be added to the PRT file with the tone type "acUserDefineTone&lt;Index&gt;".</p> <p>When you want to specify the held tone for this parameter, use the index number. For more information, see <a href="#">Uploading a Prerecorded Tones File</a> on page 1357.</p>

## Configuring Tel Profile

The Tel Profiles table lets you configure up to 9 *Tel Profiles*. A Tel Profile is a set of parameters with specific settings which can be assigned to specific calls. The Tel Profiles table includes a wide range of parameters for configuring the Tel Profile. Each of these parameters has a corresponding "global" parameter, which when configured applies to all calls. The main difference, if any, between the Tel Profile parameters and their corresponding global parameters are their default values.

Tel Profiles provide high-level adaptation when the device interworks between different equipment and protocols (at both the Tel and IP sides), each of which may require different handling by the device. For example, if specific channels require the use of the G.711 coder, you can configure a Tel Profile with this coder and assign it to these channels.

To use your Tel Profile for specific calls, you need to assign it to specific channels (trunks or endpoints) in the Trunk Groups table (see [Configuring Trunk Groups](#) on page 934).

The following procedure describes how to configure Tel Profiles through the Web interface. You can also configure it through ini file [TelProfile] or CLI (`configure voip > coders-and-profiles tel-profile`).

➤ **To configure a Tel Profile:**

1. Open the Tel Profiles table (**Setup** menu > **Signaling & Media** tab > **Coders & Profiles** folder > **Tel Profiles**).
2. Click **New**; the following dialog box appears:

3. Configure a Tel Profile according to the parameters described in the table below. For a description of each parameter, refer to the corresponding "global" parameter.
4. Click **Apply**.

**Table 19-7: Tel Profile Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' profile-name [ProfileName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
<b>Signaling</b>	
'Profile Preference' tel-preference [TelPreference]	Defines the priority of the Tel Profile, where <b>1</b> is the lowest priority and <b>20</b> the highest priority. <b>Note:</b>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If both the IP Profile and Tel Profile apply to the same call, the coders and common parameters of the Preferred profile are applied to the call.</li> <li>■ If the Preference of the Tel Profile and IP Profile are identical, the Tel Profile parameters are applied.</li> <li>■ If the coder lists of both the IP Profile and Tel Profile apply to the same call, only the coders common to both are used. The order of the coders is determined by the preference.</li> </ul>
'Fax Signaling Method' fax-sig-method [IsFaxUsed]	<p>Defines the SIP signaling method for establishing and transmitting a fax session when the device detects a fax.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No Fax</b> = (Default) No fax negotiation using SIP signaling. The fax transport method is according to the FaxTransportMode parameter.</li> <li>■ [1] <b>T.38 Relay</b> = Initiates T.38 fax relay.</li> <li>■ [2] <b>G.711 Transport</b> = Initiates fax/modem using the coder G.711 A-law/Mu-law with adaptations (see Note below).</li> <li>■ [3] <b>Fax Fallback</b> = Initiates T.38 fax relay. If the T.38 negotiation fails, the device re-initiates a fax session using the coder G.711 A-law/Mu-law with adaptations (see the Note below).</li> <li>■ [4] <b>G.711 Reject T.38</b> = Initiates fax/modem using the coder G.711 A-law/Mu-law with adaptations (see Note below), but if the incoming media is of type IMAGE, the device rejects the re-INVITE message for T.38.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Fax adaptations (for options 2 and 3): <ul style="list-style-type: none"> <li>✓ Echo Celler = On</li> <li>✓ Silence Compression = Off</li> <li>✓ Echo Celler Non-Linear Processor Mode = Off</li> <li>✓ Dynamic Jitter Buffer Minimum Delay = 40</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Dynamic Jitter Buffer Optimization Factor = 13</li> <li>■ If the device initiates a fax session using G.711 (option 2 or 3), a 'gpmd' attribute is added to the SDP in the following format: <ul style="list-style-type: none"> <li>✓ For A-law: 'a=gpmd:8 vbd=yes;ecan=on'</li> <li>✓ For Mu-law: 'a=gpmd:0 vbd=yes;ecan=on'</li> </ul> </li> <li>■ When the parameter is set to 1, 2, or 3, the parameter FaxTransportMode is ignored.</li> <li>■ When the parameter is set to 0, T.38 might still be used without the control protocol's involvement. To completely disable T.38, set FaxTransportMode to a value other than 1.</li> <li>■ For more information on fax transport methods, see <a href="#">Fax and Modem Transport Modes</a> on page 281.</li> <li>■ The corresponding global parameter is [IsFaxUsed].</li> </ul>
'Enable Digit Delivery' digit-delivery [EnableDigitDelivery]	<p>Enables the Digit Delivery feature, which sends DTMF digits of the called number to the phone line (device's analog port or digital B-channel) after the call is answered (i.e., line is off-hooked for FXS or seized for FXO) for IP-to-Tel calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>Digital interfaces: If the called number in IP-to-Tel call includes the characters 'w' or 'p', the device places a call with the first part of the called number (before 'w' or 'p') and plays DTMF digits after the call is answered. If the character 'w' is used, the device waits for detection of a dial tone before it starts playing DTMF digits. For example, if the called number is '1007766p100', the device places a call with 1007766 as the destination number, then after the call is answered it waits 1.5 seconds ('p') and plays the rest of the number (100) as DTMF digits. Additional examples: 1664wpp102, 66644ppp503, and 7774w100pp200.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Analog interfaces: The called number can include characters 'p' (1.5 seconds pause) and 'd' (detection of dial tone). If character 'd' is used, it must be the first 'digit' in the called number. The character 'p' can be used several times. For example (for FXS/FXO interfaces), the called number can be as follows: d1005, dpp699, p9p300. To add the 'd' and 'p' digits, use the usual number manipulation rules.</li> <li>■ Analog interfaces: To use this feature with FXO interfaces, configure the device to operate in one-stage dialing mode.</li> <li>■ Analog interfaces: If the parameter is enabled, it is possible to configure the FXS/FXO interface to wait for dial tone per destination phone number (before or during dialing of destination phone number). Therefore, the parameter <code>IsWaitForDialTone</code> (configurable for the entire device) is ignored.</li> <li>■ Analog interfaces: The FXS interface send SIP 200 OK responses only after the DTMF dialing is complete.</li> <li>■ The corresponding global parameter is <code>[EnableDigitDelivery]</code>.</li> </ul>
'Dial Plan Index' <code>dial-plan-index</code> <code>[DialPlanIndex]</code>	<p>Defines the Dial Plan index to use in the external Dial Plan file.</p> <p><b>Note:</b> The corresponding global parameter is <code>[DialPlanIndex]</code>.</p>
'Digital Cut Through' <code>digital-cut-through</code> <code>[DigitalCutThrough]</code>	<p>Enables PSTN CAS channels/endpoints to receive incoming IP calls even if the B-channels are in off-hook state.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = When enabled, the feature operates as follows: <ul style="list-style-type: none"> <li>a. A Tel-to-IP call is established (connected) by the device for a B-channel.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li><b>b.</b> The device receives a SIP BYE (i.e., IP side ends the call) and plays a reorder tone to the PSTN side for the duration configured by the <code>CutThroughTimeForReOrderTone</code> parameter. The device releases the call towards the IP side (sends a SIP 200 OK).</li> <li><b>c.</b> The PSTN side, for whatever reason, remains off-hook.</li> <li><b>d.</b> If a new IP call is received for this B-channel after the reorder tone has ended, the device “cuts through” the channel and connects the call immediately (despite the B-channel being in physical off-hook state) without playing a ring tone. If an IP call is received while the reorder tone is played, the device rejects the call.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is disabled and the PSTN side remains in off-hook state after the IP call ends the call, the device releases the call after 60 seconds.</li> <li>■ A special CAS table can be used to report call status events (Active/Idle) to the PSTN side during Cut Through mode (see <a href="#">Configuring CAS State Machines</a> on page 911).</li> <li>■ The corresponding global parameter is <code>[DigitalCutThrough]</code>.</li> </ul>
'Call Priority Mode' <code>call-priority-mode</code> <code>[CallPriorityMode]</code>	<p>Defines call priority handling.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default).</li> <li>■ [1] <b>MLPP</b> = Enables MLPP Priority Call handling. MLPP prioritizes call handling whereby the relative importance of various kinds of communications is strictly defined, allowing higher precedence communication at the expense of lower precedence communications. Higher priority calls override less priority calls when, for example, congestion occurs in a network.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [2] <b>Emergency</b> = Enables Preemption of IP-to-Tel E911 emergency calls. If the device receives an E911 call and there are unavailable channels to receive the call, the device terminates one of the channel calls and sends the E911 call to that channel. The preemption is done only on a channel belonging to the same Trunk Group for which the E911 call was initially destined and if the channel select mode, configured by the [ChannelSelectMode] parameter, is set to a value other than <b>By Dest Phone Number</b> (0).</li> </ul> <p>Preemption is done only if the device identifies the incoming IP-to-Tel call as an emergency call. The device identifies emergency calls by one of the following:</p> <ul style="list-style-type: none"> <li>✓ The destination number of the IP call matches one of the numbers configured by the [EmergencyNumbers] parameter. (For E911, you must configure the parameter to "911".)</li> <li>✓ The incoming SIP INVITE message contains the "emergency" value in the Priority header.</li> <li>✓ The value (URI) of the SIP Alert-Info header in the incoming INVITE message is the same as the value configured for the [EmergencyCallAlertInfoUri] parameter.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to analog and digital interfaces.</li> <li>■ For FXO interfaces, the preemption is done only on existing IP-to-Tel calls. In other words, if all the current FXO channels are busy with calls that were initiated by the FXO (i.e., Tel-to-IP calls), new incoming emergency IP-to-Tel calls are rejected.</li> <li>■ For more information, see <a href="#">Pre-empting Existing Calls for E911 IP-to-Tel Calls</a> on page 1067.</li> <li>■ The corresponding global parameter is [CallPriorityMode].</li> </ul>

Parameter	Description
<b>Behavior</b>	
'Disconnect Call on Detection of Busy Tone' disconnect-on-busy-tone [DisconnectOnBusyTone]	<p>Enables the device to disconnect the call upon detection of a busy or reorder (fast busy) tone.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b> (default)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO CAS.</li> <li>■ The corresponding global parameter is [DisconnectOnBusyTone].</li> </ul>
'Time For Reorder Tone' time-for-reorder-tone [TimeForReorderTone]	<p>Defines the duration (in seconds) that the device plays a busy or reorder tone before releasing the line. Analog interfaces: Typically, after playing the busy or reorder tone for this duration, the device starts playing an offhook warning tone.</p> <p>The valid range is 0 to 254. The default is 0 seconds for analog interfaces and 10 seconds for digital interfaces. Note that the Web interface denotes the default value as "255".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The selected busy or reorder tone is according to the SIP release cause code received from IP.</li> <li>■ The parameter is also applicable to CAS.</li> <li>■ The parameter is applicable to ISDN when the [PlayBusyTone2ISDN] parameter is set to 2.</li> <li>■ The corresponding global parameter is [TimeForReorderTone].</li> </ul>
'Enable Voice Mail Delay' enable-voice-mail-delay [EnableVoiceMailDelay]	<p>Enables and disables voice mail services.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b></li> <li>■ [1] <b>Enable</b> (default)</li> </ul> <p>The parameter is useful if you want to disable voice mail services per Trunk Group to eliminate the phenomenon of call delay on Trunks that do not implement voice mail when voice mail is configured using the global parameter, VoiceMailInterface.</p>

Parameter	Description
'Swap Tel To IP Phone Numbers' swap-teltoip-phone-numbers [SwapTelToIpPhoneNumbers]	<p>Enables the device to swap the calling and called numbers received from the Tel side (for Tel-to-IP calls). The SIP INVITE message contains the swapped numbers.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> The corresponding global parameter is [SwapTel2IPCalled&amp;CallingNumbers].</p>
'IP-to-Tel Cut-Through Call Mode' ip2tel-cutthrough_call_behavior [IP2TelCutThroughCallBehavior]	<p>Enables the Cut-Through feature, which allows phones connected to the device's FXS ports to automatically receive IP calls (if there is no other currently active call) even when in off-hook state (and no call is currently active).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Calls can only be received in on-hook state.</li> <li>■ [1] <b>Cut-Through</b> = (Enabled with tones) Calls can be received in off-hook state. When the IP side ends the call, the device can play a reorder tone to the Tel side for a user-defined duration (configured by the CutThroughTimeForReorderTone parameter). Once the tone stops playing, the FXS phone is ready to automatically answer another incoming IP call in off-hook state. A waiting call is automatically answered by the device when the current call is terminated (and if the EnableCallWaiting parameter is configured to 1).</li> <li>■ [2] <b>Cut-Through and Paging</b> = (Enabled and no tones) Calls can be received in off-hook state, but no tones are played (before or after the call) in off-hook state. The option is useful for paging calls, which provides a one-way voice path from the paging phone to the paged phones (FXS phones).</li> <li>■ [3] <b>Cut-Through and Streaming</b> = Enabled and allows playing music-on-hold (MoH) that is received from an external media (audio) player. For more information, see <a href="#">Configuring MoH from External Audio Source</a> on page 1034.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The corresponding global parameter is [CutThrough]. this global parameter currently doesn't support the <b>CutThrough+Streaming</b> option.</li> </ul>
Voice	
'DTMF Volume' dtmf-volume [DtmfVolume]	<p>Defines the DTMF gain control value (in decibels) to the Tel side.</p> <p>The valid range is -31 to 0 dB. The default is -11 dB.</p> <p><b>Note:</b> The corresponding global parameter is [DTMFVolume].</p>
'Input Gain' input-gain [InputGain]	<p>Defines the pulse-code modulation (PCM) input (received) gain control level (in decibels), which is the level of the received signal for Tel-to-IP calls.</p> <p>The valid range is -32 to 31 dB. The default is 0 dB.</p> <p><b>Note:</b> The corresponding global parameter is [InputGain].</p>
'Voice Volume' voice-volume [VoiceVolume]	<p>Defines the voice gain control (in decibels), which is the level of the transmitted signal for IP-to-Tel calls.</p> <p>The valid range is -32 to 31 dB. The default is 0 dB.</p> <p><b>Note:</b> The corresponding global parameter is [VoiceVolume].</p>
'Enable AGC' enable-agc [EnableAGC]	<p>Enables the Automatic Gain Control (AGC) feature. The AGC feature automatically adjusts the level of the received signal to maintain a steady (configurable) volume level.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For more information on AGC, see <a href="#">Automatic Gain Control (AGC)</a> on page 318.</li> <li>■ The corresponding global parameter is [EnableAGC].</li> </ul>

Parameter	Description
Analog	
'Enable Polarity Reversal' polarity-rvrsl [EnableReversePolarity]	<p>Enables the Polarity Reversal feature for call release.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = Enables polarity reversal:               <ul style="list-style-type: none"> <li>✓ FXS Interfaces: The device changes the line polarity on call answer and then changes it back on call release.</li> <li>✓ FXO Interfaces: The device sends a SIP 200 OK response when polarity reversal signal is detected (applicable only to one-stage dialing) and releases a call when a second polarity reversal signal is detected.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to FXS and FXO interfaces.</li> <li>■ The corresponding global parameter is [EnableReversalPolarity].</li> </ul>
'Enable Current Disconnect' current-disconnect [EnableCurrentDisconnect]	<p>Enables call release upon detection of a Current Disconnect signal.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> = Enables the current disconnect service.               <ul style="list-style-type: none"> <li>✓ FXO Interfaces: The device releases a call when a current disconnect signal is detected on its port.</li> <li>✓ FXS Interfaces: The device generates a 'Current Disconnect Pulse' after the call is released from the IP side.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to FXS and FXO interfaces.</li> <li>■ The current disconnect duration is configured by the [CurrentDisconnectDuration parameter].</li> <li>■ The current disconnect threshold (FXO only) is</li> </ul>

Parameter	Description
	<p>configured by the [CurrentDisconnectDefaultThreshold] parameter.</p> <ul style="list-style-type: none"> <li>■ The frequency at which the analog line voltage is sampled is configured by the [TimeToSampleAnalogLineVoltage] parameter.</li> <li>■ The corresponding global parameter is [EnableCurrentDisconnect].</li> </ul>
'DID Wink' enable-did-wink [EnableDIDWink]	<p>Enables Direct Inward Dialing (DID) using Wink-Start signaling, typically used for signaling between an E-911 switch and the PSAP.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Single</b> = The device can be used for connection to EIA/TIA-464B DID Loop Start lines. FXO (detection) and FXS (generation) are supported:               <ul style="list-style-type: none"> <li>✓ FXO Interfaces: The device dials DTMF (or MF) digits upon detection of a Wink signal, instead of a dial tone.</li> <li>✓ FXS Interfaces: The device generates a Wink signal upon detection of an off-hook state, instead of playing a dial tone.</li> </ul> <p>For example: (Wink) KP I(I) xxx-xxxx ST (Off Hook) Where:</p> <ul style="list-style-type: none"> <li>✓ I = one or two information digits</li> <li>✓ x = ANI</li> </ul> <p><b>Note:</b> The FXO interface generates such MF digits when the Enable911PSAP parameter is set to 1.</p> </li> <li>■ [2] <b>Double Wink</b> = Double-wink signaling. This is applicable to FXS interfaces only. The device generates the first Wink upon detection of an off-hook state in the line. The second Wink is generated after a user-defined interval (configured by the TimeBetweenDIDWinks parameter) after which the DTMF/MF digits are collected by the device. Digits that arrive between the first and second Wink are ignored as they contain the same number. For example:</li> </ul>

Parameter	Description
	<p>(Wink) KP 911 ST (Wink) KP I(I) xxx-xxxx ST (Off Hook)</p> <p>■ [3] <b>Wink &amp; Polarity =</b></p> <p>✓ FXS Interfaces: The device generates the first Wink after it detects an off-hook state. A polarity change from normal to reversed is generated after a user-defined time (configured by the TimeBetweenDIDWinks parameter). DTMF/MF digits are collected by the device only after this polarity change. Digits that arrive between the first Wink and the polarity change are ignored as they always contain the same number. In this mode, the device doesn't generate a polarity change to normal if the Tel-to-IP call is answered by an IP party. Polarity reverts to normal when the call is released. For example: (Wink) KP 911 ST (Polarity) KP I(I) xxx-xxxx ST (Off Hook)</p> <p>✓ FXO Interfaces: For IP-to-Tel calls:</p> <ol style="list-style-type: none"> <li>1) Upon incoming INVITE message, the FXO interface goes off-hook (seizes the line).</li> <li>2) Upon detection of a Wink signal from the Tel side (instead of a dial tone), the device dials the digits, "KP911ST" (denotes *911#).</li> <li>3) The device waits for polarity reversal change from normal to reverse for an interval of 2,000 msec.</li> <li>4) Upon detection of a polarity reversal change, the device dials the DTMF (or MF) digits of the calling party (number that dialed 911) in the format "KP&lt;ANI&gt;ST" (*ANI#), where ANI is the calling number from the INVITE. If no polarity reversal, the FXO goes idle.</li> </ol> <p>For example: (Wink) KP911ST (Polarity Change) KP02963700ST</p> <p>Note: The Enable911PSAP parameter must be set to 1.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ For FXS interfaces, the EnableReversalPolarity and PolarityReversalType parameters must be configured to 1.</li> <li>■ The parameter is applicable to FXS and FXO interfaces.</li> <li>■ The corresponding global parameter is [EnabledIDWink].</li> </ul>
'Enable 911 PSAP' enable-911-psap [Enable911PSAP]	<p>Enables the support for the E911 DID protocol, according to the Bellcore GR-350-CORE standard. The protocol defines signaling between E911 Tandem Switches and the PSAP, using analog loop-start lines. The device's FXO interface can be used instead of an E911 switch, connected directly to PSAP DID loop-start lines.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ The corresponding global parameter is [Enable911PSAP].</li> </ul>
IP Settings	
'Coders Group' coders-group [CodersGroupName]	<p>Assigns a Coder Group, which defines audio (voice) coders that can be used for the endpoints associated with the Tel Profile.</p> <p>To configure Coders Groups, see <a href="#">Configuring Coders Groups</a> on page 661.</p>
'RTP IP DiffServ' rtp-ip-diffserv [IPDiffServ]	<p>Defines the DiffServ value for Premium Media class of service (CoS) content.</p> <p>The valid range is 0 to 63. The default is 46.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For more information on DiffServ, see <a href="#">Configuring Class-of-Service QoS</a> on page 192.</li> <li>■ The corresponding global parameter is [PremiumServiceClassMediaDiffServ].</li> </ul>

Parameter	Description
'Signaling DiffServ' signaling-diffserv [SigIPDiffServ]	<p>Defines the DiffServ value for Premium Control CoS content (Call Control applications). The valid range is 0 to 63. The default is 40.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For more information on DiffServ, see <a href="#">Configuring Class-of-Service QoS</a> on page 192.</li> <li>■ The corresponding global parameter is [PremiumServiceClassControlDiffServ].</li> </ul>
'Enable Early Media' early-media [EnableEarlyMedia]	<p>Enables the Early Media feature, which sends media (e.g., ringing) before the call is established.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b> <ul style="list-style-type: none"> <li>✓ Digital: The device sends a SIP 18x response with SDP, allowing the media stream to be established before the call is answered.</li> <li>✓ Analog: The device sends a SIP 183 Session Progress response with SDP instead of a 180 Ringing, allowing the media stream to be established before the call is answered.</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Digital: The inclusion of the SDP in the 18x response depends on the ISDN Progress Indicator (PI). The SDP is sent only if PI is set to 1 or 8 in the received Proceeding, Alerting, or Progress messages. See also the ProgressIndicator2IP parameter, which if set to 1 or 8, the device behaves as if it received the ISDN messages with the PI.</li> <li>✓ CAS: See the ProgressIndicator2IP parameter.</li> <li>✓ ISDN: Sending a 183 response depends on the ISDN PI. It is sent only if PI is set to 1 or 8 in the received Proceeding or Alerting messages. Sending 183 response also depends on the ReleaseIP2ISDNCallOnProgressWithCause parameter, which must be set to any value</li> </ul>

Parameter	Description
	<p>other than 2.</p> <ul style="list-style-type: none"> <li>■ Digital: See also the IgnoreAlertAfterEarlyMedia parameter. The parameter allows, for example, to interwork Alert with PI to SIP 183 with SDP instead of 180 with SDP.</li> <li>■ Digital: You can also configure early SIP 183 response immediately upon the receipt of an INVITE, using the EnableEarly183 parameter.</li> <li>■ Analog: To send a 183 response, you must also set the ProgressIndicator2IP parameter to 1. If set to 0, a 180 Ringing response is sent.</li> <li>■ The corresponding global parameter is [EnableEarlyMedia].</li> </ul>
'Progress Indicator to IP' prog-ind-to-ip [ProgressIndicator2IP]	<p>Defines the progress indicator (PI) sent to the IP.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured: <ul style="list-style-type: none"> <li>✓ Analog: Default values are used (1 for FXO interfaces and 0 for FXS interfaces).</li> <li>✓ Digital ISDN: The PI received in ISDN Proceeding, Progress, and Alerting messages is used, as described in the options below.</li> </ul> </li> <li>■ [0] <b>No PI</b> = <ul style="list-style-type: none"> <li>✓ Analog: For IP-to-Tel calls, the device sends a 180 Ringing response to IP after placing a call to a phone (FXS) or PBX (FXO).</li> <li>✓ Digital: For IP-to-Tel calls, the device sends 180 Ringing response to the IP after receiving an ISDN Alerting, or for CAS after placing a call to the PBX/PSTN.</li> </ul> </li> <li>■ [1] <b>PI = 1</b> = <ul style="list-style-type: none"> <li>✓ Analog: For IP-to-Tel calls, if the EnableEarlyMedia parameter is set to 1, the device sends a 183 Session Progress message with SDP immediately after a call is placed to a phone/PBX. This is used to cut-through the voice path before the remote party answers the call. This allows the originating party to listen to network call progress tones such as</li> </ul> </li> </ul>

Parameter	Description
	<p>ringback tone or other network announcements.</p> <p>✓ Digital: For IP-to-Tel calls, if the parameter EnableEarlyMedia is set to 1, the device sends 180 Ringing with SDP in response to an ISDN Alerting or it sends a 183 Session Progress message with SDP in response to only the first received ISDN Proceeding or Progress message after a call is placed to PBX/PSTN over the trunk.</p> <p>■ [8] <b>PI = 8</b> = Same as <b>PI = 1</b>.</p> <p><b>Note:</b> The corresponding global parameter is [ProgressIndicator2IP].</p>
Echo Canceled	
'Echo Canceled' echo-canceller [EnableEC]	<p>Enables the device's Echo Cancellation feature (i.e., echo from voice calls is removed).</p> <p>■ [0] <b>Disable</b></p> <p>■ [1] <b>Line Echo Canceller</b> (default)</p> <p>■ [2] <b>Acoustic</b></p> <p>For more information on echo cancellation, see <a href="#">Configuring Echo Cancellation</a> on page 278.</p> <p><b>Note:</b> The corresponding global parameter is [EnableEchoCanceller].</p>
'EC NLP Mode' echo-canceller-nlp-mode [ECNlpMode]	<p>Enables Non-Linear Processing (NLP) mode for echo cancellation.</p> <p>■ [0] <b>Adaptive NLP</b> = (Default) NLP adapts according to echo changes</p> <p>■ [1] <b>Disable NLP</b></p> <p><b>Note:</b> The corresponding global parameter is [ECNLPMode].</p>
Jitter Buffer	
'Dynamic Jitter Buffer Minimum Delay' jitter-buffer-minimum-	<p>Defines the minimum delay (in msec) of the device's dynamic Jitter Buffer.</p> <p>The valid range is 0 to 150. The default delay is 10.</p>

Parameter	Description
delay [JitterBufMinDelay]	For more information on Jitter Buffer, see <a href="#">Configuring the Dynamic Jitter Buffer</a> on page 296. <b>Note:</b> The corresponding global parameter is [DJBufMinDelay].
'Dynamic Jitter Buffer Maximum Delay' jitter-buffer-maximum-delay [JitterBufMaxDelay]	Defines the maximum delay (in msec) for the device's Dynamic Jitter Buffer. The default is 300.
'Dynamic Jitter Buffer Optimization Factor' jitter-buffer-optimization-factor [JitterBufOptFactor]	Defines the Dynamic Jitter Buffer frame error/delay optimization factor. The valid range is 0 to 12. The default factor is 10. For more information on Jitter Buffer, see <a href="#">Configuring the Dynamic Jitter Buffer</a> on page 296. <b>Note:</b> <ul style="list-style-type: none"> <li>■ For data (fax and modem) calls, configure the parameter to 12.</li> <li>■ The corresponding global parameter is [DJBufOptFactor].</li> </ul>
Analog MWI	
'MWI Analog Lamp' mwi-analog-lamp [MWIAnalog]	Enables the visual display of message waiting indications (MWI). <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default).</li> <li>■ [1] <b>Enable</b> = Enables visual MWI by supplying line voltage of approximately 100 VDC to activate the phone's lamp.</li> </ul> <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The corresponding global parameter is [MWIAnalogLamp].</li> </ul>
'MWI Display' mwi-display [MWIDisplay]	Enables sending MWI information to the phone display. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Does not send MWI</li> </ul>

Parameter	Description
	<p>information to the phone's display.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = The device generates an MWI message (determined by the CallerIDType parameter), which is displayed on the MWI display.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The corresponding global parameter is [MWIDisplay].</li> </ul>
<p>'MWI Notification Timeout'</p> <p><code>mwi-ntf-timeout</code></p> <p>[MWINotificationTimeout]</p>	<p>Defines the maximum duration (timeout) that a message MWI is displayed on endpoint equipment (phones LED, screen notification or voice tone). When the timeout expires, the MWI is removed. However, each time a new MWI is sent to the endpoint, the timeout restarts its countdown again. For example, assume the timeout is configured to 10 seconds and the timeout has 2 seconds left until the current MWI is removed. If the endpoint now receives a new MWI, the timeout starts counting once again from 10 seconds, displaying both MWIs until the timeout expires.</p> <p>The valid value range is 0 to 2,000,000 seconds, where 0 means unlimited display (default).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXS interfaces.</li> <li>■ The corresponding global parameter is [MWINotificationTimeout].</li> </ul>
Analog FXO	
<p>'Two Stage Dial'</p> <p><code>is-two-stage-dial</code></p> <p>[IsTwoStageDial]</p>	<p>Defines the dialing mode for IP-to-Tel (FXO) calls.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = One-stage dialing. In this mode, the device seizes one of the available lines (according to the ChannelSelectMode parameter), and then dials the destination phone number received in the INVITE message. To specify whether the dialing must start after detection of the dial tone</li> </ul>

Parameter	Description
	<p>or immediately after seizing the line, use the <code>IsWaitForDialTone</code> parameter.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Yes</b> = (Default) Two-stage dialing. In this mode, the device seizes one of the PSTN/PBX lines without performing any dialing, connects the remote IP user to the PSTN/PBX and all further signaling (dialing and Call Progress Tones) is performed directly with the PBX without the device's intervention.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ The corresponding global parameter is <code>[IsTwoStageDial]</code>.</li> </ul>
<p>'FXO Double Answer'</p> <p><code>fxo-double-answer</code></p> <p><code>[EnableFXODoubleAnswer]</code></p>	<p>Enables the FXO Double Answer feature, which rejects (disconnects) incoming (FXO) Tel-to-IP collect calls and signals (informs) this call denial to the PSTN.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ The corresponding global parameter is <code>[EnableFXODoubleAnswer]</code>.</li> </ul>
<p>'FXO Ring Timeout'</p> <p><code>fxo-ring-timeout</code></p> <p><code>[FXORingTimeout]</code></p>	<p>Defines the delay (in msec) before the device generates a SIP INVITE (call) to the IP side upon detection of a RING_START event from the Tel (FXO) side. This occurs instead of waiting for a RING_END event.</p> <p>The feature is useful for telephony services that employ constant ringing (i.e., when no RING_END is sent). For example, Ringdown circuit is a service that sends a constant ringing current over the line, instead of cadence-based 2 seconds on, 4 seconds off. For example, when a telephone goes off-hook, a phone at the other end instantly rings.</p>

Parameter	Description
	<p>If a RING_END event is received before the timeout expires, the device doesn't initiate a call and ignores the detected ring. The device ignores RING_END events detected after the timeout expires.</p> <p>The valid value range is 0 to 50 (msec), in steps of 100-msec. For example, a value of 50 represents 5 sec. The default value is 0 (i.e., standard ring operation - the FXO interface sends an INVITE upon receipt of the RING_END event).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ If the parameter is configured for a specific FXO port, Caller ID detection doesn't occur and the [RingBeforeCallerID] and [FXONumberOfRings] parameters don't affect the outgoing INVITE for that FXO port.</li> <li>■ The corresponding global parameter is [FXORingTimeout].</li> </ul>
'Flash Hook Period' flash-hook-period [FlashHookPeriod]	<p>Defines the hook-flash period (in msec) for Tel and IP sides. For the IP side, it defines the hook-flash period reported to the IP. For the analog side, it defines the following:</p> <ul style="list-style-type: none"> <li>■ FXS interfaces: <ul style="list-style-type: none"> <li>✓ Maximum hook-flash detection period. A longer signal is considered an off-hook or on-hook event.</li> <li>✓ Hook-flash generation period upon detection of a SIP INFO message containing a hook-flash signal.</li> </ul> </li> <li>■ FXO interfaces: Hook-flash generation period.</li> </ul> <p>The valid range is 25 to 3,000. The default is 700.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable to FXS and FXO interfaces</li> <li>■ For FXO interfaces, a constant of 100 msec must be added to the required hook-flash period. For</li> </ul>

Parameter	Description
	<p>example, to generate a 450 msec hook-flash, configure the parameter to 550.</p> <ul style="list-style-type: none"> <li>■ The corresponding global parameter is [FlashHookPeriod].</li> </ul>
<p>'FXO Consultative Call Transfer'</p> <p>fxo-consult-call-transfer</p> <p>[FXOConsultCallTransfer]</p>	<p>Enables support for consultative call transfers (initiated by PSAP operators) for emergency (NG9-1-1) calls, based on the NENA i3 Standard for Next Generation 9-1-1 (NENA-STA-010.2-2016).</p> <p>When the device receives a SIP INVITE request that is a 911 call, it sends it to the PSAP operator through the FXO port interface. The PSAP operator then puts the 911 caller on hold and establishes a new call with another party (e.g., emergency provider). The PSAP operator then transfers the 911 caller to the new call party. The device uses a SIP REFER message to bridge the 911 caller with the new call party when the PSAP operator goes on hook.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to FXO interfaces.</li> <li>■ The corresponding global parameter is [FXOConsultCallTransfer].</li> </ul>

## 20 SIP Definitions

This section describes configuration of various SIP-related functionality.

### Configuring Registration Accounts

The Accounts table lets you configure up to 102 Accounts. An Account defines information for registering and authenticating (digest) Trunk Groups (e.g., PBX) or IP Groups (e.g., IP PBX) with a "serving" IP Group (e.g., ITSP).

The device initiates registration with a "serving" IP Group on behalf of the "served" Trunk Group or IP Group. Therefore, Accounts are typically required when the "served" Trunk Group or IP Group is unable to register or authenticate itself for whatever reason. Registration information includes username, password, host name (AOR), and contact user name (AOR). The device includes this information in the REGISTER message sent to the serving IP Group. Up to 10 Accounts can be configured per "served" Trunk Group or IP Group. A Trunk Group or IP Group can register to more than one IP Group (e.g., multiple ITSPs). This is done by configuring multiple entries in the Accounts table for the same served Trunk Group or IP Group, but with different serving IP Groups, username/password, host name, and contact user values.

You cannot configure more than one Account with the same "served" Trunk Group or IP Group and "serving" IP Group combination. For example, only one Account can be configured with the 'Served IP Group' parameter set to "Users-Boston" and the 'Serving IP Group' parameter set to "ITSP".

Authentication is typically required for INVITE messages sent to the "serving" IP Group. If the device receives a SIP 401 (Unauthorized) in response to a sent INVITE, the device checks for a matching "serving" and "served" entry in the Accounts table. If a matching row exists, the device authenticates the INVITE by providing the corresponding MD5 authentication username and password to the "serving" IP Group.

If the Account is not registered and the device receives a SIP dialog request (e.g., INVITE) from the Served IP Group, the device rejects the dialog and sends the Served IP Group a SIP 400 (Bad Request) response. An Account that is not registered can be due to any of the following reasons:

- You have unregistered the Served IP Group by clicking the **Register** button (discussed later in this section).
- The Serving IP Group has rejected the registration.

However, if the Account is not registered and you have enabled the Registrar Stickiness feature ('Registrar Stickiness' parameter is configured to **Enable**) or dynamic UDP port assignment feature ('UDP Port Assignment' parameter is configured to **Enable**) and the device receives a SIP dialog request (e.g., INVITE) from the Served IP Group, the device rejects the dialog and sends the Served IP Group a SIP 500 (Server Internal Error) response. In this scenario, the Account can be not registered due to any of the reasons listed previously or for the dynamic UDP port

assignment feature, there is no available port for the Account (port used for interfacing with the Serving IP Group).

- Gateway application: If no match is found in the Accounts table for incoming or outgoing calls, the username and password is taken from:
  - ✓ For FXS interfaces: Authentication table (see [Configuring Authentication](#) on page 1093)
  - ✓ 'UserName' and 'Password' parameters on the Proxy & Registration page
- SBC application: The device uses the username ('Username As Client' parameter) and password ('Password As Client' parameter) that are configured for the Serving IP Group in the IP Groups table, for user registration and authentication, in the scenarios listed below. For this mode of operation, configure the device to authenticate as a client (i.e., 'Authentication Mode' parameter in the IP Groups table for the Serving IP Group is **SBC As Client** or **SBC as Both Client and Server**).
  - ✓ If there is no Account configured for the Served IP Group and Serving IP Group in the Accounts table.
  - ✓ If there is an Account configured for the Served IP Group and Serving IP Group, but without a username and password.
- See also the following optional, related parameters:
  - ✓ [\[configure voip > sip-definition proxy-and-registration > use-rand-user](#) on page 1821] - enables the device to assign a random string to the user part of the SIP Contact header of new Accounts.
  - ✓ [\[configure voip > sip-definition settings > unreg-on-startup](#) on page 1846] - enables the device to unregister and then re-register Accounts upon a device restart.
  - ✓ [\[configure voip > sip-definition proxy-and-registration > reg-sync-mode](#) on page 1841] - enables synchronization of all Accounts (and users in the SBC User Information table - [Configuring SBC User Information Table through Web Interface](#) on page 803) that register to the same proxy server (Serving IP Group). Upon registration failure (timeout or failure response), only the Account (or SBC User Info user) that first detected the failure, continues its attempt at registering (sending REGISTER requests) to the proxy. For more information, see the parameter's description.
- Gateway application: If all trunks belonging to the Trunk Group are down, the device un-registers them. If any trunk belonging to the Trunk Group returns to service, the device registers them again. This ensures, for example, that the Proxy doesn't send SIP INVITE messages to trunks that are out of service.
- Gateway application: If registration with an IP Group fails for all Accounts of a specific Trunk Group that includes all the channels in the Trunk Group, the Trunk Group is set to Out-Of-Service if the [OOSOnRegistrationFail] parameter is set to 1 (see [Configuring Proxy and Registration Parameters](#) on page 792).
- Gateway application: To configure if the device sends a registration request to the Serving Trunk Group (SIP registrar), based on the Trunk Group's status (in-service or out-of-service) for ISDN PRI and CAS, see the [RegisterByTrunkGroupStatus] parameter.

The following procedure describes how to configure Accounts through the Web interface. You can also configure it through ini file [Account] or CLI (`configure voip > sip-definition account`).

➤ **To configure an Account:**

1. Open the Accounts table (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Accounts**).
2. Click **New**; the following dialog box appears:

The screenshot shows the 'Accounts' dialog box with two tabs: 'GENERAL' and 'CREDENTIALS'. The 'GENERAL' tab is active, displaying various configuration fields. The 'CREDENTIALS' tab is also visible, showing fields for 'User Name' and 'Password'.

GENERAL		CREDENTIALS	
Index	1	User Name	
Name		Password	
Served Trunk Group	-1		
Application Type	GW		
Served IP Group	--		
Serving IP Group	--		
Host Name			
Contact User			
Register	No		
Registrar Stickiness	Disable		
Registrar Search Mode	Current Working Server		
Re-Register on Invite Failure	Disable		

3. Configure an account according to the parameters described in the table below.
4. Click **Apply**.

Once you have configured Accounts, you can register or un-register them, as described below:

➤ **To register or un-register an Account:**

1. In the table, select the required Account entry row.
2. From the **Action** drop-down list, choose one of the following commands:
  - **Register** to register the Account.
  - **Un-Register** to un-register the Account.

**Table 20-1: Accounts Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index'	Defines an index for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' account-name [Account_AccountName]	Defines an arbitrary name to easily identify the row. The valid value is a string of up to 20 characters. <b>Note:</b> Configure each row with a unique name.
'Served Trunk Group' served-trunk-group [Account_ServedTrunkGroup]	Defines the Trunk Group that you want to register and/or authenticate.  ■ For Tel-to-IP calls, the served Trunk Group is the

Parameter	Description
	<p>source Trunk Group from where the call originated.</p> <ul style="list-style-type: none"> <li>■ For IP-to-Tel calls, the served Trunk Group is the Trunk Group to where the call is sent.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Gateway application.</p>
'Application Type' application-type [Account_ApplicationType]	<p>Defines the application type:</p> <ul style="list-style-type: none"> <li>■ [0] <b>GW</b> = (Default) Gateway application.</li> <li>■ [2] <b>SBC</b> = SBC application.</li> </ul>
'Served IP Group' served-ip-group-name [Account_ServedIPGroupName]	<p>Defines the IP Group (e.g., IP-PBX) that you want to register and/or authenticate upon its behalf.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ By default, all IP Groups are displayed.</li> <li>■ You can configure up to 30 Accounts per IP Group.</li> <li>■ The parameter is mandatory.</li> </ul>
'Serving IP Group' serving-ip-group-name [Account_ServingIPGroupName]	<p>Defines the IP Group (<i>Serving IP Group</i>) to where the device sends the SIP REGISTER requests (if enabled) for registration and authentication (of the Served IP Group).</p> <p>For the Gateway application:</p> <ul style="list-style-type: none"> <li>■ Tel-to-IP calls: The serving IP Group is the destination IP Group configured in the Trunk Group Settings table or Tel-to-IP Routing table (see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946).</li> <li>■ IP-to-Tel calls: The serving IP Group is the 'Source IP Group ID' configured in the IP-to-Tel Routing table (see <a href="#">Configuring IP-to-Tel Routing Rules</a> on page 960).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ By default, only IP Groups associated with the SRD to which the Served IP Group is associated are displayed, as well as IP Groups of Shared SRDs.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ (Gateway application only) If the Serving IP Group is associated with Proxy Set #0, you must configure the [IsProxyUsed] parameter to [1].</li> <li>■ The parameter is mandatory.</li> </ul>
'Host Name' host-name [Account_HostName]	<p>Defines the Address of Record (AOR) host name. The host name appears in SIP REGISTER From/To headers as ContactUser@HostName. For a successful registration, the host name is also included in the URI of the INVITE From header.</p> <p>The valid value is a string of up to 49 characters.</p> <p><b>Note:</b> If the parameter is not configured or if registration fails, the 'SIP Group Name' parameter value configured in the IP Groups table is used instead.</p>
'Contact User' contact-user [Account_ContactUser]	<p>Defines the AOR username. This appears in SIP REGISTER From/To headers as ContactUser@HostName, and in INVITE/200 OK Contact headers as ContactUser@&lt;device's IP address&gt;.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is not configured, the 'Contact User' parameter in the IP Groups table is used instead.</li> <li>■ If registration is disabled for the Account, or registration fails, the user part in the SIP INVITE's Contact header contains the source party number.</li> <li>■ If the source of the message is a registered user or matches a record in the SBC User Information table (see <a href="#">Configuring SBC User Information Table through Web Interface</a> on page 803), it has higher priority than the Account's configuration in deciding the user part in the INVITE's Contact header.</li> </ul>
'Register' register [Account_Register]	<p>Enables registration.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = (Default) The device only performs authentication (not registration). Authentication is</li> </ul>

Parameter	Description
	<p>typically done for INVITE messages sent to the "serving" IP Group. If the device receives a SIP 401 (Unauthorized) in response to a sent INVITE, the device checks for a matching "serving" and "served" entry in the table. If a matching row exists, the device authenticates the INVITE by providing the corresponding MD5 authentication username and password to the "serving" IP Group.</p> <ul style="list-style-type: none"> <li>■ [1] <b>Regular</b> = The device performs regular registration. For more information, see <a href="#">Regular Registration Mode</a> on page 790.</li> <li>■ [2] <b>GIN</b> = The device performs registration for legacy PBXs, using Global Identification Number (GIN). For more information, see <a href="#">Single Registration for Multiple Phone Numbers using GIN</a> on page 790.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Gateway application: To enable registration, you also need to configure the 'Registration Mode' parameter to <b>Per Account</b> in the Trunk Group Settings table (see <a href="#">Configuring Trunk Group Settings</a> on page 937).</li> <li>■ Account registration is not affected by the [IsRegisterNeeded] parameter.</li> </ul>
<p>'Registrar Stickiness'</p> <p>registrar-stickiness</p> <p>[Account_RegistrarStickiness]</p>	<p>Enables the Registrar Stickiness feature.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) Disables the Registrar Stickiness feature. After a successful initial registration of the Account with a registrar (IP address), whenever the device receives a SIP request or registration refresh, the device sends the request to whichever IP address is the currently working registrar. In other words, there is no binding to a specific IP address in the Proxy Set and at any given time, requests may be sent to a different IP address, whichever is the working one. In the case of proxy load-balancing, there is no certainty as to which IP address in the Proxy Set the request is routed.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Enable</b> = Enables the Register Stickiness feature. The device always routes SIP requests of a registered Account to the same registrar server to where the last successful REGISTER request was routed. In other words, once initial registration of the Account to one of the IP addresses in the Proxy Set (associated with the Account's Serving IP Group) is successful (i.e., 200 OK), binding ("stickiness") occurs to this specific address (registrar). All future SIP requests (e.g., INVITEs, SUBSCRIBEs and REGISTER refreshes) whose source and destination match the Account are sent to this registrar only. This applies until the registrar is unreachable or registration refresh fails, for whatever reason</li> <li>■ [2] <b>Enable for Non-REGISTER Requests</b> = Enables the Register Stickiness feature, as described for the <b>Enable</b> option (above), except for refresh REGISTER messages. When the device initiates a refresh REGISTER message for the Account, it restarts the registration process for the Account, sending the message to one of the registrar servers according to the Proxy Set of the Account's Serving IP Group. This option can be used, for example, in scenarios where proxy keep-alive is disabled (see the 'Proxy Keep-Alive' parameter in the Proxy Sets table) and restart of registration for refresh REGISTERs is always preferred.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if you have enabled Account registration ('Register' parameter configured to <b>Regular</b> or <b>GIN</b>).</li> <li>■ If an Account is registered with a registrar server which the device no longer "knows" (e.g., it was removed from the IP address results of the DNS resolution for the related Proxy Set) and the Registrar Stickiness feature is enabled, the device immediately initiates a new registration process for the Account (toward a different server of the Proxy Set).</li> </ul>

Parameter	Description
'Registrar Search Mode' registrar-search-mode [Account_RegistrarSearchMode]	<p>Defines the method for choosing an IP address (registrar) in the Proxy Set (associated with the Serving IP Group) to which the Account initially registers and performs registration refreshes, when the Register Stickiness feature is enabled. Once chosen, the Account is binded to the IP address for subsequent SIP requests.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Current Working Server</b> = (Default) For each initial and refresh registration request, the device routes to the currently working server in the list of IP addresses (configured or DNS-resolved IP addresses) in the Proxy Set. In the case of proxy load-balancing, the chosen IP address is according to the load-balancing mechanism.</li> <li>■ [1] <b>According to IMS Specifications</b> = For the initial registration request, the device performs DNS resolution if the address of the Proxy Set is configured as an FQDN. It then attempts to register to one of the listed DNS-resolved addresses (or configured IP addresses), starting with the first listed address and then going down the list sequentially. If an address results in an unsuccessful registration, the device immediately tries the next address (without waiting any retry timeout). The device goes through the list of addresses until an address results in a successful registration. If registration is unsuccessful for all addresses, the device waits a configured retry time and then goes through the list again. Once initial registration is successful, periodic registration refreshes are performed as usual. In addition to the periodic refreshes, immediate register refreshes are done upon the following triggers according to the IMS specification:               <ul style="list-style-type: none"> <li>✓ The device receives a SIP 408, 480, or 403 response from the Serving IP Group in response to an INVITE.</li> <li>✓ The transaction timeout expires for an INVITE sent to the Serving IP Group.</li> <li>✓ The device receives an INVITE from the Serving</li> </ul> </li> </ul>

Parameter	Description
	<p>IP Group from an IP address other than the address to which it is currently registered. In this case, it also rejects the INVITE with a SIP 480 response.</p> <p>If the device's physical Ethernet link to the proxy goes down, the device re-registers this Account with the proxy when the link comes up again. Re-registration occurs even if proxy keep-alive is disabled.</p> <p><b>Note:</b> This option is applicable only if you have configured the following:</p> <ul style="list-style-type: none"> <li>✓ 'Register' parameter to <b>Regular</b> or <b>GIN</b>.</li> <li>✓ 'Registrar Stickiness' parameter to <b>Enable</b>.</li> </ul> <p>■ [2] <b>Avoid Previous Registrar Until Expiry</b> = This option prevents the device from sending REGISTER requests to a registrar server where the device previously registered, if the device also registered successfully to another server since the last successful registration to the registrar server. This can occur if the registrar server has been offline for a brief time. The device avoids attempting to register to this registrar server for a duration that is calculated according to the cumulative value of the Proxy Server's last 'Expires' time and the grace time configured by the [AccountRegistrarAvoidanceTime] global parameter.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>✓ The value of the SIP Expires header in some REGISTER requests sent by the device may be less than the configured registration time (configured by [RegistrationTime]), when this option is used. The aim is to return registration to the higher priority server, soon after the avoidance time passes.</li> <li>✓ When this option is used, the Proxy Set of the Account's 'Serving IP Group' can have a maximum of three proxies (IP addresses may be resolved from a single Proxy host name).</li> </ul>

Parameter	Description
	<p>✓ Proxy Hot Swap isn't supported when this option is used.</p> <p>For example: Assume the Account is configured with 'Registrar Search Mode' set to <b>Avoid Previous Registrar Until Expiry</b> and the global parameter [AccountRegistrarAvoidanceTime] set to 180 seconds (3 minutes). In addition, the Account's 'Serving IP Group' uses a Proxy Set with three proxy server IPs (X, Y, Z; each proxy has a different priority) and uses the Homing mode.</p> <p>The following describes the timeline sequence of events:</p> <ol style="list-style-type: none"> <li>At 12:00:00, the Account successfully registers to server X; the 200 OK received from server X includes an expiry time of 8 minutes (Expires: 480 seconds).</li> <li>At 12:01:00, the device recognizes that server X is offline (using keep-alive with OPTIONS on the Proxy Set).</li> <li>When the device needs to send the next REGISTER request (by default, after half of the registration Expires time, i.e. 4 minutes, at 12:04:00), the device registers to server Y.</li> <li>At 12:05:00, the device recognizes that server X is back online. Even though server X has a higher priority than server Y, the device doesn't re-register to server X (instead, it registers to server Y) until after 12:11:00. Since the last successful registration to server X occurred at 12:00:00, the device only re-register to server X after 12:11:00 (i.e., Expires = 8 minutes + AccountRegistrarAvoidanceTime which is 3 minutes (180 seconds). In this way, the device avoids sending REGISTER requests to the previous (non-current) registrar.</li> </ol>
'Re-REGISTER on INVITE Failure' re-register-on- invite-failure [Account_	Enables the device to re-register an Account upon the receipt of specific SIP response codes (e.g., 403, 408, and 480) for a failed INVITE message sent to the Serving IP Group.

Parameter	Description
ReRegisterOnInviteFailure]	<ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = (Default) If the device receives a SIP response for a failed INVITE message, the device doesn't re-register the Account.</li> <li>■ [1] <b>Enable</b> = If the device receives a SIP response for a failed INVITE message and the response code is configured in the global parameter, AccountInviteFailureTriggerCodes, the device re-registers the Account according to the settings of the Proxy Set associated with the Account's Serving IP Group. Note that if the Proxy Set's 'Proxy Hot Swap Mode' parameter is configured to <b>Enable</b> and the 'Proxy Keep-Alive' parameter to <b>Using OPTIONS, Using OPTIONS on Active Server, or Using REGISTER</b>, then the registrar at which the INVITE failed is tried last in the list of servers in the Proxy Set.</li> </ul>
'Reg Event Package Subscription' reg-event-package-subscription [Account_ RegEventPackageSubscription]	<p>Enables the device to subscribe to the registration event package service (as defined in RFC 3680) with the registrar server (Serving IP Group) to which the Account is successfully registered and binded, when the Registrar Stickiness feature is enabled. The service allows the device to receive notifications of the Accounts registration state change with the registrar. The device subscribes to the service by sending a SUBSCRIBE message containing the Event header with the value "reg" (Event: reg). Whenever a change occurs in the registration binding state, the registrar notifies the device by sending a SIP NOTIFY message.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p><b>Note:</b> The parameter is applicable only if you have enabled the Registrar Stickiness feature (in this table):</p> <ul style="list-style-type: none"> <li>■ 'Register' parameter to <b>Regular</b> or <b>GIN</b>.</li> <li>■ 'Registrar Stickiness' parameter to <b>Enable</b>.</li> </ul>
'Register by Served IP Group Status' reg-by-served-ipg-status	<p>Defines the device's handling of Account registration based on the connectivity status of the Served IP Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Register Always</b> = (Default) Account</li> </ul>

Parameter	Description
[Account_RegByServedIPG]	<p>registration by the device doesn't depend on the connectivity status of the Served IP Group. The device sends registration requests to the Serving IP Group even if the Served IP Group is offline.</p> <p>■ [1] <b>Register Only if Online</b> = The device performs Account registration depending on the connectivity status of the Served IP Group. It sends a registration request to the Serving IP Group only if the Served IP Group is online. If the Served IP Group was registered, but then goes offline, the device unregisters it. If it becomes online again, the device re-registers it. This option is applicable only to Accounts where registration is initiated by the device (i.e., the 'Register' parameter is configured to any value other than <b>No</b>).</p> <p>The Served IP Group's connectivity status is determined by the keep-alive mechanism of its associated Proxy Set (i.e., the 'Proxy Keep-Alive' parameter is configured to <b>Using OPTIONS, Using OPTIONS on Active Server</b> or <b>Using Fake REGISTER</b>).</p> <p><b>Note:</b> The parameter is applicable only to the SBC application.</p>
'UDP Port Assignment' udp-port-assignment [Account_UDPPortAssignment]	<p>Enables the device to dynamically allocate local SIP UDP ports to Accounts using the same Serving IP Group, where each Account is assigned a unique port on the device's leg interfacing with the Accounts' Serving IP Group.</p> <p>■ [0] <b>Disable</b> = (Default) The device uses the same specific UDP port for all registrations done for this Account (traffic between the device and the Serving IP Group). This port is the one configured for the SIP Interface ('UDP Port' parameter) that is associated with the Proxy Set of the Account's Serving IP Group.</p> <p>■ [1] <b>Enable</b> = The device assigns a unique local port for each Account for which the device initiates registration. The port is taken from a configured UDP port range. The port range is configured for the SIP Interface ('Additional UDP Ports'</p>

Parameter	Description
	<p>parameter) associated with the Proxy Set of the Account's Serving IP Group. Traffic between the Serving IP Group and device is sent from and received on the assigned unique local port. If enabled for other Accounts that are configured with the same Serving IP Group, each Account is allocated a unique UDP port from the port range. For example, if you have configured two Accounts, "PBX-1" and "PBX-2", the device could assign port 6000 to "PBX-1" and 6100 to "PBX-2".</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the SBC application.</li> <li>■ If you enable the parameter, you must also enable the device to initiate registration for the Account (i.e., configure the 'Register' parameter to any value other than <b>No</b>).</li> <li>■ If the device fails to allocate a port (e.g., insufficient ports), the device doesn't send the SIP REGISTER request, but tries again within a period configured by the RegistrationRetryTime and MaxRegistrationBackoffTime parameters.</li> <li>■ If the device receives a SIP request from the Serving IP Group for the Account, on a port that was not assigned to the Account, it rejects the request (with a SIP 404 Not Found response).</li> <li>■ If the device receives a SIP request from the Served IP Group and the Account has not been allocated a valid port, the device rejects the request (with a SIP 500 Server Internal Error response).</li> <li>■ For more information on configuring the SIP Interface's port range, see <a href="#">Configuring SIP Interfaces</a> on page 570.</li> </ul>
'Account Registration Status'	<p>(Read-only field) Displays the registration status of the Account ("Registered" or "Not Registered"). You can also view Account registration status on the Registration Status page (see <a href="#">Viewing Registration Status</a> on page 1489).</p>

Parameter	Description
<b>Credentials</b>	
'User Name' user-name [Account_Username]	Defines the digest MD5 Authentication username. The valid value is a string of up to 60 characters. By default, no value is defined.
'Password' password [Account_Password]	Defines the digest MD5 Authentication password. The valid value is a string of up to 50 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The password can't be configured with wide characters.</li> <li>■ If the password contains a question mark (?) and you're configuring the parameter through CLI, you must enclose the entire password in double quotation marks (e.g., "43LSyk+?").</li> </ul>

## Regular Registration Mode

When you configure the registration mode ('Register') in the Accounts table to **Regular**, the device sends REGISTER requests to the Serving IP Group. The host name (in the SIP From/To headers) and contact user (user in From/To and Contact headers) are taken from the configured Accounts table upon successful registration. See the example below:

```
REGISTER sip:xyz SIP/2.0
Via: SIP/2.0/UDP 10.33.37.78;branch=z9hG4bKac1397582418
From: <sip:ContactUser@HostName>;tag=1c1397576231
To: <sip: ContactUser@HostName >
Call-ID: 1397568957261200022256@10.33.37.78
CSeq: 1 REGISTER
Contact: <sip:ContactUser@10.33.37.78>;expires=3600
Expires: 3600
User-Agent: Sip-Gateway/7.60A.100.022
Content-Length: 0
```

## Single Registration for Multiple Phone Numbers using GIN

When you configure the registration mode in the Accounts table to **GIN**, the Global Identifiable Number (GIN) registration method is used, according to RFC 6140. The device performs GIN-based registration of users to a SIP registrar on behalf of a SIP PBX. In effect, the PBX registers with the service provider, just as a directly hosted SIP endpoint would register. However, because a PBX has multiple user agents, it needs to register a contact address on behalf of each

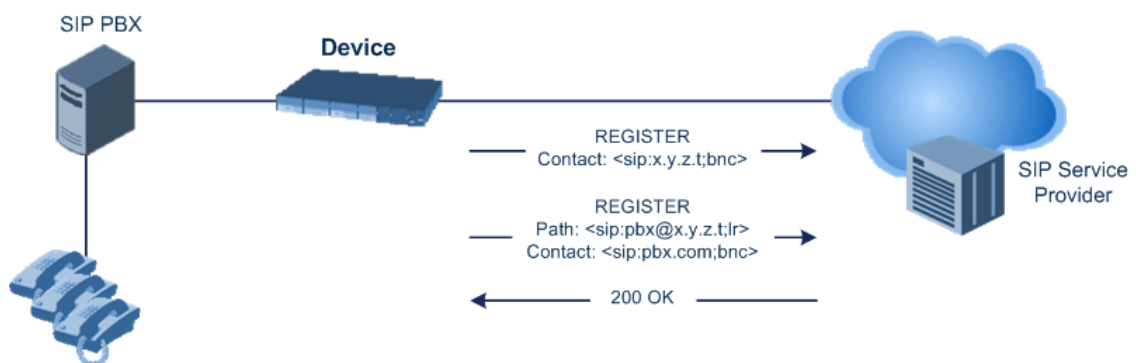

of these. Rather than performing a separate registration procedure for each user agents, GIN registration mode does multiple registrations using a single REGISTER transaction.

According to this mechanism, the PBX delivers to the service provider in the Contact header field of a REGISTER request a template from which the service provider can construct contact URIs for each of the AORs assigned to the PBX and thus, can register these contact URIs within its location service. These registered contact URIs can then be used to deliver to the PBX inbound requests targeted at the AORs concerned. The mechanism can be used with AORs comprising SIP URIs based on global E.164 numbers and the service provider's domain name or sub-domain name.

The SIP REGISTER request sent by the device for GIN registration with a SIP server provider contains the Require and Proxy-Require headers. These headers contain the token 'gin'. The Supported header contains the token 'path' and the URI in the Contact header contains the parameter 'bnc' without a user part:

Contact: <sip:198.51.100.3;bnc>;

The figure below illustrates the GIN registration process:

The figure below illustrates an incoming call using GIN:

## Registrar Stickiness

You can enable the Registrar Stickiness feature per Account. Registrar Stickiness binds an Account to one of the IP addresses (configured or DNS-resolved) in the Proxy Set associated with the Serving IP Group. Once an Account registers successfully to one of the IP addresses (i.e., SIP registrar server) in the Proxy Set, the device routes all subsequent SIP requests (INVITEs, SUBSCRIBEs and REGISTER refreshes) of the Account to this registrar. This applies until the registrar is unreachable or registration refresh fails, for whatever reason.

To configure the Registrar Stickiness feature, use the following parameters in the Accounts table:

- Registrar Stickiness: Enables the feature.
- Registrar Search Mode: Defines the method for choosing an IP address (registrar) in the Proxy Set to which the Account initially registers and performs registration refreshes. Once chosen, the Account is binded to this registrar.
- Reg Event Package Subscription: Enables the device to subscribe to the registration event package service (as defined in RFC 3680) with the registrar to which the Account is registered and binded. The service allows the device to receive notifications of the Accounts registration state change with the registrar.

## Configuring Proxy and Registration Parameters

The Proxy & Registration page allows you to configure the Proxy server and registration parameters. For a description of the parameters appearing on this page, see [Configuration Parameters Reference](#) on page 1701. To configure Proxy servers (Proxy Sets), see [Configuring Proxy Sets](#) on page 632.

To view the registration status of endpoints with a SIP Registrar/Proxy server, see [Viewing Registration Status](#) on page 1489.

### ➤ To configure the Proxy and registration parameters:

1. Open the Proxy & Registration page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Proxy & Registration**).
2. Configure the parameters as required.
3. Click **Apply**.

### ➤ To register or un-register the device to a Proxy/Registrar:

- Click the **Register** button to register.
- Click **Un-Register** button to un-register.

Instead of registering the entire device, you can register specific entities as listed below by using the **Register** button located on the page in which these entities are configured:

- FXS endpoints, FXO endpoints, BRI endpoints, Trunk Groups - Trunk Groups table (see [Configuring Trunk Groups](#) on page 934)
- Accounts - Accounts table (see [Configuring Registration Accounts](#) on page 777)

## SIP Message Authentication Example

The device supports basic and digest (MD5 or SHA- 256, configured by [SIPServerDigestAlgorithm]) authentication types, according to SIP RFC 3261. A proxy server might require authentication before forwarding an INVITE message. A Registrar/Proxy server may also require authentication for client registration. A proxy replies to an unauthenticated INVITE with a 407 Proxy Authorization Required response, containing a Proxy-Authenticate header with the form of the challenge. After sending an ACK for the 407, the user agent can then re-send the INVITE with a Proxy-Authorization header containing the credentials.

User agents, Redirect or Registrar servers typically use the SIP 401 Unauthorized response to challenge authentication containing a WWW-Authenticate header, and expect the re-INVITE to contain an Authorization header.

The following example shows the Digest Authentication procedure, including computation of user agent credentials:

1. The REGISTER request is sent to a Registrar/Proxy server for registration:

```
REGISTER sip:10.2.2.222 SIP/2.0
Via: SIP/2.0/UDP 10.1.1.200
From: <sip: 122@10.1.1.200>;tag=1c17940
To: <sip: 122@10.1.1.200>
Call-ID: 634293194@10.1.1.200

CSeq: 1 REGISTER
Contact: sip:122@10.1.1.200:
Expires:3600
```

2. Upon receipt of this request, the Registrar/Proxy returns a 401 Unauthorized response:

```
SIP/2.0 401 Unauthorized
Via: SIP/2.0/UDP 10.2.1.200
From: <sip:122@10.2.2.222 >;tag=1c17940
To: <sip:122@10.2.2.222 >
Call-ID: 634293194@10.1.1.200
Cseq: 1 REGISTER
Date: Mon, 30 Jul 2012 15:33:54 GMT
Server: Columbia-SIP-Server/1.17
Content-Length: 0
```

```
WWW-Authenticate: Digest realm="AudioCodes.com",  
nonce="11432d6bce58ddf02e3b5e1c77c010d2",  
stale=FALSE,  
algorithm=MD5
```

3. According to the sub-header present in the WWW-Authenticate header, the correct REGISTER request is created.
4. Since the algorithm is MD5:
  - The username is equal to the endpoint phone number "122".
  - The realm return by the proxy is "AudioCodes.com".
  - The password from the *ini* file is "AudioCodes".
  - The equation to be evaluated is "122:AudioCodes.com:AudioCodes". According to the RFC, this part is called A1.
  - The MD5 algorithm is run on this equation and stored for future usage.
  - The result is "a8f17d4b41ab8dab6c95d3c14e34a9e1".
5. The par called A2 needs to be evaluated:
  - The method type is "REGISTER".
  - Using SIP protocol "sip".
  - Proxy IP from *ini* file is "10.2.2.222".
  - The equation to be evaluated is "REGISTER:sip:10.2.2.222".
  - The MD5 algorithm is run on this equation and stored for future usage.
  - The result is "a9a031cfddcb10d91c8e7b4926086f7e".
6. Final stage:
  - A1 result: The nonce from the proxy response is "11432d6bce58ddf02e3b5e1c77c010d2".
  - A2 result: The equation to be evaluated is "A1:11432d6bce58ddf02e3b5e1c77c010d2:A2".
  - The MD5 algorithm is run on this equation. The outcome of the calculation is the response needed by the device to register with the Proxy.
  - The response is "b9c45d0234a5abf5ddf5c704029b38cf".

At this time, a new REGISTER request is issued with the following response:

```
REGISTER sip:10.2.2.222 SIP/2.0  
Via: SIP/2.0/UDP 10.1.1.200  
From: <sip: 122@10.1.1.200>;tag=1c23940  
To: <sip: 122@10.1.1.200>
```

Call-ID: 654982194@10.1.1.200

CSeq: 1 REGISTER

Contact: sip:122@10.1.1.200:

Expires:3600

Authorization: Digest, username: 122,  
realm="AudioCodes.com",  
nonce="11432d6bce58ddf02e3b5e1c77c010d2",  
uri="10.2.2.222",  
response="b9c45d0234a5abf5ddf5c704029b38cf"

7. Upon receiving this request and if accepted by the Proxy, the Proxy returns a 200 OK response, completing the registration transaction:

SIP/2.0 200 OK  
Via: SIP/2.0/UDP 10.1.1.200  
From: <sip: 122@10.1.1.200>;tag=1c23940  
To: <sip: 122@10.1.1.200>  
Call-ID: 654982194@10.1.1.200  
Cseq: 1 REGISTER  
Date: Thu, 26 Jul 2012 09:34:42 GMT  
Server: Columbia-SIP-Server/1.17  
Content-Length: 0

Contact: <sip:122@10.1.1.200>; expires="Thu, 26 Jul 2012 10:34:42 GMT";  
action=proxy; q=1.00

Contact: <122@10.1.1.200:>; expires="Tue, 19 Jan 2038 03:14:07 GMT";

## Configuring User Information

This section describes User Information configuration.

### Enabling the User Information Table

Before you can use the SBC User Information table (for SBC users) or GW User Information table(for Gateway users), you need to enable the User Information functionality.

➤ **To enable User Information table:**

1. Make sure that your device's License Key includes the far-end user license ("Far End Users"), which specifies the maximum number of supported users. To view the License Key, see [Viewing the License Key](#) on page 1362.
2. Open the Proxy & Registration page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Proxy & Registration**).
3. Select the 'User-Information Usage' check box [EnableUserInfoUsage]:

User-Information Usage 

4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect. The User Information table becomes available in the Web interface:

SBC Application - see [Configuring SBC User Information](#) on page 802

Gateway Application - see [Gateway User Information for PBX Extensions and "Global" Numbers](#) below

## Gateway User Information for PBX Extensions and "Global" Numbers

The GW User Information table contains information of Gateway users, which can be used for the following Gateway-related features:

- **Mapping (Manipulating) PBX Extension Numbers with Global Phone Numbers:** maps PBX extension number, connected to the device, with any "global" phone number (alphanumeric) for the IP side. In this context, the "global" phone number serves as a routing identifier for calls in the "IP world" and the PBX extension uses this mapping to emulate the behavior of an IP phone. This feature is especially useful in scenarios where unique or non-consecutive number translation per PBX is needed. This number manipulation feature supports the following call directions:

- **IP-to-Tel Calls:** Maps the called "global" number (in the Request-URI user part) to the PBX extension number. For example, if the device receives an IP call destined for "global" number 638002, it changes this called number to the PBX extension number 402, and then sends the call to the PBX extension on the Tel side.

If you have configured regular IP-to-Tel manipulation rules (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983), the device applies these rules before applying the mapping rules of the GW User Information table.

- **Tel-to-IP Calls:** Maps the calling (source) PBX extension to the "global" number. For example, if the device receives a Tel call from PBX extension 402, it changes this calling number to 638002, and then sends call to the IP side with this calling number. In addition to the "global" phone number, the display name (caller ID) configured for the PBX user in the GW User Information table is used in the SIP From header.

If you have configured regular Tel-to-IP manipulation rules (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983), the device applies these rules before applying the mapping rules of the GW User Information table.

- **Registering Users:** The device can register each PBX user configured in the GW User Information table. For each user, the device sends a SIP REGISTER to an external IP-based Registrar server, using the "global" number in the From/To headers. If authentication is necessary for registration, the device sends the user's username and password, configured in the GW User Information table, in the SIP MD5 Authorization header.

You can configure up to 500 mapping rules in the GW User Information table. These rules can be configured using any of the following methods:

- Web interface - see [Configuring Gateway User Information Table through Web Interface](#) below
- CLI - see [Configuring Gateway User Information Table through CLI](#) on page 799
- Loadable User Information file - see [Configuring Gateway User Information Table from a Loadable File](#) on page 801

- This section is applicable only to the Gateway application.
- To enable user registration, configure the following parameters:
  - ✓ Enable the 'Enable Registration' parameter [IsRegisterNeeded].
  - ✓ 'Registration Mode': **Per Endpoint** or [AuthenticationMode] set to 0
- For FXS ports, when the device needs to send a new SIP request with the Authorization header (e.g., after receiving a SIP 401 response), it uses the username and password configured in the Authentication table (see [Configuring Authentication](#) on page 1093). To use the username and password that are configured in the GW User Information table, configure the 'Password' parameter to any value other than its default value.

### Configuring Gateway User Information Table through Web Interface

You can configure the GW User Information table through the Web interface. The table allows you to do the following:

- Manually add users (described below).
- Import users from a file: From the **Action** drop-down list, choose **Import**.

- When you import a file, all previously configured entries in the table are deleted and replaced with the users from the imported file.
- For configuring users in a file for import, see [Configuring Gateway User Information Table from a Loadable File](#) on page 801

- Export the configured users to a .csv file: From the **Action** drop-down list, choose **Export** and save the file to a folder on your computer.

■ Register and un-register users:

- To register a user, select the user, and then from the **Action** drop-down list, choose **Register**.
- To un-register a user, select the user, and then from the **Action** drop-down list, choose **Un-Register**.

To configure the GW User Information table, make sure that you have enabled the feature (see [Enabling the User Information Table](#) on page 795).

The following procedure describes how to configure and register users in the GW User Information table through the Web interface.

➤ **To configure the GW User Information table through the Web interface:**

1. Open the GW User Information table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway User Information**).
2. Click **New**; the following dialog box appears:

3. Configure a user according to the table below.
4. Click **Apply**.

**Table 20-2: User Information Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'PBX Extension' [PBXExtension]	Defines the PBX extension number. The valid value is a string of up to 10 characters.

Parameter	Description
	<b>Note:</b> The parameter is mandatory.
'Global Phone Number' [GlobalPhoneNumber]	Defines the "global" phone number for the IP side.  The valid value is a string of up to 20 characters. <b>Note:</b> The parameter is mandatory.
'Display Name' [DisplayName]	Defines the Caller ID of the PBX extension.  The valid value is a string of up to 30 characters.
'Username' [Username]	Defines the username for registering the user when authentication is necessary.  The valid value is a string of up to 60 characters. By default, no value is defined.
'Password' [Password]	Defines the password for registering the user when authentication is necessary.  The valid value is a string of up to 20 characters. <b>Note:</b> The password cannot be configured with wide characters.
'Status'	(Read-only field) Displays the status of the user:  ■ "Registered"  ■ "Not Registered"

### Configuring Gateway User Information Table through CLI

The GW User Information table can be configured through CLI using the following commands:

- To add or modify a user (example):

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info gw-user-info <index, e.g., 1>
(gw-user-info-1)# username JohnDee
(gw-user-info-1)# <activate | exit>
```

- To delete a specific user, use the no command:

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# no user-info gw-user-info <index, e.g., 1>
```

- To import users from a file:

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info gw-user-info import-csv-from <URL>
```

- To export users to a .csv file:

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info gw-user-info export-csv-to <URL>
```

- To view all table entries:

```
(sip-def-proxy-and-reg)# user-info gw-user-info display
---- gw-user-info-0 ----
pbx-ext (405)
global-phone-num (405)
display-name (Ext405)
username (user405)
password (0aGzoKfh5ul=)
status (not-resgistered)
```

- To view a specific entry (example):

```
(sip-def-proxy-and-reg)# user-info gw-user-info <index, e.g., 0>
(gw-user-info-0)# display
pbx-ext (405)
global-phone-num (405)
display-name (Ext405)
username (user405)
password (0aGzoKfh5ul=)
status (not-resgistered)
```

- To search a user by pbx-ext:

```
(sip-def-proxy-and-reg)# user-info find <pbx-ext e.g., 405>
405: Found at index 0 in GW user info table, not registered
```

To configure the GW User Information table, make sure that you have enabled the feature (see [Enabling the User Information Table](#) on page 795).

### Configuring Gateway User Information Table from a Loadable File

You can configure users in a file and then upload (import) it to the GW User Information table. The users must be configured in comma-separated value (CSV) file format. You can create the file using any standard text-based editor such as Notepad, or alternatively a CSV-based program such as Microsoft Excel. The file can have any filename extension (e.g., .csv or .txt).

When you import a file, all previously configured entries in the table are deleted and replaced with the users from the imported file.

When adding users to the file, use the following syntax:

- For text-based editors:

```
PBXExtension,GlobalPhoneNumber,DisplayName,Username,Password
```

For example:

```
PBXExtension,GlobalPhoneNumber,DisplayName,Username,Password
4040,7362400,John,johnd,2798
4041,7362401,Sue,suep,1234
```

- For CSV-based programs:

```
PBXExtension,GlobalPhoneNumber,DisplayName,Username,Password
```

For example:

A	B	C	D	E
PBXExtension	GlobalPhoneNumber	DisplayName	Username	Password
4040	73682400	John	johnd	1234
4041	73682401	Sue	suep	2224

You can upload the User Information file using any of the following methods:

- Web interface - GW User Information table (see [Configuring Gateway User Information Table through Web Interface](#) on page 797)
- CLI - **gateway user-info-table import-csv-from** (see [Configuring Gateway User Information Table through CLI](#) on page 799)
- Automatic Update mechanism - [GWUserInfoFileUrl] parameter

For **backward compatibility only**, upload the User Information file using the Auxiliary Files page. Configure users with the following syntax:

[GW]

FORMAT PBXExtensionNum,GlobalPhoneNum,DisplayName,UserName>Password

For example:

[GW]

FORMAT PBXExtensionNum,GlobalPhoneNum,DisplayName,UserName>Password

4040,7362400,John,johnd,2798

4041,7362401,Sue,suep,1234

Make sure that the last line in the file ends with a carriage return (i.e., press the Enter key).

When you upload the file, the device automatically populates the GW User Information table with the file's contents and deletes all previous entries in the table.

## Configuring SBC User Information

The SBC User Information table lets you configure up to 2,000 SBC users.

You can use the table for the following:

- Registering each user to an external registrar server.
- Authenticating (for any SIP request and as a client) each user if challenged by an external server.
- Authenticating as a server incoming user requests (for SBC security).

If the device registers on behalf of users and the users don't perform registration, any SIP request destined to the user is routed to the Proxy Set associated with the user's IP Group.

You can also enable the Registration Synchronization feature (see [\[configure voip > sip-definition proxy-and-registration > reg-sync-mode](#) on page 1841] parameter). This feature synchronizes the registration process for users configured in the SBC User Information table and Accounts configured in the Accounts table (see [Configuring Registration Accounts](#) on page 777) that register to the same proxy server (Serving IP Group). If an Account or user receives a timeout (configured by [SipT1Rtx], [SipT2Rtx], or [SIPMaxRtx] parameters) or response failure (e.g., SIP 403) for a sent SIP REGISTER request, the device stops sending REGISTER messages for all Accounts and users associated with this same proxy server. The Account or user that first detected the no response (or failure) is considered the lead Account or user. Only this Account or user continues registering to the proxy server. When this Account or user receives a successful response from the proxy server, the device resumes the registration process for all the other Accounts and users associated with the same proxy server.

The SBC User Information table can be configured using any of the following methods:

- Web interface (see [Configuring SBC User Information Table through Web Interface](#) on the next page
- CLI (see [Configuring SBC User Information Table through CLI](#) on page 806

- Loadable User Information file (see [Configuring SBC User Information Table from a Loadable File](#) on page 808)

- For the SBC User Information feature, the device's License Key must include the license "Far End Users (FEU)", which specifies the maximum number of supported far-end users. If no far-end users are licensed, then this feature cannot be used.
- If you configure the device to authenticate as a server, for incoming SIP requests from users of a specific User-type IP Group, the device authenticates the users using the username and password configured in the IP Group's 'Username As Server' and 'Password As Server' parameters. However, if the user appears in the SBC User Information table and configured with a username and/or password, then the device authenticates the user with the credentials in the table. To enable the device to authenticate as a server, configure the IP Group's 'Authentication Mode' parameter to **SBC as Server**.
- The maximum number of available rows (users) that you can add in the SBC User Information table is according to the number of far-end users ("Far End Users") that is specified in the device's License Key. However, the number of licensed users cannot exceed the maximum rows supported by the device, as stated in the beginning of this section. As an example and for simplicity sake, assume that the supported number of rows is 10 and the number of licensed users is 20. In this scenario, the maximum number of available rows will be 10. If the number of licensed users is 5, the maximum number of available rows will be 5.
- This section is applicable only to the SBC application.

### Configuring SBC User Information Table through Web Interface

You can configure the SBC User Information table with SBC users through the Web interface.

- Before you can configure the SBC User Information table, you need to enable the SBC users feature (see [Enabling the User Information Table](#) on page 795) so that it's available in the Web interface.
- The maximum number of users (rows) that can be configured in the table is according to how many far-end users ("Far End Users (FEU)") are defined in the device's License Key (see [Viewing the License Key](#) on page 1362).

You can configure users in the table, by doing the following:

- Manually adding users (described below).
- Importing users from a file: From the **Action** drop-down list, choose **Import**. To configure users in a file for import, see [Configuring SBC User Information Table from a Loadable File](#) on page 808.

When you import a file, all previously configured entries in the table are deleted and replaced with the users from the imported file.

The table also allows you to do the following:

- Export configured users to a file (.csv file format): From the **Action** drop-down list, choose **Export** and save the file to a folder on your computer.
- Register and un-register users:
  - To register a user: Select the user, and then from the **Action** drop-down list, choose **Register**.
  - To unregister a user: Select the user, and then from the **Action** drop-down list, choose **Un-Register**.

The **Register** and **Un-Register** buttons are applicable only if the user's assigned IP Group (see 'IP Group' parameter below) is configured so that the device initiates registrations (i.e., IP Group's 'Registration Mode' parameter is **SBC Initiates Registration**). The device uses the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186) to determine where to send the SIP REGISTER request for the user. It searches the table for a rule whose 'Source IP Group' parameter matches the user's assigned IP Group (below), and then sends the REGISTER to the IP Group specified in the rule's 'Destination IP Group' parameter (referred to as the *serving* IP Group).

You can also enable the device to synchronize registration between all users in the SBC User Information table and all Accounts (configured in the [Configuring Registration Accounts](#) on page 777) that register to the same proxy server (*serving* IP Group). Upon registration failure (timeout or failure response) with the proxy server, only the user or Account that first detected the failure, continues its attempt at registering (sending REGISTER requests) to the proxy server. For more information, see the [configure voip > sip-definition proxy-and-registration > reg-sync-mode](#) on page 1841.

The device also uses the SBC User Information table to classify incoming SIP dialogs from users. When it receives an incoming SIP message (e.g., INVITE), it searches the table for a matching user ('Local User' parameter below) and if found, classifies it to the IP Group assigned to the user.

➤ **To configure SBC User Information table through Web interface:**

1. Open the SBC User Information table (**Setup** menu > **Signaling & Media** tab > **SBC** folder > **SBC User Information**).
2. Click **New**; the following dialog box appears:

3. Configure a user according to the table below.

4. Click **Apply**.

**Table 20-3: SBC User Information Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	<p>Defines an index number for the new table row.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Local User' [LocalUser]	<p>Defines the user and is used as the Request-URI user part for the AOR in the database.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p> <p><b>Note:</b> The parameter is mandatory.</p>
'Username' [Username]	<p>Defines the username for registering the user when authentication is necessary.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p> <p><b>Note:</b> To configure the device to act as an authentication server and challenge incoming SIP requests from this user, configure the 'Authentication Mode' parameter of the user's IP Group to <b>SBC as Server</b>. If the 'Username' parameter is not configured, the device uses the username configured in the IP Group's 'Username As Server' parameter.</p>
'Password' [Password]	<p>Defines the password for registering the user when authentication is necessary.</p> <p>The valid value is a string of up to 20 characters.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The password cannot be configured with wide characters.</li> <li>■ To configure the device to act as an authentication server and challenge incoming SIP requests from this user, configure the</li> </ul>

Parameter	Description
	'Authentication Mode' parameter of the user's IP Group to <b>SBC as Server</b> . If the 'Password' parameter is not configured, the device uses the password configured in the IP Group's 'Password As Server' parameter.
'IP Group' [IPGroupName]	<p>Assigns an IP Group to the user. The IP Group is used as the Request-URI source host part for the AOR in the database.</p> <p>To configure IP Groups, see <a href="#">Configuring IP Groups</a> on page 591.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is mandatory.</li> <li>■ You must assign the user with a <b>User</b>-type IP Group.</li> </ul>
'Status' [Status]	<p>(Read-only field) Displays the status of the user:</p> <ul style="list-style-type: none"> <li>■ "Registered": Valid configuration and the user is registered.</li> <li>■ "Not Registered": Valid configuration, but the user is not registered.</li> <li>■ "N/A": Invalid configuration because the user is not assigned to a <b>User</b>-type IP Group.</li> <li>■ "Exceeds FEU FK": The number of users (rows) in the SBC User Information table exceeds the licensed capacity for far-end users specified in the License Key ('Far End Users (FEU)').</li> </ul>

### Configuring SBC User Information Table through CLI

The SBC User Information table can be configured in the CLI using the following commands:

- To add and/or modify a user (example):

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info sbc-user-info <index, e.g., 1>
(sbc-user-info-1)# username JohnDee
(sbc-user-info-1)# <activate | exit>
```

- To delete a specific user, use the no command:

```
(sip-def-proxy-and-reg)# no user-info sbc-user-info <index, e.g., 1>
```

- To import users from a file:

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info sbc-user-info import-csv-from <URL>
```

- To export users to a .csv file:

```
# configure voip
(config-voip)# sip-definition proxy-and-registration
(sip-def-proxy-and-reg)# user-info sbc-user-info export-csv-to <URL>
```

- To view all table entries:

```
(sip-def-proxy-and-reg)# user-info sbc-user-info display
---- sbc-user-info-0 ----
local-user (JohnDee)
username (userJohn)
password (s3fn+fn=)
ip-group-id (1)
status (not-resgistered)
```

```
---- sbc-user-info-1 ----
local-user (SuePark)
username (userSue)
password (t6sn+un=)
ip-group-id (1)
status (not-resgistered)
```

- To view a specific entry (example):

```
(sip-def-proxy-and-reg)# user-info sbc-user-info <index, e.g., 0>
(sbc-user-info-0)# display
local-user (JohnDee)
username (userJohn)
password (s3fn+fn=)
ip-group-id (1)
status (not-resgistered)
```

- To search a user by local-user:

```
(sip-def-proxy-and-reg)# user-info find <local-user, e.g., JohnDoe>
JohnDee: Found at index 0 in SBC user info table, not registered
```

To configure the SBC User Information table, make sure that you have enabled the feature as described in [Enabling the User Information Table](#) on page 795.

### Configuring SBC User Information Table from a Loadable File

You can configure users in a file and then upload (import) it to the SBC User Information table. The users must be configured in comma-separated value (CSV) file format. You can create the file using any standard text-based editor such as Notepad, or alternatively a CSV-based program such as Microsoft Excel. The file can have any filename extension (e.g., .csv or .txt).

- When you import a file, all previously configured entries in the table are deleted and replaced with the users from the imported file.
- If a user is configured in the file with an IP Group that doesn't exist, the user is not assigned an IP Group when you import the file.

When adding users to the file, use the following syntax:

- For text-based editors:

```
LocalUser,UserName,Password,IPGroupName
```

For example:

```
LocalUser,UserName,Password,IPGroupName
John,johnd,2798,ITSP
Sue,suep,1234,IP-PBX
```

- For CSV-based programs:

```
LocalUser,UserName,Password,IPGroupName
```

For example:

	A	B	C	D
1	LocalUser	Username	Password	IPGroupName
2	John	johnd	2798	ITSP
3	Sue	suep	1234	IP-PBX
4				

You can upload the User Information file using any of the following methods:

- Web interface - SBC User Information table (see [Configuring SBC User Information Table through Web Interface](#) on page 803)

- CLI - **sbcs user-info-table import-csv-from** (see [Configuring SBC User Information Table through CLI](#) on page 806)
- Automatic Update mechanism - [SBCUserInfoFileUrl] parameter (see [Automatic Update Mechanism](#))

For **backward compatibility** only: When configuring a User Information file to upload through the Auxiliary Files page, use the following syntax:

[SBC]

FORMAT LocalUser,UserName,Password,IPGroupID

For example:

[SBC]

FORMAT LocalUser,UserName,Password,IPGroupID

John,johnd,2798,2

Sue,suep,1234,1

## Configuring Call Setup Rules

The Call Setup Rules table lets you configure up to 100 Call Setup Rules.

Call Setup Rules define various script-like sequences that the device runs upon the receipt of an incoming SIP dialog at call setup, before the device routes the call to its destination. You can configure multiple Call Setup Rules and group them under the same *Set ID*. This lets you run multiple Call Setup Rules for the same call setup dialog.

You can configure Call Setup Rules for any call direction - IP-to-IP (SBC), Tel-to-IP, or IP-to-Tel.

Call Setup Rules provide flexibility in implementing simple or complex script-like rules that you can use for various functionality:

- **LDAP Queries:** The device can be configured to use LDAP to query Microsoft's Active Directory (AD) server for specific user details needed for routing the call. For example, it could query for the user's office extension number, mobile number, private number, or display name. Call Setup Rules provides full flexibility in AD-lookup configuration to suit just about any deployment requirement:
  - Routing based on query results.
  - Queries based on any AD attribute.
  - Queries based on any attribute value (alphanumeric), including the use of the asterisk (\*) wildcard as well as the source number, destination number, redirect number, and SBC SIP messages. For example, the following Call Setup rule queries the attribute "proxyAddresses" for the record value "WOW:" followed by source number: "proxyAddresses=WOW:12345\*"
  - Conditional LDAP queries, for example, where the query is based on two attributes (&(telephoneNumber=4064)(company=ABC)).
  - Conditions for checking LDAP query results.

- Manipulation of call parameters such as source number, destination number, and redirect number and SBC SIP messages, while using LDAP query results.
- Multiple LDAP queries.

- **Dial Plan Queries:** You can use Call Setup Rules to query the Dial Plan table (see [Configuring Dial Plans](#) on page 825) for a specified key in a specified Dial Plan, to obtain the corresponding Dial Plan tag. Call Setup Rules can also change (modify) the name of the obtained tag. The device can then route the call using an IP-to-IP Routing rule (in the IP-to-IP Routing table) that has a matching tag (source or destination).

You can also use Call Setup Rules for complex routing schemes by using multiple Dial Plan tags. This is typically required when the source or destination of the call needs to be categorized with multiple characteristics. For example, tags can be used to categorize calls by department (source user) within a company, where only certain departments are allowed to place international calls.

- **ENUM Queries:** You can use Call Setup Rules to query an ENUM server and to handle responses from the ENUM server. ENUM translates ordinary telephone numbers (E.164 telephone numbers) into Internet addresses (SIP URIs), using the ENUM's DNS NAPTR records. For example, if the device receives an INVITE message whose destination number is in E.164 format, you can configure a Call Setup rule to query the ENUM server for the corresponding URI address, which is then used in the INVITE's Request-URI.
- **HTTP Requests (Queries):** You can use Call Setup Rules to query or notify an HTTP/S server, which is configured in the Remote Web Services table ([Configuring Remote Web Services](#) on page 438). If a response is expected from the server, the query is sent as an HTTP GET or HTTP POST request (configurable). If no response is required from the server (i.e., to notify the server of a specific condition), then an HTTP POST for notifications is sent (configurable).
- **Classification:** You can use Call Setup Rules triggered from SIP Interfaces to asynchronously query an external HTTP server (AudioCodes ARM) for a source tag, which can then be used to classify the incoming SIP dialog to a source IP Group. For additional query methods on classification based on tags, see [Configuring Classification Based on Tags](#) on page 1183.
- **Manipulation:** Manipulation (similar to Message Manipulations table) of call parameters (such as source number, destination number, and redirect number) and SBC SIP messages.
- **Conditions for Routing:** Routing conditions, for example, if the source number equals a specific value, then use the call routing rule.
- **Tag-based Routing:** You can use Call Setup Rules for tag-based routing. The Call Setup Rule Set is assigned to the IP-to-IP Routing rule ('Pre Route Call Setup Rules Set ID' parameter), whose 'Destination Type' parameter is configured to **Destination Tag** and 'Routing Tag Name' parameter to the name of the tag. When the tag is obtained by the Call Setup Rules (DstTags), the device searches the IP Groups table for a destination IP Group whose 'Tags' parameter matches this tag.

To use Call Setup Rules, you need to assign their Set ID to any of the following configuration entities:

- (SBC application) IP-to-IP Routing rules, using the 'Call Setup Rules Set ID' or 'Pre Route Call Setup Rules Set ID' parameters (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186)
- (SBC application) SIP Interface rules, using the 'Call Setup Rules Set ID' parameter (see [Configuring SIP Interfaces](#) on page 570)
- (Gateway application) Tel-to-IP Routing rules, using the 'Call Setup Rules Set ID' parameter (see [Configuring Tel-to-IP Routing Rules](#) on page 946)
- (Gateway application) IP-to-Tel Routing rules, using the 'Call Setup Rules Set ID' parameter (see [Configuring IP-to-Tel Routing Rules](#) on page 960)
- (SBC application) IP Groups, using the 'Call Setup Rules Set ID' parameter (see [Configuring IP Groups](#) on page 591)

- If you assign a Call Setup rule to an IP Group, the device runs the Call Setup rule for the classified source IP Group immediately before the routing stage. If you assign the Call Setup rule to a routing rule only, the device first locates a matching routing rule for the incoming call, runs the assigned Call Setup rule, and then routes the call according to the destination of the routing rule.
- If you want a Call Setup rule to run during the routing stage to determine the destination tag (when the 'Destination Type' parameter is configured to **Destination Tag**), you must assign the Call Setup rule in the IP-to-IP Routing table using the 'Pre Route Call Setup Rules Set ID' parameter (instead of 'Call Setup Rules Set ID'). For more information of these parameters, see the [Configuring SBC IP-to-IP Routing Rules](#) on page 1186.
- You can't run Call Setup Rules on SIP OPTIONS or any SIP message without a user-part in its URL.
- Call Setup Rules support synchronous (e.g., Dial Plan) and asynchronous (e.g., LDAP, ENUM, and HTTP) queries triggered by SIP Interfaces.

For routing, the device uses the selected routing rule for routing the call, depending on whether the condition of the Call Setup rule is met or not, and according to the 'Action Value' parameter's value when the 'Action Type' parameter is configured to **Exit**. The **Exit** value is used to discontinue with the Set ID (i.e., doesn't run remaining Call Setup Rules in the Set ID). For example, if you have 10 Call Setup Rules (#1-10) in the Set ID, you can configure rule #5 with **Exit** so that if its condition is met, it's the last one to run in the Set ID (i.e., rules #6-10 aren't run). Below explains route selection depending on condition and the **Exit** value:

- **Call Setup Rule's Condition is Met:** The device runs the Call Setup rule, and then runs the next rule in the Set ID until the last rule or until a rule whose 'Action Type' parameter is **Exit**. If there is an "exit" rule, the device's logic is according to the settings of the 'Action Value' parameter:
  - **True:** The device uses the selected routing rule to route the call.
  - **False:** The device searches for the next alternative routing rule (if exists).
  - **Abort:** The device stops (aborts) any further attempts to route the call (i.e., rejects call), even if additional alternative routing rules exist.

- **Call Setup Rule's Condition not Met:** The device runs the next Call Setup rule in the Set ID, and when it finishes running all the rules in the Set ID (and no "exit" rule exists), the Set ID ends with a "true" result. However, if there is an "exit" rule (i.e., 'Action Type' parameter is **Exit** and regardless of the 'Action Value' parameter's value), the device doesn't run the next Call Setup rule, and uses the selected routing rule to route the call.

The optional values **True**, **False**, and **Abort** for the 'Action Value' parameter, used when the 'Action Type' parameter is configured to **Exit** is applicable **only** when the Call Setup rule is run from the IP-to-IP Routing table. If run from any other configuration entity (e.g., SIP Interface), the device ignores these values.

The default result of a Call Setup rule is always "true" (**True**). Therefore, it's important to understand the logic when configuring the 'Action Type' field to **Exit**.

Examples:

- **Example 1:** To exit the Set ID with "true" if the LDAP query result is found, and with "false" if the LDAP query result isn't found:

- **Incorrect Configuration:** This rule always exits with result as "true":

- ◆ 'Condition': **ldap.found exists**
- ◆ 'Action Type': **Exit**
- ◆ 'Action Value': **True**

- **Correct Configuration:**

**Single rule:**

- ◆ 'Condition': **ldap.found !exists**
- ◆ 'Action Type': **Exit**
- ◆ 'Action Value': **False**

**Multiple rules:**

- ◆ 'Condition': **ldap.found exists**
- ◆ 'Action Type': **Exit**
- ◆ 'Action Value': **True**
- ◆ 'Condition': <leave empty>
- ◆ 'Action Type': **Exit**
- ◆ 'Action Value': **False**

- **Example 2:** Assume you've configured the following IP-to-IP Routing rules in the IP-to-IP Routing table:

- Index #1: 'Alternative Route Options' = **Route Row**; 'Destination Type' = **Destination Tag**

- Index #2: 'Alternative Route Options' = **Alternative Route Ignore Inputs**; 'Destination Type' = **Destination Tag**
- Index #3: 'Alternative Route Options' = **Alternative Route Ignore Inputs**; 'Destination Type' = **Destination Tag**
- Index #4: 'Alternative Route Options' = **Alternative Route Ignore Inputs**; 'Destination Type' = **Destination Tag**
- Index #5: 'Alternative Route Options' = **Alternative Route Ignore Inputs**; 'Destination Type' = **Destination Tag**

Assume the device is unable to route the call using rules #1 and #2, and is now processing rule #3. The device handles rule #3 according to the settings of the assigned Call Setup rule:

- 'Action Type' is **Exit** and 'Action Value' is **Abort**: If the rule's Condition is met, the device discontinues its attempt to route the call (doesn't try rules #4 or #5) and aborts call routing (i.e., call fails).
- 'Action Type' is **Exit** and 'Action Value' is **False**: If the rule's Condition is met, the device attempts to route the call using the next matching routing rule (#4).
- 'Action Type' is **Exit** and 'Action Value' is **True**: If the rule's Condition is met, the device sends a SIP INVITE message to the destination, according to routing rule #3. If the device receives a failure response to the INVITE, the device tries the next rule (i.e., #5) to route the call.

- If the source or destination numbers are manipulated by Call Setup Rules, they revert to their original values if the device moves to the next routing rule.
- For examples of Call Setup Rules, see [Examples of Call Setup Rules](#) on page 820.
- For a detailed description of the syntax for Call Setup Rules, refer to the document *SIP Message Manipulation Syntax Reference Guide* (click [here](#)).

The following procedure describes how to configure Call Setup Rules through the Web interface. You can also configure it through ini file [CallSetupRules] or CLI (`configure voip > message call-setup-rules`).

➤ **To configure a Call Setup rule:**

1. Open the Call Setup Rules table (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Call Setup Rules**).
2. Click **New**; the following dialog box appears:

3. Configure a Call Setup rule according to the parameters described in the table below.
4. Click **Apply**, and then save your settings to flash memory.

**Table 20-4: Call Setup Rules Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table record. <b>Note:</b> Each rule must be configured with a unique index.
'Name' rules-set-name [RulesSetName]	Defines an arbitrary name to easily identify the row. The valid value is a string of up to 20 characters. <b>Note:</b> Configure each row with a unique name.
'Rules Set ID' rules-set-id [RulesSetID]	Defines a Set ID for the rule. You can define the same Set ID for multiple rules to create a group of Call Setup Rules. You can configure up to 32 Set IDs, where each Set ID can include up to 10 rules. The Set ID is used to assign the Call Setup Rules to configuration entities (e.g., IP-to-IP Routing rules in the IP-to-IP Routing table). The valid value is 0 to 31. The default is 0. <b>Note:</b> You can configure up to 25 rules per Set ID.
'Request Type' request-type [QueryType]	Defines the type of query. <ul style="list-style-type: none"> <li>■ [0] <b>None</b> (default)</li> <li>■ [1] <b>LDAP</b> = The Call Setup rule runs an LDAP query with an LDAP server. To specify an LDAP server, use the 'Request Target' parameter (see below).</li> <li>■ [2] <b>Dial Plan</b> = The Call Setup rule runs a query with the Dial Plan. To specify a Dial Plan, use the 'Request Target' parameter (see below).</li> <li>■ [3] <b>ENUM</b> = The Call Setup rule runs a query with an ENUM (E.164 Number to URI Mapping) server for retrieving a SIP URI address for an E.164 telephone number. The ENUM</li> </ul>

Parameter	Description
	<p>server's address is the address configured for the 'Primary DNS' (and optionally, 'Secondary DNS') parameters of the IP Interface (in the IP Interfaces table) that is specified in the 'Request Target' parameter (see below). For a configuration example, see <a href="#">Examples of Call Setup Rules</a> on page 820.</p> <ul style="list-style-type: none"> <li>■ <b>[4] HTTP GET</b> = The Call Setup rule runs an HTTP GET request (query) with an HTTP/S server. To specify an HTTP server, use the 'Request Target' parameter (see below).</li> <li>■ <b>[5] HTTP POST Query</b> = The Call Setup rule runs an HTTP POST request (query) with an HTTP/S server and expects a response from the server. To specify an HTTP server, use the 'Request Target' parameter (see below).</li> <li>■ <b>[6] HTTP POST Notification</b> = The Call Setup rule runs an HTTP POST request to notify an HTTP/S server of a specific condition and doesn't expect a response from the server. For example, you can configure a rule to notify the server of a 911 emergency call. To specify an HTTP server, use the 'Request Target' parameter (see below).</li> </ul>
'Request Target' request-target [QueryTarget]	<p>Defines one of the following, depending on the value configured for the 'Request Type' parameter (above).</p> <ul style="list-style-type: none"> <li>■ <b>LDAP:</b> Defines an LDAP server (LDAP Server Group) on which to run an LDAP query for a defined key. To configure LDAP Server Groups, see <a href="#">Configuring LDAP Server Groups</a> on page 382.</li> <li>■ <b>Dial Plan:</b> Defines a Dial Plan (name) in which to search for a defined key. To configure Dial Plans, see <a href="#">Configuring Dial Plans</a> on page 825.</li> <li>■ <b>ENUM:</b> Specifies the ENUM server on which to run the ENUM query. The server is specified by IP Interface name (in the IP Interfaces table). The address of the ENUM server is the address of the 'Primary DNS' (and optionally, 'Secondary DNS') parameters that is configured for the specified IP Interface. If you don't specify an IP Interface or the specified IP Interface doesn't exist in the IP Interfaces table, the device uses the OAMP IP Interface.</li> <li>■ <b>HTTP GET, HTTP POST Query, and HTTP POST Notification:</b> Defines the HTTP server to where the device sends the HTTP request. To configure HTTP servers, see <a href="#">Configuring Remote Web Services</a> on page 438.</li> </ul>

Parameter	Description
	To configure the key, use the 'Request Key' parameter (see below).
'Request Key' request-key [AttributesToQuery]	<p>Defines the key to query.</p> <ul style="list-style-type: none"> <li>■ For LDAP, the key string is queried on the LDAP server.</li> <li>■ For Dial Plans, the key string is searched in the specified Dial Plan.</li> <li>■ For ENUM, the key string is queried on the ENUM server.</li> <li>■ For HTTP GET and HTTP POST queries, the key string is queried on the HTTP server.</li> </ul> <p>The valid value is a string of up to 100 characters. Combined strings and values can be configured like in the Message Manipulations table, using the '+' operator. Single quotation marks (') can be used for specifying a constant string (e.g., '12345').</p> <p>You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ To LDAP query the AD attribute "mobile" that has the value of the destination user part of the incoming call: <div>'mobile=' + param.call.dst.user</div> </li> <li>■ To LDAP query the AD attribute "telephoneNumber" that has a redirect number: <div>'telephoneNumber=' + param.call.redirect + '*'</div> </li> <li>■ To query a Dial Plan for the source number: <div>param.call.src.user</div> </li> <li>■ To query an ENUM server for the URI of the called (destination) number: <div>param.call.dst.user</div> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>To send an HTTP POST to notify the HTTP server of call connection status:</li> </ul> <div>'connectionStatus'</div> <p><b>Note:</b> The parameter is applicable only if the 'Request Type' parameter is configured to any value other than <b>None</b>.</p>
'Attributes To Get' attr-to-get [AttributesToGet]	<p>Defines the Attributes of the queried LDAP record that the device must handle (e.g., retrieve value).</p> <p>The valid value is a string of up to 255 characters. Up to five attributes can be defined, each separated by a comma (e.g., msRTCSIP-PrivateLine,msRTCSIP-Line,mobile).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>The parameter is applicable only if you configure the 'Request Type' parameter to <b>LDAP</b>.</li> <li>The device saves the retrieved attributes' values for future use in other rules until the next LDAP query or until the call is connected. Thus, the device doesn't need to re-query the same attributes.</li> </ul>
'Row Role' row-role [RowRole]	<p>Defines which condition (as configured in the 'Condition' parameter) must be met for this rule to be run.</p> <ul style="list-style-type: none"> <li>[0] <b>Use Current Condition</b> = (Default) The Condition configured for this rule must be met to run the configured action.</li> <li>[1] <b>Use Previous Condition</b> = The Condition configured for the rule located directly above this rule in the Call Setup table must be met to run the configured action. This option lets you configure multiple actions for the same Condition.</li> </ul>
'Condition' condition [Condition]	<p>Defines the condition that must exist for the device to run the configured action of the Call Setup rule.</p> <p>The valid value is a string of up to 200 characters (case-insensitive). You can also use regular expression (regex).</p> <p>You can use the built-in syntax editor to help configure the parameter. Click the <b>Editor</b> button located next to the field to open the Editor, and then simply follow the on-screen instructions.</p> <p>Examples:</p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ LDAP: <ul style="list-style-type: none"> <li>✓ ldap.attr.mobile exists (if Attribute "mobile" exists in AD)</li> <li>✓ param.call.dst.user == ldap.attr.msRTCSIP-PrivateLine (if called number is the same as the number in the Attribute "msRTCSIP-PrivateLine")</li> <li>✓ ldap.found !exists (if LDAP record not found)</li> <li>✓ ldap.err exists (if LDAP error exists)</li> </ul> </li> <li>■ Dial Plan: <ul style="list-style-type: none"> <li>✓ dialplan.found exists (if Dial Plan exists)</li> <li>✓ dialplan.found !exists (if Dial Plan queried key not found)</li> <li>✓ dialplan.result=='uk' (if corresponding tag of the searched key is "uk")</li> </ul> </li> <li>■ ENUM: <ul style="list-style-type: none"> <li>✓ enum.found exists (if ENUM record of E.164 number exists)</li> </ul> </li> <li>■ HTTP GET or HTTP POST: <ul style="list-style-type: none"> <li>• http.response.status == '200' (if the HTTP server responds with a 200 OK)</li> </ul> </li> </ul>
Action	
'Action Subject' action-subject [ActionSubject]	<p>Defines the element (e.g., SIP header, SIP parameter, SIP body, or Dial Plan tag) upon which you want to run the action if the condition (configured in the 'Condition' parameter above) is met. The valid value is a string of up to 100 characters (case-insensitive). You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ header.from contains '1234' (SBC application only)</li> <li>■ param.call.dst.user (called number)</li> <li>■ param.call.src.user (calling number)</li> <li>■ param.call.src.name (calling name)</li> <li>■ param.call.redirect (redirect number)</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ param.call.src.host (source host)</li> <li>■ param.call.dst.host (destination host)</li> <li>■ srctags (source tag)</li> <li>■ dsttags (destination tag)</li> <li>■ referredbytags (tag of transferor, which initiates call transfer)</li> <li>■ header.content-type (for HTTP POST requests)</li> </ul>
'Action Type' action-type [ActionType]	<p>Defines the type of action to run.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>None</b> = No action is run. This option is typically used for HTTP POST requests that are used for notifying the HTTP server (e.g., when the 'Request Type' parameter is configured to <b>HTTP POST Notification</b>). If you configure the parameter to this option and it is the last rule in the table, the device runs the rule and then exits the table. If it is not the last rule, the device runs the rule and then checks the next rule.</li> <li>■ [0] <b>Add</b> = (Default) Adds a new message header, parameter, or body elements.</li> <li>■ [1] <b>Remove</b> = Removes a message header, parameter, or body elements.</li> <li>■ [2] <b>Modify</b> = Sets the element to the new value (all element types).</li> <li>■ [3] <b>Add Prefix</b> = Adds a value at the beginning of the string (string element only).</li> <li>■ [4] <b>Add Suffix</b> = Adds a value at the end of the string (string element only).</li> <li>■ [5] <b>Remove Suffix</b> = Removes a value from the end of the string (string element only).</li> <li>■ [6] <b>Remove Prefix</b> = Removes a value from the beginning of the string (string element only).</li> <li>■ [20] <b>Run Rules Set</b> = Runs a different Rule Set ID, which is specified in the 'Action Value' parameter (see below)</li> <li>■ [21] <b>Exit</b> = Stops running the remaining rules in the Rule Set ID and returns a result ("true", "false", or "abort").</li> </ul>
'Action Value' action-value	<p>Defines a value for the action.</p> <p>The valid value is a string of up to 300 characters (case-</p>

Parameter	Description
[ActionValue]	<p>insensitive). You can use the built-in syntax editor to help configure the field. Click the <b>Editor</b> button located next to the field to open the Editor, and then simply follow the on-screen instructions.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ '+9723976'+ldap.attr.alternateNumber</li> <li>■ '9764000'</li> <li>■ ldap.attr.displayName</li> <li>■ enum.result.url</li> <li>■ srctags</li> <li>■ http.response.body</li> <li>■ application/x-www-form-urlencoded (for HTTP Content-Type header in HTTP requests)</li> <li>■ <b>True</b></li> <li>■ <b>False</b></li> <li>■ <b>Abort</b></li> </ul> <p><b>Note:</b> The values <b>True</b>, <b>False</b>, and <b>Abort</b> are applicable only when the 'Action Type' parameter is configured to <b>Exit</b> and only when the Call Setup rule is run from the IP-to-IP Routing table. For a description of these values, see the first part of this section.</p>

## Examples of Call Setup Rules

Below are configuration examples of Call Setup Rules.

- **Example 1:** This example configures the device to replace (manipulate) the incoming call's source number with a number retrieved from the Microsoft Active Directory (AD) by an LDAP query. The device queries the AD server for the attribute record, "telephoneNumber" whose value is the same as the received source number (e.g., "telephoneNumber=4064"). If such an Attribute exists, the device retrieves the number of the attribute record, "alternateNumber" and uses this number as the source number.

- **Call Setup Rules Table:**

- ◆ 'Rules Set ID': **1**
- ◆ 'Request Type': **LDAP**
- ◆ 'Request Target': **LDAP-DC-CORP**
- ◆ 'Request Key': **'telephoneNumber=' + param.call.src.user**

- ◆ 'Attributes to Get': **alternateNumber**
- ◆ 'Row Role': **Use Current Condition**
- ◆ 'Condition': **ldap.attr.alternateNumber exists**
- ◆ 'Action Subject': **param.call.src.user**
- ◆ 'Action Type': **Modify**
- ◆ 'Action Value': **ldap.attr.alternateNumber**
- **IP-to-IP Routing Table:**
  - ◆ (Index 1) 'Call Setup Rules Set ID' or 'Pre Route Call Setup Rules Set ID': **1**

■ **Example 2:** This example configures the device to replace (manipulate) the incoming call's calling name (caller ID) with a name retrieved from the AD by an LDAP query. The device queries the AD server for the attribute record "telephoneNumber" whose value is the same as the received source number (e.g., "telephoneNumber=5098"). If such an attribute is found, the device retrieves the name from the attribute record "displayName" and uses it as the calling name of the incoming call.

- **Call Setup Rules Table:**
  - ◆ 'Rules Set ID': **2**
  - ◆ 'Request Type': **LDAP**
  - ◆ 'Request Target': **LDAP-DC-CORP**
  - ◆ 'Request Key': **'telephoneNumber=' + param.call.src.user**
  - ◆ 'Attributes to Get': **displayName**
  - ◆ 'Row Role': **Use Current Condition**
  - ◆ 'Condition': **ldap.attr.displayName exists**
  - ◆ 'Action Subject': **param.call.src.name**
  - ◆ 'Action Type': **Modify**
  - ◆ 'Action Value': **ldap.attr.displayName**
- **IP-to-IP Routing table:** A single routing rule is assigned the Call Setup Rule Set ID.
  - ◆ (Index 1) 'Call Setup Rules Set ID' or 'Pre Route Call Setup Rules Set ID': **2**

■ **Example 3:** This example configures the device to route the incoming call according to whether or not the source number of the incoming call also exists in the AD server. The device queries the AD server for the attribute record "telephoneNumber" whose value is the same as the received source number (e.g., telephoneNumber=4064"). If such an attribute is found, the device sends the call to Teams. If the query fails, the device sends the call to the PBX (i.e., alternative routing).

- **Call Setup Rules Table:**
  - ◆ 'Rules Set ID': **3**

- ◆ 'Request Type': **LDAP**
- ◆ 'Request Target': **LDAP-DC-CORP**
- ◆ 'Request Key': **'telephoneNumber=' + param.call.src.user**
- ◆ 'Attributes to Get': **telephoneNumber**
- ◆ 'Row Role': **Use Current Condition**
- ◆ 'Condition': **ldap.found !exists**
- ◆ 'Action Subject': **-**
- ◆ 'Action Type': **Exit**
- ◆ 'Action Value': **False**

If the attribute record is found (i.e., condition not met), the rule ends with a default exit result of "true" and uses the first routing rule (Teams). If the attribute record doesn't exist (i.e., condition met), the rule exits with a "false" result and uses the second routing rule (PBX).

- **IP-to-IP Routing Table:** Two routing rules are assigned with the same matching characteristics. Only the main routing rule is assigned a Call Setup Rules Set ID.
  - ◆ 'Index': **1**
  - ◆ 'Call Setup Rules Set ID' or 'Pre Route Call Setup Rules Set ID': **3**
  - ◆ 'Destination IP Group ID': **3** (IP Group for Teams)
  - ◆ 'Index': **2**
  - ◆ 'Destination IP Group ID': **4** (IP Group for PBX)

■ **Example 4:** This example uses the msRTCSIP-DeploymentLocator AD attribute to determine if a user has migrated to Teams or not. If the LDAP query fails (attribute doesn't exist), the call fails and the device doesn't attempt (stops / aborts) to route the call, even if alternative routing rules exist.

- **Call Setup Rules Table:**
  - ◆ 'Rules Set ID': **1**
  - ◆ 'Request Type': **LDAP**
  - ◆ 'Request Target': **LDAP-DC-CORP**
  - ◆ 'Request Key': **'(&(msRTCSIP-DeploymentLocator=SRV:)(msRTCSIP-Line=tel:'+param.call.dst.user+'\*))'**
  - ◆ 'Attributes to Get': **msRTCSIP-DeploymentLocator**
  - ◆ 'Row Role': **Use Current Condition**
  - ◆ 'Condition': **ldap.attr.msRTCSIP-DeploymentLocator !exists**
  - ◆ 'Action Type': **Exit**

- ◆ 'Action Value': **Abort**
- **IP-to-IP Routing table:**
  - ◆ (Index 1) 'Call Setup Rules Set ID' or 'Pre Route Call Setup Rules Set ID': **1**

■ **Example 5:** This example enables routing based on LDAP queries and destination tags for matching routing rules. The device queries the LDAP server for the attribute record "telephoneNumber" whose value is the destination number of the incoming call (e.g., "telephoneNumber=4064"). If the attribute-value combination is found, the device retrieves the string value of the attribute record "ofiSBCRouting" and creates a destination tag with the name of the retrieved string. The destination tag is then used as a matching characteristics in the IP-to-IP Routing table.

- **Call Setup Rules Table:**
  - ◆ 'Rules Set ID': **4**
  - ◆ 'Request Type': **LDAP**
  - ◆ 'Request Target': **LDAP-DC-CORP**
  - ◆ 'Request Key': **'telephoneNumber='+param.call.dst.user**
  - ◆ 'Attributes to Get': **ofiSBCRouting**
  - ◆ 'Row Role': **Use Current Condition**
  - ◆ 'Condition': **ldap.found exists**
  - ◆ 'Action Subject': **dsttags**
  - ◆ 'Action Type': **Modify**
  - ◆ 'Action Value': **ldap.attr.ofiSBCrouting**
- **IP Groups Table:** 'Call Setup Rules Set ID': **4**
- **IP-to-IP Routing Table:**
  - ◆ 'Index': **1**
  - ◆ 'Destination Tag': **dep-sales**
  - ◆ 'Destination IP Group': **SALES**
  - ◆ 'Index': **2**
  - ◆ 'Destination Tag': **dep-mkt**
  - ◆ 'Destination IP Group': **MKT**
  - ◆ 'Index': **3**
  - ◆ 'Destination Tag': **dep-rd**
  - ◆ 'Destination IP Group': **RD**

■ **Example 6:** This example enables routing based on LDAP queries and destination tags for matching destination IP Groups. The device queries the LDAP server for the attribute

record "telephoneNumber" whose value is the destination number of the incoming call (e.g., "telephoneNumber=4064"). If the attribute-value combination is found, the device retrieves the string value of the attribute record "CountryOfResidence" and creates a destination tag with the name of the retrieved string. The value of the destination tag name is then used as a matching characteristics of the IP Group.

- **Call Setup Rules Table:**
  - ◆ 'Rules Set ID': **4**
  - ◆ 'Request Type': **LDAP**
  - ◆ 'Request Target': **LDAP-DC-CORP**
  - ◆ 'Request Key': **'telephoneNumber='+param.call.dst.user**
  - ◆ 'Attributes to Get': **CountryOfResidence**
  - ◆ 'Row Role': **Use Current Condition**
  - ◆ 'Condition': **ldap.found exists**
  - ◆ 'Action Subject': **DstTags.Country**
  - ◆ 'Action Type': **Modify**
  - ◆ 'Action Value': **ldap.attr.CountryOfResidence**
- **IP Groups Table:**
  - ◆ 'Index': **1**
  - ◆ 'Tags': **Country=UK**
  - ◆ 'Index': **2**
  - ◆ 'Tags': **Country=FR**
- **IP-to-IP Routing Table:**
  - ◆ 'Destination Type': **Destination Tag**
  - ◆ 'Pre Route Call Setup Rules Set ID': **4**
  - ◆ 'Routing Tag Name': **Country**

■ **Example 7:** This example configures the device to run an ENUM query with an ENUM server to retrieve a SIP URI address for the called E.164 telephone number. The device then replaces (manipulates) the incoming call's E.164 destination number in the SIP Request-URI header with the URI retrieved from the ENUM server. The ENUM server's address is the address configured in the 'Primary DNS' parameter for the "ITSP-450" IP Interface in the IP Interfaces table.

- **Call Setup Rules Table:**
  - ◆ 'Index': **0**
  - ◆ 'Rules Set ID': **4**

- ◆ 'Request Type': **ENUM**
  - ◆ 'Request Target': **ITSP-450**
  - ◆ 'Request Key': **param.call.dst.user**
  - ◆ 'Condition': **enum.found exists**
  - ◆ 'Action Subject': **header.request-uri.url**
  - ◆ 'Action Type': **Modify**
  - ◆ 'Action Value': **enum.result.url**
  - **IP Groups Table:**
    - ◆ 'Call Setup Rules Set ID': **4**
- **Example 8:** For an example on HTTP GET operations, see [Configuring an HTTP GET Web Service](#) on page 456.
- **Example 9:** For an example on HTTP POST (notification) operations, see [Configuring HTTP POST Web Service](#) on page 459.

## Configuring Dial Plans

Dial Plans let you categorize incoming calls (source or destination) based on source or destination number. The device categorizes them by searching in the Dial Plan for rules that match these numbers according to prefix, suffix, or whole number. The categorization result in the Dial Plan is a *tag* corresponding to the matched rule. You can then use tags to represent these calls (source or destination) as matching characteristics (source or destination tags) for various configuration entities:

- SBC application:
- IP-to-IP Routing rules (see [Using Dial Plan Tags for SBC IP-to-IP Routing](#) on page 840)
  - Outbound Manipulations rules ([Using Dial Plan Tags for SBC Outbound Manipulation](#) on page 848)
  - Call Setup Rules ([Using Dial Plan Tags for Call Setup Rules](#) on page 848)
  - Message Manipulation ([Using Dial Plan Tags for Message Manipulation](#) on page 851)

You can assign a Dial Plan to an IP Group or SRD. After Classification and Inbound Manipulation, the device checks if a Dial Plan is associated with the incoming call. It first checks the source IP Group and if no Dial Plan is assigned, it checks the SRD. If a Dial Plan is assigned to the IP Group or SRD, the device first searches the Dial Plan for a dial plan rule that matches the source number and then it searches the Dial Plan for a rule that matches the destination number. If matching dial plan rules are found, the tags configured for these rules are used in the routing or manipulation processes as source or destination tags.

In addition to using the source tag (SrcTags) and destination tag (DstTags) in the Call Setup Rules table and Message Manipulations table, you can also use the referred-by tag (ReferredByTags). This tag represents the call party that initiated (i.e., transferor) the call transfer.

■ Gateway application:

- IP-to-Tel Routing rules (see [Configuring IP-to-Tel Routing Rules](#) on page 960)
- Tel-to-IP Routing rules (see [Configuring Tel-to-IP Routing Rules](#) on page 946)

Notes for the SBC application:

- User categorization by Dial Plan is done only after the device's Classification and Inbound Manipulation processes, and before the routing process.
- Once the device successfully categorizes an incoming call by Dial Plan, it not only uses the resultant tag in the immediate routing or manipulation process, but also in subsequent routing and manipulation processes that may occur, for example, due to alternative routing or local handling of call transfer and call forwarding (SIP 3xx\REFER).
- For manipulation, tags are applicable only to outbound manipulation.
- When tags are used in the IP-to-IP Routing table to determine destination IP Groups (i.e., 'Destination Type' parameter configured to **Destination Tag**), the device searches the Dial Plan for a matching **destination** (called) prefix number only.

The figure below shows a conceptual example of routing based on tags, where users categorized as tag "A" are routed to SIP Trunk "X" and those categorized as tag "B" are routed to SIP Trunk "Y":

The Dial Plan itself is a set of dial plan rules having the following attributes:

- **Prefix:** The prefix is matched against the source or destination number of the incoming call (e.g., SIP dialog-initiating request for IP calls).
- **Tag:** The tag corresponds to the matched prefix of the source or destination number and is the categorization result.

You can use various syntax notations to configure the prefix numbers in Dial Plan rules. You can configure the prefix as a complete number (all digits) or as a partial number using some digits and various syntax notations (patterns) to allow the device to match a Dial Plan rule for similar source or destination numbers. The device also employs a "best-match" method instead of a "first-match" method to match the source or destination numbers to the patterns configured in the Dial Plan. For more information, see the description of the 'Prefix' parameter (DialPlanRule\_Prefix) described later in this section or see [Dial Plan Notations and Priority Matching](#) on page 831.

- The maximum group of numbers (consisting of single numbers or range of numbers, or both) that can be configured for prefixes and suffixes for all the Dial Plan rules can be calculated by multiplying the maximum number of supported Dial Plan rules by six. For example, if the maximum number of Dial Plan rules is 100, then the maximum group of numbers is 600 (6\*100). The following is an example of a Dial Plan rule that is configured with six groups of numbers (each separated by a comma), consisting of ranges and single numbers: [120-125,150,160-164,170,200,210-215]
- You can forcibly disconnect calls that match a specific Dial Plan tag, using the CLI command `clear voip calls tag`.

Dial Plans are configured using two tables with "parent-child" relationship:

- Dial Plan table ("parent" table): Defines the name of the Dial Plan. You can configure up to 10 Dial Plans.
- Dial Plan Rule table ("child" table): Defines the actual dial plans (rules) per Dial Plan. You can configure up to 2,000 of Dial Plan rules in total (where all can be configured for one Dial Plan or configured between different Dial Plans).

The following procedure describes how to configure Dial Plans through the Web interface. You can also configure it through other management platforms:

- **Dial Plan table:** *ini* file [DialPlan] or CLI (`configure voip > sbc dial-plan`)
- **Dial Plan Rule table:** *ini* file (DialPlanRule) or CLI (`configure voip > sbc dial-plan-rule`)

#### ➤ To configure Dial Plans:

1. Open the Dial Plan table (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Dial Plan**).
2. Click **New**; the following dialog box appears:

Dial Plan - x

GENERAL

Index	<input style="width: 70%;" type="text" value="2"/>
Name	<input style="width: 70%;" type="text"/>
Prefix Case Sensitivity	<input style="width: 70%;" type="text" value="Enable"/>

3. Configure a Dial Plan name according to the parameters described in the table below.
4. Click **Apply**.

**Table 20-5: Dial Plan Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 15 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>
'Prefix Case Sensitivity' prefix-case-sensitivity [PrefixCaseSensitivity]	Enables the matching process for the Dial Plan's prefix patterns, configured for its Dial Plan rules, to take into consideration the case (upper or lower) of alphabetical letters. <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> = Case-insensitive - the Dial Plan matching process ignores the case of the letters of the prefix pattern.</li> <li>■ [1] <b>Enable</b> = (Default) Case-sensitive - the Dial Plan matching process takes into consideration the case of the letters of the prefix pattern.</li> </ul> <b>Note:</b> The wildcards "n", "x", and "z" are always case-insensitive.

5. In the Dial Plan table, select the row for which you want to configure dial plan rules, and then click the **Dial Plan Rule** link located below the table; the Dial Plan Rule table appears.
6. Click **New**; the following dialog box appears:

Dial Plan Rule
— ×

GENERAL

Index

1

Name

Prefix

Tag

7. Configure a dial plan rule according to the parameters described in the table below.
8. Click **New**, and then save your settings to flash memory.

**Table 20-6: Dial Plan Rule Table Parameter Descriptions**

Parameter	Description
'Index' index [DialPlanRule_RuleIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [DialPlanRule_Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 15 characters.
'Prefix' prefix [DialPlanRule_Prefix]	Defines the pattern to match the number (source or destination number) of the incoming call. The pattern can match the number based on prefix, suffix, or entire number. The valid value is a string of up to 50 characters. For valid notations and syntax, see <a href="#">Dial Plan Notations and Priority Matching</a> on page 831. <b>Note:</b> Dial Plan patterns can be case-sensitive or case-insensitive, depending on the 'Prefix Case Sensitive' parameter settings.
'Tag' tag [DialPlanRule_Tag]	Defines a tag(s). You must configure the tag with a name (e.g., "India") and optionally, with a value (i.e., name=value), for example, "Country=India", where "Country" is the tag's name and "India" is the tag's value. For guidelines on configuring tags, see the notes below. The valid value is a string of up to 70 characters: <ul style="list-style-type: none"> <li>■ The tag's name can contain only the following characters: <ul style="list-style-type: none"> <li>✓ Alphanumeric characters (i.e., a-z, A-Z, and 0-9)</li> <li>✓ Special characters: <ul style="list-style-type: none"> <li>• - (dash or hyphen)</li> <li>• ! (exclamation)</li> <li>• % (percentage)</li> <li>• * (asterisk)</li> <li>• _ (underscore)</li> <li>• ~ (tilde)</li> </ul> </li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>• @ (at sign)</li> </ul> <ul style="list-style-type: none"> <li>■ The tag's value can contain any character, except the following: <ul style="list-style-type: none"> <li>✓ = (equal)</li> <li>✓ ; (semicolon)</li> <li>✓ Spaces (including tab spaces)</li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The tag is case-insensitive.</li> <li>■ You can configure a rule with multiple tags, where each is separated with a semicolon (;). For example:  "Belgium;Country1=England;Country2=India;Country3=10.1.1.1"</li> <li>■ If you configure a rule with multiple tags, you can configure only one tag that has a <b>name only</b> (i.e., without a value). All the other tags must have a name and value (name=value). For example:  "Belgium;England" is invalid as both tags have only names.  "Belgium;Country1=England;Country2=India" is valid as only one tag has only a name ("Belgium"); the others have names and values.</li> <li>■ If you configure a rule with multiple tags, for the tags that have a name and value (i.e., name=value), the name must be unique. For example:  "<b>Country</b>=England;<b>Country</b>=India" is invalid as the tag name "Country" appears twice.  "<b>Country1</b>=England;<b>Country2</b>=India" is valid.</li> <li>■ You can configure multiple rules with the same tag, but each of these rules must have a different prefix (see 'Prefix' parameter).</li> <li>■ In configuration tables that contain fields for assigning tags (e.g., IP-to-IP Routing table), if the field is left empty or configured with a single asterisk (*), any tag can match it.</li> </ul>

## Dial Plan Notations and Priority Matching

This section describes the [Dial Plan Notations](#) below you can use in your Dial Plan rules and the [Dial Plan Matching Priority](#) on page 834 between rules.

### Dial Plan Notations

The notations that you can use for configuring the 'Prefix' field in the Dial Plan Rule table are described in the table below. As this field is used in the Dial Plan to match a number pattern (source or destination) based on prefix, suffix or entire number, the notations are relevant to both prefix and suffix of the number (unless explicitly stated otherwise).

Notation	Description
<b>0-9</b>	Specific digit.
<b>a-z</b>	Lower-case letter. <b>Note:</b> Case-sensitivity of Dial Plan matching depends on the settings of the 'Prefix Case Sensitivity' parameter in the Dial Plan table.
<b>A-Z</b>	Upper-case letter. <b>Note:</b> Case-sensitivity of Dial Plan matching depends on the settings of the 'Prefix Case Sensitivity' parameter in the Dial Plan table.
<b>x</b>	Wildcard (metacharacter) that represents any single digit from 0 through 9. <b>Note:</b> <ul style="list-style-type: none"> <li>The wildcard is case-insensitive.</li> <li>To represent the character "x", precede it with the escape "\" character. For example, to represent an upper-case "X", use this syntax: \X</li> </ul>
<b>z</b>	Wildcard (metacharacter) that represents any single digit from 1 through 9. <b>Note:</b> <ul style="list-style-type: none"> <li>The wildcard is case-insensitive.</li> <li>To represent the character "z", precede it with the escape "\" character. For example, to represent a lower-case "z", use this syntax: \z</li> </ul>
<b>n</b>	Wildcard (metacharacter) that represents any single digit from 2 through 9. <b>Note:</b>

Notation	Description
	<ul style="list-style-type: none"> <li>■ The wildcard is case-insensitive.</li> <li>■ To represent the character "n", precede it with the escape "\" character. For example, to represent an upper-case "N", use this syntax: \N</li> </ul>
.	<p>(Dot) Wildcard (metacharacter) that represents any single character (letter, digit or symbol).</p> <p>To represent the dot "." character itself, precede it with the escape "\" character (see below).</p>
*	<p>(Asterisk symbol) If it is the only character in the rule, it functions as a wildcard (metacharacter) that represents any amount of digits or letters (i.e., matches everything).</p> <p>To represent the asterisk "*" symbol itself, precede it with the escape "\" character (see below).</p> <p><b>Note:</b> You can't use a non-escaped * as part of the rule. For example, the following are invalid rules: "333*" or "192\168\0\.*"</p>
\	<p>(Backslash escape character) When it prefixes the wildcard character "n", "x", "z", or ".", the character is escaped and used literally instead of the wildcard function.</p> <p>For example, "10\255\255\.x" represents the IP address 10.255.255.[0-9]. As each dot (.) is prefixed by a backslash, the device considers these dots as the "." character (and not the . wildcard). In addition, as the "x" at the end of the value is not prefixed by a backslash, the device considers it the x wildcard.</p>
#	<p>(Pound or hash symbol) When used at the end of the prefix, it represents the end of the number.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ 54324#: Represents the 5-digit number "54324".</li> <li>■ 192\168\1\.[1-9]# and 192\168\1\.[01-96]#: Represent IP addresses 192.168.1.1 to 192.168.1.96</li> </ul>
[n1-m1,n2-m2,a,b,c,...]	<p>Represents a range of numbers for the prefix. The range can include both contiguous numbers and standalone numbers.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ [123-130]: Represents a prefix number "123" through "130".</li> <li>■ [123-130,455,766,780-790]: Represents a prefix number from "123" through "130", "455", "766", or "780" through 790".</li> </ul>

Notation	Description
	<ul style="list-style-type: none"> <li>■ [123,125,130]: Represents a prefix number “123”, “125”, or “130”.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The range (number ranges and single numbers) must contain the same amount of digits, as shown in the examples above where the number ranges and single numbers all contain three digits.</li> <li>■ The device matches the numbers in the range and not the individual digits that make up the numbers. For example, if the rule’s pattern is “[001-130]”, the device matches strings such as “002”, “012”, “129” or “1001”; it doesn’t match strings “2”, “12”, “301” or “0002”.</li> <li>■ You can’t use an empty range (e.g., “+91[]”).</li> <li>■ Ranges can contain only digits (i.e., letters are not allowed).</li> <li>■ The mixed notation can be configured with up to 19 digits, for example, “[1234567891234567890,1234567891234567891]”.</li> <li>■ The range (start and end) cannot be greater than 2,147,483,647, as in the example (which is invalid) “[20000000001-40000000001]”.</li> </ul>
([...])	<p>Represents a range of numbers for the suffix.</p> <p>The range can include both contiguous numbers and standalone numbers.</p> <p>Examples:</p> <ul style="list-style-type: none"> <li>■ ([123-130]): Represents a suffix number “123” through “130”.</li> <li>■ ([123-130,455,766,780-790]): Represents a suffix number from “123” through “130”, “455”, “766”, or “780” through “790”.</li> <li>■ [123,125,130]: Represents a suffix number “123”, “125”, or “130”.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The range (number ranges and single numbers) must contain the same amount of digits, as shown in the examples above where the number ranges and single numbers all contain three digits.</li> <li>■ The device matches the numbers in the range and not the individual digits that make up the numbers. For example, if the rule’s pattern is “([001-130])”, the device matches strings such as “002”, “012”, “129” or “9129”; it doesn’t match strings “2”, “12”, “302” or “0200”.</li> <li>■ You can’t use an empty suffix range (e.g., “+91([])”).</li> <li>■ Ranges can contain only digits (i.e., letters are not allowed).</li> <li>■ The mixed notation can be configured with up to 19 digits, for example, “([1234567891234567890,1234567891234567891])”.</li> </ul>

Notation	Description
	<ul style="list-style-type: none"> <li>The range (start and end) cannot be greater than 2,147,483,647, as in the example (which is invalid) “([20000000001-40000000001])”.</li> </ul>
(...)	<p>Represents a specific suffix, which can contain digits and letters. Examples:</p> <ul style="list-style-type: none"> <li>[123-130](456): represent a number whose prefix number is “123” through “130” and whose suffix is “456”.</li> <li>123(UK): represent a number whose prefix number is “123” and whose suffix is “UK”.</li> </ul> <p><b>Note:</b> You can't use an empty suffix (e.g., "+91()").</p>

### Dial Plan Matching Priority

The device employs a "best-match" method instead of a "first-match" method to match the source or destination numbers to prefixes configured in the Dial Plan.

The matching order is done digit-by-digit and from left to right.

The **best match-priority** is listed below in chronological order:

1. Specific prefix.
2. "x" wildcard, which denotes any digit (0 through 9).
3. Number range.
4. "n" wildcard, which denotes a number from 2 through 9.
5. "z" wildcard, which denotes a number from 1 through 9.
6. Suffix, where the longest digits is first matched, for example, ([001-999]) takes precedence over ([01-99]) which takes precedence over ([1-9]).
7. "." (dot), which denotes any single character.

For example, the following table shows best matching priority for an incoming call with prefix number "5234":

**Table 20-7: Dial Plan Best Match Priority**

Dial Plan Prefix	Best Match Priority (Where 1 is Highest)
5234	1
523x	2
523[2-6]	3

Dial Plan Prefix	Best Match Priority (Where 1 is Highest)
523n	4
523z	5
523(4)	6
523.	7

When number ranges are used in Dial Plan rules (comma-separated standalone numbers or hyphenated range), best match priority is as follows:

- Dial Plan rules with ranges of **multiple standalone numbers**: The device chooses the matching rule in the Dial Plan Rule table that has the lowest row index number (i.e., listed higher up in the table). For example, if the prefix number of an incoming call is "110" and you have configured the below rules, the device chooses Index #0 because it has the lowest row index number (even though more numbers match the incoming call prefix number).

Index	Prefix
0	[1,3,5]
1	[110,120]

- Dial Plan rules with ranges of **contiguous numbers and the amount of possible matched numbers is identical**: The device chooses the matching rule in the Dial Plan Rule table that has the lowest row index number (i.e., listed higher up in the table). For example, if the prefix number of an incoming call is "110" and you have configured the below rules (each rule has a range of 3 possible matching numbers), the device chooses Index #0 because it has the lowest row index number (even though more numbers match the incoming call prefix number).

Index	Prefix
0	[1-3]
1	[10-12]

- Dial Plan rules with ranges of **contiguous number and the amount of possible matched numbers is different**: The device chooses the matching rule in the Dial Plan Rule table that has the least amount of numbers. For example, if the prefix number of an incoming call is "110" and you have configured the below rules (Index #0 with 7 possible matched numbers and Index #1 with 3 possible matched numbers), the device chooses Index #1 because it has less numbers.

Index	Prefix
-------	--------

0	[1-7]
1	[10-12]

- Dial Plan rules with ranges of **contiguous number** and **multiple standalone numbers**: The device chooses the matching rule in the Dial Plan Rule table that has the standalone number range (not contiguous range). For example, if the prefix number of an incoming call is "110" and you have configured the below rules (Index #0 is a standalone number range and Index #1 a contiguous range), the device chooses Index #0 because it is the standalone number range.

Index	Prefix
0	[1,2,3,4,5]
1	[1-3]

Additional examples of best match priority for Dial Plan rules configured with a specific number and optionally followed by the "x" notation or prefix or suffix range are shown below:

- For incoming calls with prefix number "5234", the rule with tag B is chosen (more specific for digit "4"):

Index	Prefix	Tag
0	523x	A
1	5234	B

- For incoming calls with prefix number "5234", the rule with tag A is chosen (see match priority above):

Index	Prefix	Tag
0	523x	A
1	523[1-9]	B

- For incoming calls with prefix number "53211111", the rule with tag B is chosen (more specific for fourth digit):

Index	Prefix	Tag
0	532[1-9]1111	A
1	5321	B

- For incoming calls with prefix number "53124", the rule with tag B is chosen (more specific for digit "1"):

Index	Prefix	Tag
0	53([2-4])	A
1	531(4)	B

- For incoming calls with prefix number "321444", the rule with tag A is chosen and for incoming calls with prefix number "32144", the rule with tag B is chosen:

Index	Prefix	Tag
0	321xxx	A
1	321	B

- For incoming calls with prefix number "5324", the rule with tag B is chosen (prefix is more specific for digit "4"):

Index	Prefix	Tag
0	532[1-9]	A
1	532[2-4]	B

- For incoming calls with prefix number "53124", the rule with tag C is chosen (longest suffix - C has three digits, B two digits and A one digit):

Index	Prefix	Tag
0	53([2-4])	A
1	53([01-99])	B
2	53([001-999])	C

- For incoming calls with prefix number "53124", the rule with tag B is chosen (suffix is more specific for digit "4"):

Index	Prefix	Tag
0	53([2-4])	A
1	53(4)	B

## Importing Dial Plans

You can import (upload) Dial Plans and Dial Plan Rules to the device from a comma-separated value (CSV) file located on your local PC running the Web client.

- For creating Dial Plans in a CSV file, see [Creating Dial Plan Files](#) on the next page.
- You can also import (upload) Dial Plans and Dial Plan rules from a file on a remote server, using the device's CLI: `configure voip > sbc dial-plan > import-csv-from`. For more information, refer to the *CLI Reference Guide*.

### ➤ To overwrite all existing Dial Plans with imported Dial Plan:

1. Open the Dial Plan table.
2. From the 'Action' drop-down menu, choose **Import**; the following dialog box appears:

3. Use the **Browse** button to select the Dial Plan file on your PC, and then click **OK**.

- The file import feature only imports rules of Dial Plans that already exist in the Dial Plan table. If a Dial Plan in the file doesn't exist in the table, the specific Dial Plan is not imported.
- Make sure that the names of the Dial Plans in the imported file are **identical** to the existing Dial Plan names in the Dial Plan table; otherwise, Dial Plans in the file with different names are not imported.
- When importing a file, the rules in the imported file replace all existing rules of the corresponding Dial Plan. For existing Dial Plans in the Dial Plan table that are not listed in the imported file, the device deletes all their rules. For example, if the imported file contains only the Dial Plan "MyDialPlan1" and the device is currently configured with "MyDialPlan1" and "MyDialPlan2", the rules of "MyDialPlan1" in the imported file replace the rules of "MyDialPlan1" on the device, and the rules of "MyDialPlan2" on the device are deleted (the Dial Plan name itself remains).

### ➤ To import Dial Plan rules for a specific Dial Plan:

1. Open the Dial Plan table.

2. Select the required Dial Plan, and then click the **Dial Plan Rule** link; the Dial Plan Rule table opens, displaying all the rules of the selected Dial Plan.
3. From the 'Action' drop-down menu, choose **Import**; the following dialog box appears:

4. Use the **Browse** button to select the Dial Plan file on your PC, and then click **OK**.

The rules in the imported file replace **all** existing rules of the specific Dial Plan.

### Creating Dial Plan Files

You can configure Dial Plans in an external file (\*.csv) and then import them into the device, as described in [Importing Dial Plans](#) on the previous page. You can create the file using any text-based editor such as Notepad or Microsoft Excel. The file must be saved with the \*.csv file name extension.

To configure Dial Plans in a file, use the following syntax:

```
DialPlanName,Name,Prefix,Tag
```

Where:

- *DialPlanName*: Name of the Dial Plan.
- *Name*: Name of the dial plan rule belonging to the Dial Plan.
- *Prefix*: Source or destination number prefix.
- *Tag*: Result of the user categorization and can be used as matching characteristics for routing and outbound manipulation

For example:

```
DialPlanName,Name,Prefix,Tag
PLAN1,rule_100,5511361xx,A
PLAN1,rule_101,551136184[4000-9999]#,B
MyDialPlan,My_rule_200,5511361840000#,itsp_1
MyDialPlan,My_rule_201,66666#,itsp_2
```

## Exporting Dial Plans

You can export your configured Dial Plans in comma-separated value (CSV) file format to a folder on the local PC running the Web client.

The CLI lets you export Dial Plans and Dial Plan rules to a remote server, using the `export-csv-to` command under `(config-voip)# sbc dial-plan`. For more information, refer to the document *CLI Reference Guide*.

### ➤ To export all configured Dial Plans with their corresponding Dial Plan rules:

1. Open the Dial Plan table.
2. From the 'Action' drop-down menu, choose **Export**; the following dialog box appears:

3. Select the **Save File** option, and then click **OK**; the file is saved to the default folder on your PC for downloading files.

### ➤ To export Dial Plan rules of a specific Dial Plan:

1. Open the Dial Plan table.
2. Select the required Dial Plan, and then click the **Dial Plan Rule** link; the Dial Plan Rule table opens, displaying the rules of the selected Dial Plan.
3. From the 'Action' drop-down menu, choose **Export**; a dialog box appears (as shown above).
4. Select the **Save File** option, and then click **OK**; the file is saved to the default folder on your PC for downloading files.

## Using Dial Plan Tags for SBC IP-to-IP Routing

You can use Dial Plan tags with IP-to-IP Routing rules in the IP-to-IP Routing table, where tags can be used for the following:

- Matching routing rules by source and/or destination prefix numbers (see [Using Dial Plan Tags for Matching Routing Rules](#) below)
- Locating destination IP Group (see [Using Destination Tags for Choosing Routing Destinations](#) on the next page)

### Using Dial Plan Tags for Matching Routing Rules

For deployments requiring hundreds of routing rules (which may exceed the maximum number of rules that can be configured in the IP-to-IP Routing table), you can employ tags to represent the many different calling (source URI user name) and called (destination URI user name) prefix numbers in your routing rules. Tags are typically implemented when you have users of many different called and/or calling numbers that need to be routed to the same destination (e.g., IP Group or IP address). In such a scenario, instead of configuring many routing rules to match all the required prefix numbers, you need only to configure a single routing rule using the tag to represent all the possible prefix numbers.

An example scenario where employing tags could be useful is in deployments where the device needs to service calls in a geographical area that consists of hundreds of local area codes, where each area code is serviced by one of two SIP Trunks in the network. In such a deployment, instead of configuring hundreds of routing rules to represent each local area code, you can simply configure two routing rules where each is assigned a unique tag representing a group of local area codes and the destination IP Group associated with the SIP Trunk servicing them.

- Source and destination tags can be used in the same routing rule.
- The same tag can be used for source and destination tags in the same routing rule.

#### ➤ To configure IP-to-IP routing based on tags:

1. In the Dial Plan table, configure a Dial Plan (see [Configuring Dial Plans](#) on page 825). For example, the Dial Plan file below defines two tags, "LOC" and "INTL" to represent different called number prefixes for local and long distance (International) calls:

INDEX ▾	NAME	PREFIX	TAG
0	Local	42520[3-5]	LOC
1	Local	425207	LOC
2	Local	42529	LOC
3	International	425200	INTL
4	International	425100	INTL

2. For the IP Group or SRD associated with the calls for which you want to use tag-based routing, assign the Dial Plan that you configured in Step 1.
  - IP Groups table: 'Dial Plan' parameter - see [Configuring IP Groups](#) on page 591
  - SRDs table: 'Dial Plan' parameter - see [Configuring SRDs](#) on page 558

3. In the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), configure a routing rule with the required destination and whose matching characteristics include the tag(s) that you configured in your Dial Plan in Step 1. The tags are assigned under the **Match** group, using the following parameters:
  - 'Source Tags': tag denoting the calling user
  - 'Destination Tags': tag denoting the called user

### Using Destination Tags for Choosing Routing Destinations

You can use Dial Plans (see [Configuring Dial Plans](#) on page 825) or Call Setup Rules (see [Configuring Call Setup Rules](#) on page 809) to define tags for determining destination IP Groups for routing incoming calls.

One of the benefits of using tags is that it can reduce the number of IP-to-IP Routing rules that you would normally need to configure. For example, assume that you need to route calls from IP Group "A" to two different IP Groups, "B" and "C", based on called (destination) prefix number (e.g., 102 and 103). When not using tags, you would need to configure two IP-to-IP Routing rules, where one rule sends calls with prefix number 102 to IP Group "B" and another rule sends calls with prefix number 103 to IP Group "C". When using tags, you would only need to configure a single IP-to-IP Routing rule whose destination IP Group is based on a tag.

The following briefly describes the tag-based routing process:

#### ■ Using Dial Plans for Determining Destination Tags:

- a. The device searches the Dial Plan index that is associated with the source IP Group of the incoming SIP dialog, for a Dial Plan rule whose 'Prefix' parameter is configured with the same called prefix number as the SIP dialog (e.g., 102). If found, the device inspects the tags in the Dial Plan rule's 'Tag' parameter (e.g., "Country=England;City=London;Essex").
- b. The device searches for a matching rule in the IP-to-IP Routing table and if the 'Destination Type' parameter is configured to **Destination Tag**, it checks the tag name configured in the 'Routing Tag Name' parameter and compares it with the tags found in the Dial Plan rule. If the parameter is configured to "default", the device selects the first tag name in the Dial Plan rule that is configured without a value (e.g., "Holland" in Step 1 below). If the parameter is configured with a tag name (e.g., "Country"), the device selects the tag name with its value (e.g., "Country=England") in the Dial Plan rule.
- c. The device searches the IP Groups table and IP Group Set table for an IP Group whose 'Tags' parameter is configured with the same tag as configured for the matching IP-to-IP Routing rule. If found, the device routes the call to this IP Group.

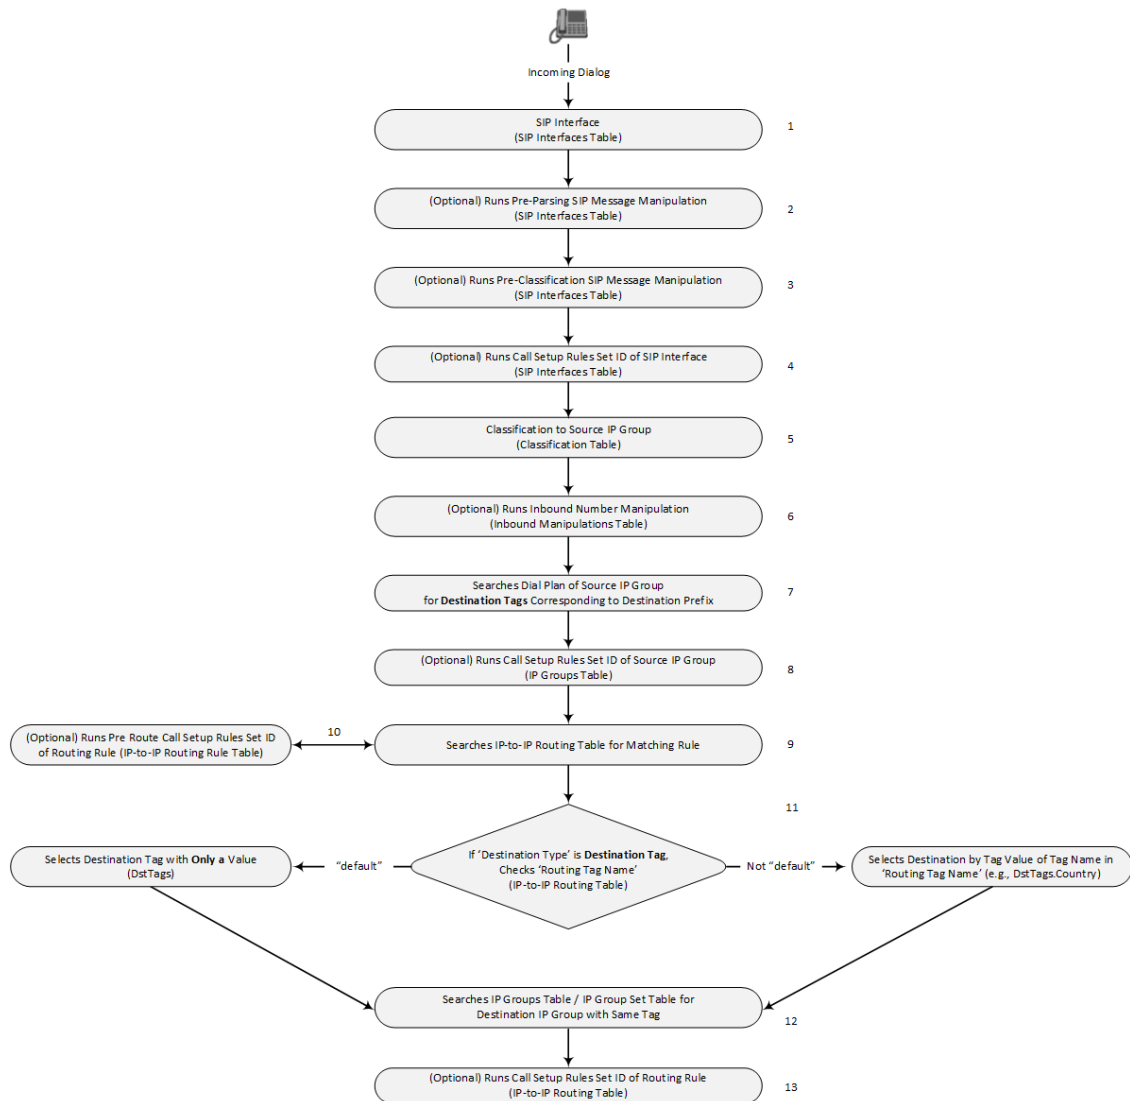

#### ■ Using Call Setup Rules for Determining Destination Tags:

- a. The device runs the Call Setup Rule Set ID that is assigned to the 'Pre Route Call Setup Rules Set ID' parameter of the matching IP-to-IP Routing rule ('Destination Type'

parameter is **Destination Tag**). The Call Setup Rule Set determines the destination tag name (e.g., DstTags.Country in the 'Action Subject' parameter of the Call Setup Rule).

- b. The device checks if the resultant tag name equals the tag name in the 'Routing Tag Name' parameter of the IP-to-IP Routing rule. If the parameter is configured to "default", the device selects the tag that only has a value (e.g., "Holland"). If the parameter is configured with a tag name (e.g., "Country"), the device selects the tag name with its value (e.g., "Country=England").
- c. The device searches the IP Groups table and IP Group Set table for an IP Group whose 'Tags' parameter is configured with the same tag (e.g., "Country=England"), as determined during the routing stage. If found, the device routes the call to the matched IP Group.

The following flow chart shows the device's SIP dialog processing when destination tags are used to determine destination IP Groups:

The following procedure provides an example of how to configure tag-based routing using a Dial Plan and is based on the following scenario:

- Calls from IP Group "HQ" with destination (called) prefix number 102 are sent to IP Group "ENG".
- Calls from IP Group "HQ" with destination (called) prefix number 103 are sent to IP Group "BEL".
- Destination IP Groups are determined by Dial Plan tags:
  - Tag "Country=England" is used to send calls to IP Group "ENG".
  - Tag "Country=Belgium" is used to send calls to IP Group "BEL".

For an example of using a Call Setup Rule for tag-based routing, click [Example 6: This example enables routing based on LDAP queries and destination tags for matching destination IP Groups. The device queries the LDAP server for the attribute record "telephoneNumber" whose value is the destination number of the incoming call \(e.g., "telephoneNumber=4064"\). If the attribute-value combination is found, the device retrieves the string value of the attribute record "CountryOfResidence" and creates a destination tag with the name of the retrieved string. The value of the destination tag name is then used as a matching characteristics of the IP Group. on page 823.](#)

➤ **To configure tag-based routing using Dial Plans:**

1. In the Dial Plan table, configure a Dial Plan with Dial Plan rules, where the 'Prefix' parameter is the **destination** (called) prefix number. In our example, a Dial Plan called "Dial Plan 1" is configured with two Dial Plan rules:

Parameter	Index 0	Index 1
'Name'	UK	Bel-Neth
'Prefix'	102	103
'Tag'	Country=England;City=London	Holland;City=Amsterdam;Country=Belgium

The following displays the configuration in the Web interface of the Dial Plan rule for Index 0:

Dial Plan Rule [UK]
— x

GENERAL

Index

0

Name

- UK

Prefix

- 102

Tag

- Country=England;City=London

Regarding the 'Tag' parameter:

- Only one tag name **without** a value can be configured. In the above example, "Holland" is the tag name without a value. For example, configuring "Holland;France", which is two tag names without values is invalid.
- Tag names with values (i.e., name=value) must be unique in a Dial Plan rule. In the above example, "Country=England" is a tag name with value. For example, configuring the parameter to "Country=England;Country=Scotland" is invalid. A valid configuration would be "Country=England;Country1=Scotland".

2. In the IP Groups table, configure your IP Groups. Make sure that you assign the source IP Group with the Dial Plan that you configured in Step 1 and that you configure each destination IP Group with one of the required Dial Plan tags. If the tag has a value, include it as well. In our example, we'll configure three IP Groups:

Parameter	Index 0	Index 1	Index 2
'Name '	HQ	ENG	BEL
'Dial Plan'	Dial Plan 1	-	-
'Tags'	-	Country=England	Country=Belgium

3. In the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), add a routing rule and configure the 'Destination Type' parameter to **Destination Tag** and the 'Routing Tag Name' to one of your Dial Plan tag names. In our example, the tag "Country" is used:

Parameter	Index 0
'Name'	Europe
'Source IP Group'	HQ
'Destination Type'	<b>Destination Tag</b>
'Routing Tag Name'	Country

- Configure the 'Routing Tag Name' parameter to the name of the tag (without a value, if exists). For example, instead of "Country=England", configure it to "Country" only.
- For tag-based routing, if you want to determine the destination tag during the device's routing stage in the IP-to-IP Routing table (i.e., 'Destination Type' set to **Destination Tag**), use the 'Pre Route Call Setup Rules Set ID' parameter. The device uses the resultant tag name to find a matching IP Group (i.e., with same tag) in the IP Groups table.
- In the IP-to-IP Routing table, the device always runs the Call Setup Rules Set of the 'Pre Route Call Setup Rules Set ID' parameter before the Call Setup Rules Set of the 'Call Setup Rules Set ID' parameter (if configured). Therefore, if you're using the 'Pre Route Call Setup Rules Set ID' parameter for tag-based routing, once the Call Setup Rules Set finishes running and the tag and matching IP Group is determined, the device runs the Call Setup Rules Set of the 'Call Setup Rules Set ID' parameter. This second Call Setup Rules Set can now access the **already** matched IP Group (Param.IPG.Dst).
- If the same Dial Plan tag is configured for an IP Group in the IP Groups table and an IP Group Set in the IP Group Set table, the IP Group Set takes precedence and the device sends the SIP dialog to the IP Group(s) belonging to the IP Group Set.

### Dial Plan Backward Compatibility

This section is for backward compatibility **only**. It is recommended to migrate your Dial Plan configuration to the latest Dial Plan feature (see [Using Dial Plan Tags for SBC IP-to-IP Routing](#) on page 840).

Configure prefix tags in the Dial Plan file using the following syntax:

```
[ PLAN<index> ]
<prefix number>,0,<prefix tag>
```

where:

- *Index* is the Dial Plan index
- *prefix number* is the called or calling number prefix (ranges can be defined in brackets)
- *prefix tag* is the user-defined prefix tag of up to nine characters, representing the prefix number

Each prefix tag type - called or calling - must be configured in a dedicated Dial Plan index number. For example, Dial Plan 1 can be for called prefix tags and Dial Plan 2 for calling prefix tags.

The example Dial Plan file below defines the prefix tags "LOCL" and "INTL" to represent different called number prefixes for local and long distance calls:

```
[ PLAN1 ]
42520[3-5],0,LOCL
425207,0,LOCL
42529,0,LOCL
425200,0,INTL
425100,0,INTL
....
```

- Called and calling prefix tags can be used in the same routing rule.
- When using prefix tags, you need to configure manipulation rules to remove the tags before the device sends the calls to their destinations.

The following procedure describes how to configure IP-to-IP routing using prefix tags.

➤ **To configure IP-to-IP routing using prefix tags:**

1. Configure a Dial Plan file with prefix tags, and then upload the file to the device.
2. Add the prefix tags to the numbers of specific incoming calls using Inbound Manipulation rules:
  - a. Open the Inbound Manipulations table (see [Configuring IP-to-IP Inbound Manipulations](#) on page 1231), and then click **New**.
  - b. Configure matching characteristics for the incoming call (e.g., set 'Source IP Group' to "1").
  - c. From the 'Manipulated Item' drop-down list, select **Source** to add the tag to the calling URI user part, or **Destination** to add the tag to the called URI user part.
  - d. Configure the Dial Plan index for which you configured your prefix tag, in the 'Prefix to Add' or 'Suffix to Add' fields, using the following syntax: \$DialPlan<x>, where x is the Dial Plan index (0 to 7). For example, if the called number is 4252000555, the device manipulates it to LOCL4252000555.
3. Add an SBC IP-to-IP routing rule using the prefix tag to represent the different source or destination URI user parts:
  - a. Open the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186), and then click **New**.
  - b. Configure the prefix tag in the 'Source Username Pattern' or 'Destination Username Pattern' fields (e.g., "LOCL", without the quotation marks).
  - c. Continue configuring the rule as required.
4. Configure a manipulation rule to remove the prefix tags before the device sends the message to the destination:

- a. Open the Outbound Manipulations table (see [Configuring IP-to-IP Outbound Manipulations](#) on page 1236), and then click **New**.
- b. Configure matching characteristics for the incoming call (e.g., set 'Source IP Group' to "1"), including calls with the prefix tag (in the 'Source Username Pattern' or 'Destination Username Pattern' fields, enter the prefix tag to remove).
- c. Configure the 'Remove from Left' or 'Remove from Right' fields (depending on whether you added the tag at the beginning or end of the URI user part, respectively), enter the number of characters making up the tag.

## Using Dial Plan Tags for SBC Outbound Manipulation

You can use Dial Plan tags to denote source and/or destination URI user names in Outbound Manipulation rules in the Outbound Manipulations table.

### ➤ To configure Outbound Manipulation based on tags:

1. In the Dial Plan table, configure a Dial Plan (see [Configuring Dial Plans](#) on page 825).
2. In the IP Group or SRD associated with the calls for which you want to use tag-based routing, assign the Dial Plan that you configured in Step 1.
  - IP Groups table: 'Dial Plan' parameter - see [Configuring IP Groups](#) on page 591
  - SRDs table: 'Dial Plan' parameter - see [Configuring SRDs](#) on page 558
3. In the Outbound Manipulations table (see [Configuring IP-to-IP Outbound Manipulations](#) on page 1236), configure a rule with the required manipulation and whose matching characteristics include the tag(s) that you configured in your Dial Plan in Step 1. The tags are assigned using the following parameters:
  - 'Source Tags': tag denoting the calling users
  - 'Destination Tags': tag denoting the called users

## Using Dial Plan Tags for Call Setup Rules

You can use Dial Plan tags in Call Setup rules, configured in the Call Setup Rules table (see [Configuring Call Setup Rules](#) on page 809).

You can assign the Call Setup rule to an IP Group. The device runs the Call Setup rule for the source IP Group to which the incoming SIP dialog is classified, immediately before the routing process (i.e., Classification > Manipulation > Dial Plan table > Call Setup rules > Routing). The result of the Call Setup rule (i.e., source or destination tag) can be used in the IP-to-IP Routing table for any of the following:

- As matching characteristics to find a suitable IP-to-IP Routing rule (initial route). To implement this, configure the rule's 'Source Tag' or 'Destination Tag' parameters to the resultant tag of the Call Setup rule.

- To determine the destination of the IP-to-IP Routing rule (initial route). To implement this, configure the rule's 'Destination Type' parameter to **Destination Tag** and the 'Routing Tag Name' parameter to the resultant tag of the Call Setup rule. The SIP dialog is sent to the IP Group that is configured with this same tag ('Tags' parameter in the IP Groups table).

When tags are used to determine the route's destination: If the IP-to-IP Routing rule (initial route) is also configured with a Call Setup rule ('Call Setup Rules Set ID' parameter) and it results in a different tag, and additional IP-to-IP Routing rules are configured as alternative routes ('Alternative Route Options' parameter), or the initial route is also configured with call forking ('Group Policy' is **Forking**), and the 'Destination Type' for these rules is configured to **Destination Tag**, then this new tag is used for the destination (instead of the tag used for the initial route).

You can configure Call Setup rules to query the Dial Plan table for a specified key (prefix) in a specified Dial Plan to obtain the corresponding tag. The Call Setup rule can then perform many different manipulations (based on Message Manipulation syntax), including modifying the name of the tag. The tags can be used only in the 'Condition', 'Action Subject' and 'Action Value' fields.

## Using Dial Plans for IP-to-Tel or Tel-to-IP Call Routing

For deployments requiring hundreds of routing rules (which may exceed the maximum number of rules that can be configured in the routing tables), you can employ Dial Plan tags to represent the many different calling (source) and called (destination) prefix numbers as matching input characteristics in your IP-to-Tel and Tel-to-IP routing rules. Tags are typically implemented when you have users of many different called and/or calling numbers that need to be routed to the same destination. In such a scenario, instead of configuring many routing rules to match all the required prefix numbers, you need only to configure a single routing rule using the tag to represent all the possible prefix numbers.

An example scenario where employing tags could be useful is in deployments where the device needs to service calls in a geographical area that consists of many local area codes, where the area codes are serviced by different SIP Trunks (for Tel-to-IP) and Trunk Groups (for IP-to-Tel). Another example includes routing local calls and International calls using different SIP Trunks. In such a scenario, instead of configuring hundreds of routing rules to represent each local area code and the International dialing code, you can simply configure two routing rules where one is assigned a unique tag representing the local area codes and the other is assigned a tag representing International calls.

- Source and destination tags can be used in the same routing rule.
- The same tag can be used for source and destination tags in the same routing rule.

The procedure below describes how to configure tag-based routing for Gateway calls based on the following example setup:

- **Tel-to-IP routing:** Local calls whose destination tag is "NYPSP0" are routed to IP Group "SP-0" and calls whose destination tag is "NYPSP1" are routed to IP Group "SP-1".
- **IP-to-Tel routing:** Local calls whose destination tag is "NYPSP0" are routed to Trunk Group 1 and calls whose destination tag is "NYPSP1" are routed to Trunk Group 2.

➤ **To configure tag-based routing for IP-to-Tel and Tel-to-IP calls:**

1. Open the Dial Plan table (see [Configuring Dial Plans](#) on page 825), and then configure your Dial Plan rules, for example:

Dial Plan Name	Dial Plan Rule			Comment
	Name	Prefix	Tag	
TEL2IP	Local1	21[2-4]	NYPSP0	Denotes local area codes with prefixes 212, 213, and 214
	Local2	332	NYPSP0	Denotes local area code with prefix 332
	Local3	34[7,9]	NYPSP1	Denotes local area codes with prefixes 347 and 349
	Local4	9[17,29]	NYPSP1	Denotes local area codes with prefixes 917 and 929
IP2TEL	Local1	21[2-4]	NYPSP0	See above
	Local2	332	NYPSP0	See above
	Local3	34[7,9]	NYPSP1	See above
	Local4	9[17,29]	NYPSP1	See above

2. Open the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**), and then select the Dial Plans from the Dial Plan table that you want to use for each routing table:
  - From the 'IP-to-Tel Dial Plan Name' drop-down list, select the Dial Plan (e.g., "IP2TEL") that you want to use for IP-to-Tel routing rules.
  - From the 'Tel-to-IP Dial Plan Name' drop-down list, select the Dial Plan (e.g., "TEL2IP") that you want to use for Tel-to-IP routing rules.

IP-to-Tel Dial Plan Name •  [View](#)

Tel-to-IP Dial Plan Name •  [View](#)

3. Open the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946), and then configure a routing rule with the required destination and whose matching characteristics include the tag(s) that you configured in your Dial Plan for Tel-to-IP routing. The tags are assigned using the 'Source Tag' and 'Destination Tag' parameters. In our example, configure two routing rules:
  - Routing rule 1:
    - ◆ 'Destination Tag': **NYPSP0**
    - ◆ 'Destination IP Group': **SP-0**
  - Routing rule 2:
    - ◆ 'Destination Tag': **NYPSP1**
    - ◆ 'Destination IP Group': **SP-1**
4. Open the IP-to-Tel Routing table (see [Configuring IP-to-Tel Routing Rules](#) on page 960), and then configure a routing rule with the required destination and whose matching characteristics include the tag(s) that you configured in your Dial Plan for IP-to-Tel routing. The tags are assigned using the 'Source Tag' and 'Destination Tag' parameters. In our example, configure two routing rules:
  - Routing rule 1:
    - ◆ 'Destination Tag': **NYPSP0**
    - ◆ 'Destination Type': **Trunk Group**
    - ◆ 'Trunk Group ID': **1**
  - Routing rule 2:
    - ◆ 'Destination Tag': **NYPSP1**
    - ◆ 'Destination Type': **Trunk Group**
    - ◆ 'Trunk Group ID': **2**

## Using Dial Plan Tags for Message Manipulation

You can use Dial Plan tags (*srctags* and *dsttags*) in Message Manipulation rules, configured in the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856). The tags can be used only in the 'Condition' and 'Action Value' fields. For example, you can configure a rule that adds the SIP header "City" with the value "ny" (i.e., City: ny) to all outgoing SIP INVITE messages associated with the source tag "ny":

**Message Manipulations**

GENERAL		ACTION	
Index	0	Action Subject	header.City
Name	New Header for Tag ny	Action Type	Add
Manipulation Set ID	0	Action Value	srctags
Row Role	Use Current Condition		

MATCH	
Message Type	invite.request
Condition	srctags=='ny'

Dial Plan tags cannot be modified using Message Manipulation rules.

## Using Dial Plans for Microsoft Local Media Optimization

When the device is deployed in a Microsoft Teams environment for its Local Media Optimization feature, you need to specify which Dial Plan in the Dial Plan table the device must search for common groups between Teams sites. Teams sites that share the same group number means that their communication path is considered good voice quality and calls between them are intended for direct media calls. In other words, if the source and destination Teams sites share a common group, the device processes the call as a direct media call.

The specified Dial Plan uses the 'Prefix' parameter to define the names of the Teams sites (e.g., "Singapore" and "Thailand") and the 'Tag' parameter lists the groups to which the Teams site belongs (e.g., "Group=2,7"). Microsoft's proprietary SIP header, MS-X-UserSite in the incoming SIP message received from the Teams client indicates the site to which the client belongs (e.g., "Singapore"). If the destination IP Group's 'Teams Local Media Optimization Site' parameter is configured to "Thailand", the device checks the Dial Plan if these two Teams sites share the same group (e.g., "2"). If they do belong to the same group, the device processes the call as a direct media (bypass) call. Each Teams site can belong to multiple groups.

- You can specify only one Dial Plan for this feature.
- The feature described in this section is applicable only to Teams-to-PSTN calls.
- For an overview of Microsoft's Local Media Optimization feature, see [Microsoft Teams with Local Media Optimization](#) on page 520
- This section is applicable only to the SBC application.

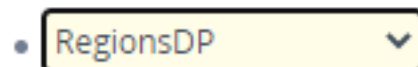

➤ **To use Dial Plan for Microsoft Local Media Optimization:**

1. Open the Dial Plan table (see [Configuring Dial Plans](#) on page 825), and then configure a Dial Plan containing Dial Plan rules of Teams sites and the groups they belong to. For example, a Dial Plan called "RegionsDP" is configured with rules that include the Teams sites Singapore, Thailand and Hong Kong and the groups that each belong to:

INDEX	NAME	PREFIX	TAG
0	TeamsDialPlan1	Singapore	Group=2,3
1	TeamsDialPlan2	Thailand	Group=2,5
2	TeamsDialPlan3	HongKong	Group= 5,6,7

2. Open the SIP Definitions General Settings page (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **SIP Definitions General Settings**), and then from the 'Regions Connectivity Dial Plan' drop-down list, select the Dial Plan that you configured in Step 1 (e.g., **RegionsDP**):

Regions Connectivity Dial Plan

3. Open the IP Groups table (see [Configuring IP Groups](#) on page 591), and then for each IP Group representing a Teams site, configure the 'Teams Local Media Optimization Site' parameter to the site's name. The site's name must be the same name as configured in the Dial Plan rule (configured in Step 2). For example, below shows the IP Group for the Singapore Teams site:

Teams Local Media Optimization Site

Singapore

## Configuring Push Notification Servers

The Push Notification Servers table lets you configure up to five Push Notification Servers. The device uses this table to determine which Push Notification Server to send push notification requests for a specific user. The device searches the table for a row that is configured with the user's 'pn-provider' parameter value and if located, sends the push notification request to the Push Notification Server, using the address of the associated Remote Web Service.

The Push Notification Service uses Push Notification Servers to send push notifications to "wake" end-user equipment (typically, mobile platforms) that have gone to "sleep" (e.g., to save resources such as battery life) so that they can receive traffic. The device can handle calls (and registration) for such SIP user agents (UAs), by interoperating with these third-party, Push Notification Servers (over HTTP, using RESTful APIs). For more information on Push Notification Service, see [Configuring Push Notification Service](#) on page 1288.

Before you can configure a Push Notification Server in this table, you need to configure a Remote Web Service (HTTP-based server) to represent the Push Notification Server. The Remote Web Service defines the actual address (and other required parameters) of the server.

You must configure the Remote Web Service with the 'Type' parameter set to **General**. To configure Remote Web Services, see [Configuring Remote Web Services](#) on page 438.

The Push Notification Service is applicable only to the SBC application.

The following procedure describes how to configure Push Notification Servers through the Web interface. You can also configure it through ini file [PushNotificationServers] or CLI (configure voip > sip-definition push-notification-servers).

➤ **To configure Push Notification Server:**

1. Open the Push Notification Servers table (**Setup** menu > **Signaling & Media** tab > **SIP Definitions** folder > **Push Notification Servers**).
2. Click **New**; the following dialog box appears:

3. Configure a Push Notification Server according to the parameters described in the table below.
4. Click **Apply**.

**Table 20-8: Push Notification Servers Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Provider' provider [Provider]	Defines the type of the Push Notification Service. The type of the service provider is indicated in the SIP Contact header's 'pn-provider' parameter of the REGISTER message that is sent by the user to the device. For example, Android-based mobile phone platforms typically use Firebase Cloud Messaging (FCM) for its Push Notification Service. The value of the 'pn-provider' parameter for this service type is "fcm". Therefore, you would need to configure the 'Provider' parameter to "fcm" (without quotation marks).  The valid value is a string of up to 10 characters. By default, no value is defined. To denote any provider, use the asterisk (*)

Parameter	Description
	<p>wildcard character.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ You can configure this parameter to the * (asterisk) wildcard character for only one table row.</li> <li>■ The parameter is mandatory.</li> </ul>
<p>'Remote Web Service'</p> <p>remote-http-service</p> <p>[RemoteHTTPService]</p>	<p>Assigns a Remote Web Service, which defines the URL address (and other related parameters) of the HTTP-based Push Notification Server.</p> <p>To configure Remote Web Services, see <a href="#">Configuring Remote Web Services</a> on page 438.</p> <p><b>Note:</b> The parameter is mandatory.</p>
<p>'Protocol'</p> <p>protocol</p> <p>[Protocol]</p>	<p>Defines the protocol for exchanging information between the device and the Push Notification Server.</p> <ul style="list-style-type: none"> <li>■ [0] AC-Proprietary = (Default) The device exchanges information with the server using the JavaScript Object Notation (JSON) format.</li> </ul>

## 21 SIP Message Manipulation

This section describes SIP message manipulation.

If you have configured call routing from the device's SBC application (IP-to-IP routing) to the device's Gateway application for IP-to-Tel routing, the device uses the initial SIP message as if it's a new call. Therefore, if any manipulations were done on the SIP message by the SBC application, the device ignores them.

### Configuring SIP Message Manipulation

The Message Manipulations table lets you configure up to 100 Message Manipulation rules. A Message Manipulation rule defines a manipulation sequence for SIP messages. SIP message manipulation enables the normalization of SIP messaging fields between communicating network segments. For example, it allows service providers to design their own policies on the SIP messaging fields that must be present before a SIP call enters their network. Similarly, enterprises and small businesses may have policies for the information that can enter or leave their networks for policy or security reasons from a service provider. SIP message manipulations can also be implemented to resolve incompatibilities between SIP devices inside the enterprise network.

Each Message Manipulation rule is configured with a Manipulation Set ID. You can create groups (sets) of Message Manipulation rules by assigning each of the relevant Message Manipulation rules to the same Manipulation Set ID. The Manipulation Set ID is then used to assign the rules to specific calls:

- SBC application: Message manipulation rules can be applied pre- or post-classification:
  - Pre-classification Process: Message manipulation can be done on incoming SIP dialog-initiating messages (e.g., INVITE) prior to the classification process. You configure this by assigning the Manipulation Set ID to the SIP Interface on which the call is received (see [Configuring SIP Interfaces](#) on page 570).
  - Post-classification Process: Message manipulation can be done on inbound and/or outbound SIP messages after the call has been successfully classified. Manipulation occurs only after the routing process - inbound message manipulation is done first, then outbound number manipulation (see [Configuring IP-to-IP Outbound Manipulations](#) on page 1236), and then outbound message manipulation. For viewing the call processing flow, see [Call Processing of SIP Dialog Requests](#) on page 1125. You configure this by assigning the Manipulation Set ID to the relevant IP Group in the IP Groups table (see [Configuring IP Groups](#) on page 591).
- Gateway application: Message Manipulation rules are applied to calls as follows:
  - Manipulating Inbound SIP INVITE Messages: Message manipulation can be applied only to all inbound calls (not specific calls). This is done by assigning a Manipulation Set ID, using the "global" parameter [GWInboundManipulationSet].

- **Manipulating Outbound SIP INVITE Messages:** Message manipulation can be done for specific calls, by assigning a Manipulation Set ID to an IP Group in the IP Groups table, using the 'Outbound Message Manipulation Set' parameter. Message manipulation can be applied to all outbound calls (except for IP Groups that have been assigned a Manipulation Set ID). This is done by assigning a Manipulation Set ID, using the "global" parameter [GWOutboundManipulationSet].
- **SIP requests initiated by the device (Gateway and SBC applications):** You can apply Message Manipulation rules to SIP requests that are initiated by the device, for example, SIP REGISTERS for certain entities (e.g., Accounts) and keep-alive by SIP OPTIONS. If the destination of the request is an IP Group, then the device uses the Inbound and Outbound Manipulation Sets that are assigned to the IP Group. If there is no IP Group for the destination or the IP Group is not assigned an Inbound or Outbound Manipulation Set, then the global parameters [GWInboundManipulationSet] or [GWOutboundManipulationSet] are used. The [GWInboundManipulationSet] parameter defines the Message Manipulation Set that is applied to incoming responses for requests that the device initiated. The [GWOutboundManipulationSet] parameter defines the Message Manipulation Set that is applied to outgoing requests that the device initiates.

The device also supports a built-in SIP message normalization feature that can be enabled per Message Manipulation rule. The normalization feature removes unknown SIP message elements before forwarding the message. These elements can include SIP headers, SIP header parameters, and SDP body fields.

The SIP message manipulation feature supports the following:

- Manipulation on SIP message type (Method, Request/Response, and Response type)
- Addition of new SIP headers
- Removal of SIP headers ("black list")
- Modification of SIP header components such as values, header values (e.g., URI value of the P-Asserted-Identity header can be copied to the From header), call's parameter values
- Deletion of SIP body (e.g., if a message body is not supported at the destination network this body is removed)
- Translating one SIP response code to another
- Topology hiding (generally present in SIP headers such as Via, Record Route, Route and Service-Route).
- Configurable identity hiding (information related to identity of subscribers, for example, P-Asserted-Identity, Referred-By, Identity and Identity-Info)
- Multiple manipulation rules on the same SIP message
- Apply conditions per rule - the condition can be on parts of the message or call's parameters
- Apply Message Manipulation Set twice on SIP REGISTER messages -- first on the initial incoming unauthenticated REGISTER, and then again on the incoming authenticated SIP

message received after the device sends a SIP 401 response for challenging the initial REGISTER request. For more information and for enabling this feature, see the [AuthenticatedMessageHandling] parameter.

- Multiple manipulation rules using the same condition. The following figure shows a configuration example where Rules #1 and #2 ('Row Rule' configured to **Use Previous Condition**) use the same condition as configured for Rule #0 ('Row Rule' configured to **Use Current Condition**). For more information, see the description of the 'Row Rule' parameter in this section.

INDEX ↕	NAME	MANIPULATION SET ID	MESSAGE TYPE	CONDITION	ACTION SUBJECT	ACTION TYPE	ACTION VALUE	ROW ROLE
0	To Header Urgent	1	Invite.Request	Header.Request-URL.URI	Header.To	Modify	Header.To + ";urgent=1"	Use Current Condition
1	Add Emergency	1			Header.Priority	Add	'emergency'	Use Previous Condition
2	User-Agent	1			Header.User-Agent	Modify	'trunk-a'	Use Previous Condition

The following figure illustrates an example of a SIP message that is manipulated by the device as follows:

1. Removes the "Unknown\_header: unknown\_value" in the incoming message.
2. Changes the P-Asserted-Identity header value to "sip:200@10.33.216.1" in the outgoing message.

This manipulation example is done by configuring two Message Manipulation rules, where Rule #1 is assigned to the source IP Group and Rule #2 to the destination IP Group.

Parameter	Rule 1	Rule 2
Message Type	Invite.request	Invite.request
Condition	Header.Unkown_header !contains 'unknown_value'	Header.P-Asserted-Identity.URL.User == 'Susan'
Action Subject	Header.Unkown_header	Header.P-Asserted-Identity

Parameter	Rule 1	Rule 2
Action Type	Remove	Modify
Action Value		'<sip:200@212.3.216.1>'

- For a detailed description of the syntax used for configuring Message Manipulation rules, refer to the document *SIP Message Manipulation Reference Guide* (click [here](#)).
- If you have configured call routing from the device's SBC application (IP-to-IP routing) to the device's Gateway application for IP-to-Tel routing, the device uses the initial SIP message as if it's a new call. Therefore, if any manipulations were done on the SIP message by the SBC application, the device ignores them.
- For the SBC application: Inbound message manipulation is done only after the Classification, inbound and outbound number manipulation, and routing processes.
- Each message can be manipulated twice - on the source leg and on the destination leg (i.e., source and destination IP Groups).
- Unknown SIP parts can only be added or removed.
- SIP manipulations do not allow you to remove or add mandatory SIP headers. They can only be modified and only on requests that initiate new dialogs. Mandatory SIP headers include To, From, Via, CSeq, Call-Id, and Max-Forwards.
- The IP Group's 'SIP Group Name' parameter overrides inbound message manipulation rules that manipulate the host name in Request-URI, To, and/or From SIP headers. If you configure a SIP Group Name for the IP Group (see [Configuring IP Groups](#) on page 591) and you want to manipulate the host name in these SIP headers, you must apply your manipulation rule (Manipulation Set ID) to the IP Group as an Outbound Message Manipulation Set ('Outbound Message Manipulation Set' parameter), when the IP Group is the destination of the call. If you apply the Manipulation Set as an Inbound Message Manipulation Set ('Inbound Message Manipulation Set' parameter), when the IP Group is the source of the call, the manipulation rule will be overridden by the SIP Group Name.
- When configuring a Message Manipulation rule for manipulating a SIP header, the maximum length (characters) of the header's value in the incoming SIP message that can be manipulated is 4,096.

The following procedure describes how to configure Message Manipulation rules through the Web interface. You can also configure it through ini file [MessageManipulations] or CLI (configure voip > message message-manipulations).

➤ **To configure SIP message manipulation rules:**

1. Open the Message Manipulations table (**Setup** menu > **Signaling & Media** tab > **Message Manipulation** folder > **Message Manipulations**).
2. Click **New**; the following dialog box appears:

3. Configure a Message Manipulation rule according to the parameters described in the table below.

4. Click **Apply**.

An example of configured message manipulation rules are shown in the figure below:

INDEX	NAME	MANIPULATION SET ID	MESSAGE TYPE	CONDITION	ACTION SUBJECT	ACTION TYPE	ACTION VALUE
0	ITSP A	0	invite.response.200		header.to.url.user	Add Suffix	'.com'
1		0	invite.response.200		header.from.url.user	Modify	header.p-asserted-id.url.user
2		0	invite.request		header.from.url.user	Modify	'200'
3		2	invite.request	header.from.url.user==Unknown	header.from.url.user	Modify	param.ipg.src.user
4		2	invite.request		header.priority	Remove	

- **Index 0:** Adds the suffix ".com" to the host part of the To header.
- **Index 1:** Changes the user part of the From header to the user part of the P-Asserted-ID.
- **Index 2:** Changes the user part of the SIP From header to "200".
- **Index 3:** If the user part of the From header equals "unknown", then it is changed according to the srcIPGroup call's parameter.
- **Index 4:** Removes the Priority header from an incoming INVITE message.

**Table 21-1: Message Manipulations Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' manipulation-name [ManipulationName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters.
'Manipulation Set ID' manipulation-set-id [ManSetID]	Defines a Manipulation Set ID for the rule. You can define the same Manipulation Set ID for multiple rules to create a group of rules. The Manipulation Set ID is used to assign the manipulation rules to an IP Group (in the IP Groups table) for inbound and/or outbound

Parameter	Description
	<p>messages.</p> <p>The valid value is 0 to 29. The default is 0.</p> <p><b>Note:</b> You can configure up to 200 rules per Manipulation Set ID.</p>
<p>'Row Role'</p> <p>row-role</p> <p>[RowRole]</p>	<p>Determines which message manipulation condition (configured by the 'Condition' parameter) to use for the rule.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Use Current Condition</b> = (Default) The condition configured in the table row of the rule is used.</li> <li>■ [1] <b>Use Previous Condition</b> = The condition configured in the first table row above the rule that is configured to <b>Use Current Condition</b> is used. For example, if Index 3 is configured to <b>Use Current Condition</b> and Index 4 and 5 are configured to <b>Use Previous Condition</b>, Index 4 and 5 use the condition configured for Index 3. A configuration example is shown in the beginning of this section. The option allows you to use the same condition for multiple manipulation rules.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When configured to <b>Use Previous Condition</b>, the 'Message Type' and 'Condition' parameters are not applicable and if configured are ignored.</li> <li>■ When multiple manipulation rules apply to the same header, the next rule applies to the resultant string of the previous rule.</li> </ul>
Match	
<p>'Message Type'</p> <p>message-type</p> <p>[MessageType]</p>	<p>Defines the SIP message type that you want to manipulate.</p> <p>The valid value is a string (case-insensitive) denoting the SIP message. You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow</p>

Parameter	Description
	<p>the on-screen instructions.</p> <p>For example:</p> <ul style="list-style-type: none"> <li>■ Empty = rule applies to all messages</li> <li>■ Invite = rule applies to all INVITE requests and responses</li> <li>■ Invite.Request = rule applies to INVITE requests</li> <li>■ Invite.Response = rule applies to INVITE responses</li> <li>■ subscribe.response.2xx = rule applies to SUBSCRIBE confirmation responses</li> </ul> <p><b>Note:</b> Currently, SIP 100 Trying messages cannot be manipulated.</p>
<p>'Condition'</p> <p>condition</p> <p>[Condition]</p>	<p>Defines the condition that must exist for the rule to be applied.</p> <p>The valid value is a string of up to 200 characters (case-insensitive). You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p>For example:</p> <ul style="list-style-type: none"> <li>■ header.from.url.user== '100' (indicates that the user part of the From header must have the value "100")</li> <li>■ header.contact.param.expires &gt; '3600'</li> <li>■ header.to.url.host contains 'domain'</li> <li>■ param.call.dst.user != '100'</li> </ul>
Action	
<p>'Action Subject'</p> <p>action-subject</p> <p>[ActionSubject]</p>	<p>Defines the SIP header upon which the manipulation is performed.</p> <p>The valid value is a string (case-insensitive). You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor,</p>

Parameter	Description
	and then simply follow the on-screen instructions.
'Action Type' action-type [ActionType]	<p>Defines the type of manipulation.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Add</b> = (Default) Adds new header/param/body (header or parameter elements).</li> <li>■ [1] <b>Remove</b> = Removes header/param/body (header or parameter elements).</li> <li>■ [2] <b>Modify</b> = Sets element to the new value (all element types).</li> <li>■ [3] <b>Add Prefix</b> = Adds value at the beginning of the string (string element only).</li> <li>■ [4] <b>Add Suffix</b> = Adds value at the end of the string (string element only).</li> <li>■ [5] <b>Remove Suffix</b> = Removes value from the end of the string (string element only).</li> <li>■ [6] <b>Remove Prefix</b> = Removes value from the beginning of the string (string element only).</li> <li>■ [7] <b>Normalize</b> = Removes unknown SIP message elements before forwarding the message.</li> </ul>
'Action Value' action-value [ActionValue]	<p>Defines a value that you want to use in the manipulation.</p> <p>The default value is a string (case-insensitive) in the following syntax:</p> <ul style="list-style-type: none"> <li>■ string/&lt;message-element&gt;/&lt;call-param&gt; +</li> <li>■ string/&lt;message-element&gt;/&lt;call-param&gt;</li> </ul> <p>For example:</p> <ul style="list-style-type: none"> <li>■ 'itsp.com'</li> <li>■ header.from.url.user</li> <li>■ param.call.dst.user</li> <li>■ param.call.dst.host + '.com'</li> <li>■ param.call.src.user + '&lt;' + header.from.url.user + '@' + header.p-</li> </ul>

Parameter	Description
	<p>asserted-id.url.host + '&gt;'</p> <p>■ Func.To-Upper(Param.Call.Src.Host)</p> <p>You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p><b>Note:</b> Only single quotation marks must be used.</p>

## Configuring Message Condition Rules

The Message Conditions table lets you configure up to 82 Message Condition rules. A Message Condition defines special conditions (requisites) for incoming SIP messages. These rules can be used as additional matching criteria for the following:

- Classification rules in the Classification table (see [Configuring Classification Rules](#) on page 1171)
- IP-to-IP routing rules in the IP-to-IP Routing table (see [Configuring SBC IP-to-IP Routing Rules](#) on page 1186)
- Outbound Manipulation rules in the Outbound Manipulations table (see [Configuring IP-to-IP Outbound Manipulations](#) on page 1236)

Message Condition rules are configured using the same syntax as that used for Conditions when configuring Message Manipulation rules in the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856). You can configure simple Message Condition rules, for example, "header.to.host contains company", meaning SIP messages whose To header has a host part containing the string "company". You also can configure complex rules using the "AND" or "OR" Boolean operands and also use regular expressions (regex), for example:

- "body.sdp regex pcmu" can be used to enable routing based on the offered codec (G.711 Mu) in the incoming SDP message.
- "body.sdp regex (AVP[0-9| |\s]\*\s8[\s| |\n])" can be used to enable routing based on payload type 8 in the incoming SDP message.

- The Message Condition rule is applied only to the original incoming SIP message, prior to any manipulation made by the device on the message.
- For a description on SIP message manipulation syntax, refer to the document *Syntax for SIP Message Manipulation Reference Guide*.

The following procedure describes how to configure Message Condition rules through the Web interface. You can also configure it through ini file [ConditionTable] or CLI (`configure voip > sbc routing condition-table`).

➤ **To configure a Message Condition rule:**

1. Open the Message Conditions table (**Setup** menu > **Signaling & Media** tab > **Message Manipulation** folder > **Message Conditions**).
2. Click **New**; the following dialog box appears:

3. Configure a Message Condition rule according to the parameters described in the table below.
4. Click **Apply**.

An example of configured Message Condition rules is shown in the figure below:

INDEX ↕	NAME	CONDITION
0	IP Group user	param.ipg.src.type==user
1	Contains SIP Via Header	header.via.exists
2	"101" user part in From header	header.from.url.user=="101"

- **Index 0:** Incoming SIP dialog that is classified as belonging to a User-type IP Group.
- **Index 1:** Incoming SIP dialog that contains a SIP Via header.
- **Index 2:** Incoming SIP dialog with "101" as the user part in the SIP From header.

**Table 21-2: Message Conditions Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 59 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ The value can't contain a forward slash (/).</li> <li>■ The value can't be configured with the character string "any" (upper or lower case).</li> </ul>
'Condition' condition	Defines the condition of the SIP message. The valid value is a string of up to 299 characters. You can use the built-

Parameter	Description
[Condition]	<p>in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p><b>Note:</b> Enclose the user and host parts in single quotation marks ('...').</p>

## Configuring SIP Message Policy Rules

The Message Policies table lets you configure up to 20 SIP Message Policy rules. You can use SIP Message Policy rules to block (*blocklist*) unwanted incoming SIP messages or to permit (*allowlist*) the receipt of desired SIP messages. You can configure legal and illegal characteristics of SIP messages. SIP Message Policy rules are helpful against VoIP fuzzing (also known as robustness testing), which sends different types of packets to its "victims" for finding bugs and vulnerabilities. For example, the attacker might try sending a SIP message containing either an oversized parameter or too many occurrences of a parameter.

You can also enable the Message Policy to protect the device against incoming SIP messages with malicious signature patterns, which identify specific scanning tools used by attackers to search for SIP servers in a network. To configure Malicious Signatures, see [Configuring Malicious Signatures](#) on page 1247.

Each Message Policy rule can be configured with the following:

- Maximum message length
- Maximum header length
- Maximum message body length
- Maximum number of headers
- Maximum number of bodies
- Option to send 400 "Bad Request" response if message request is rejected
- Blocklist and allowlist for defined methods (e.g., INVITE)
- Blocklist and allowlist for defined bodies
- Malicious Signatures

The Message Policies table provides a default Message Policy called "Malicious Signature DB Protection" (Index 0), which is based only on Malicious Signatures and discards SIP messages identified with any of the signature patterns configured in the Malicious Signature table.

To apply a SIP Message Policy rule to calls, you need to assign it to the SIP Interface associated with the relevant IP Group (see [Configuring SIP Interfaces](#) on page 570).

The following procedure describes how to configure Message Policy rules through the Web interface. You can also configure it through ini file [MessagePolicy] or CLI (`configure voip > message message-policy`).

➤ **To configure SIP Message Policy rules:**

1. Open the Message Policies table (**Setup** menu > **Signaling & Media** tab > **Message Manipulation** folder > **Message Policies**).
2. Click **New**; the following dialog box appears:

3. Configure a Message Policy rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 21-3: Message Policies Table Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't contain a forward slash (/).</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
<b>Limits</b>	
'Max Message Length' max-message-length [MaxMessageLength]	Defines the maximum SIP message length. The valid value is up to 65,000 characters. The default is 65,000.
'Max Header Length' max-header-length	Defines the maximum SIP header length. The valid value is up to 4,096 characters. The default is

Parameter	Description
[MaxHeaderLength]	4,096.
'Max Body Length' max-body-length [MaxBodyLength]	Defines the maximum SIP message body length. This is the value of the Content-Length header. The valid value is up to 61,440 characters. The default is 61,440.
'Max Num Headers' max-num-headers [MaxNumHeaders]	Defines the maximum number of SIP headers. The valid value is any number up to 64. The default is 64. <b>Note:</b> The device supports up to 20 SIP Record-Route headers that can be received in a SIP INVITE request or a 200 OK response. If it receives more than this, it responds with a SIP 513 'Message Too Large' response.
'Max Num Bodies' max-num-bodies [MaxNumBodies]	Defines the maximum number of bodies (e.g., SDP) in the SIP message. The valid value is any number up to 64. The default is 64.
Policies	
'Send Rejection' send-rejection [SendRejection]	Defines whether the device sends a SIP response if it rejects a message request due to the Message Policy. The default response code is SIP 400 "Bad Request". To configure a different response code, use the [MessagePolicyRejectResponseType] parameter.  ■ [0] <b>Policy Reject</b> = (Default) The device discards the message and sends a SIP response to reject the request.  ■ [1] <b>Policy Drop</b> = The device discards the message without sending any response.
SIP Method Blocklist-Allowlist Policy	
'Method List' method-list [MethodList]	Defines the SIP methods for the blocklist or allowlist. Multiple methods are separated by a backslash (\), for example, "INVITE\BYE" (without quotations). The values are case-insensitive.
'Method List Type' method-list-type [MethodListType]	Defines the policy (blocklist or allowlist) for the SIP methods specified in the 'Method List' parameter (above).  ■ [0] <b>Policy Blocklist</b> = The specified methods are rejected.

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Policy Allowlist</b> = (Default) Only the specified methods are allowed; the others are rejected.</li> </ul>
SIP Body Blocklist-Allowlist Policy	
'Body List' body-list [BodyList]	Defines the SIP body type (i.e., value of the Content-Type header) to blocklist or allowlist. For example, application/sdp.  The values of the parameter are case-sensitive.
'Body List Type' body-list-type [BodyListType]	Defines the policy (blocklist or allowlist) for the SIP body specified in the 'Body List' parameter (above). <ul style="list-style-type: none"> <li>■ [0] <b>Policy Blocklist</b> =The specified SIP body is rejected.</li> <li>■ [1] <b>Policy Allowlist</b> = (Default) Only the specified SIP body is allowed; the others are rejected.</li> </ul>
Malicious Signature	
'Malicious Signature Database' signature-db-enable  [UseMaliciousSignatureDB]	Enables the use of the Malicious Signature database (signature-based detection). <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> To configure Malicious Signatures, see <a href="#">Configuring Malicious Signatures</a> on page 1247.  <b>Note:</b> The parameter is applicable only to the SBC application.

## Configuring Pre-Parsing Manipulation Rules

The Pre-Parsing Manipulation Set table lets you configure up to 10 Pre-Parsing Manipulation Sets. Pre-Parsing Manipulation allows you to manipulate incoming SIP messages (dialog-initiating and in-dialog) before they are parsed (as an object) by the device. In other words, messages can be manipulated in their original format (plain text) as received from the network. Pre-Parsing Manipulation may be useful, for example, to overcome parser strictness or to “allow” possible parsing errors.

To use a configured Pre-Parsing Manipulation Set, you need to assign it to a SIP Interface (see [Configuring SIP Interfaces](#) on page 570). The device performs Pre-Parsing Manipulation before Pre-Classification Manipulation and Classification.

Pre-Parsing Manipulation rules are defined by the SIP message element to manipulate (for example, INVITE), the pattern based on regular expression (regex) to search for (match) in the incoming message, and the regex pattern to replace the matched pattern.

- For a detailed description of supported regex syntax, refer to the document *Syntax for SIP Message Manipulation Reference Guide*.
- If you have configured call routing from the device's SBC application (IP-to-IP routing) to the device's Gateway application for IP-to-Tel routing, the device uses the initial SIP message as if it's a new call. Therefore, if any manipulations were done on the SIP message by the SBC application, the device ignores them.

Pre-Parsing Manipulation is configured using two tables with "parent-child" relationship:

- **Pre-Parsing Manipulation Sets table ("parent"):** Defines a descriptive name for the Pre-Parsing Manipulation Set.. You can configure up to 10 Pre-Parsing Manipulation Sets.
- **Pre-Parsing Manipulation Rules table ("child"):** Defines the actual manipulation rule. You can configure up to 30 rules in total (for all Pre-Parsing Manipulation Sets combined).

The following procedure describes how to configure Pre-Parsing Manipulation Sets through the Web interface. You can also configure it through other management platforms:

- **Pre-Parsing Manipulation Sets table:** *ini* file [PreParsingManipulationSets] or CLI (`configure voip > message pre-parsing-manip-sets`)
- **Pre-Parsing Manipulation Rules table:** *ini* file [PreParsingManipulationRules] or CLI (`configure voip > message pre-parsing-manip-rules`)

#### ➤ To configure Pre-Parsing Manipulation Sets:

1. Open the Pre-Parsing Manipulation Sets table (**Setup** menu > **Signaling & Media** tab > **Message Manipulation** folder > **Pre-Parsing Manipulation Sets**).
2. Click **New**; the following dialog box appears:

3. Configure a Pre-Parsing Manipulation Set name according to the parameters described in the table below.
4. Click **Apply**.

**Table 21-4: Pre-Parsing Manipulation Set Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' name [Name]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value cannot contain a forward slash (/).</li> </ul>

- In the Pre-Parsing Manipulation Sets table, select the row, and then click the **Pre-Parsing Manipulation Rules** link located below the table; the Pre-Parsing Manipulation Rules table appears.
- Click **New**; the following dialog box appears:

The screenshot shows a dialog box titled "Pre-Parsing Manipulation Rules". It is divided into two main sections: "MATCH" and "ACTION".  
 In the "MATCH" section, there is a field for "Index" containing the value "0" and a field for "Message Type". Below these fields is an "Editor" button.  
 In the "ACTION" section, there is a field for "Pattern" and a field for "Replace-With". Below these fields is another "Editor" button.

- Configure a rule according to the parameters described in the table below.
- Click **New**, and then save your settings to flash memory.

**Table 21-5: Pre-Parsing Manipulation Rules Table Parameter Descriptions**

Parameter	Description
Match	
'Index' [PreParsingManipulationRules_ RuleIndex]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Message Type' message-type [PreParsingManipulationRules_ MessageType]	Defines the SIP message type to which you want to apply the rule. The following syntax is supported: <ul style="list-style-type: none"> <li>■ To apply the rule to any message type, leave the field empty or configure it to <b>any</b>.</li> <li>■ SIP requests:               <ul style="list-style-type: none"> <li>✓ <b>any.request:</b> The rule is applied to any request.</li> </ul> </li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ <b>&lt;SIP Method&gt;.request:</b> The rule is applied to the specified SIP Method (e.g., invite.request).</li> <li>■ SIP responses: <ul style="list-style-type: none"> <li>✓ <b>any.response:</b> The rule is applied to any response.</li> <li>✓ <b>response.&lt;response code&gt;:</b> The rule is applied to messages with the specified response (e.g., response.200 for SIP 200 or response.1xx for any provisional response).</li> </ul> </li> </ul> <p>You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p>
Action	
'Pattern' pattern [PreParsingManipulationRules_ Pattern]	<p>Defines a pattern, based on regex, to search for (match) in the incoming message.</p> <p>For more information on regex, refer to the document <i>Syntax for SIP Message Manipulation Reference Guide</i>.</p>
'Replace-With' replace-with [PreParsingManipulationRules_ ReplaceWith]	<p>Defines a pattern, based on regex, to replace the matched pattern (defined above). You can use the built-in syntax editor to help you configure the field. Click the <b>Editor</b> button located alongside the field to open the Editor, and then simply follow the on-screen instructions.</p> <p>For more information on regex, refer to the document <i>Syntax for SIP Message Manipulation Reference Guide</i>.</p>

# Part V

## Gateway Application

## 22 Overview

This section describes configuration of the Gateway application. The Gateway application refers to IP-to-Tel and Tel-to-IP call routing. The term *Tel* refers to:

■ Analog:

- FXS equipment such as a fax machine or plain old telephone service (POTS)
- FXO equipment such as a PBX

■ Digital: PSTN

IP-to-Tel refers to calls received by the device from the IP network and then sent to the PSTN or an analog endpoint connected directly or indirectly to the device. Tel-to-IP refers to calls received by the device from an analog endpoint connected directly or indirectly to the device or the PSTN and then sent to the IP network.

- FXO (Foreign Exchange Office) is the interface replacing the analog telephone and connects to a Public Switched Telephone Network (PSTN) line from the Central Office (CO) or to a Private Branch Exchange (PBX). The FXO is designed to receive line voltage and ringing current, supplied from the CO or the PBX (just like an analog telephone). An FXO VoIP device interfaces between the CO/PBX line and the Internet.
- FXS (Foreign Exchange Station) is the interface replacing the Exchange (i.e., the CO or the PBX) and connects to analog telephones, dial-up modems, and fax machines. The FXS is designed to supply line voltage and ringing current to these telephone devices. An FXS VoIP device interfaces between the analog telephone devices and the Internet.

### Call Processing Summary

The device processes Gateway calls as shown below:

■ IP-to-Tel Call:

■ Tel-to-IP Call:

## 23 Digital PSTN

This section describes the configuration of the device's Gateway application for its' digital interfaces (PSTN).

### Configuring Trunk Settings

The Trunk Settings page allows you to configure the device's PSTN trunks. This includes selecting the PSTN protocol and configuring related parameters. This page also lets you perform the following maintenance procedures:

- **Taking a Trunk Out of Service:** Some parameters can be configured when the trunk is in service, while others require you to take the trunk out of service. To take a trunk out of service, click the **Stop Trunk** button. Once a trunk is "stopped", all current calls are dropped and no new calls can be made on the trunk.
- **Deactivating an E1/T1 Trunk:** To deactivate a trunk, click the **Deactivate** button. Deactivation temporarily disconnects (logically) the trunk from the PSTN network. Upon trunk deactivation, the device generates an AIS alarm on the trunk to the far-end. As a result, an RAI alarm signal may be received by the device. A subsequent trunk activation, done by clicking the **Activate** button, reconnects the trunk to the PSTN network and clears the AIS alarm. Trunk deactivation is typically used for maintenance such as checking the trunk's physical integrity.
- **Creating a Loopback Line:** You can create (and remove) remote loopback for DS1 lines. This is done by clicking the **Create Loopback** button. To remove the loopback, click the **Remove Loopback** button.

- The parameters displayed on the Trunk Settings page depend on the configured protocol (see the 'Protocol Type' parameter).
- When modifying an already configured trunk through the Web interface, some parameters are unavailable (grayed out) until you stop the trunk.
- To delete a configured trunk, configure the 'Protocol Type' parameter to **NONE**.
- You can't configure trunks that are deactivated.
- You can't activate or deactivate a stopped trunk.
- You can't stop a trunk that is providing the device's clock. To stop such a trunk, assign a different trunk to provide the device's clock or enable the 'TDM Bus PSTN Auto Clock' parameter (see [TDM and Timing](#) on page 908).
- If you configure the 'Protocol Type' parameter to **NONE** (i.e., no protocol type) and no other trunks have been configured, after selecting a PRI protocol type, you must restart the device.
- BRI trunks can operate with E1 or T1 trunks.
- All PRI trunks of the device must be of the same line type (E1 or T1). However, different variants of the same line type can be configured on different trunks. For example, E1 Euro ISDN and E1 CAS (subject to the constraints in the device's Release Note).
- The ISDN BRI North American variants (NI-2, DMS-100, and 5ESS) are partially supported by the device. Please contact the sales representative of your purchased device before implementing this protocol.
- If the protocol type is CAS, you can assign or modify a dial plan (in the 'Dial Plan' field) and perform this without stopping the trunk.
- When configuring the device through ini file, if you want to configure a parameter for a specific trunk, append the parameter name with an underscore followed by the trunk's ID (i.e., <Parameter Name>\_x, where x denotes the trunk ID and 0 denotes trunk ID 1). For example, ProtocolType\_4 configures the protocol type for trunk ID 5.
- For a description of all the trunk parameters, see [PSTN Parameters](#) on page 1988.

The following procedure describes how to configure trunks through the Web interface. You can also configure trunks through ini file parameters or CLI (`configure voip > interface`).

➤ **To configure a new trunk:**

1. Open the Trunk Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Trunks & Groups** > **Trunks**).

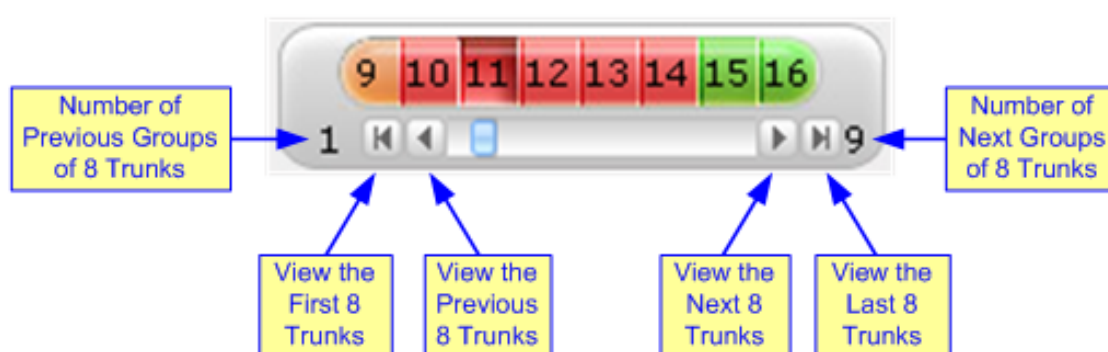

## Trunk Settings

GENERAL		ADVANCED SETTINGS	
Module ID	1	PSTN Alert Timeout	-1
Trunk ID	1	Out-Of-Service Behavior	Not Configured
Trunk Configuration State	Not Configured	Remove Calling Name	Use Global Parameters
Protocol Type	NONE	Play Ringback Tone to Trunk	Not Configured
		Call Rerouting Mode	None
		Description	

On the top of the page, a bar with Trunk number icons displays the status of each trunk according to the following color codes:

- **Grey:** Disabled
  - **Green:** Active
  - **Yellow:** RAI alarm (also appears when you deactivate a Trunk by clicking the **Deactivate** button)
  - **Red:** LOS/LOF alarm
  - **Blue:** AIS alarm
  - **Orange:** D-channel alarm (ISDN only)
2. Select the trunk that you want to configure, by clicking the required trunk number icon. The bar initially displays the first eight trunk number icons (i.e., trunks 1 through 8), if they exist. To scroll through the trunk number icons (i.e., view the next / last or previous / first group of eight trunks), see the figure below. If the scroll bar displays all available trunks, the scroll bar buttons are unavailable.

3. To configure a new trunk:
- Configure the trunk parameters as required.
  - Click the **Apply Trunk Settings** button.
4. To modify an already configured trunk:

- If you only need to modify parameters that don't require the trunk to be stopped (see previous note), simply modify their values, and then click **Submit**.
- If you need to modify parameters that require the trunk to be stopped (see previous note), click the **Stop Trunk** button, modify their values, and then click the **Apply Trunk Settings** button to apply the changes to the selected trunk (or click **Apply to All Trunks** to apply the changes to all trunks); the 'Trunk Configuration State' read-only field displays "Active".

5. Restart the device with a save-to-flash for your settings to take effect.

**Table 23-1: Trunk Settings Table Parameter Descriptions**

Parameter	Description
General	
'Module ID'	(Read-only) Displays the module number to which the trunk belongs.
'Trunk ID'	(Read-only) Displays the selected trunk ID number.
'Trunk Configuration State'	(Read-only) Displays the status of the trunk: <ul style="list-style-type: none"> <li>■ "Not Configured": The trunk is not configured.</li> <li>■ "Active": The trunk is configured and currently active.</li> <li>■ "Inactive": The trunk is configured, but was stopped and is inactive (not operational).</li> </ul>
'Protocol Type' <pre>configure voip &gt; interface e1- t1 bri &gt; protocol [ProtocolType]</pre>	Defines the PSTN protocol for the specific trunk. <ul style="list-style-type: none"> <li>■ [0] <b>NONE</b></li> <li>■ [1] <b>E1 EURO ISDN</b> = ISDN PRI Pan-European (CTR4) protocol</li> <li>■ [2] <b>T1 CAS</b> = Common T1 robbed bits protocols including E&amp;M wink start, E&amp;M immediate start, E&amp;M delay dial/start and loop-start and ground start.</li> <li>■ [3] <b>T1 RAW CAS</b></li> <li>■ [4] <b>T1 TRANSPARENT</b> = Transparent protocol, where no signaling is provided by the device. Timeslots 1 to 24 of all trunks are mapped to DSP channels.</li> <li>■ [5] <b>E1 TRANSPARENT 31</b> = Transparent protocol, where no signaling is provided by the device. Timeslots 1 to 31 of each trunk are mapped to DSP channels.</li> <li>■ [6] <b>E1 TRANSPARENT 30</b> = Transparent protocol, where</li> </ul>

Parameter	Description
	<p>no signaling is provided by the device. Timeslots 1 to 31, excluding time slot 16 of all trunks are mapped to DSP channels.</p> <ul style="list-style-type: none"> <li>■ [7] <b>E1 MFCR2</b> = Common E1 MFC/R2 CAS protocols (including line signaling and compelled register signaling).</li> <li>■ [8] <b>E1 CAS</b> = Common E1 CAS protocols (including line signaling and MF/DTMF address transfer).</li> <li>■ [9] <b>E1 RAW CAS</b></li> <li>■ [10] <b>T1 NI2 ISDN</b> = National ISDN 2 PRI protocol</li> <li>■ [11] <b>T1 4ESS ISDN</b> = ISDN PRI protocol for the Lucent™/AT&amp;T™ 4ESS switch.</li> <li>■ [12] <b>T1 5ESS 9 ISDN</b> = ISDN PRI protocol for the Lucent™/AT&amp;T™ 5ESS-9 switch.</li> <li>■ [13] <b>T1 5ESS 10 ISDN</b> = ISDN PRI protocol for the Lucent™/AT&amp;T™ 5ESS-10 switch.</li> <li>■ [14] <b>T1 DMS100 ISDN</b> = ISDN PRI protocol for the Nortel™ DMS switch.</li> <li>■ [15] <b>J1 TRANSPARENT</b></li> <li>■ [16] <b>T1 NTT ISDN</b> = ISDN PRI protocol for the Japan - Nippon Telegraph Telephone (known also as INS 1500).</li> <li>■ [17] <b>E1 AUSTEL ISDN</b> = ISDN PRI protocol for the Australian Telecom.</li> <li>■ [18] <b>E1 HKT ISDN</b> = ISDN PRI (E1) protocol for the Hong Kong - HKT.</li> <li>■ [19] <b>E1 KOR ISDN</b> = ISDN PRI protocol for Korean Operator (similar to ETSI).</li> <li>■ [20] <b>T1 HKT ISDN</b> = ISDN PRI (T1) protocol for the Hong Kong - HKT.</li> <li>■ [21] <b>E1 QSIG</b> = ECMA 143 QSIG over E1</li> <li>■ [22] <b>E1 TNZ</b> = ISDN PRI protocol for Telecom New Zealand (similar to ETSI)</li> <li>■ [23] <b>T1 QSIG</b> = ECMA 143 QSIG over T1</li> <li>■ [30] <b>E1 FRENCH VN6 ISDN</b> = France Telecom VN6</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [31] <b>E1 FRENCH VN3 ISDN</b> = France Telecom VN3</li> <li>■ [34] <b>T1 EURO ISDN</b> = ISDN PRI protocol for Euro over T1</li> <li>■ [35] <b>T1 DMS100 Meridian ISDN</b> = ISDN PRI protocol for the Nortel™ DMS Meridian switch</li> <li>■ [36] <b>T1 NI1 ISDN</b> = National ISDN 1 PRI protocol</li> <li>■ [40] <b>E1 NI2 ISDN</b> = National ISDN 2 PRI protocol over E1</li> <li>■ [50] <b>BRI EURO ISDN</b> = Euro ISDN over BRI</li> <li>■ [51] <b>BRI NI2 ISDN</b></li> <li>■ [52] <b>BRI DMS 100 ISDN</b></li> <li>■ [53] <b>BRI 5ESS 10 ISDN</b></li> <li>■ [54] <b>BRI QSIG</b> = QSIG over BRI</li> <li>■ [55] <b>BRI VN6</b> = VN6 over BRI</li> <li>■ [56] <b>BRI NTT</b> = BRI ISDN Japan (Nippon Telegraph)</li> <li>■ [57] <b>BRI IUA</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, stop the trunk prior to configuring it.</li> <li>■ All PRI trunks must be configured with the same protocol type (E1 or T1). The device can support different variants of CAS and PRI protocols on different E1/T1 spans (no more than four simultaneous PRI variants).</li> <li>■ BRI trunks can operate together with E1 or T1 trunks.</li> <li>■ The ISDN BRI North American variants (NI-2, DMS-100, and 5ESS) are partially supported by the device. Please contact the sales representative of your purchased device before implementing this protocol.</li> </ul>
<b>Trunk Configuration</b>	
<b>'Clock Master'</b> <pre>configure voip &gt; interface e1-t1 &gt; clock-master [ClockMaster]</pre>	<p>Defines the Tx clock source of the E1/T1 line.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Recovered</b> = (Default) Generates the clock according to the Rx of the E1/T1 line.</li> <li>■ [1] <b>Generated</b> = Generates the clock according to the internal TDM bus.</li> </ul>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ To configure the source of the internal TDM bus clock, see the [TDMBusClockSource] parameter.</li> <li>■ The parameter is applicable only to E1/T1 interfaces.</li> </ul>
<p>'Auto Clock Trunk Priority'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; clock- priority clock- priority</pre> <p>[AutoClockTrunkPriority]</p>	<p>Defines the trunk priority for auto-clock fallback for the specific trunk.</p> <p>The valid range is 0 to 100, where 0 (default) is the highest priority and 100 indicates that the device doesn't perform a fallback to the trunk (typically used to mark untrusted source of clock).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ To enable auto-clock fallback, configure the [TDMBusPSTNAutoClockEnable] parameter to 1.</li> </ul>
<p>'Line Code'</p> <pre>configure voip &gt; interface e1-t1 &gt; line-code</pre> <p>[LineCode]</p>	<p>Defines the line code for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>B8ZS</b> = (Default) B8ZS line code (applicable only to T1 trunks).</li> <li>■ [1] <b>AMI</b> = AMI line code.</li> <li>■ [2] <b>HDB3</b> = HDB3 line code (applicable only to E1 trunks).</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ The parameter is applicable only to E1/T1 trunks.</li> <li>■ The parameter is not configurable for BRI interfaces; the device automatically uses the Modified Alternate Mark Invert (MAMI) line code.</li> </ul>
'Line Build Out Loss'	Defines the line build out loss for the specific trunk.

Parameter	Description
<pre>configure voip &gt; interface e1-t1 &gt; line-build-out- loss</pre> <p>[LineBuildOut.Loss]</p>	<ul style="list-style-type: none"> <li>■ [0] <b>0 dB</b> (default)</li> <li>■ [1] <b>-7.5 dB</b></li> <li>■ [2] <b>-15 dB</b></li> <li>■ [3] <b>-22.5 dB</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ The parameter is applicable only to T1 trunks.</li> </ul>
<p>'Trace Level'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; trace- level</pre> <p>[TraceLevel]</p>	<p>Defines the trace level for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No Trace</b> (default)</li> <li>■ [1] <b>Full ISDN Trace</b></li> <li>■ [2] <b>Layer 3 ISDN Trace</b></li> <li>■ [3] <b>Only ISDN Q.931 Messages Trace</b></li> <li>■ [4] <b>Layer 3 ISDN No Duplication Trace</b></li> </ul>
<p>'Framing Method'</p> <pre>configure voip &gt; interface e1-t1 &gt; framing</pre> <p>[FramingMethod]</p>	<p>Defines the physical framing method for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Extended Super Frame</b> = (Default) Depends on protocol type: <ul style="list-style-type: none"> <li>✓ E1: E1 CRC4 MultiFrame Format extended G.706B (same as c)</li> <li>✓ T1: T1 Extended Super Frame with CRC6 (same as D)</li> </ul> </li> <li>■ [1] <b>Super Frame</b> = T1 SuperFrame Format (as B).</li> <li>■ [a] <b>E1 FRAMING DDF</b> = E1 DoubleFrame Format - CRC4 is forced to off</li> <li>■ [b] <b>E1 FRAMING MFF CRC4</b> = E1 CRC4 MultiFrame Format - CRC4 is always on</li> <li>■ [c] <b>E1 FRAMING MFF CRC4 EXT</b> = E1 CRC4 MultiFrame Format extended G.706B - auto negotiation is on. If the negotiation fails, it changes automatically to CRC4 off (ddf)</li> <li>■ [A] <b>T1 FRAMING F4</b> = T1 4-Frame multiframe.</li> <li>■ [B] <b>T1 FRAMING F12</b> = T1 12-Frame multiframe (D4).</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [C] <b>T1 FRAMING ESF</b> = T1 Extended SuperFrame without CRC6</li> <li>■ [D] <b>T1 FRAMING ESF CRC6</b> = T1 Extended SuperFrame with CRC6</li> <li>■ [E] <b>T1 FRAMING F72</b> = T1 72-Frame multiframe (SLC96)</li> <li>■ [F] <b>T1 FRAMING ESF CRC6 J2</b> = J1 Extended SuperFrame with CRC6 (Japan)</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ The parameter is not configurable for BRI interfaces; the device automatically sets the BRI framing method. If you configure the 'ISDN Termination Side' parameter (see below) to <b>User side</b>, the 'Clock Master' parameter (see above) is automatically set to <b>Recovered</b>. If you configure the 'ISDN Termination Side' parameter to <b>Network side</b>, the 'Clock Master' parameter is automatically set to <b>Generated</b>.</li> </ul>
ISDN/BRI Configuration	
<p>'ISDN Termination Side'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; isdn- termination-side [TerminationSide]</pre>	<p>Defines the ISDN termination side for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>User side</b> = (Default) ISDN User Termination Equipment (TE) side.</li> <li>■ [1] <b>Network side</b> = ISDN Network Termination (NT) side.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For clock synchronization of E1/T1 interfaces, to configure if the clock is recovered (from the line) or generated (by the device), see the 'Clock Master' parameter (above).</li> <li>■ For clock synchronization of BRI interfaces: <ul style="list-style-type: none"> <li>✓ If the parameter is configured to <b>Network side</b>, the clock is generated by the device.</li> <li>✓ If the parameter is configured to <b>User side</b>, the clock is recovered from the line.</li> </ul> </li> <li>■ If you are modifying the parameter for an already</li> </ul>

Parameter	Description
	<p>configured trunk through the Web interface, first stop the trunk.</p> <ul style="list-style-type: none"> <li>■ Select <b>User side</b> when the PSTN or PBX side is configured as <b>Network side</b>, and vice versa. If you don't know the device's ISDN termination side, select <b>User side</b>. If the D-channel alarm is indicated, choose <b>Network side</b>.</li> <li>■ The BRI and PRI ports are configured similarly, using the parameter.</li> </ul>
<b>'BRI Layer2 Mode'</b> configure voip > interface bri > isdn-layer2-mode [BriLayer2Mode]	<p>Defines Point-to-Point (P2P) or Point-to-Multipoint (P2MP) mode for BRI ports.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Point to Point</b> (default)</li> <li>■ [1] <b>Point to Multipoint</b></li> </ul> <p><b>Note:</b> The parameter is applicable only to BRI interfaces.</p>
<b>'Q.931 Layer Response Behavior'</b> configure voip > interface bri e1- t1 > isdn-bits-ns- behavior [ISDNIBehavior]	<p>Defines (by bit-field) several behavior options that influence the behavior of the Q.931 protocol.</p> <ul style="list-style-type: none"> <li>■ [0] = Disable (default).</li> <li>■ [1] <b>NO STATUS ON UNKNOWN IE</b> = Q.931 Status message isn't sent if Q.931 received message contains an unknown/unrecognized IE. By default, the Status message is sent.  <b>Note:</b> This value is applicable only to ISDN variants in which sending of Status message is optional.</li> <li>■ [2] <b>NO STATUS ON INV OP IE</b> = Q.931 Status message isn't sent if an optional IE with invalid content is received. By default, the Status message is sent.  <b>Note:</b> This option is applicable only to ISDN variants in which sending of Status message is optional.</li> <li>■ [4] <b>ACCEPT UNKNOWN FAC IE</b> = Accepts unknown/unrecognized Facility IE. Otherwise, the Q.931 message that contains the unknown Facility IE is rejected (default).  <b>Note:</b> This option is applicable only to ISDN variants where a complete ASN1 decoding is performed on Facility IE.</li> <li>■ [128] <b>SEND USER CONNECT ACK</b> = The Connect ACK message is sent in response to received Q.931 Connect; otherwise, the Connect ACK is not sent.</li> </ul>

Parameter	Description
	<p><b>Note:</b> This option is applicable only to Euro ISDN User side outgoing calls.</p> <ul style="list-style-type: none"> <li>■ [512] <b>EXPLICIT INTERFACE ID</b> = Enables configuration of T1 NFAS Interface ID. For more information on NFAS, see the [ISDNNFASInterfaceID_x] parameter. <b>Note:</b> This value is applicable only to 4/5ESS, DMS, NI-2 and HKT variants.</li> <li>■ [2048] <b>ALWAYS EXPLICIT</b> = Always set the Channel Identification IE to explicit Interface ID, even if the B-channel is on the same trunk as the D-channel. <b>Note:</b> This value is applicable only to 4/5ESS, DMS and NI-2 variants.</li> <li>■ [32768] <b>ACCEPT MU LAW</b> =Mu-Law is also accepted in ETSI.</li> <li>■ [65536] <b>EXPLICIT PRES SCREENING</b> = The calling party number (octet 3a) is always present even when presentation and screening are at their default. <b>Note:</b> This option is applicable only to ETSI, NI-2, and 5ESS.</li> <li>■ [131072] <b>STATUS INCOMPATIBLE STATE</b> = Clears the call on receipt of Q.931 Status with incompatible state. Otherwise, no action is taken (default).</li> <li>■ [262144] <b>STATUS ERROR CAUSE</b> = Clear call on receipt of Status according to cause value.</li> <li>■ [524288] <b>ACCEPT A LAW</b> =A-Law is also accepted in 5ESS.</li> <li>■ [2097152] <b>RESTART INDICATION</b> = Upon receipt of a Restart message, acEV_PSTN_RESTART_CONFIRM is generated.</li> <li>■ [4194304] <b>FORCED RESTART</b> = On data link (re)initialization, send RESTART (Class 7) if there is no call.</li> <li>■ [134217728] <b>NS BRI DL ALWAYS UP (0x08000000)</b> = By default, a BRI trunk configured as Network side requests to disconnect the D-channel when there are no active calls on the trunk. If you select this option, such a request is ignored by a Network side trunk. If the option is configured for a User side trunk, it accepts the</li> </ul>

Parameter	Description
	<p>disconnect request but attempts to re-establish D-channel synchronization immediately afterward.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>✓ After a device restart or trunk initialization (i.e., configuration is applied), it's possible that D-channel synchronization is only established upon the first incoming or outgoing call.</li> <li>✓ If this option is configured for a User side trunk, it may cause the D-channel alarm to be raised and cleared periodically because the opposite Network side may try to disconnect the D-channel if there are no ongoing calls.</li> </ul> <p>■ [67108864] <b>NS ACCEPT ANY CAUSE</b> = Accept any Q.850 Cause IE from ISDN.</p> <p><b>Note:</b> This option is applicable only to Euro ISDN.</p> <p>■ [536870912] <b>QSI ACCEPT ALCATEL FAC</b> = Alcatel coding for redirect number and display name is accepted by the device.</p> <p><b>Note:</b> This option is applicable only to QSIG (and relevant for specific Alcatel PBXs such as OXE).</p> <p>■ [1073741824] <b>QSI ENCODE INTEGER</b> = If this bit is set, INTEGER ASN.1 type is used in operator coding (compliant to new ECMA standards); otherwise, OBJECT IDENTIFIER ASN.1 type is used.</p> <p><b>Note:</b> This option is applicable only to QSIG.</p> <p>■ [2147483648] <b>5ESS National Mode For Bch Maintenance</b> = Use the National mode of AT&amp;T 5ESS for B-channel maintenance.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ When configuring through the Web interface, click the arrow button and then for each required option select <b>1</b> to enable.</li> <li>■ When configuring through ini file, to support multiple behaviors, configure the parameter with a summation of the individual feature values. For example, to support</li> </ul>

Parameter	Description
	<p>both [512] and [2048] features, configure the parameter to 2560 (i.e., 512 plus 2048).</p> <ul style="list-style-type: none"> <li>■ For BRI terminal endpoint identifier (TEI) configuration, instead of using this parameter, use the following parameters: [BriTEIConfigP2P_x], [BriTEIConfigP2MP_x], [BriTEIAssignTrigger_x], and [BriTEIRemoveTrigger_x].</li> </ul>
<p>'Outgoing Calls Behavior'</p> <pre>configure voip &gt; interface bri e1- t1 &gt; isdn-bits- outgoing-calls- behavior [ISDNOutCallsBehavior]</pre>	<p>Defines (by bit-field) several options that influence the behavior of the ISDN Stack outgoing calls. To select the options, click the arrow button, and then for each required option, select <b>1</b> to enable. The default is <b>0</b> (i.e., disabled).</p> <ul style="list-style-type: none"> <li>■ [2] <b>USER SENDING COMPLETE</b> = The default behavior of the device (when this bit is not set) is to automatically generate the Sending-Complete IE in the Setup message. This behavior is used when overlap dialing is not needed. When overlap dialing is needed, set this bit and the behavior is changed to suit the scenario, i.e., Sending-Complete IE is added when required in the Setup message for Enblock mode or in the last Digit with Overlap mode.</li> <li>■ [16] <b>USE MU LAW</b> = The device sends G.711-m-Law in outgoing voice calls. When disabled, the device sends G.711-A-Law in outgoing voice calls.  <b>Note:</b> This option is applicable only to the Korean variant.</li> <li>■ [128] <b>DIAL WITH KEYPAD</b> = The device uses the Keypad IE to store the called number digits instead of the CALLED_NB IE.  <b>Note:</b> This option is applicable only to the Korean variant (Korean network). This is useful for Korean switches that don't accept the CALLED_NB IE.</li> <li>■ [256] <b>STORE CHAN ID IN SETUP</b> = The device forces the sending of a Channel-Id IE in an outgoing Setup message even if it's not required by the standard (i.e., optional) and no Channel-Id has been specified in the establishment request. This is useful for improving required compatibility with switches. On BRI lines, the Channel-Id IE indicates 'any channel'. On PRI lines it indicates an unused channel ID, preferred only.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [512] <b>USE A LAW</b> = The device sends G.711 A-Law in outgoing voice calls. When disabled, the device sends the default G.711-Law in outgoing voice calls. <b>Note:</b> The option is applicable only to the E10 variant (T1 ISDN).</li> <li>■ [1024] = Numbering plan/type for T1 IP-to-Tel calling numbers are defined according to the manipulation tables or according to the RPID header (default). Otherwise, the plan/type for T1 calls are set according to the length of the calling number. <b>Note:</b> The option is applicable only to T1 ISDN.</li> <li>■ [2048] = The device accepts any IA5 character in the called_nb and calling_nb strings and sends any IA5 character in the called_nb, and is not restricted to extended digits only (i.e., 0-9,*,#).</li> <li>■ [16384] <b>DLCI REVERSED OPTION</b> = Behavior bit used in the IUA interface groups to indicate that the reversed format of the DLCI field must be used. <b>Note:</b> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ When configuring through <i>ini</i> file, to support multiple options, enter a summation of the individual feature values. For example, to support both [2] and [16] features: ISDNOutCallsBehavior = 18</li> </ul> </li> </ul>
'Incoming Calls Behavior' configure voip > interface el- t1 bri > isdn- bits-incoming- calls-behavior [ISDNInCallsBehavior]	<p>Defines (by bit-field) several options that influence how the ISDN Stack INCOMING calls behave.</p> <ul style="list-style-type: none"> <li>■ [32] <b>DATA CONN RS</b> = The device automatically sends a Q.931 Connect (answer) message on incoming Tel calls (Q.931 Setup).</li> <li>■ [64] <b>VOICE CONN RS</b> = The device sends a Connect (answer) message on incoming Tel calls.</li> <li>■ [2048] <b>CHAN ID IN FIRST RS</b> = The device sends Channel ID in the first response to an incoming Q.931 Call Setup message. If not set, the Channel ID is sent only if the device requires changing the proposed Channel ID.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [4096] <b>USER SETUP ACK</b> = (Default) The Setup Ack message is sent by the SIP Gateway application layer and not automatically by the PSTN stack.</li> <li>■ [8192] <b>CHAN ID IN CALL PROC</b> = The device sends Channel ID in a Q.931 Call Proceeding message.</li> <li>■ [65536] <b>PROGR IND IN SETUP ACK</b> = (Default) The device includes Progress Indicator (PI=8) in Setup Ack message if an empty called number is received in an incoming Setup message. This option is applicable to the overlap dialing mode. The device also plays a dial tone (for TimeForDialTone) until the next called number digits are received.</li> <li>■ [2147483648] <b>USER SCREEN INDICATOR</b> = When the device receives two Calling Number IE's in the Setup message, the device, by default, uses only one of the numbers according to the following: <ul style="list-style-type: none"> <li>✓ Network provided, Network provided: first calling number is used</li> <li>✓ Network provided, User provided: first calling number is used</li> <li>✓ User provided, Network provided: second calling number is used</li> <li>✓ User provided, user provided: first calling number is used</li> </ul> <p>When this bit is configured, the device behaves as follows:</p> <ul style="list-style-type: none"> <li>✓ Network provided, Network provided: first calling number is used</li> <li>✓ Network provided, User provided: second calling number is used</li> <li>✓ User provided, Network provided: first calling number is used</li> <li>✓ User provided, user provided: first calling number is used</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already</li> </ul> </li> </ul>

Parameter	Description
	<p>configured trunk through the Web interface, first stop the trunk.</p> <ul style="list-style-type: none"> <li>■ In the Web interface, the parameter displays the summation of the enabled optional bit values in hex format. For example, the default value is 0x11000 (69632 in decimal), which is a summation of the two bit options, USER SETUP ACK (0x01000 or 4096 in decimal) and PROGR IND IN SETUP ACK (0x10000 or 65536 in decimal) that are enabled by default (i.e., 4096 + 65536 = 69632).</li> <li>■ When configuring through <i>ini</i> file, to support multiple options, enter a summation of the individual feature values. For example, to support both [2048] and [65536] features: ISDNInCallsBehavior = 67584</li> </ul>
<p>'General Call Control Behavior'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; isdn- bits-cc-behavior [ISDNGeneralCCBehavior]</pre>	<p>Defines (by bit-field) several general CC behavior options. To select the options, click the arrow button, and then for each required option, select <b>1</b> to enable. The default is <b>0</b> (i.e., disabled).</p> <ul style="list-style-type: none"> <li>■ [2] = Data calls with interworking indication use 64 kbps B-channels (physical only).</li> <li>■ [8] <b>REVERSE CHAN ALLOC ALGO</b> = Channel ID allocation algorithm.</li> <li>■ [16] = The device clears down the call if it receives a NOTIFY message specifying 'User-Suspended'. A NOTIFY (User-Suspended) message is used by some networks (e.g., in Italy or Denmark) to indicate that the remote user has cleared the call, especially in the case of a long distance voice call.</li> <li>■ [32] <b>CHAN ID 16 ALLOWED</b> = Applies only to ETSI E1 lines (30B+D). Enables handling the differences between the newer QSIG standard (ETS 300-172) and other ETSI-based standards (ETS 300-102 and ETS 300-403) in the conversion of B-channel ID values into timeslot values: <ul style="list-style-type: none"> <li>✓ In 'regular ETSI' standards, the timeslot is identical to the B-channel ID value, and the range for both is 1 to 15 and 17 to 31. The D-channel is identified as channel-id #16 and carried into the timeslot #16.</li> <li>✓ In newer QSIG standards, the channel-id range is 1</li> </ul> </li> </ul>

Parameter	Description
	<p>to 30, but the timeslot range is still 1 to 15 and 17 to 31. The D-channel is not identified as channel-id #16, but is still carried into the timeslot #16.</p> <p>When this bit is set, the channel ID #16 is considered as a valid B-channel ID, but timeslot values are converted to reflect the range 1 to 15 and 17 to 31. This is the new QSIG mode of operation. When this bit is not set (default), the channel_id #16 is not allowed, as for all ETSI-like standards.</p> <ul style="list-style-type: none"> <li>■ [64] <b>USE T1 PRI</b> = PRI interface type is forced to T1.</li> <li>■ [128] <b>USE E1 PRI</b> = PRI interface type is forced to E1.</li> <li>■ [256] <b>START WITH B CHAN OOS</b> = B-channels start in the Out-Of-Service state (OOS).</li> <li>■ [512] <b>CHAN ALLOC LOWEST</b> = CC allocates B-channels starting from the lowest available B-channel id.</li> <li>■ [1024] <b>CHAN ALLOC HIGHEST</b> = CC allocates B-channels starting from the highest available B-channel id.</li> <li>■ [4096] <b>NO B CHANEL CONTROL</b> = When this bit is set, B-channels allocation and control is left according to the application level. Call control doesn't control / allocate B-channels. The application provides the B-channel information within the appropriate ACU primitives. Call Control simply provides the received Channel-ID IE contents to the user, without checking its availability, validity or consistency with other calls in progress. This bit should be set when the B-channel can be changed in Q.931 Proceeding, Alerting, or Connect.</li> <li>■ [16384] <b>CC_TRANSPARENT_UUI</b> = The UUI-protocol implementation of CC is disabled allowing the application to freely send UUI elements in any primitive, regardless of the UUI-protocol requirements (UUI Implicit Service 1). This allows more flexible application control on the UUI. When this bit is not set (default behavior), CC implements the UUI-protocol as specified in the ETS 300-403 standards for Implicit Service 1.</li> <li>■ [65536] <b>GTD5 TBCT</b> = CC implements the VERIZON-GTD-5 Switch variant of the TBCT Supplementary Service, as specified in FSD 01-02-40AG Feature Specification Document from Verizon. Otherwise, TBCT is</li> </ul>

Parameter	Description
	<p>implemented as specified in GR-2865-CORE specification (default behavior).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ When configuring through <i>ini</i> file, to support multiple options, enter a summation of the individual feature values. For example, to support both [16] and [32] features: <code>ISDNGeneralCCBehavior = 48</code></li> </ul>
<p>'ISDN NS Behaviour 2'</p> <pre>configure voip &gt; interface el- t1 bri &gt; isdn- bits-ns-extension- behavior</pre> <p>[ISDNNSBehaviour2]</p>	<p>Defines (by bit-field) several options that influence the behavior of the Q.931 protocol for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [8] <b>NS BEHAVIOUR2 ANY UUI</b> = Any User to User Information Element (UUIE) is accepted for any protocol discriminator. This is useful for interoperability with non-standard switches.</li> <li>■ [16] <b>NS BEHAVIOUR2 DISPLAY</b> = The Display IE is accepted even if it is not defined in the QSIG ISDN protocol standard. This is applicable only when configuration is QSI.</li> <li>■ [64] <b>NS BEHAVIOUR2 FAC REJECT</b> = When this bit is set, the device answers with a Facility IE message with the Reject component on receipt of Facility IE with unknown/invalid Invoke component. This bit is implemented in QSIG and ETSI variants.</li> <li>■ [256] <b>RESTART CLASS 7 IN FORCE RESTART</b> = When this bit is set, the device sends RESTART (Class 7) if there is no call, on data link (re)initialization.</li> </ul>
<p>'NFAS Group Number'</p> <pre>configure voip &gt; interface el-t1 &gt; isdn-nfas-group- number</pre> <p>[NFASGroupNumber]</p>	<p>Defines the ISDN Non-Facility Associated Signaling (NFAS) group number (NFAS member) for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] 0 = (Default) Non-NFAS trunk.</li> <li>■ [1-12] 1 to 12 = NFAS group number.</li> </ul> <p>Trunks belonging to the same NFAS group have the same number. With NFAS, you can use a single D-channel to control multiple PRI interfaces.</p> <p><b>Note:</b></p>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ For the parameter to take effect, a device restart is required.</li> <li>■ The parameter is applicable only to T1 ISDN protocols.</li> <li>■ For more information on NFAS, see <a href="#">ISDN Non-Facility Associated Signaling (NFAS)</a> on page 926.</li> </ul>
<b>'NFAS Interface ID'</b> <code>configure voip &gt;</code> <code>interface e1-t1 &gt;</code> <code>isdn-nfas-</code> <code>interface-id</code> <b>[ISDNNFASInterfaceID]</b>	<p>Defines a different Interface ID for the specific trunk. The valid range is 0 to 100. The default interface ID equals the trunk's ID.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ To set the NFAS interface ID, configure the <code>[ISDNBehavior_x]</code> parameter to include '512' feature per T1 trunk.</li> <li>■ The parameter is applicable only to T1 ISDN protocols.</li> <li>■ For more information on NFAS, see <a href="#">ISDN Non-Facility Associated Signaling (NFAS)</a> on page 926.</li> </ul>
<b>'D-channel Configuration'</b> <code>configure voip &gt;</code> <code>interface e1-t1 &gt;</code> <code>isdn-nfas-</code> <code>dchannel-type</code> <b>[DChConfig]</b>	<p>Defines the specific trunk as primary, backup (optional), or B-channel.</p> <ul style="list-style-type: none"> <li>■ [0] <b>PRIMARY</b>= (Default) Primary Trunk - contains a D-channel that is used for signaling.</li> <li>■ [1] <b>BACKUP</b> = Backup Trunk - contains a backup D-channel that is used if the primary D-channel fails.</li> <li>■ [2] <b>NFAS</b> = NFAS Trunk - contains only 24 B-channels, without a signaling D-channel.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you are modifying the parameter for an already configured trunk through the Web interface, first stop the trunk.</li> <li>■ The parameter is applicable only to T1 ISDN protocols.</li> <li>■ For more information on NFAS, see <a href="#">ISDN Non-Facility</a></li> </ul>

Parameter	Description
	<a href="#">Associated Signaling (NFAS)</a> on page 926.
<b>CAS Configuration</b>	
<b>'Dial Plan'</b> <pre>configure voip &gt; interface e1-t1 &gt; cas-dial-plan-name</pre> <b>[CASTrunkDialPlanName_x]</b>	<p>Defines the CAS Dial Plan name for the specific trunk.</p> <p>The range is up to 11 characters.</p> <p>For example, the following configures an E1_MFCR2 trunk with a single protocol (Trunk 5):</p> <pre>ProtocolType_5 = 7 CASFileName_0='R2_Korea_CP_ANI.dat' CASTableIndex_5 = 0 DialPlanFileName = 'DialPlan_USA.dat' CASTrunkDialPlanName_5 = 'AT_T'</pre>
<b>'CAS Table per Trunk'</b> <pre>configure voip &gt; interface e1-t1 &gt; cas-table-index</pre> <b>[CASTableIndex_x]</b>	<p>Defines the CAS protocol for the specific trunk from a list of CAS protocols defined by the parameter CASFileName_x.</p> <p>For example, the below configuration specifies Trunks 0 and 1 to use the E&amp;M Winkstart CAS (E_M_WinkTable.dat) protocol, and Trunks 2 and 3 to use the E&amp;M Immediate Start CAS (E_M_ImmediateTable.dat) protocol:</p> <pre>CASFileName_0 = 'E_M_WinkTable.dat' CASFileName_1 = 'E_M_ImmediateTable.dat' CASTableIndex_0 = 0 CASTableIndex_1 = 0 CASTableIndex_2 = 1 CASTableIndex_3 = 1</pre> <p><b>Note:</b> To configure CAS tables per B-channel, see the [CASChannelIndex] parameter.</p>
<b>'CAS Table per Channel'</b> <pre>configure voip &gt; interface e1-t1 &gt; cas-channel-index</pre> <b>[CASChannelIndex]</b>	<p>Defines the loaded CAS protocol table index per B-channel pertaining to a CAS trunk. The parameter is assigned a string value and can be set in one of the following two formats:</p> <ul style="list-style-type: none"> <li>■ <b>CAS table per channel:</b> Each channel is separated by a comma and the value entered denotes the CAS table index used for that channel. The syntax is &lt;CAS index&gt;,&lt;CAS index&gt; (e.g., "1,2,1,2..."). For this format, 31 indices must be defined for E1 trunks (including dummy for B-channel 16), or 24 indices for T1 trunks. Below is an example for configuring a T1 CAS trunk (Trunk 5) with several CAS variants:</li> </ul> <pre>ProtocolType_5 = 7 CASFILENAME_0='E_M_FGBWinkTable.dat'</pre>

Parameter	Description
	<pre> CASFILENAME_1='E_M_FGDWinkTable.dat' CASFILENAME_2='E_M_WinkTable.txt' CasChannelIndex_5 = '0,0,0,1,1,1,2,2,2,0,0,0,1,1,1,0,1,2,0,2, 1,2,2,2' CASDelimitersPaddingUsage_5 = 1 </pre> <p>■ <b>CAS table per channel group:</b> Each channel group is separated by a colon and each channel is separated by a comma. The syntax is &lt;x-y channel range&gt;:&lt;CAS table index&gt;, (e.g., "1-10:1,11-31:3"). Every B-channel (including 16 for E1) must belong to a channel group. Below is an example for configuring an E1 CAS trunk (Trunk 5) with several CAS variants:</p> <pre> ProtocolType_5 = 8 CASFILENAME_2='E1_R2D' CASFILENAME_7= E_M_ImmediateTable_A- Bit.txt' CasChannelIndex_5 = '1-10:2,11-20:7,21- 31:2' </pre> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ To configure the parameter, first stop the trunk.</li> <li>■ Only one of these formats can be implemented (not both).</li> <li>■ When the parameter is not configured, a single CAS table is used for the entire trunk (configured by the [CASTableIndex] parameter).</li> </ul>
Advanced Settings	
<p>'PSTN Alert Timeout'</p> <pre> configure voip &gt; interface e1- t1 bri &gt; pstn- alrt-timeout [TrunkPSTNAlertTimeout] </pre>	<p>Defines the Alert Timeout (ISDN T301 timer) in seconds for outgoing calls to PSTN for the specific trunk. This timer is used between the time that an ISDN Setup message is sent to the Tel side (IP-to-Tel call establishment) and a Connect message is received. If Alerting is received, the timer is restarted.</p> <p>The range is 1 to 600. The default is 180.</p>
<p>'Local ISDN Ringback Tone Source'</p> <pre> configure voip &gt; interface e1- </pre>	<p>Defines if the ringback tone is played to the ISDN by the PBX/PSTN or by the device for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>PBX</b> = (Default) PBX/PSTN plays the ringback tone.</li> </ul>

Parameter	Description
<pre>t1 bri &gt; local- isdn-rbt-src</pre> <p>[LocalISDNRBSrc]</p>	<p>■ [1] <b>Gateway</b> = The device plays the ringback tone.</p> <p><b>Note:</b> The parameter is used together with the [PlayRBTone2Trunk] parameter.</p>
<p>'Set PI in Rx Disconnect Message'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; pi-in-rx- disc-msg</pre> <p>[PIForDisconnectMsg]</p>	<p>Defines the device's behavior for the specific trunk when a Disconnect message is received from the ISDN before a Connect message is received.</p> <p>■ [-1] <b>Not Configured</b> = (Default) Sends a 183 SIP response according to the received progress indicator (PI) in the ISDN Disconnect message. If PI = 1 or 8, the device sends a 183 response, enabling the PSTN to play a voice announcement to the IP side. If there isn't a PI in the Disconnect message, the call is released.</p> <p>■ [0] <b>No PI</b> = Doesn't send a 183 response to IP. The call is released.</p> <p>■ [1] <b>PI = 1</b> = Sends a 183 response to IP.</p> <p>■ [8] <b>PI = 8</b> = Sends a 183 response to IP.</p>
<p>'ISDN Transfer Capabilities'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; isdn- xfer-cab</pre> <p>[ISDNTransferCapability]</p>	<p>Defines the IP-to-ISDN Transfer Capability of the Bearer Capability IE in ISDN Setup messages for the specific trunk (where the x in the ini file parameter name denotes the trunk number and where 0 is Trunk 1).</p> <p>■ [-1] <b>Not Configured</b></p> <p>■ [0] <b>Audio 3.1</b> (default)</p> <p>■ [1] <b>Speech</b></p> <p>■ [2] <b>Data</b></p> <p>■ [3] <b>Audio 7</b></p> <p><b>Note:</b> If the parameter is not configured or configured to <b>Not Configured</b>, Audio 3.1 capability is used.</p>
<p>'Progress Indicator to ISDN'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; pi-to- isdn</pre> <p>[ProgressIndicator2ISDN]</p>	<p>Defines the Progress Indicator (PI) in ISDN messages that are sent to the PSTN for the specific trunk.</p> <p>■ [-1] <b>Not Configured</b> = (Default) The PI in ISDN messages is set according to the [PlayRBTone2Tel] parameter.</p> <p>■ [0] <b>No PI</b> = PI is not sent to ISDN.</p> <p>■ [1] <b>PI = 1</b> = The PI value is sent to PSTN in Q.931/Proceeding and Alerting messages. Typically, the</p>

Parameter	Description
	<p>PSTN/PBX cuts through the audio channel without playing local ringback tone, enabling the originating party to hear remote Call Progress Tones or network announcements.</p> <ul style="list-style-type: none"> <li>■ [2] <b>PI = 2</b> = The PI value is sent to PSTN in Q.931/Proceeding and Alerting messages. The destination address is non-ISDN.</li> <li>■ [8] <b>PI = 8</b> = The PI value is sent to PSTN in Q.931/Proceeding and Alerting messages. Typically, the PSTN/PBX cuts through the audio channel without playing local ringback tone, enabling the originating party to hear remote Call Progress Tones or network announcements.</li> </ul>
<p>'Select Receiving of Overlap Receiving'</p> <pre>configure voip &gt; interface el- t1 bri &gt; ovrlp- rcving-type [ISDNRxOverlap]</pre>	<p>Defines the receiving (Rx) type of ISDN overlap dialing for Tel-to-IP calls for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [0] <b>None</b> = (Default) Disabled.</li> <li>■ [1] <b>Local receiving</b> = ISDN Overlap Dialing - the complete number is sent in the INVITE Request-URI user part. The device receives ISDN called number that is sent in the 'Overlap' mode. The ISDN Setup message is sent to IP only after the number (including the Sending Complete IE) is fully received (via Setup and/or subsequent Info Q.931 messages). In other words, the device waits until it has received all the ISDN signaling messages containing parts of the called number, and only then it sends a SIP INVITE with the entire called number in the Request-URI.</li> <li>■ [2] <b>Through SIP</b> = Interworking of ISDN Overlap Dialing to SIP according to RFC 3578. The device sends the first received digits from the ISDN Setup message to the IP side in the initial INVITE message. For each subsequently received ISDN Info Q.931 message, the device sends the collected digits to the IP side in re-INVITE messages.</li> <li>■ [3] <b>Through SIP INFO</b> = Interworking of ISDN Overlap Dialing to SIP according to RFC 3578. The device sends the first received digits from the ISDN Setup message to the IP side in the initial INVITE message. For each subsequently received ISDN Info Q.931 message, the device sends the collected digits to the IP side in INFO</li> </ul>

Parameter	Description
	<p>messages.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ When configured to <b>Through SIP</b> or <b>Through SIP INFO</b>, you can configure the minimum number of overlap digits to collect before sending the first SIP message for routing the call, using the [MinOverlapDigitsForRouting] parameter.</li> <li>■ When configured to <b>Through SIP</b> or <b>Through SIP INFO</b>, even if SIP 4xx responses are received during this ISDN overlap receiving, the device doesn't release the call.</li> <li>■ The [MaxDigits] parameter can be used to limit the length of the collected number for ISDN overlap dialing (if Sending Complete is not received).</li> <li>■ If a digit map pattern is defined (using the [DigitMapping] or [DialPlanIndex] parameters), the device collects digits until a match is found (e.g., for closed numbering schemes) or until a timer expires (e.g., for open numbering schemes). If a match is found (or the timer expires), the digit collection process is terminated even if Sending Complete is not received.</li> <li>■ To enable ISDN overlap dialing for IP-to-Tel calls, use the [ISDNTxOverlap] parameter.</li> <li>■ For more information on ISDN overlap dialing, see <a href="#">ISDN Overlap Dialing</a> on page 930.</li> </ul>
<p>'B-Channel Negotiation'</p> <pre>configure voip &gt; interface e1- t1 bri &gt; b- channel-nego-for- trunk [BChannelNegotiationForTrunk]</pre>	<p>Defines the ISDN B-channel negotiation mode for the specific trunk.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) The negotiation mode is according to the global parameter [BChannelNegotiation].</li> <li>■ [0] <b>Preferred</b></li> <li>■ [1] <b>Exclusive</b></li> <li>■ [2] <b>Any</b></li> </ul> <p><b>Note:</b> The <b>Any</b> option is applicable only if you configure the 'ISDN Termination Side' parameter to <b>User side</b>.</p>
<p>'Out-Of-Service Behavior'</p> <pre>configure voip &gt;</pre>	<p>Defines the method for setting the trunk to out-of-service state for the specific trunk. The parameter is applicable to</p>

Parameter	Description
<pre>interface bri e1- t1 &gt; dig-oos- behavior</pre> <p>[DigitalOOSBehaviorForTrunk_x]</p>	<p>the Busy Out feature (see the [EnableBusyOut] parameter) and the Lock/Unlock per Trunk Group feature performed in the Trunk Group Settings table of the Web interface.</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) The out-of-service method is according to the global parameter [DigitalOOSBehavior].</li> <li>■ [0] <b>Default</b> = <ul style="list-style-type: none"> <li>✓ ISDN: Sends ISDN Service messages to indicate out-of-service or in-service state for ISDN variants that support Service messages. For ISDN variants that do not support Service messages, the device sends an Alarm Indication Signal (AIS) alarm.</li> <li>✓ CAS: Sends an Alarm Indication Signal (AIS) alarm.</li> </ul> </li> <li>■ [1] <b>Service</b> = (Applicable only to T1 ISDN variants that support this method)Sends ISDN Service messages indicating out-of-service or in-service state. <ul style="list-style-type: none"> <li>✓ Graceful out-of-service disabled: The device rejects new incoming calls and immediately takes all channels (idle and busy) out-of-service, by sending Service messages on the B-channels. The device disconnects busy channels before it sends out-of-service Service messages on them.</li> <li>✓ Graceful out-of-service enabled: The device rejects new incoming calls. If at least one busy channel exists during the graceful period, the device immediately takes all idle channels out-of-service and sends out-of-service Service messages to the other B-channels as soon as they become idle. When graceful period ends, the device disconnects all non-idle channels and then sends out-of-service Service messages to them.</li> </ul> </li> </ul> <p>When connectivity is restored for the Busy Out feature or the Trunk Group is unlocked, the device brings all the trunks back into service by sending in-service Service messages to all their B-channels.</p> <li>■ [2] <b>D-Channel</b> = (Applicable only to ISDN and fully configured trunks) Takes the D-channel down or brings it up.</li>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ Graceful out-of-service disabled: The device rejects new incoming calls and immediately takes the D-channel down.</li> <li>✓ Graceful out-of-service enabled: The device rejects new incoming calls. Only when all channels are idle (when graceful period ends or when all channels become idle before graceful period ends, whichever occurs first), does the device take the D-channel down.</li> </ul> <p>When connectivity is restored for the Busy Out feature or the Trunk Group is unlocked, the device brings the D-channels up again.</p> <p><b>Note:</b> For partially configured trunks (only some channels configured), this option only rejects new calls for the trunk; the D-channel remains up.</p> <ul style="list-style-type: none"> <li>■ [3] <b>Alarm</b> = Sends or clears a PSTN Alarm Indication Signal (AIS) alarm.</li> <li>✓ Graceful out-of-service disabled: The device rejects new incoming calls and immediately sends an AIS alarm.</li> <li>✓ Graceful out-of-service enabled: The device rejects new incoming calls and only when all channels are idle (when graceful period ends or when all channels become idle before graceful period ends, whichever occurs first), does the device send an alarm on the trunk.</li> </ul> <p>When connectivity is restored for the Busy Out feature or the Trunk Group is unlocked, the device clears the alarm.</p> <p><b>Note:</b> For partially configured trunks (only some channels configured), this option only rejects new calls for the trunk; no alarm is sent.</p> <ul style="list-style-type: none"> <li>■ [4] <b>Block</b> = (Applicable only to CAS) Blocks the B-channels.</li> <li>✓ Graceful out-of-service disabled: The device rejects new incoming calls and immediately blocks all channels (idle and busy). The device disconnects busy channels before blocking them.</li> </ul>

Parameter	Description
	<p>✓ Graceful out-of-service enabled: The device rejects new incoming calls. If at least one busy channel exists during the graceful period, the device immediately blocks all idle channels, and blocks the other B-channels as soon as they become idle. When graceful period ends, the device disconnects all non-idle channels and then blocks them.</p> <p>When connectivity is restored for the Busy Out feature or the Trunk Group is unlocked, the device unblocks all the B-channels.</p> <p>■ [5] <b>Service and D-Channel</b> = (Applicable only to T1 ISDN variants that support this method) Sends ISDN Service messages to indicate out-of-service or in-service state and takes the D-channel down or brings it up.</p> <p>✓ Graceful out-of-service disabled:</p> <ul style="list-style-type: none"> <li>• Fully configured trunk (all channels): The device rejects new incoming calls, disconnects busy channels, and takes the D-channel down.</li> <li>• Partially configured trunk (only some channels configured): The device rejects new incoming calls, disconnects busy channels, and sends out-of-service Service messages to all the configured channels (D-channel remains up).</li> </ul> <p>✓ Graceful out-of-service enabled: The device rejects new incoming calls and does the following:</p> <ul style="list-style-type: none"> <li>• Fully configured trunk (all channels): <ul style="list-style-type: none"> <li>&gt; If all channels are idle when the graceful period begins, the device immediately takes the channels out-of-service without sending out-of-service Service messages and instead, only takes the D-channel down.</li> <li>&gt; If at least one channel is busy during the graceful period, the device immediately takes all idle channels out-of-service and sends out-of-service Service messages to these B-channels. Thus, the PSTN/PBX side can detect that these calls are in out-of-service state and doesn't send new calls to these out-of-service channels, eliminating the scenario of loss of calls due to</li> </ul> </li> </ul>

Parameter	Description
	<p>rejection.</p> <ul style="list-style-type: none"> <li>&gt; If a channel is released (call ends) during the graceful period and there are still other busy channels, the device sends an out-of-service Service message to the idle channel.</li> <li>&gt; When the last channel is released in the trunk (or Trunk Group), the device takes all the channels out-of-service (locks the Trunk Group) without sending an out-of-service Service message; instead, it only takes the D-channel down. The device disconnects busy channels before it takes the D-channel down. When connectivity is restored for the Busy Out feature or the Trunk Group is unlocked, the device brings the D-channel up again without sending any Service messages to the B-channels.</li> </ul> <ul style="list-style-type: none"> <li>• Partially configured trunk (only some channels configured): Same as above, but the D-channel remains up and out-of-service Service message is sent to remaining busy channels.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Before configuring the parameter, stop the trunk (<b>Stop Trunk</b> button in the Trunk Settings page), configure the parameter, and then restart the trunk (<b>Apply Trunk Settings</b> button in the Trunk Settings page) for the settings to take effect.</li> <li>■ To configure the out-of-service method for all trunks, see the global parameter [DigitalOOSBehavior].</li> <li>■ To lock and unlock Trunk Groups in the Trunk Group Settings table, see <a href="#">Configuring Trunk Group Settings</a> on page 937.</li> <li>■ For a description of the Busy Out feature and for enabling the feature, see the [EnableBusyOut] parameter.</li> <li>■ To configure the graceful out-of-service period, see the [GracefulBusyOutTimeout] parameter.</li> <li>■ If the ISDN variant doesn't support the configured out-of-service option, the device sets the parameter to</li> </ul>

Parameter	Description
	<p><b>Default.</b></p> <ul style="list-style-type: none"> <li>■ When configuring the parameter through ini file, replace the "x" in the parameter's name with the required trunk number (where 0 is Trunk 1).</li> </ul>
<p>'Digital Out-Of-Service Behavior'</p> <pre>configure voip &gt; gateway digital settings &gt; dig- oos-behavior [DigitalOOSBehavior]</pre>	<p>Defines the method for setting all digital trunks to out-of-service state. To configure the out-of-service method per trunk, see the [DigitalOOSBehaviorForTrunk_x] parameter.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Default</b> = (Default) For a detailed description, see option [0] of the [DigitalOOSBehaviorForTrunk_x] parameter (per trunk setting).</li> <li>■ [1] <b>Service</b> = Sends an ISDN Service message indicating out-of-service state (or in-service). For a detailed description, see option [1] of the [DigitalOOSBehaviorForTrunk_x] parameter (per trunk setting).</li> <li>■ [2] <b>D-Channel</b> = Takes the D-Channel down or brings it up. For a detailed description, see option [2] of the [DigitalOOSBehaviorForTrunk_x] parameter (per trunk setting).</li> <li>■ [3] <b>Alarm</b> = Sends or clears a PSTN Alarm Indication Signal (AIS) alarm. For a detailed description, see option [3] of the [DigitalOOSBehaviorForTrunk_x] parameter (per trunk setting).</li> <li>■ [4] <b>Block</b> = Blocks the trunk. For a detailed description, see option [4] of the [DigitalOOSBehaviorForTrunk_x] parameter (per trunk setting).</li> <li>■ [5] <b>Service and D-Channel</b> = Sends ISDN Service messages to indicate out-of-service or in-service state and takes the D-channel down or brings it up. This can be used to help you easily identify the trunk.</p> <p>The valid value is a string of up to 40 alphanumeric characters (0-9, a-z, and A-Z).</p> <p>By default, the value is undefined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Spaces between characters are not supported.</li> <li>■ You can also configure the port's description on the Monitor page, as described in <a href="#">Configuring a Description for Telephony Ports</a> on page 1338.</li> </ul>

## TDM and Timing

This section describes the configuration of the TDM and clock timing parameters.

### TDM Bus Clock Settings

In a traditional TDM service network such as PSTN, both ends of the TDM connection must be synchronized. If synchronization is not achieved, voice frames are either dropped (to prevent a

buffer overflow condition) or inserted (to prevent an underflow condition). In both cases, connection quality and reliability is affected.

- PSTN line clock (see [Recovering Clock from PSTN Line Interface](#) below)
- Internal clock (see [Configuring Internal Clock as Clock Source](#) on the next page)

When the device is used in a 'non-span' configuration, the internal device clock must be used (as explained above).

### Recovering Clock from PSTN Line Interface

This section provides a brief description for configuring synchronization based on recovering clock from the PSTN line interface. For a full description of the clock parameters, see [PSTN Parameters](#) on page 1988.

#### ➤ To configure synchronization based on clock from PSTN line:

1. Open the TDM Bus Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **TDM Bus Settings**).

TDM Bus Clock Source	<input type="text" value="Internal"/> ⚡
TDM Bus PSTN Auto FallBack Clock	<input type="checkbox"/> ⚡
TDM Bus PSTN Auto Clock Reverting	<input type="checkbox"/> ⚡
TDM Bus Local Reference	<input type="text" value="1"/>

- a. From the 'TDM Bus Clock Source' drop-down list (TDMBusClockSource), select **Network** to recover the clock from the line interface.
- b. In the 'TDM Bus Local Reference' field (TDMBusPSTNLocalReference), enter the trunk from which the clock is derived.

- The E1/T1 trunk should recover the clock from the remote side (see below description of the 'Clock Master' parameter).
- The BRI trunk should be configured as an ISDN user-side.

- c. Enable automatic switchover to the next available "slave" trunk if the device detects that the local-reference trunk is no longer capable of supplying the clock to the system:
  - i. Select the 'TDM Bus PSTN Auto FallBack Clock' check box (TDMBusPSTNAutoClockEnable):

TDM Bus PSTN Auto FallBack Clock ☒ ⚡

- ii. Select the 'TDM Bus PSTN Auto Clock Reverting' check box (TDMBusPSTNAutoClockRevertingEnable) to enable the device to switch back to a previous trunk that returns to service if it has higher switchover priority:

TDM Bus PSTN Auto Clock Reverting  

- iii. In the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878), configure the priority level of the trunk for taking over as a local-reference trunk, using the 'Auto Clock Trunk Priority' parameter (AutoClockTrunkPriority). A value of 100 means that it never uses the trunk as local reference.
2. (E1/T1 Trunks Only) Configure the PSTN trunk to recover/derive clock from/to the remote side of the PSTN trunk (i.e. clock slave or clock master): In the Trunk Settings page, configure the 'Clock Master' parameter (ClockMaster) to one of the following:
    - Recovered - to recover clock (i.e. slave)
    - Generated - to transmit clock (i.e. master)

### Configuring Internal Clock as Clock Source

You can configure the device to use its internal clock source. The internal clock source is a stratum 4E-compliant clock source. When the device has no line interfaces, the device should be configured in this mode.

#### ➤ To configure internal clock as clock source:

1. Configure the clock source as the device's internal oscillator:
  - a. Open the TDM Bus Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **TDM Bus Settings**).
  - b. From the 'TDM Bus Clock Source' drop-down list [TDMBusClockSource], select **Internal**:

TDM Bus Clock Source

2. (E1/T1 Trunks Only) Configure the line to drive the clock on all trunks:
  - a. Open the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878).
  - b. From the 'Clock Master' drop-down list [ClockMaster], select **Generated** (for all trunks):

Clock Master

3. Restart the device with a save-to-flash for your settings to take effect.

## Configuring CAS State Machines

The CAS State Machine table lets you modify various timers and other basic parameters to define the initialization of the CAS state machine without changing the state machine itself (no compilation is required). The change doesn't affect the state machine itself, but rather the configuration.

The CAS table used can be chosen in two ways (using the parameter `CasChannelIndex`):

- Single CAS table per trunk
- Different CAS table per group of B-channels in a trunk

- CAS is applicable only to ISDN PRI interfaces.
- Prior to configuring CAS, you must enable the `CASOrientedBoard` ini file parameter (and restart the device with a save-to-flash for your settings to take effect).

### ➤ To modify the CAS state machine parameters:

1. Open the CAS State Machine page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Trunks & Groups** > **CAS State Machines**).

CAS State Machine

CAS Table Name	Generate Digit On Time	Generate Inter Digit Time	DTMF Max Detection Time	DTMF Min Detection Time	Max Incoming Address Digits	Max Incoming ANI Digits	Collect ANI	Digit Signaling System	Related Trunks
Earth_Calling.dat	-1	-1	-1	-1	-1	-1	Default ▼	Default ▼	

2. Ensure that the trunk is inactive. The trunk number displayed in the 'Related Trunks' field must be green. If it is red, indicating that the trunk is active, click the trunk number to open the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878), select the required Trunk number icon, and then click **Stop Trunk**.
3. In the CAS State Machine table, modify the required parameters according to the table below.
4. Once you have completed the configuration, activate the trunk if required in the Trunk Settings page, by clicking the trunk number in the 'Related Trunks' field, and in the Trunk Settings page, select the required Trunk number icon, and then click **Apply Trunk Settings**.
5. Click **Apply**, and then restart the device.

- The CAS state machine can only be configured using the Web-based management tool.
- Don't modify the default values unless you fully understand the implications of the changes and know the default values. Every change affects the configuration of the state machine parameters and the call process related to the trunk you are using with this state machine.
- You can modify CAS state machine parameters only if the following conditions are met:
  - ✓ Trunks are inactive (stopped), i.e., the 'Related Trunks' field displays the trunk number in green.
  - ✓ State machine is not in use or is in restart, or when it is not related to any trunk. If it is related to a trunk, you must delete the trunk or de-activate (*Stop*) the trunk.
- Field values displaying "-1" indicate CAS default values. In other words, CAS state machine values are used.
- The modification of the CAS state machine occurs at the CAS application initialization only for non-default values (-1).
- For more information on the CAS Protocol table, refer to the document *CAS Protocol Table Configuration Note*.

Table 23-2: CAS State Machine Parameters Description

Parameter	Description
'Generate Digit On Time' [CasStateMachineGenerateDigitOnTime]	Generates digit on-time (in msec). The value must be a positive value. The default is -1 (use value from CAS state machine).
'Generate Inter Digit Time' [CasStateMachineGenerateInterDigitTime]	Generates digit off-time (in msec). The value must be a positive value. The default is -1 (use value from CAS state machine).
'DTMF Max Detection Time' [CasStateMachineDTMFMaxOnDetectionTime]	Detects digit maximum on time (according to DSP detection information event) in msec units. The value must be a positive value. The default is -1 (use value from CAS state machine).
'DTMF Min Detection Time' [CasStateMachineDTMFMinOnDetectionTime]	Detects digit minimum on time (according to DSP detection information event) in msec units. The digit time length must be longer than this value to receive a detection. Any number may be used, but the value must be less than

Parameter	Description
	<p>CasStateMachineDTMFMaxOnDetection Time.</p> <p>The value must be a positive value. The default is -1 (use value from CAS state machine).</p>
'MAX Incoming Address Digits' [CasStateMachineMaxNumOfIncomingAddress Digits]	<p>Defines the limitation for the maximum address digits that need to be collected. After reaching this number of digits, the collection of address digits is stopped. The value must be an integer. The default is -1 (use value from CAS state machine).</p>
'MAX Incoming ANI Digits' [CasStateMachineMaxNumOfIncomingANIDigits]	<p>Defines the limitation for the maximum ANI digits that need to be collected. After reaching this number of digits, the collection of ANI digits is stopped. The value must be an integer. The default is -1 (use value from CAS state machine).</p>
'Collect ANI' [CasStateMachineCollectANI]	<p>In some cases, when the state machine handles the ANI collection (not related to MFCR2), you can control the state machine to collect ANI or discard ANI.</p> <ul style="list-style-type: none"> <li>■ [0] <b>No</b> = Don't collect ANI.</li> <li>■ [1] <b>Yes</b> = Collect ANI.</li> <li>■ [-1] <b>Default</b> = Default value - use value from CAS state machine.</li> </ul>
'Digit Signaling System' [CasStateMachineDigitSignalingSystem]	<p>Defines which Signaling System to use in both directions (detection\generation).</p> <ul style="list-style-type: none"> <li>■ [0] <b>DTMF</b> = Uses DTMF signaling.</li> <li>■ [1] <b>MF</b> = (Default) Uses MF signaling.</li> <li>■ [-1] <b>Default</b> = Default value - use value from CAS state machine.</li> </ul>

## Configuring Digital Gateway Parameters

The Digital Gateway Parameters page allows you to configure miscellaneous digital parameters. For a description of these parameters, see [Configuration Parameters Reference](#) on page 1701.

➤ **To configure the digital gateway parameters:**

1. Open the Digital Gateway Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Digital Gateway** > **Digital Gateway Settings**).

GENERAL		CALLER & CALLEE	
B-channel Negotiation	Exclusive	Remove CLI when Restricted	No
MFC R2 Category	1	Remove Calling Name	Disable
Add IE in SETUP		Use EndPoint Number As Calling Number Tel2IP	Disable
ISDN Transfer on Connect	Alert	Use EndPoint Number As Calling Number IP2Tel	Disable
Trunk Groups to Send IE		ISDN SubAddress Format	ASCII
Trunk Status Reporting Mode to Proxy	Disable	Enable Calling Party Category	Disable
TDM Over IP Min Calls	0	Calling Party Category Mode	None
ISDN Facility Trace	Disable		

REDIRECT NUMBER		SCREENING INDICATOR	
Swap Redirect and Called Numbers	No	Send Screening Indicator to IP	Not Configured
		Send Screening Indicator to ISDN	Not Configured

2. Configure the parameters as required.
3. Click **Apply**.

## Tunneling Applications

This section discusses the device's support for VoIP tunneling applications.

### TDM Tunneling

The device's TDM Tunneling feature allows you to tunnel groups of digital trunk spans or timeslots (B-channels) over the IP network. TDM Tunneling uses the device's internal routing (without Proxy control) capabilities to receive voice and data streams from TDM spans or individual timeslots, convert them into packets, and then transmit them over the IP network (using point-to-point or point-to-multipoint device distributions). A device opposite it (or several devices when point-to-multipoint distribution is used) converts the IP packets back into TDM traffic. Each timeslot can be targeted to any other timeslot within a trunk in the opposite device.

TDM tunneling is applicable only to ISDN PRI.

When TDM Tunneling is enabled ('TDM Tunneling' parameter configured to **Enable**) on the originating device, the originating device automatically initiates SIP calls from all enabled B-channels belonging to the spans that are configured with the protocol type **Transparent** (for ISDN trunks) or **Raw CAS** (for CAS trunks). The called number of each call is the internal phone number of the B-channel from where the call originates.

The IP-to-Tel Routing table is used to define the destination IP address of the terminating device. The terminating device automatically answers these calls if the 'Protocol Type' parameter is configured to **E1 TRANSPARENT 31** or **T1 RAW CAS** (for T1) or **E1 RAW CAS** (for E1), and the [ChannelSelectMode] parameter to 0 (**By Dest Phone Number**).

You can configure both devices to also operate in symmetric mode. To do so, configure the 'TDM Tunneling' parameter configured to **Enable** [EnableTDMOverIP] and configure the Tel-to-IP Routing table in both devices. After restarting, each device initiates calls to the other device. The first call for each B-channel is answered by the other device.

The device continuously monitors the established connections. If for some reason, one or more calls are released, the device automatically re-establishes these 'broken' connections. When a failure in a physical trunk or in the IP network occurs, the device re-establishes the tunneling connections when the network is restored.

It's recommended to use the keep-alive mechanism for each connection, by activating the 'session expires' timeout and using SIP re-INVITE messages.

The device supports the configuration (TDMoIPInitiateInviteTime and TDMoIPInviteRetryTime parameters) of the following timers for the TDM-over-IP tunneling application:

- Time between successive INVITEs sent from the same trunk.
- Time between call release and the new INVITE that is sent on the same channel. The call can be released if the device receives a 4xx or 5xx response.

By using profiles (see [Configuring Tel Profile](#) on page 755), you can configure the TDM Tunneling feature to choose different settings based on a timeslot or groups of timeslots. For example, you can use low-bit-rate vocoders to transport voice and 'Transparent' coder to transport data (e.g., for D-channel). You can also use profiles to assign ToS (for DiffServ) per source - a timeslot carrying data or signaling is assigned a higher priority value than a timeslot carrying voice.

For tunneling CAS trunks, configure the 'Protocol Type' parameter to **T1 RAW CAS** (for T1) or **E1 RAW CAS** (for E1) and enable RFC 2833 CAS relay mode ('CAS Transport Type' parameter to **CAS RFC2833 Relay**).

For TDM over IP, configure the [CallerIDTransportType] parameter to 0 (disabled), which means transparent.

Below is an example of *ini* files for two devices implementing TDM Tunneling for four E1 spans. In this example, both devices are dedicated to TDM tunneling.

## [ \TelProfile ]

## DSP Pattern Detector

For TDM tunneling applications, you can use the DSP pattern detector feature to initiate the echo canceller at call start. The device can be configured to support detection of a specific one-byte idle data pattern transmitted over digital E1/T1 timeslots. The device can be configured to detect up to four different one-byte data patterns. When the defined idle data pattern is detected, the channel resets its echo canceller.

### ➤ To configure DSP pattern detector:

1. On the DSP Settings page (**Setup** menu > **Signaling & Media** tab > **Media** folder > **DSP Settings**), do the following:
  - a. Select the 'IPMedia Detectors' check box [EnableDSIPMDetectors]:

IPMedia Detectors ☒

- b. Select the 'Enable Pattern Detector' check box [EnablePatternDetector]:

Enable Pattern Detector ☒

2. Configure the number (e.g., 5) of consecutive patterns to trigger the pattern detection event, using the ini file parameter [PDThreshold].
3. Configure the patterns that can be detected by the Pattern Detector, using the ini file parameter [PDPattern]. For example:

PDPattern = 84, 85, 212, 213 ; for idle patterns 54, 55, D4 and D5

## Configuring Private Wire Interworking

You can configure the device to interwork in a private wire system, where one side is IP (SIP) based and the other side is legacy, digital PSTN (E1/T1 CAS) based.

The feature is applicable only to IP-to-Tel calls and E1/T1 CAS.

Private wire is a generic term used to describe static point-to-point voice connections between two locations. Private Wires are typically used by a number of communities such as military, railways, emergency services, and financial services. Historically, private wire services were achieved by running direct private connections (telephone cables) between offices in the same building. In private wire services, dialing is unnecessary and there is a direct, "always on" and immediate connection.

Trading turret systems are also part of private wire services. A trading turret or dealer board is a specialized telephony key system that is generally used by financial traders on their trading desk. Trading turrets enable users to prioritize incoming call activity from customers or counter-

parties and make calls to these same people instantaneously by pushing a single button to access dedicated point-to-point telephone lines (commonly called Ringdown circuits). No dialing is necessary; the user simply picks up the handset or pushes a button and a dedicated line is seized. Thus, many turrets have multiple handsets and multi-channel speaker units, allowing immediate connection with multiple parties (e.g., 30 channels). These channels remain constantly open throughout the trading day.

Today, private wire services are evolving from digital TDM architectures to IP-based architectures. The device can be used for interworking between these two architectures, where you have the PSTN switch (PBX) using the E1/T1 CAS protocol on one side, and a SIP-based private wire (turret system) trunk on the other side. The device converts the CAS channels into a SIP call with a called and calling number and if required, passes the ABCD bit state changes through SIP messages, and vice versa. The following diagram shows an example of private-wire interworking by the device:

SIP-based private wire calls are established as any other INVITE dialog, but with the addition of the following headers:

- SIP Supported header with the value "pw-info-package" (i.e., Supported: pw-info-package).
- SIP Recv-Info header with the value "pw-info-package" and with the parameter "pw-type=" with a value denoting the private wire state, which can be:

- Ring Down state:

```
Recv-Info: pw-info-package;pw-type=ringdown
```

- Hook Switch:

```
Recv-Info: pw-info-package;pw-type=hookswitch
```

- TOS:

```
Recv-Info: pw-info-package;pw-type=tos
```

The following is an example of an INVITE message for a private wire call:

```
INVITE sip:109701@10.221.108.249:5060;transport=tcp SIP/2.0
Via:SIP/2.0/TCP10.221.109.4:5060;oc-
node=101;branch=z9hG4bKqkYGTNi7Husc11Jlmw6d9g;rport
From: <sip:uas@10.221.109.4>;tag=ENvIDQ
To: <sip:109701@10.221.108.249:5060;transport=tcp>
Call-ID: WHuqvQgdIZB27ewgrhJRYw
CSeq: 835392 INVITE
Contact: <sip:10.221.109.4:5060;transport=tcp;oc-node=101>
Max-Forwards: 70
Content-Type: application/sdp
Content-Length: 635
Supported: pw-info-package
Recv-Info: pw-info-package;pw-type=ringdown
```

Once a SIP-based private wire is established, the private wire user may wish to signal any of the following private wire events to the far-end private wire user, at any time during the "always-on" call:

- **Hook Switch (On Hook and Off Hook states):** This event signals a change in the state of an electronic hook switch. An example is when the user connects a wireless headset to the phone.
- **Ring Down (Ring and No Ring states):** This event signals a ring or no ring state. An example is when the user lifts the handset or pushes a button on the phone to alert the far-end user, which instantly sends ringing to the far end (even though they are already connected). This is also known as Automatic Ring Down (ARD) or Manual Ring Down (MRD).
- **TOS (transmission only service):** If neither Ring Down or Hook Switch modes are specified in the INVITE, TOS is assumed. In this case, the device ignores all CAS signaling, replies with 200 OK and opens a media channel.

These special private wire events are signaled during a call using the SIP INFO message in association with the INFO package (per IETF draft). The INFO package is the INFO message's body, which is in XML schema. The root element of the XML is "<pwsignal>", which contains two child elements:

- "<ringDown>" - requests a local Ring Down alert
- "<hookSwitch>" - requests a Hook Switch alert:
  - ◆ "onHook" - signals that the endpoint is not in use
  - ◆ "offHook" - signals that the endpoint is in use

The following is an example of the XML for private wire signaling in the SIP INFO message:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsd:schema targetNamespace="urn:bt-trs:params:xml:ns:private-wire:0"
  xmlns="urn:bt-trs:params:xml:ns:private-wire:0"

The following is an example of the message flow for the interworking private wire Ring Down state between the private wire trunk and the E1/T1 CAS trunk:

The following is an example of the message flow for interworking private wire Hook Switch states between the private wire trunk and the E1/T1 CAS trunk:

➤ **To configure private wire interworking:**

1. Enable TDM tunneling for private wire services, by doing one of the following:
  - **Globally:** Open the Digital Gateway Parameters page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Digital Gateway** > **Digital Gateway Parameters**), and then from the 'TDM Tunneling' drop-down list, select **Private Wire**:

TDM Tunneling Private Wire ⚡

- **Per Trunk:** Configure the ini file parameter [EnableTDMOverIPforTrunk].
2. Configure the ini file parameter [EnableReansweringInfo] to 1.
  3. Upload a CAS table file that supports your private wire service. For loading files to the device, see [Uploading Auxiliary Files](#) on page 1347.
  4. In the Trunk Settings page (see [Configuring Trunk Settings](#) on page 878), configure your E1 or T1 CAS Trunk. Make sure that you select the CAS table file that you loaded in the previous step, in the 'CAS Table per Trunk' field:

☒ CAS Table per Trunk Private\_Wire .dat (200

5. In the Trunk Groups table (see [Configuring Trunk Groups](#) on page 934), configure the Trunk Group ID for the E1/T1 CAS Trunk, as shown in the following example:

Group Index	Module	From Trunk	To Trunk	Channels	Phone Number	Trunk Group ID	Tel Profile Name
1	Module 1 PRI	1	1	1-30	4000	1	None

6. In the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937), configure the method for selecting channels for the E1/T1 CAS Trunk to **By Dest Phone Number**, as shown in the following example:

INDEX	NAME	TRUNK GROUP ID	CHANNEL SELECT MODE ▾
0	PW	1	By Dest Phone Number

7. In the IP-to-Tel Routing table (see [Configuring IP-to-Tel Routing Rules](#) on page 960), configure IP-to-Tel Routing rules.

## QSIG Tunneling

The device supports QSIG tunneling over SIP, according to IETF Internet-Draft draft-elwell-sipping-qsig-tunnel-03 ("Tunnelling of QSIG over SIP") and ECMA-355/ISO/IEC 22535. This is applicable to all ISDN variants. QSIG tunneling can be applied to all calls or to specific calls using IP Profiles.

TDM tunneling is applicable only to PRI and BRI.

QSIG tunneling sends all QSIG messages as raw data in corresponding SIP messages using a dedicated message body. This is used, for example, to enable two QSIG subscribers connected to the same or different QSIG PBX to communicate with each other over an IP network. Tunneling is supported in both directions (Tel-to-IP and IP-to-Tel).

The term tunneling means that messages are transferred 'as is' to the remote side without being converted (QSIG > SIP > QSIG). The advantage of tunneling over QSIG-to-SIP interworking is that by using interworking, QSIG functionality can only be partially achieved. When tunneling is used, all QSIG capabilities are supported and the tunneling medium (the SIP network) doesn't need to process these messages.

QSIG messages are transferred in SIP messages in a separate Multipurpose Internet Mail Extensions (MIME) body. Therefore, if a message contains more than one body (e.g., SDP and QSIG), multipart MIME must be used. The Content-Type of the QSIG tunneled message is 'application/QSIG'. The device also adds a Content-Disposition header in the following format:

Content-Disposition: signal; handling=required.

QSIG tunneling is done as follows:

- **Call setup (originating device):** The QSIG Setup request is encapsulated in the SIP INVITE message without being altered. After the SIP INVITE request is sent, the device doesn't encapsulate the subsequent QSIG message until a SIP 200 OK response is received. If the originating device receives a 4xx, 5xx, or 6xx response, it disconnects the QSIG call with a 'no route to destination' cause.
- **Call setup (terminating device):** After the terminating device receives a SIP INVITE request with a 'Content-Type: application/QSIG', it sends the encapsulated QSIG Setup message to the Tel side and sends a 200 OK response (no 1xx response is sent) to IP. The 200 OK response includes an encapsulated QSIG Call Proceeding message (without waiting for a Call Proceeding message from the Tel side). If tunneling is disabled and the incoming INVITE includes a QSIG body, a 415 response is sent.

- **Mid-call communication:** After the SIP connection is established, all QSIG messages are encapsulated in SIP INFO messages.
- **Call tear-down:** The SIP connection is terminated once the QSIG call is complete. The Release Complete message is encapsulated in the SIP BYE message that terminates the session.

➤ **To enable QSIG tunneling:**

1. Open the Digital Gateway Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Digital Gateway** > **Digital Gateway Settings**).
2. Select the 'Enable QSIG Tunneling' check box (EnableQSIGTunneling) on the originating and terminating devices:

Enable QSIG Tunneling ☒

3. Configure the [QSIGTunnelingMode] parameter for defining the format of encapsulated QSIG message data in the SIP message MIME body (0 for ASCII presentation; 1 for binary encoding).
4. Configure the [ISDNDuplicateQ931BuffMode] parameter to 128 to duplicate all messages.
5. Configure the [ISDNInCallsBehavior] parameter to 4096.
6. Configure the [ISDNRxOverlap] parameter to 0 for tunneling of QSIG overlap-dialed digits (see below for description).

The [ISDNInCallsBehavior] and [ISDNRxOverlap] parameters enable tunneling of QSIG overlap-dialed digits (Tel to IP). In this configuration, the device **delays** the sending of the QSIG Setup Ack message upon receipt of the QSIG Setup message. Instead, the device sends the Setup Ack message to QSIG only when it receives the SIP INFO message with Setup Ack encapsulated in its MIME body. The PBX sends QSIG Information messages (to complete the Called Party Number) only after it receives the Setup Ack. The device relays these Information messages encapsulated in SIP INFO messages to the remote party.

## ISDN Non-Facility Associated Signaling (NFAS)

In regular T1 ISDN trunks, a single 64 kbps channel carries signaling for the other 23 B-channels of that particular T1 trunk. This channel is called the D-channel and usually resides on timeslot # 24. ISDN Non-Facility Associated Signaling (NFAS) enables the use of a single D-channel to control multiple PRI interfaces.

NFAS is applicable only to T1 trunks.

With NFAS it is possible to define a group of T1 trunks, called an *NFAS group*, in which a single D-channel carries ISDN signaling messages for the entire group. The NFAS group's B-channels are used to carry traffic such as voice or data. The NFAS mechanism also enables definition of a backup D-channel on a different T1 trunk, to be used if the primary D-channel fails.

The device supports up to 12 NFAS groups. Each group can comprise up to 10 T1 trunks and each group must contain different T1 trunks. Each T1 trunk is called an "NFAS member". The T1 trunk whose D-channel is used for signaling is called the "Primary NFAS Trunk". The T1 trunk whose D-channel is used for backup signaling is called the "Backup NFAS Trunk". The primary and backup trunks each carry 23 B-channels while all other NFAS trunks each carry 24 B-channels.

The NFAS group is identified by an NFAS GroupID number (possible values are 1 to 12). To assign a number of T1 trunks to the same NFAS group, use the `NFASGroupNumber_x = groupID` (where x is the physical trunk ID (0 to the maximum number of trunks) or the Web interface (see [Configuring Trunk Settings](#) on page 878).

The parameter `DchConfig_x = Trunk_type` defines the type of NFAS trunk. `Trunk_type` is set to 0 for the primary trunk, to 1 for the backup trunk, and to 2 for an ordinary NFAS trunk. 'x' denotes the physical trunk ID (0 to the maximum number of trunks). You can also use the Web interface (see [Configuring Trunk Settings](#) on page 878).

For example, to assign the first four T1 trunks to NFAS group #1, in which trunk #0 is the primary trunk and trunk #1 is the backup trunk, use the following configuration:

```
NFASGroupNumber_0 = 1
NFASGroupNumber_1 = 1
NFASGroupNumber_2 = 1
NFASGroupNumber_3 = 1
DchConfig_0 = 0      ;Primary T1 trunk
DchConfig_1 = 1      ;Backup T1 trunk
DchConfig_2 = 2      ;24 B-channel NFAS trunk
DchConfig_3 = 2      ;24 B-channel NFAS trunk
```

The NFAS parameters are described in [PSTN Parameters](#) on page 1988.

## NFAS Interface ID

Several ISDN switches require an additional configuration parameter per T1 trunk that is called 'Interface Identifier'. In NFAS T1 trunks, the Interface Identifier is sent explicitly in Q.931 Setup / Channel Identification IE for all NFAS trunks, except for the B-channels of the Primary trunk (see note below).

The Interface ID can be defined per member (T1 trunk) of the NFAS group, and must be coordinated with the configuration of the Switch. The default value of the Interface ID is identical to the number of the physical T1 trunk (0 for the first trunk, 1 for the second T1 trunk, and so on, up to the maximum number of trunks).

To define an explicit Interface ID for a T1 trunk (that is different from the default), use the following parameters:

- `ISDNIBehavior_x = 512` (x = 0 to the maximum number of trunks identifying the device's physical trunk)

- ISDNNFASInterfaceID\_x = ID (x = 0 to 255)

- Usually the Interface Identifier is included in the Q.931 Setup/Channel Identification IE only on T1 trunks that doesn't contain the D-channel. Calls initiated on B-channels of the Primary T1 trunk, by default, don't contain the Interface Identifier. Setting the parameter ISDNIBehavior\_x to 2048' forces the inclusion of the Channel Identifier parameter also for the Primary trunk.
- The parameter ISDNNFASInterfaceID\_x = ID can define the 'Interface ID' for any Primary T1 trunk, even if the T1 trunk is not a part of an NFAS group. However, to include the Interface Identifier in Q.931 Setup/Channel Identification IE configure ISDNIBehavior\_x = 2048 in the *ini* file.

## Working with DMS-100 Switches

The DMS-100 switch requires the following NFAS Interface ID definitions:

- InterfaceID #0 for the Primary trunk
- InterfaceID #1 for the Backup trunk
- InterfaceID #2 for a 24 B-channel T1 trunk
- InterfaceID #3 for a 24 B-channel T1 trunk, and so on for subsequent T1 trunks

For example, if four T1 trunks on a device are configured as a single NFAS group with Primary and Backup T1 trunks that is used with a DMS-100 switch, the following parameters should be used:

```
NFASGroupNumber_0 = 1
NFASGroupNumber_1 = 1
NFASGroupNumber_2 = 1
NFASGroupNumber_3 = 1
DchConfig_0 = 0 ;Primary T1 trunk
DchConfig_1 = 1 ;Backup T1 trunk
DchConfig_2 = 2 ;B-Channel NFAS trunk
DchConfig_3 = 2 ;B-channel NFAS trunk
```

If there is no NFAS Backup trunk, the following configuration should be used:

```
ISDNNFASInterfaceID_0 = 0
ISDNNFASInterfaceID_1 = 2
ISDNNFASInterfaceID_2 = 3
ISDNNFASInterfaceID_3 = 4
ISDNIBehavior = 512 ;The parameter should be added because of
;ISDNNFASInterfaceID configuration above
NFASGroupNumber_0 = 1
NFASGroupNumber_1 = 1
NFASGroupNumber_2 = 1
```

```
NFASGroupNumber_3 = 1
DchConfig_0 = 0 ;Primary T1 trunk
DchConfig_1 = 2 ;B-Channel NFAS trunk
DchConfig_2 = 2 ;B-Channel NFAS trunk
DchConfig_3 = 2 ;B-channel NFAS trunk
```

## Creating an NFAS-Related Trunk Configuration

The procedures for creating and deleting an NFAS group must be performed in the correct order, as described below.

### ➤ To create an NFAS Group:

1. If there's a backup ('secondary') trunk for this group, it must be configured first.
2. Configure the primary trunk before configuring any NFAS ('slave') trunk.
3. Configure NFAS ('slave') trunks.

### ➤ To stop / delete an NFAS Group:

1. Stop or delete (by setting ProtocolType to 0, i.e., 'None') all NFAS ('slave') trunks.
2. Stop or delete (by setting ProtocolType to 0, i.e., 'None') the backup trunk if a backup trunk exists.
3. Stop or delete (by setting ProtocolType to 0, i.e., 'None') the primary trunk.

- All trunks in the group must be configured with the same values for trunk parameters TerminationSide, ProtocolType, FramingMethod, and LineCode.
- After stopping or deleting the backup trunk, delete the group and then reconfigure it.

## Performing Manual D-Channel Switchover in NFAS Group

If an NFAS group is configured with two D-channels (Primary and Backup), you can do a manual switchover between these D-channels.

### ➤ To manually switchover from active to standby D-channel:

1. Open the NFAS Group & D-Channel Status page (**Monitor** menu > **PSTN Status** tab > **NFAS Group & D-Channel Status**).
2. Select the required NFAS group, and then click the **Switch Activity** button.

- The **Switch Activity** button is unavailable (i.e, grayed out) if a switchover cannot be done due to, for example, alarms or unsuitable states.
- This feature is applicable only to T1 ISDN protocols supporting NFAS, and only if the NFAS group is configured with two D-channels.

## ISDN Overlap Dialing

Overlap dialing is a dialing scheme used by several ISDN variants to send and/or receive called number digits one after the other (or several at a time). This is in contrast to en-bloc dialing in which a complete number is sent in one message.

The device supports the following ISDN overlap dialing methods:

- Collects ISDN called party number digits and then sends the SIP INVITE to the IP side with the complete destination number (see [Collecting ISDN Digits and Sending Complete Number in SIP](#) below)
- Interworks ISDN overlap dialing with SIP, according to RFC 3578 (see [Interworking ISDN Overlap Dialing with SIP According to RFC 3578](#) on the next page)

ISDN overlap dialing is applicable to PRI and BRI.

## Collecting ISDN Digits and Sending Complete Number in SIP

The device can support an overlap dialing mode whereby the device collects the called party number digits from ISDN Q.931 Information messages or DTMF signals, and then sends a SIP INVITE message to the IP side containing the complete destination number.

ISDN overlap dialing for incoming ISDN calls can be configured for the entire device or per ISDN trunk. This is configured using the global parameter, [ISDNRxOverlap] or the [ISDNRxOverlap\_x] parameter (where x denotes the trunk number), respectively.

By default (see the [ISDNINCallsBehavior] parameter), the device plays a dial tone to the ISDN user side when it receives an empty called number from the ISDN. In this scenario, the device includes the Progress Indicator in the SetupAck ISDN message that it sends to the ISDN side.

The device can also mute in-band DTMF detection until it receives the complete destination number from the ISDN. This is configured by the [MuteDTMFInOverlap] parameter. The Information digits can be sent in-band in the voice stream, or out-of-band using Q.931 Information messages. If Q.931 Information messages are used, the DTMF in-band detector must be disabled. Note that when at least one digit is received in the ISDN Setup message, the device stops playing a dial tone.

The device stops collecting digits (from the ISDN) upon the following scenarios:

- The device receives a Sending Complete IE in the ISDN Setup or Information messages, indicating no more digits.

- The timeout between received digits expires (configured by the [TimeBetweenDigits] parameter).
- The maximum number of received digits has been reached (configured by the [MaxDigits parameter]).
- A match is found with the defined digit map (configured by the [DigitMapping] parameter).

Relevant parameters (described in [PSTN Parameters](#) on page 1988):

- [ISDNRxOverlap\_x = 1] (can be configured per trunk)
- [TimeBetweenDigits]
- [MaxDigits]
- [MuteDTMFInOverlap]
- [DigitMapping]

To configure ISDN overlap dialing using the Web interface, see [Configuring Trunk Settings](#) on page 878.

## Interworking ISDN Overlap Dialing with SIP According to RFC 3578

With overlap dialing disabled, the device expects to receive the digits all at once (enbloc) or with very little delay between digits and then sends the complete number in a single message. Overlap signaling sends portions of the number in separate messages as it collects the digits from the sender. The interval between receiving the digits (*time between digits*) is relatively long. However, overlap dialing allows the device to begin call setup (routing) even before all digits have been collected. For example, if the dialed (destination) number is "3312418", the device first receives the digits "331" and then routes the call based on these digits. It then delivers the remaining 4 digits "2418" in overlap mode. The device supports the interworking of ISDN overlap dialing to SIP and vice versa, according to RFC 3578.

- **Interworking ISDN overlap dialing to SIP (Tel to IP):** The device sends the first digits (e.g., "331") received from the ISDN Setup message to the IP side in the initial SIP INVITE message. Each time it receives additional (collected) digits, which are received from subsequent Q.931 Information messages, it sends them to the IP side in SIP re-INVITE or SIP INFO messages. You can use the following parameters to configure overlap dialing for Tel-to-IP calls:
  - ISDNRxOverlap: Enables Tel-to-IP overlap dialing and defines how the device sends the collected digits to the IP side - in SIP re-INVITE [2] or INFO messages [3].
  - MinOverlapDigitsForRouting: Defines the minimum number of overlap digits to collect from the Tel side before the device can send the first SIP message (INVITE) for routing the call to the IP side.
  - MaxDigits: Defines the maximum number of collected digits that can be received from the Tel side (if ISDN Sending Complete IE is not received). When the number of collected digits reaches the maximum, the device uses these digits for the called destination number.

- **TimeBetweenDigits:** Defines the maximum time (in seconds) that the device waits between digits received from the Tel side. When the time expires, the device uses the collected digits to dial the called destination number.
- **MuteDTMFInOverlap:** Enables the device to ignore in-band DTMF digits received during overlap dialing.

If the device receives SIP 4xx responses during the overlap dialing (while collecting digits), it doesn't release the call.

- **Interworking SIP to ISDN overlap dialing (IP to Tel):** The device sends the first digits (e.g., "331") received from the initial SIP INVITE message to the Tel side in an ISDN Setup message. Each time it receives additional (collected) digits for the same dialog, which are received from subsequent SIP re-INVITE messages or SIP INFO messages, it sends them to the Tel side in SIP Q.931 Information messages. For each subsequent re-INVITE or SIP INFO message received, the device sends a SIP 484 "Address Incomplete" response to the IP side to maintain the current dialog session and to receive additional digits from subsequent re-INVITE or INFO messages. You can use the following parameters to configure overlap dialing for IP-to-Tel calls:

- **ISDNtxOverlap:** Enables IP-to-Tel overlap dialing and defines how the device receives the collected digits from the IP side - in SIP re-INVITE [1] or INFO messages [2].
- **TimeBetweenDigits:** Defines the maximum time (in seconds) that the device waits between digits received from the IP side. When the time expires, the device uses the collected digits to dial the called destination number.

For IP-to-Tel overlap dialing, to send ISDN Setup messages without including the Sending Complete IE, you must configure the `ISDNOutCallsBehavior` parameter to `USER SENDING COMPLETE` [2].

For more information on the above mentioned parameters, see [PSTN Parameters](#) on page 1988. To configure ISDN overlap dialing using the Web interface, see [Configuring Trunk Settings](#) on page 878.

## Redirect Number and Calling Name (Display)

The following tables define the device's redirect number and calling name (Display) support for various ISDN variants according to NT (Network Termination) / TE (Termination Equipment) interface direction:

**Table 23-3: Calling Name (Display) per ISDN Variant**

NT/TE Interface	DMS-100	NI-2	4/5ESS	Euro ISDN	QSIG	NTT	KOR
NT-to-TE	Yes	Yes	Yes	Yes	Yes	Yes	Yes
TE-to-NT	Yes	Yes	Yes	No	Yes	No	No

**Table 23-4: Redirect Number per ISDN Variant**

NT/TE Interface	DMS-100	NI-2	4/5ESS	Euro ISDN	QSIG
NT-to-TE	Yes	Yes	Yes	Yes	Yes
TE-to-NT	Yes	Yes	Yes	Yes*	Yes

\* When using ETSI DivertingLegInformation2 in a Facility IE (not Redirecting Number IE).

## 24 Trunk Groups

This section describes Trunk Group configuration.

### Configuring Trunk Groups

The Trunk Groups table lets you configure up to 24 Trunk Groups. A Trunk Group is a logical group of physical trunks and channels. A Trunk Group can include multiple trunks and a range of channels. To enable and activate the channels, you need to configure the Trunk Group and assign it telephone numbers. Channels that are not configured in this table are disabled.

Once you have configured your Trunk Group, you can use it for call routing. To configure IP-to-Tel routing rules, see [Configuring IP-to-Tel Routing Rules](#) on page 960. To configure Tel-to-IP routing rules, see [Configuring Tel-to-IP Routing Rules](#) on page 946.

The following procedure describes how to configure Trunk Groups through the Web interface. You can also configure it through ini file [TrunkGroup\_x] or CLI (`configure voip > gateway trunk-group`).

It's recommended **not** to configure a Trunk Group with Trunk Group ID **0**. A Trunk Group with ID 0 doesn't support some of the device's features (e.g., not counted in performance monitoring).

#### ➤ To configure a Trunk Group:

1. Open the Trunk Groups table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Trunks & Groups** > **Trunk Groups**).

Add Phone Context As Prefix Disable ▾  
 Trunk Group Index 1-12 ▾

GROUP INDEX	MODULE	FROM TRUNK	TO TRUNK	CHANNELS	PHONE NUMBER	TRUNK GROUP ID	TEL PROFILE NAME
1	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text" value="None"/>
2	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text"/>	<input type="text" value="None"/>

Register
Un-Register

2. Configure a Trunk Group according to the parameters described in the table below.

### 3. Click **Apply**.

You can also register all your Trunk Groups. The registration method per Trunk Group is configured by the 'Registration Mode' parameter in the Trunk Group Settings page (see [Configuring Trunk Group Settings](#) on page 937).

- To register Trunk Groups, click the **Register** button.
- To unregister Trunk Groups, click the **Unregister** button.

**Table 24-1: Trunk Group Table Parameter Descriptions**

Parameter	Description
'Module' module [Module]	Defines the telephony interface module for which you want to define the Trunk Group.
'From Trunk' first-trunk-id [FirstTrunkId]	Defines the starting physical Trunk number in the Trunk Group. The number of listed Trunks depends on the device's hardware configuration. <b>Note:</b> The parameter is applicable only to digital interfaces.
'To Trunk' last-trunk-id [LastTrunkId]	Defines the ending physical Trunk number in the Trunk Group. The number of listed Trunks depends on the device's hardware configuration. <b>Note:</b> The parameter is applicable only to digital interfaces.
'Channels' first-b-channel [FirstBChannel] last-b-channel [LastBChannel]	<ul style="list-style-type: none"> <li>■ Analog: Defines the ports (channels) on the module.</li> <li>■ Digital: Defines the Trunk's B-channels .</li> </ul> <p>To enable channels, enter the channel numbers. You can enter a range of channels by using the syntax <i>n-m</i>, where <i>n</i> represents the lower channel number and <i>m</i> the higher channel number. For example, "1-4" (without quotation marks) specifies channels 1 through 4. For digital interfaces, to represent all the Trunk's B-channels, enter a single asterisk (*).</p> <p><b>Note:</b> For digital interface, the number of defined channels must not exceed the maximum number of the Trunk's B-channels.</p>
'Phone Number' first-phone-number	Defines the telephone number(s) of the channels. The valid value can be up to 50 characters.

Parameter	Description
[FirstPhoneNumber]	<p>For a range of channels, enter only the first telephone number. Subsequent channels are assigned the next consecutive telephone number. For example, if you enter 400 for channels 1 to 4, then channel 1 is assigned phone number 400, channel 2 is assigned phone number 401, and so on.</p> <p>These numbers are also used for channel allocation for IP-to-Tel calls if the Trunk Group's 'Channel Select Mode' parameter is set to <b>By Dest Phone Number</b>.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If this field includes alphabetical characters and the phone number is defined for a range of channels (e.g., 1-4), then the phone number must end with a number (e.g., 'user1').</li> <li>■ This field is optional. The logical numbers defined in this field are used when an incoming Tel call doesn't contain the calling number or called number (the latter being determined by the [ReplaceEmptyDstWithPortNumber] parameter). These numbers are used to replace them.</li> <li>■ This field is ignored if routing of IP-to-Tel calls is done according to the Supplementary Services table, where multiple line extension numbers are configured per port (see <a href="#">Configuring Multi-Line Extensions and Supplementary Services</a> on page 1073). For this routing method, the 'Channel Select Mode' parameter must be configured to <b>Select Trunk By Supplementary Services Table</b> in the Trunk Group Settings table (see <a href="#">Configuring Trunk Group Settings</a> on the next page).</li> </ul>
'Trunk Group ID' trunk-group-id [TrunkGroupNum]	<p>Defines the Trunk Group ID for the specified channels. The same Trunk Group ID can be assigned to more than one group of channels. If an IP-to-Tel call is assigned to a Trunk Group, the IP call is routed to the channel(s) pertaining to that Trunk Group ID. The valid value can be 0 to 100.</p> <p><b>Note:</b> Currently, Trunk Group ID #0 is not counted in the device's performance monitoring and no SNMP alarms are sent for it.</p>

Parameter	Description
'Tel Profile Name' tel-profile-id [ProfileName]	Assigns a Tel Profile to the Trunk Group. To configure Tel Profiles, see <a href="#">Configuring Tel Profile</a> on page 755.

## Configuring Trunk Group Settings

The Trunk Group Settings table lets you configure various settings per Trunk Group ID, which is assigned to a Trunk Group in [Configuring Trunk Groups](#) on page 934. The main configuration includes the following:

- Channel select method, which defines how the device allocates incoming IP-to-Tel calls to the channels of a Trunk Group.
- Registration method for registering Trunk Groups to remote IP servers (*Serving IP Group*).

The Trunk Group Settings table also provides an **Action** drop-down button with commands that let you perform various actions per configured Trunk Group:

- **Lock / Unlock:** Locks (blocks) a Trunk Group in order to take its member trunks out-of-service. For more information, see [Locking and Unlocking Trunk Groups](#) on page 1335.
- **Register / Un-Register:** Initiates a registration request for the Trunk Group with a Serving IP Group. For more information, see the description of the 'Registration Mode' parameter of the Trunk Group Settings table in this section.

The following procedure describes how to configure settings for Trunk Groups through the Web interface. You can also configure it through ini file [TrunkGroupSettings] or CLI (`configure voip > gateway trunk-group-setting`).

### ➤ To configure Trunk Group settings per Trunk Group ID:

1. Open the Trunk Group Settings table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Trunks & Groups** > **Trunk Group Settings**).
2. Click **New**; the following dialog box appears:

3. Configure settings for a Trunk Group ID according to the parameters described in the table below.
4. Click **Apply**.

**Table 24-2: Trunk Group Settings Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	<p>Defines an index number for the new table row. Up to 101 rows can be configured.</p> <p><b>Note:</b> Each row must be configured with a unique index.</p>
'Name' trunk-group-name [TrunkGroupName]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value can be a string of up to 40 characters. By default, no name is configured.</p> <p>if you enable the [UseSIPtgrp] or [UseBroadsoftDTG] parameters, the name also represents the Trunk Group in the SIP 'tgrp' parameter in outgoing INVITE messages (according to RFC 4904) and/or REGISTER messages (depending on the [UseSIPtgrp] parameter settings). For example, if you configure the parameter to "ITSP-ABC":  <code>sip:+16305550100;tgrp=ITSP-ABC;trunk-context=+1-630@isp.example.net;user=phone</code></p> <p>If you don't configure the 'Name' parameter, the Trunk Group number is set as the value in the 'tgrp' parameter, for example:  <code>sip:+16305550100;tgrp=TG-1;trunk-context=+1-630@isp.example.net;user=phone</code></p> <p><b>Note:</b> Configure each row with a unique name.</p>
'Trunk Group ID' trunk-group-id [TrunkGroupId]	<p>Defines the Trunk Group by its ID number, which you configured in <a href="#">Configuring Trunk Groups</a> on page 934.</p>
'Channel Select Mode' channel-select-mode [ChannelSelectMode]	<p>Defines the method by which IP-to-Tel calls are assigned to the channels of the Trunk Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>By Dest Phone Number</b> = The channel is selected according to the called (destination) number. If the number is not located, the call is released. If the channel is unavailable (e.g., busy), the call is put on call waiting (if call waiting is enabled and no other call is on call waiting); otherwise, the call is released.</li> <li>■ [1] <b>Channel Cyclic Ascending</b> = The next available channel in the Trunk Group, in ascending cyclic order is selected. After the device reaches the highest channel</li> </ul>

Parameter	Description
	<p>number in the Trunk Group, it selects the lowest channel number in the Trunk Group, and then starts ascending again.</p> <ul style="list-style-type: none"> <li>■ [2] <b>Always Ascending</b> = The lowest available channel in the Trunk Group is selected, and if unavailable, the next higher channel is selected.</li> <li>■ [3] <b>Cyclic Descending</b> = The next available channel in descending cyclic order is selected. The next lower channel number in the Trunk Group is always selected. When the device reaches the lowest channel number in the Trunk Group, it selects the highest channel number in the Trunk Group, and then starts descending again.</li> <li>■ [4] <b>Always Descending</b> = The highest available channel in the Trunk Group is selected, and if unavailable, the next lower channel is selected.</li> <li>■ [5] <b>Dest Number &amp; Cyclic Ascending</b> = The channel is selected according to the called number. If the called number isn't found, the next available channel in ascending cyclic order is selected.</li> </ul> <p><b>Note:</b> If the called number is located, but the port associated with the number is busy, the call is released.</p> <ul style="list-style-type: none"> <li>■ [6] <b>By Source Phone Number</b> = The channel is selected according to the calling number.</li> <li>■ [7] <b>Trunk Cyclic Ascending</b> = The channel from the first channel of the next trunk (adjacent to the trunk from which the previous channel was selected) is selected.</li> </ul> <p><b>Note:</b> This option is applicable only to digital interfaces.</p> <ul style="list-style-type: none"> <li>■ [8] <b>Trunk &amp; Channel Cyclic Ascending</b> = The device implements the Trunk Cyclic Ascending and Cyclic Ascending methods to select the channel. This method selects the next physical trunk in the Trunk Group, and then selects the B-channel of this trunk according to the Cyclic Ascending method (i.e., selects the channel after the last allocated channel).</li> </ul> <p>For example, if the Trunk Group includes two physical trunks, 0 and 1:</p> <ul style="list-style-type: none"> <li>✓ For the first incoming call, the first channel of Trunk 0 is selected.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ For the second incoming call, the first channel of Trunk 1 is selected.</li> <li>✓ For the third incoming call, the second channel of Trunk 0 is selected.</li> </ul> <p><b>Note:</b> This option is applicable only to digital interfaces.</p> <ul style="list-style-type: none"> <li>■ [9] <b>Ring to Hunt Group</b> = The device allocates IP-to-Tel calls to all the FXS ports (channels) in the Trunk Group (i.e., a ringing group). When a call is received for the Trunk Group, all telephones connected to the FXS ports belonging to the Trunk Group start ringing. The call is eventually received by whichever telephone first answers the call (after which the other phones stop ringing).</li> </ul> <p><b>Note:</b> This option is applicable only to FXS interfaces.</p> <ul style="list-style-type: none"> <li>■ [10] <b>Select Trunk by Supp-Serv Table</b> = The BRI port/module is selected according to the settings in the Supplementary Services table (see <a href="#">Configuring Multi-Line Extensions and Supplementary Services</a> on page 1073), allowing the routing of IP-to-Tel calls to specific BRI endpoints according to extension number.</li> </ul> <p><b>Note:</b> This option is applicable only to FXS and BRI interfaces.</p> <ul style="list-style-type: none"> <li>■ [11] <b>By Dest Number &amp; Ascending</b> = The device allocates channels to incoming IP-to-Tel calls as follows: <ul style="list-style-type: none"> <li>a. The device attempts to route the call to the channel that is associated with the destination (called) number. If located, the call is sent to that channel.</li> <li>b. If the number is not located or the channel is unavailable (e.g., busy), the device searches in ascending order for the next available channel in the Trunk Group. If located, the call is sent to that channel.</li> <li>c. If all channels are unavailable, the call is released.</li> </ul> </li> </ul> <p><b>Note:</b> If the parameter is not configured, the Trunk Group's channel select method is according to the global parameter [ChannelSelectMode].</p>
'Registration Mode' registration-mode [RegistrationMode]	<p>Defines the registration method of the Trunk Group.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Per Endpoint</b> = Each channel in the Trunk Group</li> </ul>

Parameter	Description
	<p>registers individually. The registrations are sent to the 'Serving IP Group ID' if configured in the table; otherwise, it is sent to the default Proxy, and if no default Proxy, then to the Registrar IP.</p> <ul style="list-style-type: none"> <li>■ <b>[1] Per Gateway</b> = (Default) Single registration for the entire device. This is applicable only if a default Proxy or Registrar IP is configured and Registration is enabled (i.e., parameter [IsRegisterUsed] is set to 1). In this mode, the SIP URI user part in the From, To, and Contact headers is set to the value of the global registration parameter, [GWRegistrationName] or username if [GWRegistrationName] is not configured.</li> <li>■ <b>[4] Don't Register</b> = No registrations are sent by endpoints pertaining to the Trunk Group. For example, if the device is configured globally to register all its endpoints (using the parameter [ChannelSelectMode]), you can exclude some endpoints from being registered by assigning them to a Trunk Group and configuring the Trunk Group registration mode to <b>Don't Register</b>.</li> <li>■ <b>[5] Per Account</b> = Registrations are sent (or not) to an IP Group according to the settings in the Accounts table (see <a href="#">Configuring Registration Accounts</a> on page 777).</li> </ul> <p>An example is shown below of a REGISTER message for registering endpoint "101" using the registration Per Endpoint mode:</p> <pre>REGISTER sip:SipGroupName SIP/2.0 Via: SIP/2.0/UDP 10.33.37.78;branch=z9hG4bKac862428454 From: &lt;sip:101@GatewayName&gt;;tag=1c862422082 To: &lt;sip:101@GatewayName&gt; Call-ID: 9907977062512000232825@10.33.37.78 CSeq: 3 REGISTER Contact: &lt;sip:101@10.33.37.78&gt;;expires=3600 Expires: 3600 User-Agent: Sip-Gateway/7.60A.100.022 Content-Length: 0</pre> <p>The "SipGroupName" in the Request-URI is configured in the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591).</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is not configured, registration is done according to the global registration parameter [ChannelSelectMode].</li> <li>■ To enable Trunk Group registration, configure the global parameter [IsRegisterNeeded] to 1. This is unnecessary for <b>Per Account</b> registration mode.</li> <li>■ If the device is configured globally to register Per Endpoint and an channel group includes four channels to register Per Gateway, the device registers all channels except the first four channels. The group of these four channels sends a single registration request.</li> <li>■ When configured to <b>Per Account</b>, you can configure (using the [RegisterByTrunkGroupStatus] parameter) if the device sends a registration request to the Serving Trunk Group (SIP registrar), based on the Trunk Group's status (in-service or out-of-service) for ISDN PRI and CAS.</li> </ul>
'Used By Routing Server' used-by-routing-server [UsedByRoutingServer]	<p>Enables the use of the Trunk Group by ARM for routing decisions.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Not Used</b> (default)</li> <li>■ [1] <b>Used</b></li> </ul> <p>For more information on routing by ARM, see <a href="#">Centralized Routing by ARM (AudioCodes Routing Manager)</a> on page 451.</p>
SIP Configuration	
'Gateway Name' gateway-name [GatewayName]	<p>Defines the host name of the SIP From header in INVITE messages, and the From and To headers in REGISTER requests.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> If the parameter is not configured, the global parameter [SIPGatewayName] is used.</p>
'Contact User' contact-user [ContactUser]	<p>Defines the user part for the SIP Contact URI in INVITE messages, and the From, To, and Contact headers in REGISTER requests.</p> <p>The valid value is a string of up to 60 characters. By default, no value is defined.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only if the 'Registration Mode' parameter is configured to <b>Per Account</b> and registration based on the Accounts table is successful.</li> <li>■ If registration fails, the user part in the INVITE Contact header is set to the source party number.</li> <li>■ The 'Contact User' parameter in the Accounts table overrides this parameter (see <a href="#">Configuring Registration Accounts</a> on page 777).</li> </ul>
'Serving IP Group' serving-ip-group [ServingIPGroupName]	<p>Assigns an IP Group to where the device sends INVITE messages for calls received from the Trunk Group. The actual destination to where the INVITE messages are sent is according to the Proxy Set associated with the IP Group. The Request-URI host name in the INVITE and REGISTER messages (except for <b>Per Account</b> registration mode) is set to the value of the 'SIP Group Name' parameter configured in the IP Groups table (see <a href="#">Configuring IP Groups</a> on page 591).</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If the parameter is not configured, the INVITE messages are sent to the default Proxy or according to the Tel-to-IP Routing table (see <a href="#">Configuring Tel-to-IP Routing Rules</a> on page 946).</li> <li>■ If the PreferRouteTable parameter is set to 1 (see <a href="#">Configuring Proxy and Registration Parameters</a> on page 792), the routing rules in the Tel-to-IP Routing table take precedence over the selected Serving IP Group ID.</li> </ul>
'MWI Interrogation Type' mwi-interrogation-type [MWIInterrogationType]	<p>Defines message waiting indication (MWI) QSIG-to-IP interworking for interrogating MWI supplementary services.</p> <ul style="list-style-type: none"> <li>■ [255] <b>Not configured</b>.</li> <li>■ [0] <b>None</b> = Disables the feature.</li> <li>■ [1] <b>Use Activate Only</b> = MWI Interrogation messages are not sent and only "passively" responds to MWI Activate requests from the PBX.</li> <li>■ [2] <b>Result Not Used</b> = MWI Interrogation messages are sent, but the result is not used. Instead, the device waits for MWI Activate requests from the PBX.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [3] <b>Use Result</b> = MWI Interrogation messages are sent, its results are used, and the MWI Activate requests are used. MWI Activate requests are interworked to SIP NOTIFY MWI messages. The SIP NOTIFY messages are sent to the IP Group defined by the [NotificationIPGroupName] parameter.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ The parameter appears in the table only if the [VoiceMailInterface] parameter is set to 3 (QSIG) (see <a href="#">Configuring Voice Mail</a> on page 1086).</li> </ul>
Status	
'Admin State' [AdminState]	<p>(Read-only) Displays the administrators state:</p> <ul style="list-style-type: none"> <li>■ "Locked": The Lock command has been chosen from the Action drop-down button.</li> <li>■ "Unlocked": The Unlock command has been chosen from the Action drop-down button.</li> </ul>
'Status'	<p>(Read-only) Displays the current status of the trunks/channels in the Trunk Group:</p> <ul style="list-style-type: none"> <li>■ "In Service": Indicates that all channels in the Trunk Group are in service, for example, when the Trunk Group is unlocked or Busy Out state cleared (see the [EnableBusyOut] parameter for more information).</li> <li>■ "Going Out Of Service": Appears as soon as you choose the Lock command and indicates that the device is starting to lock the Trunk Group and take channels out of service.</li> <li>■ "Going Out Of Service (&lt;duration remaining of graceful period&gt; sec / &lt;number of calls still active&gt; calls)": Appears when the device is locking the Trunk Group and indicates the number of busy channels and the time remaining until the graceful period ends, after which the device locks the channels regardless of whether the call has ended or not.</li> <li>■ "Out Of Service": All fully configured trunks in the Trunk Group are out of service, for example, when the Trunk</li> </ul>

Parameter	Description
	Group is locked or in Busy Out state (see the [EnableBusyOut] parameter).

## 25 Routing

This section describes the configuration of call routing for the Gateway application.

### Configuring Tel-to-IP Routing Rules

The Tel-to-IP Routing table lets you configure up to 180 Tel-to-IP routing rules. Tel-to-IP routing rules are used to route calls from the Tel side to an IP destination.

Configuration of Tel-to-IP routing rules includes two areas:

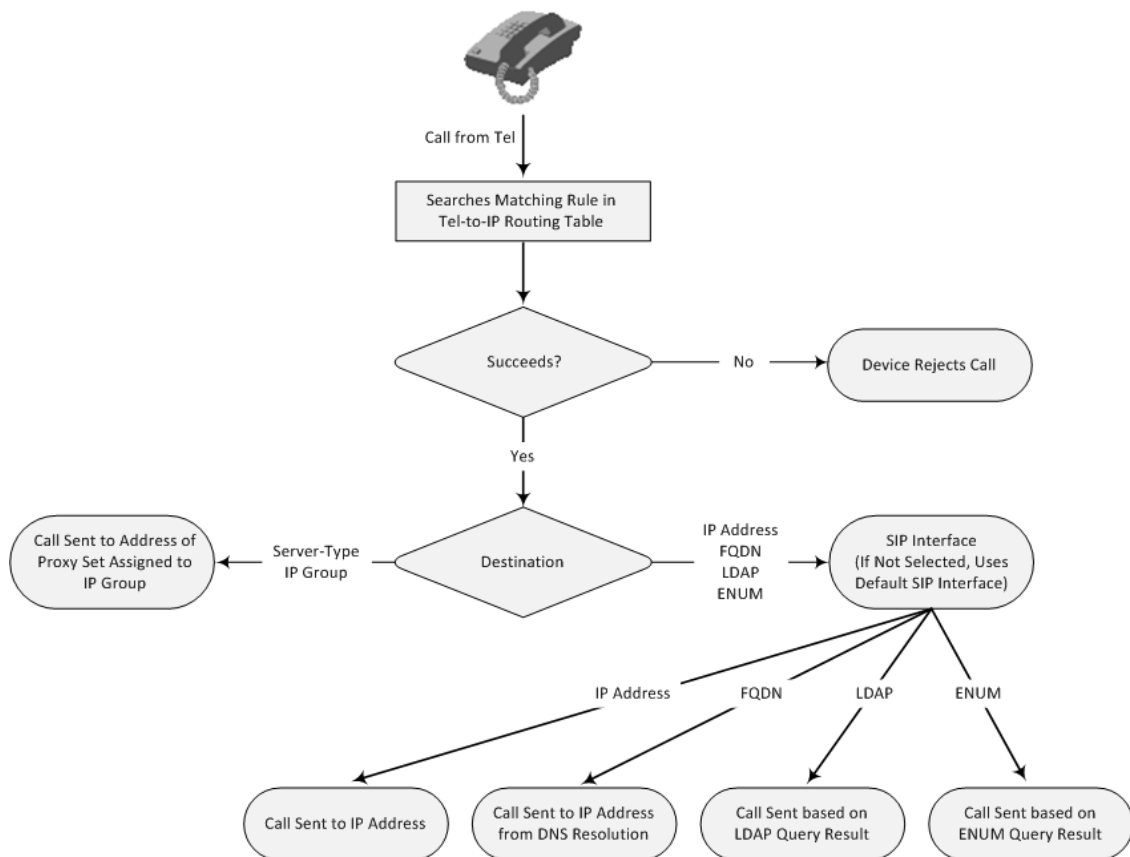

- **Match:** Defines the characteristics of the incoming Tel call (e.g., Trunk Group on which the call is received). You can configure routing rules with one or more of the following incoming Tel characteristics:
  - Source Trunk Group (from where the call is received)
  - Source (calling) and destination (called) telephone number prefix and suffix
  - Source and destination Dial Plan tags
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (i.e., routes the call to the specified IP destination). You can configure the IP destination to one of the following:
  - IP address or FQDN.
  - E.164 Telephone Number Mapping (ENUM service).
  - Lightweight Directory Access Protocol (LDAP). For more information, see [LDAP-based Services](#) on page 378 and [Routing for Microsoft Teams or Skype for Business using Microsoft Entra ID](#) on page 406.
  - IP Group. When an IP Group is selected, the device sends the call to the IP address configured for the Proxy Set that is associated with the IP Group (configured in [Configuring IP Groups](#) on page 591). The SRD associated with the IP Group determines the:
    - ◆ SIP Interface (SIP port and control network interface) - important when using multiple SIP control VLANs
    - ◆ Media Realm (port and network interface for media / RTP voice)
    - ◆ SRD-related features on which the call is routed

If you configure the routing rule to send the call to any destination other than an IP Group (e.g., an IP address), you need to select a SIP Interface for the call. If no SIP Interface is selected, the device uses the SIP Interface associated with the default SRD (Index 0). If you have deleted this SRD or SIP Interface, for whatever reason, the device drops the call. The SIP Interface determines many attributes for the destination:

- Device's logical SIP port and network interface through which the call signaling is sent

- Device's logical RTP port and network interface through which the media is sent (Media Realm)
- Other features that can be configured for the SIP Interface
- SRD. As one of the attributes of a SIP Interface is an SRD and as you can configure multiple SIP Interfaces per SRD, the specific SIP Interface not only determines the above-mentioned attributes, but also the SRD for routing the call.

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it sends the call to the IP destination configured for that rule. If it doesn't find a matching rule, it rejects the call.

In addition to normal Tel-to-IP routing, you can configure the following features:

- **Least Cost Routing (LCR):** If the LCR feature is enabled, the device searches the routing table for matching routing rules and then selects the one with the lowest call cost. The call cost of the routing rule is done by assigning it a Cost Group. To configure Cost Groups, see [Least Cost Routing](#) on page 461. If two routing rules have identical costs, the rule appearing higher up in the table (i.e., first-matched rule) is used. If a selected route is unavailable, the device uses the next least-cost routing rule. However, even if a matched rule is not assigned a Cost Group, the device can select it as the preferred route over other matched routing rules with Cost Groups, according to the optional, default LCR settings configured by the Routing Policy (see [Configuring a Gateway Routing Policy Rule](#) on page 967).

- **Call Forking:** If the Tel-to-IP Call Forking feature is enabled, the device can send a Tel call to multiple IP destinations. An incoming Tel call with multiple matched routing rules (e.g., all with the same source prefix numbers) can be sent (forked) to multiple IP destinations if all these rules are configured with a Forking Group. The call is established with the first IP destination that answers the call.
- **Call Restriction:** Calls whose matching routing rule is configured with the destination IP address of 0.0.0.0 are rejected.
- **Always Use Routing Table:** Even if a proxy server is used, the SIP Request-URI host name in the outgoing INVITE message is obtained from this table. Using this feature, you can assign a different SIP URI host name for different called and/or calling numbers. This feature is enabled using the AlwaysUseRouteTable parameter.
- **IP Profiles:** IP Profiles can be assigned to destination addresses (also when a proxy is used).
- **Alternative Routing (when a proxy isn't used):** An alternative IP destination (alternative routing rule) can be configured for specific calls ("main" routing rule). When the "main" route fails (e.g., busy), the device can send the call to the alternative route. You must configure the alternative routing rules in table rows (indices) that are located anywhere **below** the "main" routing rule. For example, if you configure a "main" routing rule in Index 4, the alternative routing rule can be configured in Index 6. In addition, you must configure the alternative routing rules with identical matching characteristics (e.g., destination prefix number) as the "main" routing rule, but assigned with different destination IP addresses. Instead of an IP address, you can use an FQDN to resolve into two IP addresses. For more information on alternative routing, see [Alternative Routing for Tel-to-IP Calls](#) on page 969.
- **Advice of Charge (AOC):** AOC is a pre-billing feature that tasks the rating engine with calculating the cost of using a service (Tel-to-IP call) and relaying that information to the customer. AOC, which is configured in the Charge Codes table, can be applied per Tel-to-IP routing rule.

- Instead of using the table for Tel-to-IP routing, you can use ARM to handle the routing decisions. For more information on routing by ARM, see [Centralized Routing by ARM \(AudioCodes Routing Manager\)](#) on page 451.
- You can configure up to three alternative routing rules per "main" routing rule in the Tel-to-IP Routing table.
- By default, the device applies telephone number manipulation (if configured) only after processing the routing rule. You can change this and apply number manipulation before processing the routing rule (see the RouteModeTel2IP parameter).
- By default, if the device receives a REFER message, it forwards the message to the destination specified in the message. Alternatively, if you want the device to search again for a matching routing rule in the Tel-to-IP Routing table and to then forward the REFER message to the destination of the matched rule, you need to configure the [SIPReRoutingMode] parameter to [2].
- When using a proxy server, it is unnecessary to configure routing rules in the Tel-to-IP Routing table unless you require one of the following:
  - ✓ Alternative routing (fallback) when communication with the proxy server fails.
  - ✓ IP security, whereby the device routes only received calls whose source IP addresses are configured in the table. Enable IP security using the SecureCallsFromIP parameter.
  - ✓ Filter Calls to IP feature. The device checks the table before a call is routed to the proxy server. However, if the number is not allowed (i.e., the number is not specified in the table or a Call Restriction routing rule is configured), the call is rejected.
  - ✓ Obtain different SIP URI host names (per called number).
  - ✓ Assign IP Profiles to calls.
  - ✓ For the table to take precedence over a proxy server for routing calls, you need to configure the PreferRouteTable parameter to 1. The device checks the 'Destination IP Address' field in the table for a match with the outgoing call; a proxy is used only if a match is not found.

The following procedure describes how to configure Tel-to-IP routing rules through the Web interface. You can also configure it through ini file [Prefix] or CLI (`configure voip > gateway routing tel2ip-routing`).

➤ **To configure Tel-to-IP routing rules:**

1. Open the Tel-to-IP Routing table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing > Tel > IP Routing**).
2. Click **New**; the following dialog box appears:

**Tel-to-IP Routing**

3. Configure a routing rule according to the parameters described in the table below.

4. Click **Apply**.

The following table shows configuration examples of Tel-to-IP routing rules:

**Table 25-1: Example of Tel-to-IP Routing Rules**

Parameter	Rule 1	Rule 2	Rule 3	Rule 4	Rule 5	Rule 6	Rule 7	Rule 8
<b>Matching Characteristics of Incoming Call</b>								
'Source Trunk Group ID'	-	-	-	4	-	*	*	*
'Source Phone Pattern'	100	100	*	*	*	*	*	*
'Destination Phone Pattern'	10	10	20	[5,7-9]	00	100	100	100
<b>Action</b>								
'Destination IP Group'	-	-	ITS P-ZA	-	-	-	-	-
'Destination IP Address'	10.33.45.63	10.33.45.50		itsp.com	0.0.0.0	10.33.45.68	10.33.45.67	domain.com
'IP'	ABC	ABC	-	-	-	-	-	-

Parameter	Rule 1	Rule 2	Rule 3	Rule 4	Rule 5	Rule 6	Rule 7	Rule 8
Profile'								
'Forking Group'	-	-	-	-	-	1	2	1
'Cost Group ID'	Weekend-Low	Weekend_High	-	-	-	-	-	-

Below are descriptions of each rule:

- **Rules 1 and 2 (Least Cost Routing):** For both rules, the called (destination) phone number prefix is 10, the caller's (source) phone number prefix is 100, and the call is assigned IP Profile "ABC". However, Rule 1 is assigned a cheaper Cost Group than Rule 2, and therefore, the call is sent to the destination IP address (10.33.45.63) associated with Rule 1.
- **Rule 3 (IP Group destination):** For all callers (\*), if the called phone number prefix is 20, the call is sent to IP Group "ITSP-ZA".
- **Rule 4 (domain name destination):** For called phone number prefixes 5, 7, 8, or 9, and the caller belongs to Trunk Group ID 4, the call is sent to the domain "itsp.com".
- **Rule 5 (block):** For all callers (\*), if the called phone number prefix is 00, the call is rejected (IP address 0.0.0.0).
- **Rule 6, 7, and 8 (Forking Group):** For all callers (\*), if the called phone number prefix is 100, the call is sent to Rule 7 and 9 (belonging to Forking Group "1"). If their destinations are unavailable and alternative routing is enabled, the call is sent to Rule 8 (Forking Group "2").

**Table 25-2: Tel-to-IP Routing Table Parameter Descriptions**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' route-name [RouteName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters. By default, no value is defined. <b>Note:</b> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The name can't be configured with the character string</li> </ul>

Parameter	Description
	"any" (upper or lower case).
'Connectivity Status'	<p>(Read-only field) Displays the connectivity status of the routing rule's destination. The destination can be an IP address or an IP Group, as configured in the 'Destination IP Address' and 'Destination IP Group' fields respectively.</p> <p>For IP Groups, the status indicates the connectivity with the SIP proxy server's address configured for the Proxy Set that is associated with the IP Group. For the status to be displayed, the Proxy Keep-Alive feature, which monitors the connectivity with proxy servers per Proxy Set, must be enabled for the Proxy Set (see <a href="#">Configuring Proxy Sets</a> on page 632). If a Proxy Set is configured with multiple proxies for redundancy, the status may change according to the proxy server with which the device attempts to verify connectivity. For example, if there is no response from the first configured proxy address, the status displays "No Connectivity". However, if there is a response from the next proxy server in the list, the status changes to "OK".</p> <p>If there is connectivity with the destination, the field displays "OK" and the device uses the routing rule if required. The routing rule is not used if any of the following is displayed:</p> <ul style="list-style-type: none"> <li>■ "n/a" = IP Group is unavailable.</li> <li>■ "No Connectivity" = No connection with the destination (no response to the SIP OPTIONS).</li> <li>■ "QoS Low" = Poor Quality of Service (QoS) of the destination.</li> <li>■ "DNS Error" = No DNS resolution. This status is applicable only when a domain name is used (instead of an IP address).</li> <li>■ "Not Available" = Destination is unreachable due to networking issues.</li> </ul>
Match	
'Source Trunk Group ID' src-trunk-group-id [SrcTrunkGroupID]	<p>Defines the Trunk Group from where the call is received. To denote any Trunk Group, use the asterisk (*) symbol. By default, no Trunk Group is defined (-1).</p>

Parameter	Description
'Source Phone Pattern' src-phone-pattern [SourcePrefix]	<p>Defines the prefix and/or suffix of the calling (source) telephone number. You can use special notations for denoting the prefix. For example, [100-199](100,101,105) denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. To denote any prefix, use the asterisk (*) symbol (default) or to denote calls without a calling number, use the \$ sign. For a description of available notations, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The number can include up to 50 digits.</p>
'Source Tags' src-tags [SrcTags]	<p>Assigns a Dial Plan tag to denote a group of users by calling (source) number prefixes and/or suffixes.</p> <p>The valid value is a string of up to 70 characters. The tag is case insensitive.</p> <p>To configure Dial Plan tags, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The tag must belong to the Dial Plan that is assigned for Tel-to-IP routing. To do this, use the 'Tel-to-IP Dial Plan Name' (Tel2IPDialPlanName) parameter.</li> <li>■ The device uses the tag before or after manipulation, depending on the 'Tel-to-IP Routing Mode' (RouteModeTel2IP) parameter. If configured to <b>Route calls before manipulation</b>, the tag is used before manipulation. If configured to <b>Route calls after manipulation</b>, the tag is used after manipulation.</li> </ul>
'Destination Phone Pattern' dst-phone-pattern [DestinationPrefix]	<p>Defines the called (destination) telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, if you want to match this rule to user parts whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". As another example, the pattern "[100-199](100,101,105)" denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. To denote any number, use the asterisk (*) symbol (default). To denote calls without a called number, use the dollar (\$) sign. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The number can include up to 50 digits.</p>

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For LDAP-based routing, enter the LDAP query keyword as the prefix number to denote the IP domain: <ul style="list-style-type: none"> <li>✓ "PRIVATE" = Private number</li> <li>✓ "OCS" = Skype for Business / OCS client number</li> <li>✓ "PBX" = PBX / IP PBX number</li> <li>✓ "MOBILE" = Mobile number</li> <li>✓ "LDAP_ERR" = LDAP query failure</li> </ul> </li> </ul> <p>For more information, see <a href="#">Routing for Microsoft Teams or Skype for Business using Microsoft Entra ID</a> on page 406.</p> <ul style="list-style-type: none"> <li>■ If you want to configure re-routing of ISDN Tel-to-IP calls to fax destinations, enter the value string "FAX" (case-sensitive) as the destination phone prefix. For more information, see the [FaxReroutingMode] parameter.</li> </ul>
'Destination Tags' dest-tags [DestTags]	<p>Assigns a Dial Plan tag to denote a group of users by called (destination) number prefixes and/or suffixes.</p> <p>The valid value is a string of up to 70 characters. The tag is case insensitive.</p> <p>To configure Dial Plan tags, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The tag must belong to the Dial Plan that is assigned for IP-to-Tel routing. To do this, use the 'Tel-to-IP Dial Plan Name' (Tel2IPDialPlanName) parameter.</li> <li>■ The device uses the tag before or after manipulation, depending on the 'Tel-to-IP Routing Mode' (RouteModeTel2IP) parameter. If configured to <b>Route calls before manipulation</b>, the tag is used before manipulation. If configured to <b>Route calls after manipulation</b>, the tag is used after manipulation.</li> </ul>
Action	
'Destination IP Group'	Assigns an IP Group to where you want to route the call.

Parameter	Description
dst-ip-group-id [DestIPGroupName]	<p>The SIP INVITE message is sent to the IP address configured for the Proxy Set that is associated with the IP Group.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If you select an IP Group, you do not need to configure a destination IP address. However, if both parameters are configured in the table, the INVITE message is sent only to the IP Group.</li> <li>■ If the destination is a User-type IP Group, the device searches for a match of the Request-URI in the received INVITE to an AOR registration record in the device's database. The INVITE is then sent to the IP address of the registered contact.</li> <li>■ If the AlwaysUseRouteTable parameter is set to 1 (see <a href="#">Configuring IP Groups</a> on page 591), the Request-URI host name in the INVITE message is set to the value configured for the 'Destination IP Address' parameter (in this table); otherwise, if no IP address is defined, it is set to the value of the 'SIP Group Name' parameter (configured in the IP Groups table).</li> <li>■ The parameter is used as the 'Serving IP Group' in the Accounts table for acquiring authentication username/password for this call (see <a href="#">Configuring Registration Accounts</a> on page 777).</li> <li>■ To configure Proxy Sets, see <a href="#">Configuring Proxy Sets</a> on page 632.</li> </ul>
'SIP Interface' dest-sip-interface-name [DestSIPInterfaceName]	<p>Assigns a SIP Interface to the routing rule. The call is sent to its' destination through this SIP interface.</p> <p>To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</p> <p><b>Note:</b> If a SIP Interface is not assigned, the device uses the SIP Interface associated with the default SRD (Index 0). If, for whatever reason, you have deleted the default SRD and there are no SRDs, the call is rejected.</p>
'Destination IP Address' dst-ip-address [DestAddress]	<p>Defines the IP address (in dotted-decimal notation or FQDN) to where the call is sent. If an FQDN is used (e.g., domain.com), DNS resolution is done according to the DNSQueryType parameter.</p>

Parameter	Description
	<p>For ENUM-based routing, enter the string "ENUM". The device sends an ENUM query containing the destination phone number to an external DNS server (configured in the IP Interfaces table). The ENUM reply includes a SIP URI which is used as the Request-URI in the subsequent outgoing INVITE and for routing (if a proxy is not used). To configure the type of ENUM service (e.g., e164.arpa), see the [EnumService] parameter.</p> <p>For LDAP-based routing, enter the string "LDAP" to denote the IP address of the LDAP server. For more information, see <a href="#">Routing for Microsoft Teams or Skype for Business using Microsoft Entra ID</a> on page 406.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is ignored if you have configured a destination IP Group in the 'Destination IP Group' field (in this table).</li> <li>■ To reject calls, enter the IP address 0.0.0.0. For example, if you want to prohibit international calls, then in the 'Destination Phone Prefix' field, enter 00 and in the 'Destination IP Address' field, enter 0.0.0.0.</li> <li>■ For routing calls between phones connected to the device (i.e., local routing), enter the device's IP address. If the device's IP address is unknown (e.g., when DHCP is used), enter IP address 127.0.0.1.</li> <li>■ When using domain names, enter the DNS server's IP address or alternatively, configure these names in the Internal DNS table (see <a href="#">Configuring the Internal DNS Table</a> on page 199).</li> </ul>
'IP Profile' ip-profile-id [ProfileName]	<p>Assigns an IP Profile to the routing rule in the outgoing direction. The IP Profile allows you to assign various configuration attributes (e.g., voice coder) per routing rule. To configure IP Profiles, see <a href="#">Configuring IP Profiles</a> on page 674.</p> <p>If you do not configure the parameter, the device uses the following IP Profile:</p> <ul style="list-style-type: none"> <li>■ If an IP Group is configured for the destination ('Destination IP Group' parameter), the device uses the IP Profile associated with the IP Group.</li> <li>■ If no IP Group is configured, the device uses IP Profile 0</li> </ul>

Parameter	Description
'Destination Port' dst-port [DestPort]	Defines the destination port to where you want to route the call.
'Transport Type' transport-type [TransportType]	<p>Defines the transport layer type used for routing the call.</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured and the transport type is according to the settings of the global parameter, SIPTransportType.</li> <li>■ [0] UDP</li> <li>■ [1] TCP</li> <li>■ [2] TLS</li> </ul>
Advanced	
'Call Setup Rules Set ID' call-setup-rules-set-id [CallSetupRulesSetId]	<p>Assigns a Call Setup Rule Set ID to the routing rule. The device performs the Call Setup rules of this Set ID if the incoming call matches the characteristics of the routing rule. The device routes the call to the destination according to the routing rule's configured action only after it has performed the Call Setup rules.</p> <p>By default, no value is defined.</p> <p>To configure Call Setup rules, see <a href="#">Configuring Call Setup Rules</a> on page 809.</p>
'Forking Group' forking-group [ForkingGroup]	<p>Defines a Forking Group number for the routing rule. This enables forking of incoming Tel calls to multiple IP destinations. The device sends simultaneous INVITE messages and handles multiple SIP dialogs until one of the calls is answered. When one of the calls is answered, the other calls are dropped.</p> <p>Each Forking Group can contain up to 10 members. In other words, up to 10 routing rules can be configured with the same Forking Group number.</p> <p>By default, no value is defined.</p> <p>If all matched routing rules belong to the same Forking Group number, the device sends an INVITE to all the destinations belonging to this group. If matched routing rules belong to different Forking Groups, the device sends the call to the Forking Group of the first matched routing rule. If the call cannot be established with any of the destinations associated with the Forking Group and</p>

Parameter	Description
	<p>alternative routing is enabled, the device forks the call to the Forking Group of the next matched routing rules, as long as the Forking Group is defined with a <b>higher</b> number than the previous Forking Group. For example:</p> <ul style="list-style-type: none"> <li>■ Table index entries 1 and 2 are defined with Forking Group "1", and index entries 3 and 4 with Forking Group "2": The device first sends the call according to index entries 1 and 2, and if unavailable and alternative routing is enabled, sends the call according to index entries 3 and 4.</li> <li>■ Table index entry 1 is defined with Forking Group "2", and index entries 2, 3, and 4 with Forking Group "1": The device sends the call according to index entry 1 only and ignores the other index entries even if the destination is unavailable and alternative routing is enabled. This is because the subsequent index entries are defined with a Forking Group number that is lower than that of index entry 1.</li> <li>■ Table index entry 1 is defined with Forking Group "1", index entry 2 with Forking Group "2", and index entries 3 and 4 with Forking Group "1": The device first sends the call according to index entries 1, 3, and 4 (all belonging to Forking Group "1"), and if the destination is unavailable and alternative routing is enabled, the device sends the call according to index entry 2.</li> <li>■ Table index entry 1 is defined with Forking Group "1", index entry 2 with Forking Group "3", index entry 3 with Forking Group "2", and index entry 4 with Forking Group "1": The device first sends the call according to index entries 1 and 4 (all belonging to Forking Group "1"), and if the destination is unavailable and alternative routing is enabled, the device sends the call according to index entry 2 (Forking Group "3"). Even if index entry 2 is unavailable and alternative routing is enabled, the device ignores index entry 3 because it belongs to a Forking Group that is lower than index entry 2.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ For Tel-to-IP call forking, enable the 'Tel-to-IP Call Forking Mode' (<i>Tel2IPCallForkingMode</i>) parameter.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ You can configure the device to immediately send the INVITE message to the first member of the Forking Group (as in normal operation) and then only after a user-defined interval, send the INVITE messages simultaneously to the other members. If the device receives a SIP 4xx or 5xx in response to the first INVITE, it immediately sends INVITEs to all the other members, regardless of the interval. To configure this feature, see the <code>ForkingDelayTimeForInvite</code> ini file parameter.</li> <li>■ You can implement Forking Groups when the destination is an LDAP server or a domain name using DNS. In such scenarios, the INVITE is sent to all the queried LDAP or resolved IP addresses, respectively. You can also use LDAP routing rules with standard routing rules for Forking Groups.</li> <li>■ When the <code>UseDifferentRTPportAfterHold</code> parameter is enabled, every forked call is sent with a different RTP port. Thus, ensure that the device has sufficient available RTP ports for these forked calls.</li> </ul>
'Cost Group' <code>cost-group-id</code> [CostGroup]	<p>Assigns a Cost Group to the routing rule for determining the cost of the call (i.e., Least Cost Routing or LCR). By default, no value is defined.</p> <p>To configure Cost Groups, see <a href="#">Configuring Cost Groups</a> on page 464.</p> <p><b>Note:</b> To implement LCR and its Cost Groups, you must enable LCR</p> <ul style="list-style-type: none"> <li>■ To implement LCR and its Cost Groups, the Routing Policy must be enabled for LCR (see <a href="#">Configuring a Gateway Routing Policy Rule</a> on page 967). If LCR is disabled, the device ignores the parameter.</li> <li>■ The Routing Policy also determines whether matched routing rules that are <b>not</b> assigned Cost Groups are considered as a higher or lower cost route compared to matching routing rules that are assigned Cost Groups. For example, if the 'Default Call Cost' parameter in the Routing Policy is configured to <b>Lowest Cost</b>, even if the device locates matching routing rules that are assigned Cost Groups, the first-matched routing rule without an assigned Cost Group is considered as the lowest cost route and thus, chosen</li> </ul>

Parameter	Description
	as the preferred route.
'Charge Code' charge-code [MeteringCode]	<p>Assigns a Charge Code to the routing rule for generating metering pulses (Advice of Charge).</p> <p>By default, no value is defined.</p> <p>To configure Charge Codes, see <a href="#">Configuring Charge Codes</a> on page 1082.</p> <p><b>Note:</b> The parameter is applicable only to FXS, Euro ISDN PRI, Euro ISDN BRI.</p>

## Configuring IP-to-Tel Routing Rules

The IP-to-Tel Routing table lets you configure up to 120 IP-to-Tel routing rules. IP-to-Tel routing rules route incoming IP calls to Trunk Groups. The specific channel pertaining to the Trunk Group to which the call is routed is determined according to the Trunk Group's channel selection mode. The channel selection mode can be configured per Trunk Group (see [Configuring Trunk Group Settings](#) on page 937) or for all Trunk Groups, using the global parameter ChannelSelectMode.

Configuration of IP-to-Tel routing rules includes two areas:

- **Match:** Defines the characteristics of the incoming IP call (e.g., source IP address from which the call is received).
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (i.e., routes the call to the specified Tel/Trunk Group destination).

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it sends the call to the Tel destination configured for that rule. If it doesn't find a matching rule, it rejects the call.

If an IP-to-Tel call cannot be routed to the Trunk Group, the device can route it to an alternative destination:

- **Routing to an Alternative Trunk Group:** If the device sends the IP call to the Tel destination and a subsequent call release reason (cause) code (e.g., 17 for User Busy) is received from the Tel side, and you have configured this release reason code in the Reasons for IP-to-Tel Alternative Routing table, the device re-routes the call to an alternative Trunk Group if an alternative routing rule has been configured in the table. Alternative routing rules must be configured in table rows (indices) located anywhere below the "main" routing rule. For example, if you configure a "main" routing rule in Index 4, the alternative routing rule can be configured in Index 6. In addition, you must configure alternative routing rules with identical matching characteristics (e.g., destination prefix number) to the "main" routing rule, but assigned with different destinations (Trunk Groups). For more information on IP-to-Tel alternative routing and for configuring call release reasons for alternative routing, see [Alternative Routing to Trunk upon Q.931 Call Release Cause Code](#) on page 977.

- **Routing to an IP Destination (i.e., Call Redirection):** The device can re-route the IP-to-Tel call to an alternative IP destination, using SIP 3xx responses. For more information, see [Alternative Routing to an IP Destination upon a Busy Trunk](#) on page 980.
- **Routing to an Alternative Physical FXO Port or Trunk within Same Trunk Group:** The device can re-route an IP-to-Tel call to a different physical FXO port or trunk if the destined FXO port or trunk within the same Trunk Group is out of service (e.g., physically disconnected). When the physical FXO port or trunk is disconnected, the device sends the SNMP trap, GWAPP\_TRAP\_BUSYOUT\_LINK notifying of the out-of-service state for the specific FXO line or trunk number. When the FXO port or physical trunk is physically reconnected, this trap is sent notifying of the back-to-service state.

- Instead of using the table for IP-to-Tel routing, you use ARM to handle the routing decisions. For more on routing by ARM, see [Centralized Routing by ARM \(AudioCodes Routing Manager\)](#) on page 451.
- You can configure up to three alternative routing rules per "main" routing rule in the table.
- If your deployment includes calls of many different called (source) and/or calling (destination) numbers that need to be routed to the same destination, you can employ user-defined prefix tags to represent these numbers. Thus, instead of configuring many routing rules, you need to configure only one routing rule using the prefix tag as the source and destination number matching characteristics, and a destination for the calls. For more information on prefix tags, see [Configuring IP-to-Tel Routing Rules](#).
- By default, the device applies destination telephone number manipulation (if configured) only after processing the routing rule. You can change this and apply number manipulation before processing the routing rule (see the [RouteModeIP2Tel] parameter). To configure number manipulation, see [Configuring Source-Destination Number Manipulation Rules](#) on page 983.

The following procedure describes how to configure IP-to-Tel routing rules through the Web interface. You can also configure it through ini file [PSTNPrefix] or CLI (`configure voip > gateway routing ip2tel-routing`).

➤ **To configure IP-to-Tel routing rules:**

1. Open the IP-to-Tel Routing table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing > IP > Tel Routing**).
2. Click **New**; the following dialog box appears:

3. Configure a routing rule according to the parameters described in the table below.

4. Click **Apply**.

The following table shows configuration examples of Tel-to-IP routing rules:

**Table 25-3: Example of IP-to-Tel Routing Rules**

Parameter	Rule 1	Rule 2	Rule 3
'Source Host Pattern'	-	-	abcd.domain
'Destination Phone Pattern'	1x	[501-502]	-
'Source Phone Pattern'	-	101	-
'Trunk Group ID'	3	2	4
'IP Profile'	ITSP-A	ITSP-B	-

Below provides descriptions of each rule:

- **Rule 1:** If the incoming IP call destination phone prefix is between 10 and 19, the call is assigned settings configured for IP Profile "ITSP-A" and routed to Trunk Group ID 3.
- **Rule 2:** If the incoming IP call destination phone prefix is between 501 and 502 and source phone prefix is 101, the call is assigned settings configured for IP Profile "ITSP-B" and routed to Trunk Group ID 2.
- **Rule 3:** If the incoming IP call has a From URI host prefix as abcd.com, the call is routed to Trunk Group ID 4.

**Table 25-4: IP-to-Tel Routing Table Parameter Description**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name'	Defines a descriptive name, which is used when associating

Parameter	Description
route-name [RouteName]	<p>the row in other tables.</p> <p>The valid value is a string of up to 40 characters. By default, no value is defined.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The name can't be configured with the character string "any" (upper or lower case).</li> </ul>
Match	
'Source SIP Interface' src-sip-interface-name [SrcSIPInterfaceName]	<p>Defines the SIP Interface on which the incoming IP call is received.</p> <p>The default is Any (i.e., any SIP Interface).</p> <p>To configure SIP Interfaces, see <a href="#">Configuring SIP Interfaces</a> on page 570.</p> <p><b>Note:</b> If the incoming INVITE is received on the specified SIP Interface and the SIP Interface associated with the specified IP Group in the 'Source IP Group' parameter (in this table) is different, the incoming SIP call is rejected. If the 'Source IP Group' parameter is not defined, the SIP Interface associated with the default SRD (Index 0) is used. If there is no valid source IP Group, the call is rejected.</p>
'Source IP Address' src-ip-address [SourceAddress]	<p>Defines the source IP address of the incoming IP call.</p> <p>The IP address must be configured in dotted-decimal notation (e.g., 10.8.8.5); not as an FQDN. The default is the asterisk (*) symbol, meaning any IP address.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The source IP address is obtained from the Contact header in the INVITE message.</li> <li>■ You can configure from where the source IP address is obtained, using the SourceIPAddressInput parameter.</li> <li>■ The source IP address can include the following wildcards: <ul style="list-style-type: none"> <li>✓ "x": denotes single digits. For example, 10.8.8.xx represents all the addresses between 10.8.8.10 and 10.8.8.99.</li> <li>✓ "*": denotes any number between 0 and 255. For example, 10.8.8.* represents all addresses between 10.8.8.0 and 10.8.8.255.</li> </ul> </li> </ul>

Parameter	Description
'Source Phone Pattern' src-phone-pattern  [SourcePrefix]	<p>Defines the calling (source) telephone number.</p> <p>The valid value can be up to 49 digits. You can use special patterns to denote the number. For example, "[100-199](100,101,105)" denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. To denote any number, use the asterisk (*) symbol (default). To denote calls without a calling number, use the dollar (\$) sign. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p><b>Note:</b> If the SIP P-Asserted-Identity header is present in the incoming INVITE message, the value of the parameter is compared to the URI user part in the P-Asserted-Identity header (not the From header).</p>
'Source Host Pattern' src-host-pattern  [SrcHostPrefix]	<p>Defines the URI host part in the From header of the incoming INVITE message.</p> <p>You can use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". To denote any host part, use the asterisk (*) symbol. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>By default, no value is defined.</p> <p><b>Note:</b> If the P-Asserted-Identity header is present in the incoming INVITE message, the value of the parameter is compared to the P-Asserted-Identity URI host name (and not the From header).</p>
'Source Tags' src-tags  [SrcTags]	<p>Assigns a Dial Plan tag to denote a group of source URI user names.</p> <p>The valid value is a string of up to 70 characters. The tag is case insensitive.</p> <p>To configure Dial Plan tags, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The tag must belong to the Dial Plan that is assigned for IP-to-Tel routing. To do this, use the 'IP-to-Tel Dial Plan Name' (IP2TelDialPlanName) parameter.</li> <li>■ The device uses the tag before or after manipulation, depending on the 'IP-to-Tel Routing Mode' (RouteModeIP2Tel) parameter. If configured to <b>Route calls</b></li> </ul>

Parameter	Description
	<p><b>before manipulation</b>, the tag is used before manipulation. If configured to <b>Route calls after manipulation</b>, the tag is used after manipulation.</p>
'Destination Phone Pattern' dst-host-pattern [DestPrefix]	<p>Defines the called (destined) telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, "[100-199](100,101,105)" denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. To denote any prefix, use the asterisk (*) symbol (default). To denote calls without a called number, use the dollar (\$) sign. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The value can include up to 49 digits.</p>
'Destination Host Pattern' dst-phone-pattern [DestHostPrefix]	<p>Defines the Request-URI host name of the incoming INVITE message.</p> <p>You can use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". To denote any host part, use the asterisk (*) symbol. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>By default, no value is defined.</p>
'Destination Tags' dest-tags [DestTags]	<p>Assigns a prefix tag to denote destination URI user names corresponding to the tag configured in the associated Dial Plan.</p> <p>The valid value is a string of up to 70 characters. The tag is case insensitive.</p> <p>To configure Dial Plan tags, see <a href="#">Configuring Dial Plans</a> on page 825.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The tag must belong to the Dial Plan that is assigned for IP-to-Tel routing. To do this, use the 'IP-to-Tel Dial Plan Name' (IP2TelDialPlanName) parameter.</li> <li>■ The device uses the tag before or after manipulation, depending on the 'IP-to-Tel Routing Mode' (RouteModelIP2Tel) parameter. If configured to <b>Route calls before manipulation</b>, the tag is used before manipulation. If configured to <b>Route calls after manipulation</b>, the tag is used after manipulation.</li> </ul>

Parameter	Description
<b>Action</b>	
'Destination Type' dst-type [DestType]	<p>Defines the type of Tel destination.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Trunk Group</b> (default)</li> <li>■ [1] <b>Trunk</b></li> </ul>
'Trunk Group ID' trunk-group-id [TrunkGroupId]	<p>Defines the Trunk Group ID to where the incoming SIP call is sent.</p> <p><b>Note:</b> This parameter is applicable only if you configure the 'Destination Type' parameter (see above) to <b>Trunk Group</b>.</p>
'Trunk ID' trunk-id [TrunkId]	<p>Defines the Trunk to where the incoming SIP call is sent.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ If both 'Trunk Group ID' and 'Trunk ID' parameters are configured in the table, the routing is done according to the 'Trunk Group ID' parameter.</li> <li>■ To configure the method for selecting the trunk's channel to which the IP call is sent, see the global parameter, ChannelSelectMode.</li> </ul>
'Source IP Group' src-ip-group-id [SrcIPGroupName]	<p>Assigns an IP Group from where the SIP message (INVITE) is received.</p> <p>By default, no value is defined.</p> <p>To configure IP Groups, see <a href="#">Configuring IP Groups</a> on page 591.</p> <p>The IP Group can be used as the 'Serving IP Group' in the Accounts table for obtaining authentication username/password for the call. To configure registration accounts, see <a href="#">Configuring Registration Accounts</a> on page 777.</p>
'IP Profile' ip-profile-id [ProfileName]	<p>Assigns an IP Profile to the call.</p> <p>To configure IP Profiles, see <a href="#">Configuring IP Profiles</a> on page 674.</p>
'Call Setup Rules Set' ID call-setup-rules-set-id [CallSetupRulesSetId]	<p>Assigns a Call Setup Rule Set ID to the routing rule. The device performs the Call Setup rules of this Set ID if the incoming call matches the characteristics of the routing rule. The device routes the call to the destination according to the routing rule's configured action, only after it has performed the Call Setup rules.</p> <p>To configure Call Setup rules, see <a href="#">Configuring Call Setup Rules</a></p>

Parameter	Description
	on page 809.

## Configuring a Gateway Routing Policy Rule

The Routing Policies table lets you edit the default Routing Policy rule. The Routing Policy is used for Gateway call routing and defines the following:

- LDAP server (LDAP Server Group) for LDAP-based call routing (LDAP or Call Setup Rules queries). LDAP-based routing is applicable to Tel-to-IP routing ([Configuring Tel-to-IP Routing Rules](#) on page 946) and IP-to-Tel routing ([Configuring IP-to-Tel Routing Rules](#) on page 960).
- Enables Least Cost Routing (LCR), and defines default call cost (highest or lowest) and average call duration for Tel-to-IP routing rules that are not assigned LCR Cost Groups. The default call cost determines whether matched routing rules that are not assigned a Cost Group are considered as a higher or lower cost route compared to other matching routing rules that are assigned Cost Groups. If you disable LCR, the device ignores the Cost Groups assigned to Tel-to-IP routing rules in the Tel-to-IP Routing table. LCR is applicable only to Tel-to-IP routing.

The following procedure describes how to configure Routing Policy rules through the Web interface. You can also configure it through ini file [GwRoutingPolicy] or CLI (`configure voip > gateway routing gw-routing-policy`).

### ➤ To edit the Routing Policy rule:

1. Open the Routing Policies table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Policies**).
2. Click **New**; the following dialog box appears:

**Routing Policies [GwRoutingPolicy]**

**GENERAL**

Index: 0

Name: GwRoutingPolicy

LDAP Servers Group Name: -- [View](#)

LCR Feature: Disable

Default Call Cost: Lowest Cost

LCR Call Duration [min]: 1

3. Configure the Routing Policy rule according to the parameters described in the table below.

4. Click **Apply**.**Table 25-5: Routing Policies Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	(Read-only) Displays the index number of the table row.
'Name' name [Name]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters. The default value is "GwRoutingPolicy".</p>
'LDAP Servers Group Name' ldap-srv-group-name [LdapServersGroupName]	<p>Assigns an LDAP Server Group to the Routing Policy. IP-to-Tel and Tel-to-IP routing rules that require LDAP-based routing (or Call Setup Rules) use the LDAP server(s) assigned to the LDAP Server Group.</p> <p>By default, no value is defined.</p> <p>For more information on LDAP Server Groups, see <a href="#">Configuring LDAP Server Groups</a> on page 382.</p>
'LCR Feature' lcr-enable [LCREnable]	<p>Enables the Least Cost Routing (LCR) feature for the Routing Policy.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Disable</b> (default)</li> <li>■ [1] <b>Enable</b></li> </ul> <p>For more information on LCR, see <a href="#">Least Cost Routing</a> on page 461.</p> <p><b>Note:</b> LCR is applicable only to Tel-to-IP routing.</p>
'Default Call Cost' lcr-default-cost [LCRDefaultCost]	<p>Defines whether routing rules in the Tel-to-IP Routing table that are not assigned a Cost Group are considered a higher cost or lower cost route compared to other matched routing rules that are assigned Cost Groups.</p> <ul style="list-style-type: none"> <li>■ [0] <b>Lowest Cost</b> = (Default) The device considers a matched routing rule that is not assigned a Cost Group as the lowest cost route. Therefore, it uses the routing rule.</li> <li>■ [1] <b>Highest Cost</b> = The device considers a matched routing rule that is not assigned a Cost Group as the highest cost route. Therefore, it is only used if the other matched routing rules that are assigned Cost Groups are unavailable.</li> </ul>

Parameter	Description
'LCR Call Duration' lcr-call-length [LCRAverageCallLength]	<p>Defines the average call duration (in minutes) and is used to calculate the variable portion of the call cost. This is useful, for example, when the average call duration spans over multiple time bands. The LCR is calculated as follows:</p> $\text{cost} = \text{call connect cost} + (\text{minute cost} * \text{average call duration})$ <p>The valid value is 0-65533. The default is 1.</p> <p>For example, assume the following Cost Groups:</p> <ul style="list-style-type: none"> <li>■ "Weekend A": call connection cost is 1 and charge per minute is 6. Therefore, a call of 1 minute cost 7 units.</li> <li>■ "Weekend B": call connection cost is 6 and charge per minute is 1. Therefore, a call of 1 minute cost 7 units.</li> </ul> <p>Therefore, for calls under one minute, "Weekend A" carries the lower cost. However, if the average call duration is more than one minute, "Weekend B" carries the lower cost.</p>

## Alternative Routing for Tel-to-IP Calls

The device supports various alternative Tel-to-IP call routing methods, as described in this section.

### IP Destinations Connectivity Feature

The device can be configured to check the integrity of the connectivity to IP destinations of Tel-to-IP routing rules in the Tel-to-IP Routing table. The IP Connectivity feature can be used for the Alternative Routing feature, whereby the device attempts to re-route calls from unavailable Tel-to-IP routing destinations to available ones (see [Alternative Tel-to-IP Routing Based on IP Connectivity](#) on the next page).

The device supports the following methods for checking the connectivity of IP destinations:

- **Network Connectivity:** The device checks the network connectivity by sending "keep-alive" SIP OPTIONS messages to the IP destination. If the device receives a SIP 200 OK in response (or any response, even an error response), it considers the destination available. If the destination doesn't respond to the OPTIONS message, it considers the destination unavailable. You can configure the time interval for sending these OPTIONS messages, using the 'Tel-to-IP Alt Routing Keep-Alive Time' parameter on the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**):

Tel-to-IP Alt Routing Keep-Alive Time

60

- **Quality of Service (QoS):** You can enable the device to check the QoS of IP destinations. The device measures the QoS according to RTCP statistics of previously established calls with the IP destination. The RTCP includes packet delay (in milliseconds) and packet loss (in percentage). If these measured statistics exceed a user-defined threshold, the destination is considered unavailable. Note that if call statistics is not received within two minutes, the QoS data is reset. These thresholds are configured using the following parameters:
  - 'Max Allowed Packet Loss for Alt Routing' (IPConnQoSMaxAllowedPL): defines the threshold value for packet loss after which the IP destination is considered unavailable.
  - 'Max Allowed Delay for Alt Routing' (IPConnQoSMaxAllowedDelay): defines the threshold value for packet delay after which the IP destination is considered unavailable

These parameters are configured in the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**), as shown below:

Max Allowed Packet Loss for Alt Routing [%]	<input type="text" value="20"/>
Max Allowed Delay for Alt Routing [msec]	<input type="text" value="250"/>

- **DNS Resolution:** When a host name (FQDN) is used (instead of an IP address) for the IP destination, it is resolved into an IP address by a DNS server. The device checks network connectivity and QoS of the resolved IP address. If the DNS host name is unresolved, the device considers the connectivity of the IP destination as unavailable.

You can view the connectivity status of IP destinations in the following Web interface pages:

- **Tel-to-IP Routing table:** The connectivity status of the IP destination per routing rule is displayed in the 'Status' column. For more information, see [Configuring Tel-to-IP Routing Rules](#) on page 946.
- **IP Connectivity:** This page displays a more informative connectivity status of the IP destinations used in Tel-to-IP routing rules in the Tel-to-IP Routing table. For viewing this page, see [Viewing IP Connectivity](#) on page 1491.

## Alternative Tel-to-IP Routing Based on IP Connectivity

You can configure the device to route Tel-to-IP calls to an alternative IP destination when the connectivity state of an IP destination is unavailable. The alternative routing rules are configured in the Tel-to-IP Routing table. These rules must be configured anywhere below the "main" routing rule and with identical matching characteristics (e.g., destination prefix number) to the "main" routing rule. The device uses the first alternative route that is available. For more information on configuring alternative Tel-to-IP routing rules in the Tel-to-IP Routing table, see [Configuring Tel-to-IP Routing Rules](#) on page 946.

- Alternative routing based on IP connectivity is applicable only when a proxy server is **not** used.
- You can also enable the Busy Out feature, whereby the device can take specified actions if all IP destinations of matching routing rules in the Tel-to-IP Routing table do not respond to connectivity checks. For more information, see the [EnableBusyOut] parameter.
- If you enable the [AltRoutingTel2IPEnable] parameter, the Busy Out feature doesn't function with the Proxy Set keep-alive mechanism (see [Alternative Tel-to-IP Routing Based on SIP Responses](#) on page 973). To use the Busy Out feature with the Proxy Set keep-alive mechanism (for IP Groups), disable the [AltRoutingTel2IPEnable] parameter.

The device searches for an alternative routing rule (IP destination) when any of the following connectivity states are detected with the IP destination of the "main" routing rule:

- No response received from SIP OPTIONS messages.
- Poor QoS according to the configured thresholds for packet loss and delay.
- No response from a DNS-resolved IP address, where the domain name (FQDN) is configured for the IP destination. If the device sends the INVITE message to the first IP address and receives no response, the device makes a user-defined number of attempts (configured by the [HotSwapRtx] parameter) to send it again (re-transmit). If there is still no response after all the attempts, it sends it to the next DNS-resolved IP address, and so on. For example, if you configure the parameter to "3" (without quotation marks) and the device receives no response from the first IP address, it attempts up to three times to send the INVITE to the first IP address and if unsuccessful, it attempts to send the call to the next DNS-resolved IP address, and so on.
- No response for in-dialog request from a DNS-resolved IP address, where the domain name is received in the Contact header of an incoming setup or target refresh SIP message (e.g., 200 OK). If no response is received from the first IP address, the device tries to send it again for up to a user-defined number of attempts (configured by the [HotSwapRtx] parameter). If there is still no response, it attempts to send the SIP request to the next DNS-resolved IP address, and so on.

The connectivity status of the IP destination is displayed in the 'Status' column of the Tel-to-IP Routing table per routing rule. If it displays a status other than "ok", the device considers the IP destination as unavailable and attempts to re-route the call to an alternative destination. For more information on the IP connectivity methods and viewing IP connectivity status, see [IP Destinations Connectivity Feature](#) on page 969.

The table below shows an example of alternative routing where the device uses an available alternative routing rule in the Tel-to-IP Routing table to re-route the initial Tel-to-IP call.

**Table 25-6: Alternative Routing based on IP Connectivity Example**

	Destination Phone Prefix	IP Destination	IP Connectivity Status	Rule Used?
<b>Main Route</b>	40	10.33.45.68	"No Connectivity"	No
<b>Alternative Route #1</b>	40	10.33.45.70	"QoS Low"	No
<b>Alternative Route #2</b>	40	10.33.45.72	"ok"	Yes

The following procedure describes how to configure alternative Tel-to-IP routing based on IP connectivity.

➤ **To configure alternative Tel-to-IP routing based on IP connectivity:**

1. In the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946), add alternative Tel-to-IP routing rules for specific calls.
2. Open the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**):

Enable Tel-to-IP Alt Routing	• <span>Enable</span> ▼
Tel-to-IP Alt Routing Mode	• <span>Connectivity</span> ▼
Tel-to-IP Alt Routing Keep-Alive Time	<span>60</span>

3. Under the Alternative Route group, do the following:
  - a. From the 'Enable Tel-to-IP Alt Routing' [AltRoutingTel2IPEnable] drop-down list, select **Enable** to enable alternative Tel-to-IP routing based on IP connectivity.
  - b. From the 'Tel-to-IP Alt Routing Mode' drop-down list [AltRoutingTel2IPMode], configure the IP connectivity reason for triggering alternative routing.
    - ◆ **Connectivity:** Alternative routing is performed if SIP OPTIONS message to the initial destination fails
    - ◆ **QoS:** Alternative routing is performed if poor QoS is detected. QoS is quantified according to delay and packet loss calculated according to previous calls.
    - ◆ **Both** (above)
  - c. (For Analog Interfaces Only) In the 'Alternative Routing Tone Duration' field, configure the duration for which the device plays a tone to the Tel endpoint (for analog interfaces) whenever an alternative route is used.
  - d. Enable the connectivity feature (see [IP Destinations Connectivity Feature](#) on page 969).

## Alternative Tel-to-IP Routing Based on SIP Responses

The device can do alternative routing based on the received SIP response code (i.e., 4xx, 5xx, 6xx, or 8xx). If the received SIP response code is also configured in the Reasons for Tel-to-IP Alternative Routing table, the device attempts to re-route the call to an alternative destination (if configured). You can configure up to 10 SIP response codes in the Reasons for Tel-to-IP Alternative Routing table.

Typically, the device does alternative routing when there is no response to an INVITE message. This is done after a user-defined number of INVITE re-transmissions, configured by the [SIPMaxRtx] parameter. In such a scenario, the device issues itself the SIP response code 408 (Request Timeout). You can also configure the device to do alternative routing for the following proprietary response codes that are issued by the device itself:

- **805 IP Profile Call Limit:** The device generates this response code when Call Admission Control (CAC) limits are exceeded for an IP Group. The CAC rules are configured in the IP Profiles table (see [Configuring IP Profiles](#) on page 674). When this occurs, the device sends a SIP 480 (Temporarily Unavailable) response to the SIP user agent (UA).
- **806 Media Limits Exceeded:** The device generates Release Cause Code 806 when the call is terminated due to crossed thresholds of QoE metrics such as MOS, packet delay, and packet loss (configured in the Quality of Experience Profile table - see [Configuring Quality of Experience Profiles](#) on page 528) and/or media bandwidth (configured in the Bandwidth profile table - see [Configuring Bandwidth Profiles](#) on page 535). When this occurs, the device sends a SIP 480 (Temporarily Unavailable) response to the SIP entity. When the threshold is crossed, the device maintains the existing call and applies alternative routing only to subsequent calls. To configure alternative routing based on Release Cause 806, do the following :
  - a. Assign an IP Group with a QoE and/or Bandwidth profile that rejects calls if the threshold is crossed.
  - b. Configure Release Cause Code 806 in the Reasons for Tel-to-IP Alternative Routing table.
  - c. Configure an alternative routing rule.

The device always routes at least two calls to the destination that has crossed the threshold, so that it can continue measuring QoE / bandwidth. When the threshold drops below the configured QoE / bandwidth threshold (i.e., good QoE), the device stops using the alternative routing rule and starts routing the calls using the initial routing rule.

- You can also enable the Busy Out feature, whereby the device can take specified actions if all Proxy Sets of associated destination IP Groups of matching routing rules in the Tel-to-IP Routing table do not respond to connectivity checks. For more information, see the [EnableBusyOut] parameter.
- If you enable the [AltRoutingTel2IPEnable] parameter for the IP Connectivity feature (see [Alternative Tel-to-IP Routing Based on IP Connectivity](#) on page 970), the Busy Out feature doesn't function with the Proxy Set keep-alive mechanism (see below). To use the Busy Out feature with the Proxy Set keep-alive mechanism (for IP Groups), disable the [AltRoutingTel2IPEnable] parameter.
- The device also plays a tone to the analog endpoint whenever an alternative route is used. This tone is played for a user-defined time, configured by the [AltRoutingToneDuration] parameter

Depending on configuration, alternative routing uses one of the following configuration entities:

- **Tel-to-IP Routing Rules:** Alternative routing rules can be configured for a specific routing rule in the Tel-to-IP Routing table. If the destination of the "main" routing rule is unavailable, the device searches the table for the next matching rule (e.g., destination phone number), and if available attempts to re-route the call to the IP destination configured for this alternative routing rule. For more information on configuring alternative Tel-to-IP routing rules, see [Configuring Tel-to-IP Routing Rules](#) on page 946. The table below shows an example of alternative routing where the device uses the first available alternative routing rule to re-route the initial, unsuccessful Tel-to-IP call destination.

**Table 25-7: Alternative Routing based on SIP Response Code Example**

	Destination Phone Prefix	IP Destination	SIP Response	Rule Used?
<b>Main Route</b>	40	10.33.45.68	408 Request Timeout	No
<b>Alternative Route #1</b>	40	10.33.45.70	486 Busy Here	No
<b>Alternative Route #2</b>	40	10.33.45.72	200 OK	Yes

- **Proxy Sets:** Proxy Sets are used for Server-type IP Groups (e.g., an IP PBX or proxy), which define the address (IP address or FQDN) of the server. As you can configure multiple proxy servers per Proxy Set, the device supports proxy redundancy, which works together with the alternative routing feature. If the destination of a routing rule in the Tel-to-IP Routing

table is a Server-type IP Group, the device routes the call to the IP destination configured for the Proxy Set associated with the IP Group. If the IP destination of the Proxy Set is offline, the device attempts to re-route the call to another online proxy destination with the highest priority. To enable the Proxy Redundancy feature for a Proxy Set, configure the 'Proxy Hot Swap Mode' parameter to **Enable** and the 'Proxy Keep-Alive' parameter to **Using OPTIONS**. For more information on proxy redundancy, see [Configuring Proxy Sets](#) on page 632.

The device assumes that all proxy servers belonging to a Proxy Set are synchronized with regards to registered users. Therefore, when the device locates an available proxy using the Hot Swap feature, it doesn't re-register the users; new registration (refresh) is done as normal.

The following procedure describes how to configure alternative Tel-to-IP routing based on SIP response codes through the Web. You can also configure it through ini file [AltRouteCauseTel2Ip] or CLI (`configure voip > gateway routing alt-route-cause-tel2ip`).

➤ **To configure alternative Tel-to-IP routing based on SIP response codes:**

1. Configure SIP response codes (call failure reasons) that invoke alternative Tel-to-IP routing:
  - a. Open the Reasons for Tel-to-IP Alternative Routing table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Alternative Routing Reasons** > **Reasons for Tel > IP**).
  - b. Click **New**; the following dialog box appears:

- c. Configure a SIP response code for alternative routing according to the parameters described in the table below.
  - d. Click **Apply**.

**Table 25-8: Reasons for Tel-to-IP Alternative Routing Table Parameter Descriptions**

Parameter	Description
'Index'	Defines an index number for the new table row.

Parameter	Description
[Index]	<b>Note:</b> Each row must be configured with a unique index.
'Release Cause' rel-cause [ReleaseCause]	Defines a SIP response code that if received, the device attempts to route the call to an alternative destination (if configured).

2. Enable alternative routing based on SIP responses:
  - a. Open the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**).
  - b. From the 'Redundant Routing Mode' drop-down list, select one of the following:
    - ◆ **Routing Table:** The device uses the Tel-to-IP Routing table for alternative routing.
    - ◆ **Proxy:** The device uses the Proxy Set redundancy feature for alternative routing.

Redundant Routing Mode

Routing Table

3. If you are using the Tel-to-IP Routing table, configure alternative routing rules with identical call matching characteristics, but different IP destinations. If you are using the Proxy Sets table, configure redundant proxies.

## Alternative Tel-to-IP Routing upon SIP 3xx with Multiple Contacts

You can configure how the device handles received SIP 3xx responses containing multiple alternative contacts. The 3xx response indicates that the original destination is unavailable (e.g., 301 "Moved Permanently – user cannot be found") and that the call can be redirected to alternative destinations specified in the SIP Contact headers.

You can configure the device to handle the receipt of 3xx responses in one of the following ways:

- The device tries each contact sequentially in the Contact headers, until a successful destination is found. If a contact responds with a SIP 486 or 600, the device doesn't redirect the call to the next contact, but instead rejects the call.
- The device tries each contact sequentially in the Contact headers. If a SIP 6xx Global Failure response is received (e.g., 600 Busy Everywhere), the device doesn't redirect the call to the next contact, but instead rejects the call.
- The device redirects the call to the first contact listed in the Contact header. If the contact responds with a SIP response that is configured in the Reasons for Tel-to-IP Alternative Routing table (see [Alternative Tel-to-IP Routing Based on SIP Responses](#) on page 973), the device tries to redirect the call to the next contact, and so on. If a contact responds with a response that is not configured in the table, the device doesn't try to redirect the call to the next contact, but instead rejects the call.

➤ **To configure handling of SIP 3xx response with multiple contacts:**

1. Open the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**).
2. From the '3xx Use Alt Route Reasons' drop-down list, select the required handling.

3xx Use Alt Route Reasons

3. Click **Apply**.

If a SIP 401 or 407 response is received from a contact, the device doesn't try to redirect the call to the next contact. Instead, the device continues with regular authentication as indicated by these response types.

## PSTN Fallback

The PSTN Fallback feature enables the device to re-route a Tel-to-IP call to the legacy PSTN using one of its trunks if the IP destination is unavailable. For example, if poor voice quality is detected over the IP network, the device attempts to re-route the call to the PSTN.

The following procedure describes how to configure alternative Tel-to-IP routing to the PSTN.

➤ **To configure alternative Tel-to-IP routing to the PSTN:**

1. In the Tel-to-IP Routing table (see [Configuring Tel-to-IP Routing Rules](#) on page 946), configure an alternative routing rule with the same call matching characteristics (e.g., phone number destination) as the "main" routing rule, but where the destination is the IP address of the device itself.
2. In the IP-to-Tel Routing table (see [Configuring IP-to-Tel Routing Rules](#) on page 960), configure an IP-to-Tel routing rule to route calls received from the device (i.e., its IP address) to a specific Trunk Group connected to the PSTN. This configuration is necessary as the re-routed call is now considered an IP-to-Tel call.

The PSTN Fallback feature is applicable only to digital interfaces.

## Alternative Routing for IP-to-Tel Calls

This section describes configuration for alternative IP-to-Tel call routing.

### Alternative Routing to Trunk upon Q.931 Call Release Cause Code

You can configure up to 10 ISDN Q.931 release cause codes. If the device receives a configured release cause code from the Tel side, it routes the IP-to-Tel call to an alternative Trunk Group, if configured.

Alternative IP-to-Tel routing rules are configured in the IP-to-Tel Routing table. These rules must be configured anywhere below the "main" routing rule and with identical matching characteristics (e.g., destination prefix number) to the "main" routing rule. The device uses the first alternative route that is available. For more information on configuring alternative IP-to-Tel routing rules in the IP-to-Tel Routing table, see [Configuring IP-to-Tel Routing Rules](#) on page 960.

A release cause code indicates that the IP-to-Tel call has been rejected or disconnected on the Tel side. The release cause codes are configured in the Reasons for IP-to-Tel Alternative Routing table. For example, you can configure alternative IP-to-Tel routing for scenarios where the initial Tel destination is busy and a Q.931 Cause Code No. 17 is received (or for other call releases that issue the default Cause Code No. 3).

You can configure a default release cause code that the device issues itself upon the following scenarios:

- The device initiates a call release whose cause is unknown.
- No free channels (i.e., busy) in the Trunk Group.
- No appropriate routing rule located in the IP-to-Tel Routing table.
- Phone number is not located in the IP-to-Tel Routing table.

The default release code is Cause Code No. 3 (No Route to Destination). You can change the default code as follows:

➤ **To change the default Q.931 release code:**

1. Open the Gateway Advanced Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Gateway Advanced Settings**).
2. In the 'Default Release Cause' field, enter the release cause code:

Default Release Cause

3. Click **Apply**.

- If a Trunk is disconnected or not synchronized, the device issues itself the internal Cause Code No. 27. This cause code is mapped (by default) to SIP 502.
- The default release cause is described in the Q.931 notation and translated to corresponding SIP 40x or 50x values (e.g., Cause Code No. 3 to SIP 404, and Cause Code No. 34 to SIP 503).
- For analog interfaces: For information on mapping PSTN release causes to SIP responses, see [Mapping PSTN Release Cause to SIP Response for Analog Interfaces](#) on page 1022.
- For mapping SIP-to-Q.931 and Q.931-to-SIP release causes, see [Configuring Release Cause Mapping](#) on page 1009.

The following procedure describes how to configure alternative routing reasons for IP-to-Tel calls through the Web interface. You can also configure it through ini file [AltRouteCauseIP2Tel] or CLI (`configure voip > gateway routing alt-route-cause-ip2tel`).

➤ To configure alternative Trunk Group routing based on Q.931 cause codes:

1. Open the Routing Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Routing Settings**).
2. From the 'Redundant Routing Mode' drop-down list, select **Routing Table** so that the device uses the IP-to-Tel Routing table for alternative routing:

Redundant Routing Mode      Routing Table ▼

3. Open the IP-to-Tel Routing table, and then configure alternative routing rules with the same call matching characteristics as the "main" routing rule, but with different Trunk Group destinations.
4. Configure Q.931 cause codes that invoke alternative IP-to-Tel routing:
  - a. Open the Reasons for IP-to-Tel Alternative Routing table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Alternative Routing Reasons** > **Reasons for IP > Tel**).
  - b. Click **New**; the following dialog box appears:

- c. Configure a Q.931 release cause code for alternative routing according to the parameters described in the table below.
- d. Click **Apply**.

**Table 25-9: Reasons for IP-to-Tel Alternative Routing Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Release Cause' rel-cause [ReleaseCause]	Defines a Q.931 release code that if received, the device attempts to route the call to an alternative destination (if configured).

## Alternative Routing to an IP Destination upon a Busy Trunk

The Forward on Busy Trunk Destination table lets you configure up to 100 alternative routing rules for forwarding (i.e., call redirection) IP-to-Tel calls to an alternative IP destination (instead of the Tel destination) using SIP 3xx responses. The alternative routing is triggered upon the following:

- Digital interfaces: Trunk Group has no free channels (i.e., “busy”).
- Analog interfaces: Unavailable FXS / FXO Trunk Group. This feature can be used, for example, to forward calls to another FXS / FXO endpoint.

The feature is not applicable to Trunk Groups whose 'Channel Select Mode' parameter is configured to **By Dest Phone Number**, **Dest Number & Cyclic Ascending**, or **By Dest Number & Ascending** in the Trunk Group Settings table (see [Configuring Trunk Group Settings](#) on page 937).

This feature is configured per Trunk Group. The alternative destination can be defined as a host name or as a SIP Request-URI user name and host part (i.e., user@host). For example, the below configuration forwards IP-to-Tel calls to destination user “112” at host IP address 10.13.4.12, port 5060, using transport protocol TCP, if Trunk Group ID 2 is unavailable:

```
ForwardOnBusyTrunkDest 1 = 2, 112@10.13.4.12:5060;transport=tcp;
```

When configured with user@host, the original destination number is replaced by the user part.

The device forwards calls using this table **only** if no alternative IP-to-Tel routing rule has been configured in the IP-to-Tel Routing table or alternative routing fails and the following reason(s) in the SIP Diversion header of 3xx messages exists:

- Digital interfaces: “out-of-service” - all trunks are unavailable/disconnected
- "unavailable":
  - Digital interfaces: All trunks are busy or unavailable
  - Analog interfaces: All FXS / FXO lines pertaining to a Trunk Group are busy or unavailable

The following procedure describes how to configure Forward on Busy Trunks through the Web interface. You can also configure it through ini file [ForwardOnBusyTrunkDest] or CLI (configure voip > gateway routing fwd-on-busy-trk-dst).

### ➤ To configure a Forward on Busy Trunk Destination rule:

1. Open the Forward on Busy Trunk Destination table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Routing** > **Forward on Busy Trunk Destination**).
2. Click **New**; the following dialog box appears:

**Forward On Busy Trunk Destination**

**GENERAL**

Index: 0

Trunk Group ID: 1

Forward Destination: 10.13.5.67

The figure above displays a configuration that forwards IP-to-Tel calls destined for Trunk Group ID 1 to destination IP address 10.13.5.67 if conditions mentioned earlier exist.

3. Configure a rule according to the parameters described in the table below.
4. Click **Apply**, and then restart the device with a save-to-flash for your settings to take effect.

**Table 25-10: Forward on Busy Trunk Destination Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Trunk Group ID' trunk-group-id [TrunkGroupId]	Defines the Trunk Group ID to where the IP call is destined.
'Forward Destination' forward-dst [ForwardDestination]	Defines the alternative IP destination for the call used if the Trunk Group is busy or unavailable.  The valid value can be an IP address in dotted-decimal notation, an FQDN, or a SIP Request-URI user name and host part (i.e., user@host). The following syntax can also be used: host:port;transport=xxx (i.e., IP address, port and transport type). <b>Note:</b> <ul style="list-style-type: none"> <li>■ If you do not specify a port, the device uses UDP port 5060.</li> <li>■ When configured with a user@host, the original destination number is replaced by the user part.</li> </ul>

## Alternative Routing upon ISDN Disconnect

You can configure when the device sends a call to an alternative route if it receives an ISDN Q.931 Disconnect message with a Progress Indicator (PI) IE from the Tel side for IP-to-Tel calls.

The Disconnect message indicates that the call cannot be established due to, for example, a busy state on the Tel side.

The feature is applicable only to digital interfaces.

You can enable or disable this mode of operation:

- **Disabled:** The device doesn't immediately disconnect the call. Instead, it waits for any subsequent media from the Tel side (e.g., "this number is currently busy") and forwards it to the IP side (SIP 183 for early media). Only when it receives a Q.931 Release message, does the device disconnect the call (sends a SIP BYE message to the IP side). If you have configured an alternative route, the device sends the IP call to the alternative route.
- **Enabled:** The device immediately sends the IP call to an alternative route, if you have configured one. If no alternative route has been configured and the Disconnect message is received with PI, the device forwards the subsequent early media to the IP side. The device disconnects the IP call only upon receipt of the subsequent Release message.

➤ **To configure alternative routing upon receipt of ISDN Disconnect:**

1. Open the Digital Gateway Parameters page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Digital Gateway** > **Digital Gateway Settings**).
2. Select the 'Disconnect Call With PI If Alt' check box (DisconnectCallwithPIIfAlt):

Disconnect Call With PI If Alt

3. Click **Apply**.

## Alternative Routing from FXO to IP

You can enable the device to automatically switch the destination of an FXS call from FXO (PSTN) to IP (SIP Trunk) when the PSTN disconnects the FXS subscriber. When a PSTN disconnects a subscriber, the device automatically (or manually through TR-104), recognizes the signal of the call placed by the subscriber and then re-routes the call to a SIP Trunk. This is configured by the [TR104FXOSwitchover] parameter.

For more information on this application, please contact the sales representative of your purchased device.

## 26 Manipulation

This section describes configuration of various manipulation processes for the Gateway application.

### Configuring Redirect Reasons

You can manipulate call redirect (diversion) reasons between IP (SIP) and Tel (ISDN). The SIP Diversion header contains the information on the redirection of the call, including the reason (e.g., 'reason=user-busy'). The ISDN provides the Redirect Number and the Reason for Redirection. You can configure the following redirect manipulations:

- Redirect Number screening indicator (e.g., User Failed) in ISDN Setup messages for IP-to-Tel calls. Configuration is done using the [SetIp2TelRedirectScreeningInd] parameter.
- IP-to-Tel redirect reason for IP-to-Tel calls in the ISDN message if redirect information is received from the IP side. Configuration is done using the [SetIp2TelRedirectReason] parameter.
- Tel-to-IP redirect reason in SIP messages for Tel-to-IP calls if redirect information is received from the Tel side. Configuration is done using the [SetTel2IpRedirectReason] parameter.

The section is applicable only to digital interfaces.

#### ➤ To configure redirect reason manipulation:

1. Open the Manipulations Settings page (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Manipulations Settings**).

Set IP-to-Tel Redirect Reason	Not Configured ▼
Redirect Number IP to Tel	Not Configured ▼
Set Tel-to-IP Redirect Reason	Not Configured ▼

2. Configure the parameters as required, and then click **Apply**.

### Configuring Source-Destination Number Manipulation Rules

The number manipulation tables let you configure rules for manipulating source and destination telephone numbers for IP-to-Tel and Tel-to-IP calls. Number manipulation include the following tables:

#### ■ Tel-to-IP calls:

- Source Phone Number Manipulation for Tel-to-IP Calls (up to 120 entries)
- Destination Phone Number Manipulation for Tel-to-IP Calls (up to 120 entries)

**■ IP-to-Tel calls:**

- Source Phone Number Manipulation for IP-to-Tel Calls (up to 120 entries)
- Destination Phone Number Manipulation for IP-to-Tel Calls (up to 120 entries)

Configuration of number manipulation rules includes two areas:

- **Match:** Defines the matching characteristics of the incoming call (e.g., prefix of destination number).
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (e.g., removes a user-defined number of digits from the left of the number).

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it applies the manipulation configured for that rule. In other words, a rule at the top of the table takes precedence over a rule defined lower down in the table. Therefore, define more specific rules above more generic rules. For example, if you configure the source prefix number as "551" for rule index 1 and "55" for rule index 2, the device uses rule index 1 for numbers that start with 551 and uses rule index 2 for numbers that start with 550, 552, 553, and so on until 559. However, if you configure the source prefix number as "55" for rule index 1 and "551" for rule index 2, the device applies rule index 1 to all numbers that start with 55, including numbers that start with 551. If the device doesn't find a matching rule, no manipulation is done on the call.

You can perform a second "round" (additional) of source and destination number manipulations for IP-to-Tel calls on an already manipulated number. The initial and additional number manipulation rules are both configured in the number manipulation tables for IP-to-Tel calls. The additional manipulation is performed on the initially manipulated number. Thus, for complex number manipulation schemes, you only need to configure relatively few manipulation rules in these tables (that would otherwise require many rules). To enable this additional manipulation, use the following parameters:

- Source number manipulation - [PerformAdditionalIP2TELSrcManipulation]
- Destination number manipulation - [PerformAdditionalIP2TELDestinationManipulation]

Telephone number manipulation can be useful, for example, for the following:

- Stripping or adding dialing plan digits from or to the number, respectively. For example, a user may need to first dial 9 before dialing the phone number to indicate an external line. This number 9 can then be removed by number manipulation before the call is setup.
- Allowing or blocking Caller ID information according to destination or source prefixes. For more information on Caller ID for analog interfaces, see [Configuring Caller Display Information](#) on page 1097.
- For digital interfaces only: Assigning Numbering Plan Indicator (NPI) and Type of Numbering (TON) to IP-to-Tel calls. The device can use a single global setting for NPI/TON classification or it can use the setting in the manipulation tables on a call-by-call basis.

- Number manipulation can be performed before or after a routing decision is made. For example, you can route a call to a specific Trunk Group according to its original number, and then you can remove or add a prefix to that number before it is routed. To determine when number manipulation is performed, use the 'IP to Tel Routing Mode' parameter (RouteModeIP2Tel) and 'Tel-to-IP Routing Mode' parameter (RouteModeTel2IP).
- The device manipulates the number in the following order: 1) strips digits from the left of the number, 2) strips digits from the right of the number, 3) retains the defined number of digits, 4) adds the defined prefix, and then 5) adds the defined suffix.

The following procedure describes how to configure number manipulation rules through the Web interface. You can also configure this using the following management tools:

- **Destination Phone Number Manipulation for IP-to-Tel Calls table:** ini file [NumberMapIP2Tel] or CLI (configure voip > gateway manipulation dst-number-map-ip2tel)
- **Destination Phone Number Manipulation for Tel-to-IP Calls table:** ini file [NumberMapTel2IP] or CLI (configure voip > gateway manipulation dst-number-map-tel2ip)
- **Source Phone Number Manipulation for IP-to-Tel Calls table:** ini file [SourceNumberMapIP2Tel] or CLI (configure voip > gateway manipulation src-number-map-ip2tel)
- **Source Phone Number Manipulation for Tel-to-IP Calls table:** ini file [SourceNumberMapTel2IP] or CLI (configure voip > gateway manipulation src-number-map-tel2ip)

➤ **To configure a number manipulation rule:**

1. Open the required Phone Number Manipulation table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Dest Number IP->Tel**, **Dest Number Tel->IP**, **Source Number IP->Tel**, or **Source Number Tel->IP**).
2. Click **New**; the following dialog box appears:

GENERAL		ACTION	
Index	0	Stripped Digits From Left	0
Name		Stripped Digits From Right	0
		Number of Digits to Leave	255
<b>MATCH</b>		Prefix to Add	
Source Trunk Group	-1	Suffix to Add	
Source Phone Pattern	*	TON	
Destination Phone Pattern	*	NPI	
		Presentation	

3. Configure a number manipulation rule according to the parameters described in the table below.
4. Click **Apply**.

The table below shows configuration examples of Tel-to-IP source phone number manipulation rules configured in the Source Phone Number Manipulation for Tel-to-IP Calls table:

**Table 26-1: Configuration Examples of Source Phone Number Manipulation for Tel-to-IP Calls**

Parameter	Rule 1	Rule 2	Rule 3	Rule 4	Rule 5
Destination Phone Pattern	03		*	*	[6,7,8]
Source Phone Pattern	201	1001	123451001#	[30-40]x	2001
Stripped Digits From Left	-	4	-	-	5
Stripped Digits From Right	-	-	-	1	-
Prefix to Add	971	5	-	2	3
Suffix to Add	-	23	8	-	-
Number of Digits to Leave	-	-	4	-	-
Presentation	Allowed	Restricted	-	-	-

Below is a description of each rule:

- **Rule 1:** When the destination number has the prefix 03 (e.g., 035000), source number prefix 201 (e.g., 20155), and from source IP Group ID 2, the source number is changed to, for example, 97120155.
- **Rule 2:** When the source number has prefix 1001 (e.g., 1001876), it is changed to 587623.
- **Rule 3:** When the source number has prefix 123451001 (e.g., 1234510012001), it is changed to 20018.
- **Rule 4:** When the source number has prefix from 30 to 40 and a digit (e.g., 3122), it is changed to 2312.
- **Rule 5:** When the destination number has the prefix 6, 7, or 8 (e.g., 85262146), source number prefix 2001, it is changed to 3146.

**Table 26-2: Phone Number Manipulation Tables Parameter Descriptions**

Parameter	Description
General	

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' manipulation-name [ManipulationName]	Defines a descriptive name, which is used when associating the row in other tables.  The valid value is a string of up to 40 characters. By default, no value is defined. <b>Note:</b> Configure each row with a unique name.
Match	
'Source IP Address' src-ip-address [SourceAddress]	Defines the source IP address of the caller. This is obtained from the Contact header in the INVITE message.  The default is the asterisk (*) wildcard (i.e., any address). <b>Note:</b> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Destination Phone Number Manipulation for IP-to-Tel Calls table and Source Phone Number Manipulation for IP-to-Tel Calls table.</li> <li>■ The source IP address can include the 'x' wildcard to represent single digits. For example, 10.8.8.xx represents all IP addresses between 10.8.8.10 to 10.8.8.99.</li> <li>■ The source IP address can include the asterisk (*) wildcard to represent any number between 0 and 255. For example, 10.8.8.* represents all IP addresses between 10.8.8.0 and 10.8.8.255.</li> </ul>
'Destination IP Group' dst-ip-group-name [DestIPGroupID]	Defines the IP Group to where the call is sent.  The default is Any (i.e., any IP Group). <b>Note:</b> The parameter is applicable only to the Destination Phone Number Manipulation for Tel-to-IP Calls table.
'Source Trunk Group' src-trunk-group-id [SrcTrunkGroupID]	Defines the source Trunk Group ID for Tel-to-IP calls.  The default is -1 (i.e., any Trunk Group). <b>Note:</b> The parameter is applicable only to the number manipulation tables for Tel-to-IP calls.
'Source Phone Pattern' src-pattern [SourcePrefix]	Defines the source (calling) telephone number.  You can use special patterns (notations) to denote the number. For example, "[100-199](100,101,105)" denotes a

Parameter	Description
	<p>number that starts with 100 to 199 and ends with 100, 101 or 105. You can use the dollar (\$) sign to denote calls without a calling number. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default is the asterisk (*) symbol, meaning any source number.</p>
'Source Host Pattern' src-host-pattern [SrcHost]	<p>Defines the URI host part of the incoming SIP INVITE message in the From header.</p> <p>You can use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default is the asterisk (*) symbol, meaning any source host part.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Destination Phone Number Manipulation for IP-to-Tel Calls table and Source Phone Number Manipulation for IP-to-Tel Calls table.</li> <li>■ If the P-Asserted-Identity header is present in the incoming INVITE message, then the value of the parameter is compared to the P-Asserted-Identity URI host name (instead of the From header).</li> </ul>
'Destination Phone 'Pattern' dst-pattern [DestinationPrefix]	<p>Defines the destination (called) telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, "[100-199](100,101,105)" denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can also use the dollar (\$) sign to denote calls without a called number. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default is the asterisk (*) symbol, meaning any destination number.</p>
'Destination Host Pattern' dst-host-pattern [DestHost]	<p>Defines the Request-URI host part of the incoming SIP INVITE message.</p> <p>You can use special patterns (notations) to denote the host</p>

Parameter	Description
	<p>part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default is the asterisk (*) symbol, meaning any destination host part.</p> <p><b>Note:</b> The parameter is applicable only to the Destination Phone Number Manipulation for IP-to-Tel Calls table and Source Phone Number Manipulation for IP-to-Tel Calls table.</p>
'Source IP Group' src-ip-group-id [SrcIPGroupID]	<p>Defines the IP Group from where the IP call originated. The default is Any (i.e., any IP Group).</p> <p><b>Note:</b> The parameter is applicable only to the Destination Phone Number Manipulation for IP-to-Tel Calls table and Source Phone Number Manipulation for IP-to-Tel Calls table.</p>
Action	
'Stripped Digits From Left' remove-from-left [RemoveFromLeft]	<p>Defines the number of digits to remove from the left of the telephone number prefix. For example, if you enter 3 and the phone number is 5551234, the new phone number is 1234.</p>
'Stripped Digits From Right' remove-from-right [RemoveFromRight]	<p>Defines the number of digits to remove from the right of the telephone number prefix. For example, if you enter 3 and the phone number is 5551234, the new phone number is 5551.</p>
'Number of Digits to Leave' num-of-digits-to-leave [LeaveFromRight]	<p>Defines the number of digits that you want to keep from the right of the phone number. For example, if you enter 4 and the phone number is 00165751234, then the new number is 1234.</p>
'Prefix to Add' prefix-to-add [Prefix2Add]	<p>Defines the number or string that you want added to the front of the telephone number. For example, if you enter 9 and the phone number is 1234, the new number is 91234.</p>
'Suffix to Add' suffix-to-add [Suffix2Add]	<p>Defines the number or string that you want added to the end of the telephone number. For example, if you enter 00 and the phone number is 1234, the new number is 123400.</p>

Parameter	Description
'TON' ton [NumberType]	<p>Defines the Type of Number (TON).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Unknown</b> (default)</li> <li>■ [1] <b>International-Level2 Regional</b></li> <li>■ [2] <b>National-Level1 Regional</b></li> <li>■ [3] <b>Network-PSTN Specific</b></li> <li>■ [4] <b>Subscriber-Level0 Regional</b></li> <li>■ [6] <b>Abbreviated</b></li> </ul> <p>The applicable values depend on the NPI value:</p> <ul style="list-style-type: none"> <li>■ If you select <b>Unknown</b> for NPI, you can select <b>Unknown</b>.</li> <li>■ If you select <b>Private</b> for NPI, you can set TON to one of the following: <ul style="list-style-type: none"> <li>✓ <b>Unknown</b></li> <li>✓ <b>International-Level2 Regional</b></li> <li>✓ <b>National-Level1 Regional</b></li> <li>✓ <b>PISN Specific</b></li> <li>✓ <b>Subscriber-Level0 Regional</b></li> </ul> </li> <li>■ If you select <b>E.164 Public</b> for NPI, you can set TON to one of the following: <ul style="list-style-type: none"> <li>✓ <b>Unknown</b></li> <li>✓ <b>International-Level2 Regional</b></li> <li>✓ <b>National-Level1 Regional</b></li> <li>✓ <b>Network-PSTN Specific</b></li> <li>✓ <b>Subscriber-Level0 Regional</b></li> <li>✓ <b>Abbreviated</b></li> </ul> </li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ TON can be used in the SIP Remote-Party-ID header by using the EnableRPIHeader and AddTON2RPI parameters.</li> <li>■ For more information on available NPI/TON values, see <a href="#">Numbering Plans and Type of Number</a> on page 1023.</li> </ul>

Parameter	Description
'NPI' np i [NumberPlan]	<p>Defines the Numbering Plan Indicator (NPI).</p> <ul style="list-style-type: none"> <li>■ [-1] = Not configured and the value received from PSTN/IP is used.</li> <li>■ [0] <b>Unknown</b> (default)</li> <li>■ [1] <b>E.164 Public</b></li> <li>■ [9] <b>Private</b></li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to digital interfaces.</li> <li>■ NPI can be used in the SIP Remote-Party-ID header by using the EnableRPIHeader and AddTON2RPI parameters.</li> <li>■ For more information on available NPI/TON values, see <a href="#">Numbering Plans and Type of Number</a> on page 1023.</li> </ul>
'Presentation' is-presentation- restricted [IsPresentationRestricted]	<p>Enables caller ID.</p> <ul style="list-style-type: none"> <li>■ <b>Not Configured</b> = Privacy is determined according to the Caller ID table (see <a href="#">Configuring Caller Display Information</a> on page 1097). This option is applicable only to analog interfaces.</li> <li>■ [0] <b>Allowed</b> = Sends Caller ID information when a call is made using these destination/source prefixes.</li> <li>■ [1] <b>Restricted</b> = Restricts Caller ID information for these prefixes.</li> </ul> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Source Phone Number Manipulation for IP-to-Tel Calls table and Source Phone Number Manipulation for Tel-to-IP Calls table.</li> <li>■ If you configure the parameter to <b>Restricted</b> and the 'Asserted Identity Mode' (AssertedIdMode) parameter to <b>Add P-Asserted-Identity</b>, the From header in the INVITE message includes the following:</li> </ul> <p>From: 'anonymous' &lt;sip:            anonymous@anonymous.invalid&gt; and            'privacy: id' header</p>

## Manipulating Number Prefix

The device supports a notation for adding a prefix where part of the prefix is first extracted from a user-defined location in the original destination or source number. The notation is entered in the 'Prefix to Add' field in the Number Manipulation tables (see [Configuring Source-Destination Number Manipulation Rules](#) on page 983):  $x[n,l]y...$

where,

- $x$  = any number of characters/digits to add at the beginning of the number (i.e. first digits in the prefix).
- $[n,l]$  = defines the location in the original destination or source number where the digits  $y$  are added:
  - $n$  = location (number of digits counted from the left of the number) of a specific string in the original destination or source number.
  - $l$  = number of digits that this string includes.
- $y$  = prefix to add at the specified location.

For example, assume that you want to manipulate an incoming IP call with destination number "+5492028888888" (i.e., area code "202" and phone number "8888888") to the number "0202158888888". To perform such manipulation, the following configuration is required in the Number Manipulation table:

1. The following notation is used in the 'Prefix to Add' field:

0[5,3]15

where,

- 0 is the number to add at the beginning of the original destination number.
  - [5,3] denotes a string that is located after (and including) the fifth character (i.e., the first '2' in the example) of the original destination number, and its length being three digits (i.e., the area code 202, in the example).
  - 15 is the number to add immediately after the string denoted by [5,3] - in other words, 15 is added after (i.e. to the right of) the digits 202.
2. The first seven digits from the left are removed from the original number, by entering "7" in the 'Stripped Digits From Left' field.

**Table 26-3: Example of Configured Rule for Manipulating Prefix using Special Notation**

Parameter	Rule 1
Destination Phone Pattern	+5492028888888
Source Phone Pattern	*

Parameter	Rule 1
Source IP Address	*
Stripped Digits from Left	7
Prefix to Add	0[5,3]15

In this configuration example, the following manipulation process occurs:

1. The prefix is calculated as 020215.
2. The first seven digits from the left are removed from the original number, thereby changing the number to 8888888.
3. The prefix that was previously calculated is then added.

## SIP Calling Name Manipulations

The calling name manipulation tables let you configure up to 120 manipulation rules for manipulating the calling name (i.e., caller ID) in SIP messages for IP-to-Tel and Tel-to-IP calls. Manipulation includes modifying or removing the calling name. For example, assume that an incoming SIP INVITE message includes the following header:

```
P-Asserted-Identity: "company:john" sip:6666@78.97.79.104
```

Using the Calling Name Manipulation for IP-to-Tel Calls table, "company" can be changed to "worker" in the outgoing INVITE, as shown below:

```
P-Asserted-Identity: "worker:john" sip:996666@10.13.83.10
```

The calling name manipulation tables include the following:

- Calling Name Manipulation for IP-to-Tel Calls table
- Calling Name Manipulation for Tel-to-IP Calls table

Configuration of calling name manipulation rules includes two areas:

- **Match:** Defines the matching characteristics of an incoming call (e.g., prefix of destination number).
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (e.g., removes a user-defined number of digits from the left of the calling name).

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it applies the manipulation configured for that rule.

To use the Calling Name Manipulation for Tel-to-IP Calls table for retrieving the calling name (display name) from an Active Directory using LDAP queries, see [Querying Microsoft Entra ID for Calling Name](#) on page 413.

The following procedure describes how to configure calling name manipulation rules through the Web interface. You can also configure these rules using the following management tools:

- Calling Name Manipulation for Tel-to-IP Calls table: *ini* file [CallingNameMapTel2Ip] or CLI (configure voip > gateway manipulation calling-name-map-tel2ip)
- Calling Name Manipulation for IP-to-Tel Calls table: *ini* file [CallingNameMapIp2Tel] or CLI (configure voip > gateway manipulation calling-name-map-ip2tel)

➤ **To configure calling name manipulation rules:**

1. Open the required calling name manipulations table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Calling Name IP->Tel** or **Calling Name Tel->IP**).
2. Click **New**; the following dialog box appears:

3. Configure a manipulation rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 26-4: Calling Name Manipulation Tables Parameter Descriptions**

Parameter	Description
<b>General</b>	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Name' manipulation-name [ManipulationName]	Defines a descriptive name, which is used when associating the row in other tables. The valid value is a string of up to 40 characters.

Parameter	Description
	<p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ Configure each row with a unique name.</li> <li>■ The parameter value can't be configured with the character string "any" (upper or lower case).</li> </ul>
<b>Match</b>	
'Destination Phone Pattern' dst-pattern [DestinationPrefix]	<p>Defines the destination (called) telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, "[100-199] (100,101,105)" denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can use the dollar (\$) sign to denote calls without a called number. For available notations, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any destination number.</p>
'Source Phone Pattern' src-pattern [SourcePrefix]	<p>Defines the source (calling) telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, "[100-199] (100,101,105)" denotes a number that starts with 100 to 199 and ends with 100, 101 or 105. You can also use the dollar (\$) sign to denote calls without a calling number. For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p>

Parameter	Description
	The default value is the asterisk (*) symbol, meaning any source number.
'Calling Name Pattern' calling-name-pattern [CallingNamePrefix]	<p>Defines the calling name (i.e., caller ID).</p> <p>The valid value is a string of up to 50 alphanumeric characters (e.g., "JohnD20") or any of the following special patterns (notations):</p> <ul style="list-style-type: none"> <li>■ Dollar (\$) sign - denotes calls without a calling name.</li> <li>■ Asterisk (*) sign - denotes any calling name.</li> </ul> <p>The default value is * .</p>
'Source Trunk Group ID' src-trunk-group-id [SrcTrunkGroupID]	<p>Defines the source Trunk Group ID from where the Tel-to-IP call was received.</p> <p>The default value is -1, which denotes any Trunk Group.</p> <p><b>Note:</b> The parameter is applicable only to the Calling Name Manipulation for Tel-to-IP Calls table.</p>
'Source IP Address' src-ip-address [SourceAddress]	<p>Defines the source IP address of the caller for IP-to-Tel calls. The source IP address appears in the SIP Contact header in the INVITE message.</p> <p>The default value is the asterisk (*) symbol (i.e., any IP address). The source IP address can include the following wildcards:</p> <ul style="list-style-type: none"> <li>■ "x" wildcard: represents single digits. For example, 10.8.8.xx represents all IP addresses between 10.8.8.10 to 10.8.8.99.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ "*" (asterisk) wildcard: represents any number between 0 and 255. For example, 10.8.8.* represents all IP addresses between 10.8.8.0 and 10.8.8.255.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Calling Name Manipulation for IP-to-Tel Calls table.</p>
'Source Host Pattern' src-host-pattern [SrcHost]	<p>Defines the URI host part of the incoming SIP INVITE message in the From header.</p> <p>The valid value is a string of up to 49 alphanumeric characters. You can also use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any source host part.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Calling Name Manipulation for IP-to-Tel Calls table.</li> <li>■ If the P-Asserted-Identity header is present in the incoming INVITE message, the value of the parameter is compared to the P-Asserted-Identity URI host name (instead of the From header).</li> </ul>

Parameter	Description
'Destination Host Pattern' dst-host-pattern [DestHost]	<p>Defines the Request-URI host part of the incoming SIP INVITE message.</p> <p>The valid value is a string of up to 49 alphanumeric characters. You can also use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any destination host part.</p> <p><b>Note:</b> The parameter is applicable only to the Calling Name Manipulation for IP-to-Tel Calls table.</p>
Action	
'Stripped Characters From Left' remove-from-left [RemoveFromLeft]	<p>Defines the number of characters to remove from the left of the calling name.</p> <p>For example, if you enter 3 and the calling name is "company:john", the new calling name is "pany:john".</p>
'Stripped Characters From Right' remove-from-right [RemoveFromRight]	<p>Defines the number of characters to remove from the right of the calling name.</p> <p>For example, if you enter 3 and the calling name is "company:name", the new name is "company:n".</p>
'Number of Characters to Leave'	<p>Defines the number of characters that you want to keep from the</p>

Parameter	Description
num-of-digits-to-leave [LeaveFromRight]	right of the calling name. For example, if you enter 4 and the calling name is "company:name", the new name is "name".
'Prefix to Add' prefix-to-add [Prefix2Add]	Defines the number or string to add at the front of the calling name. For example, if you enter ITSP and the calling name is "company:name", the new name is ITSPcompany:john".
'Suffix to Add' suffix-to-add [Suffix2Add]	Defines the number or string to add at the end of the calling name. For example, if you enter 00 and calling name is "company:name", the new name is "company:name00".

## Configuring Redirect Number Manipulation

Each redirect number manipulation table lets you configure up to 20 rules for manipulating the redirect number received in SIP messages. The redirect number manipulation tables include:

- **Redirect Number IP-to-Tel table:** (Applicable only to ISDN) Defines IP-to-Tel redirect number manipulation. You can manipulate the value of the received SIP Diversion, Resource-Priority, or History-Info headers, which is then added to the Redirecting Number Information Element (IE) in the ISDN Setup message sent to the Tel side. This also includes the reason for the call redirection.
- **Redirect Number Tel-to-IP table:** Defines Tel-to-IP redirect number manipulation. You can manipulate the prefix of the redirect number received from the Tel side, in the outgoing SIP Diversion, Resource-Priority, or History-Info headers sent to the IP side.

Configuration of redirect number manipulation rules includes two areas:

- **Match:** Defines the matching characteristics of an incoming call (e.g., prefix of redirect number).
- **Action:** Defines the action that is done if the incoming call matches the characteristics of the rule (e.g., removes a user-defined number of digits from the left of the redirect number).

The device searches the table from **top to bottom** for the **first** rule that matches the characteristics of the incoming call. If it finds a matching rule, it applies the manipulation configured for that rule.

- If the device copies the received destination number to the outgoing SIP redirect number (enabled by the CopyDest2RedirectNumber parameter), no redirect number Tel-to-IP manipulation is done.
- The manipulation rules are done in the following order: 'Stripped Digits From Left', 'Stripped Digits From Right', 'Number of Digits to Leave', 'Prefix to Add', and then 'Suffix to Add'.
- The device uses the 'Redirect Prefix' parameter before it manipulates the prefix.

The following procedure describes how to configure redirect number manipulation rules through the Web interface. You can also configure these rules using the following management tools:

- Redirect Number IP-to-Tel table: ini file [RedirectNumberMapIp2Tel] or CLI (`configure voip > gateway manipulation redirect-number-map-ip2tel`)
- Redirect Number Tel-to-IP table: ini file [RedirectNumberMapTel2Ip] or CLI (`configure voip > gateway manipulation redirect-number-map-tel2ip`)

➤ **To configure a redirect number manipulation rule:**

1. Open the required redirect number manipulation table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Redirect Number Tel** > **IP** or **Redirect Number IP** > **Tel**).
2. Click **New**; the following dialog box appears (e.g., Redirect Number Tel-to-IP table):

3. Configure a manipulation rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 26-5: Redirect Number Manipulation Tables Parameter Description**

Parameter	Description
General	
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
'Name' manipulation-name [ManipulationName]	<p>Defines a descriptive name, which is used when associating the row in other tables.</p> <p>The valid value is a string of up to 40 characters.</p> <p><b>Note:</b> The parameter value can't be configured with the character string "any" (upper or lower case).</p>
<b>Match</b>	
'Destination Phone Pattern' dst-pattern [DestinationPrefix]	<p>Defines the destination (called) telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, if you want to match this rule to a number whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any destination number.</p> <p>Digital interfaces: For manipulating the diverting and redirected numbers for call diversion, you can use the strings "DN" and "RN" to denote the destination prefix of these numbers. For more information, see <a href="#">Manipulating Redirected and Diverted Numbers for Call Diversion</a> on page 1005.</p>
'Redirect Phone Pattern' redirect-pattern [RedirectPrefix]	<p>Defines the redirect telephone number.</p> <p>You can use special patterns (notations) to denote the number. For example, if you want to match this rule to a number whose last four digits (i.e., suffix) are 4 followed by any three digits (e.g., 4008), then configure this parameter to "(4xxx)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any redirect number.</p>
'Source Trunk Group ID' src-trunk-group-id [SrcTrunkGroupID]	<p>Defines the Trunk Group from where the Tel call is received.</p> <p>To denote any Trunk Group, leave this field empty. The value -1 indicates that this field is ignored in the rule.</p> <p><b>Note:</b> The parameter is applicable only to the Redirect Number Tel-to-IP table.</p>
'Source IP Address'	<p>Defines the IP address of the caller. The IP address appears in the SIP Contact header of the incoming INVITE message.</p>

Parameter	Description
src-ip-address [SourceAddress]	<p>The default value is the asterisk (*) symbol (i.e., any IP address). The value can include the following wildcards:</p> <ul style="list-style-type: none"> <li>■ "x": represents single digits, for example, 10.8.8.xx denotes all addresses between 10.8.8.10 and 10.8.8.99.</li> <li>■ "*": represents any number between 0 and 255, for example, 10.8.8.* denotes all addresses between 10.8.8.0 and 10.8.8.255.</li> </ul> <p><b>Note:</b> The parameter is applicable only to the Redirect Number IP-to-Tel table.</p>
'Source Host Pattern' src-host-pattern [SrcHost]	<p>Defines the URI host part of the caller. The host name appears in the SIP From header of the incoming SIP INVITE message.</p> <p>You can use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any source host part.</p> <p><b>Note:</b></p> <ul style="list-style-type: none"> <li>■ The parameter is applicable only to the Redirect Number IP-to-Tel table.</li> <li>■ If the P-Asserted-Identity header is present in the incoming INVITE message, the value of the parameter is compared to the P-Asserted-Identity URI host name (instead of to the From header).</li> </ul>
'Destination Host Pattern' dst-host-pattern [DestHost]	<p>Defines the Request-URI host part, which appears in the incoming SIP INVITE message.</p> <p>You can use special patterns (notations) to denote the host part. For example, if you want to match this rule to host parts that end (suffix) in ".com", then configure this parameter to "(.com)". For available patterns, see <a href="#">Patterns for Denoting Phone Numbers and SIP URIs</a> on page 1697.</p> <p>The default value is the asterisk (*) symbol, meaning any destination host part.</p> <p><b>Note:</b> The parameter is applicable only to the Redirect Number IP-to-Tel table.</p>

Parameter	Description
<b>Action</b>	
'Stripped Digits From Left' remove-from-left [RemoveFromLeft]	Defines the number of digits to remove from the left of the redirect number prefix.  For example, if you enter 3 and the redirect number is 5551234, the new number is 1234.
'Stripped Digits From Right' remove-from-right [RemoveFromRight]	Defines the number of digits to remove from the right of the redirect number prefix.  For example, if you enter 3 and the redirect number is 5551234, the new number is 5551.
'Number of Digits to Leave' num-of-digits-to-leave [LeaveFromRight]	Defines the number of digits that you want to retain from the right of the redirect number.
'Prefix to Add' prefix-to-add [Prefix2Add]	Defines the number or string that you want added to the front of the redirect number.  For example, if you enter 9 and the redirect number is 1234, the new number is 91234.
'Suffix to Add' suffix-to-add [Suffix2Add]	Defines the number or string that you want added to the end of the redirect number.  For example, if you enter 00 and the redirect number is 1234, the new number is 123400.
'TON' ton [NumberType]	<p>Defines the Type of Number (TON).</p> <ul style="list-style-type: none"> <li>■ [-1] = (Default) Not configured</li> <li>■ [0] <b>Unknown</b> (default)</li> <li>■ [1] <b>International-Level2 Regional</b></li> <li>■ [2] <b>National-Level1 Regional</b></li> <li>■ [3] <b>Network-PSTN Specific</b></li> <li>■ [4] <b>Subscriber-Level0 Regional</b></li> <li>■ [6] <b>Abbreviated</b></li> </ul> <p>The applicable values depend on the NPI value:</p> <ul style="list-style-type: none"> <li>■ If NPI is set to <b>Unknown</b>, you can set TON to Unknown.</li> <li>■ If NPI is set to Private, you can set TON to one of the following:</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>✓ <b>Unknown</b></li> <li>✓ <b>International-Level2 Regional</b></li> <li>✓ <b>National-Level1 Regional</b></li> <li>✓ <b>Network-PSTN Specific</b></li> <li>✓ <b>Subscriber-Level0 Regional</b></li> </ul> <p>■ If NPI is set to <b>E.164 Public</b>, you can set TON to one of the following:</p> <ul style="list-style-type: none"> <li>✓ <b>Unknown</b></li> <li>✓ <b>International-Level2 Regional</b></li> <li>✓ <b>National-Level1 Regional</b></li> <li>✓ <b>Network-PSTN Specific</b></li> <li>✓ <b>Subscriber-Level0 Regional</b></li> <li>✓ <b>Abbreviated</b></li> </ul> <p>For more information on available NPI/TON values, see <a href="#">Numbering Plans and Type of Number</a> on page 1023.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
'NPI' npi [NumberPlan]	<p>Defines the Numbering Plan Indicator (NPI).</p> <ul style="list-style-type: none"> <li>■ [-1] <b>Not Configured</b> = (Default) Value received from PSTN/IP is used</li> <li>■ [0] <b>Unknown</b></li> <li>■ [1] <b>E.164 Public</b></li> <li>■ [9] <b>Private</b></li> </ul> <p>For more information on available NPI/TON values, see <a href="#">Numbering Plans and Type of Number</a> on page 1023.</p> <p><b>Note:</b> The parameter is applicable only to digital interfaces.</p>
'Presentation' is-presentation-restricted [IsPresentationRestricted]	<p>Enables caller ID.</p> <ul style="list-style-type: none"> <li>■ <b>Not Configured</b> = Privacy is determined according to the Caller ID table (see <a href="#">Configuring Caller Display Information</a> on page 1097). This option is applicable only to analog interfaces.</li> <li>■ [0] <b>Allowed</b> = Sends Caller ID information when a call is made using these destination / source prefixes.</li> </ul>

Parameter	Description
	<ul style="list-style-type: none"> <li>■ [1] <b>Restricted</b> = Restricts Caller ID information for these prefixes.</li> </ul> <p><b>Note:</b> If you configure the parameter to <b>Restricted</b> and the 'AssertedIdMode' parameter to <b>Add P-Asserted-Identity</b>, the From header in the INVITE message includes the following:</p> <pre>From: 'anonymous' &lt;sip:anonymous@anonymous.invalid&gt; and 'privacy: id' header.</pre>

## Manipulating Redirected and Diverted Numbers for Call Diversion

You can configure manipulation rules to manipulate the Diverted-to and Diverting numbers received in the incoming Call Redirection Facility message for call diversion, which is interworked to outgoing SIP 302 responses.

This feature is applicable only to the Gateway application - Euro ISDN and QSIG variants in the IP-to-Tel call direction.

The incoming redirection Facility message includes, among other parameters, the Diverted-to number and Diverting number. The Diverted-to number (i.e., new destination) is mapped to the user part in the Contact header of the SIP 302 response. The Diverting number is mapped to the user part in the Diversion header of the SIP 302 response. These two numbers can be manipulated by entering the following special strings in the 'Destination Phone Pattern' field of the Redirect Number Tel-to-IP table:

- "RN" - used in the rule to manipulate the Redirected number (i.e., originally called number or Diverting number).
- "DN" - used in the rule to manipulate the Diverted-to number (i.e., the new called number or destination). This manipulation is done on the user part in the Contact header of the SIP 302 response.

For example, assume the following required manipulation:

- Manipulate Redirected number 6001 (originally called number) to 6005
- Manipulate Diverted-to number 8002 (the new called number or destination) to 8005

The configuration in the Redirect Number Tel-to-IP table is as follows:

**Table 26-6: Redirect Number Configuration Example**

Parameter	Rule 1	Rule 2
Destination Phone Pattern	RN	DN
Redirect Phone Pattern	6	8
Stripped Digits From Right	1	1
Suffix to Add	5	5
Number of Digits to Leave	5	-

After the above manipulation is done, the device sends the following outgoing SIP 302 response:

```
SIP/2.0 302 Moved Temporarily
Via: SIP/2.0/TLS 10.33.45.68;branch=z9hG4bKac54132643;alias
From: "MP118 1" <sip:8001@10.33.45.68>;tag=1c54119560
To: <sip:6001@10.33.45.69;user=phone>;tag=1c664560944
Call-ID: 541189832710201115142@10.33.45.68
CSeq: 1 INVITE
Contact: <sip:8005@10.33.45.68;user=phone>
Supported: em,timer,replaces,path,early-session,resource-priority
Allow:
REGISTER,OPTIONS,INVITE,ACK,CANCEL,BYE,NOTIFY,PRACK,REFER,INFO,SUBSCRIBE,UPDATE
Diversions: <tel:6005>;reason=unknown;counter=1
Server: Sip-Gateway/7.60A.100.022
Reason: SIP ;cause=302 ;text="302 Moved Temporarily"
Content-Length: 0
```

## Mapping NPI/TON to SIP Phone-Context

The Phone Contexts table lets you configure up to 20 rules for mapping the Numbering Plan Indication (NPI) and Type of Number (TON) to the SIP 'phone-context' parameter, and vice versa. The 'phone-context' parameter appears in the standard SIP headers where a phone number is used (i.e., Request-URI, To, From, and Diversion). When a call is received from the Tel side, the device searches the table for a matching rule (i.e., same NPI and TON values). If a matching rule is found, the device uses the rule's corresponding 'phone-context' value in the outgoing SIP INVITE message. The same mapping occurs when an INVITE with a 'phone-context' parameter is received.

For example, for a Tel-to-IP call with NPI/TON set as E164 National (values 1/2), the device can send the following SIP INVITE URI:

```
sip:12365432;phone-context=na.e.164.nt.com
```

For an IP-to-Tel call, if the incoming INVITE contains this 'phone-context' (e.g. "phone-context=na.e.164.nt.com"), the NPI/TON of the called number in the outgoing Setup message is changed to E164 National.

The following procedure describes how to configure NPI/TON-SIP phone-context mapping rules through the Web interface. You can also configure it through ini file [PhoneContext] or CLI (configure voip > gateway manipulation phone-context-table).

➤ **To configure NPI/TON-SIP phone-context mapping rules:**

1. Open the Phone Contexts table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Phone Contexts**).
2. Click **New**; the following dialog box appears:

3. Configure a mapping rule according to the parameters described in the table below.
4. Click **Apply**.

- You can configure multiple rows with the same NPI/TON or same SIP 'phone-context'. In such a configuration, a Tel-to-IP call uses the first matching rule in the table.
- To add the incoming SIP 'phone-context' parameter as a prefix to the outgoing ISDN Setup message (for digital interfaces) with called and calling numbers, select the 'Add Phone Context As Prefix' check box ☒ [AddPhoneContextAsPrefix].

**Table 26-7: Phone Contexts table Parameter Description**

Parameter	Description
'Index'	Defines an index number for the new table row.
[Index]	<b>Note:</b> Each row must be configured with a unique index.

Parameter	Description
'NPI' npi [Npi]	<p>Defines the Number Plan Indicator (NPI).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Unknown</b> (default)</li> <li>■ [1] <b>E.164 Public</b></li> <li>■ [9] <b>Private</b></li> </ul> <p>For a detailed list of the available NPI/TON values, see <a href="#">Numbering Plans and Type of Number</a> on page 1023.</p>
'TON' ton [Ton]	<p>Defines the Type of Number (TON).</p> <ul style="list-style-type: none"> <li>■ [0] <b>Unknown</b></li> <li>■ [1] <b>International-Level2 Regional</b></li> <li>■ [2] <b>National-Level1 Regional</b></li> <li>■ [3] <b>Network-PSTN Specific</b></li> <li>■ [4] <b>Subscriber-Level0 Regional</b></li> <li>■ [6] <b>Abbreviated</b></li> </ul> <p>The applicable values depend on the NPI value:</p> <ul style="list-style-type: none"> <li>■ If you select <b>Unknown</b> as NPI, you can select <b>Unknown</b>.</li> <li>■ If you select <b>Private</b> as NPI, you can select one of the following: <ul style="list-style-type: none"> <li>✓ [0] <b>Unknown</b></li> <li>✓ [1] <b>International-Level2 Regional</b></li> <li>✓ [2] <b>National-Level1 Regional</b></li> <li>✓ [3] <b>Network-PSTN Specific</b></li> <li>✓ [4] <b>Subscriber-Level0 Regional</b></li> </ul> </li> <li>■ If you select <b>E.164 Public</b> as NPI, you can select one of the following: <ul style="list-style-type: none"> <li>✓ [0] <b>Unknown</b></li> <li>✓ [1] <b>International-Level2 Regional</b></li> <li>✓ [2] <b>National-Level1 Regional</b></li> <li>✓ [3] <b>Network-PSTN Specific</b></li> <li>✓ [4] <b>Subscriber-Level0 Regional</b></li> <li>✓ [6] <b>Abbreviated</b></li> </ul> </li> </ul>
'SIP Phone-Context'	Defines the SIP 'phone-context' URI parameter.

Parameter	Description
context [Context]	

## Configuring Release Cause Mapping

When a call is disconnected, the reason for the disconnection (or call failure) is sent by the side (IP or Tel) on which the call disconnection occurred. From the IP side, a SIP response is sent (e.g., 406); from the Tel side, an ISDN cause code is sent (e.g., 6). You can configure ISDN-SIP release cause mapping rules, as discussed in this section.

The feature is applicable only to digital interfaces.

## SIP-to-ISDN Release Cause Mapping

This section shows SIP-to-ISDN release cause mapping.

### Configuring SIP-to-ISDN Release Cause Mapping

The Release Cause Mapping from SIP to ISDN table lets you configure up to 12 SIP response code to ISDN ITU-T Q.850 release cause code (call failure) mapping rules. The table lets you override the default SIP-to-ISDN release cause mappings, listed in [Fixed Mapping of SIP Response to ISDN Release Reason](#) on the next page. When the device receives a SIP response from the IP side, it searches the table for a matching SIP response. If found, the device sends the corresponding Q.850 Release Cause to the PSTN. If the SIP response is not configured in the table, the default, fixed SIP-to-ISDN release reason mapping is used.

For Tel-to-IP calls, you can also map less commonly used SIP responses to a single, default ISDN release cause code, using the [DefaultCauseMapISDN2IP] parameter. The parameter defines a default ISDN cause code that is always used, except when the following Release Causes are received: Normal Call Clearing (16), User Busy (17), No User Responding (18) or No Answer from User (19).

The following procedure describes how to configure SIP-to-ISDN release cause mapping through the Web interface. You can also configure it through ini file [CauseMapSIP2ISDN] or CLI (configure voip > gateway manipulation cause-map-sip2isdn).

#### ➤ To configure a SIP-to-ISDN release cause mapping rule:

1. Open the Release Cause Mapping from SIP to ISDN table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Release Cause SIP > ISDN**).
2. Click **New**; the following dialog box appears:

*Release Cause Mapping from SIP to ISDN*

**GENERAL**

Index: 0

SIP Response: -1

Q.850 Causes: -1

3. Configure a mapping rule according to the parameters described in the table below.

4. Click **Apply**.

**Table 26-8: Release Cause Mapping from SIP to ISDN Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'SIP Response' sip-response [SipResponse]	Defines the SIP response code. For example, you can enter "406" (without quotation marks) to represent the SIP 406 Not Acceptable response.
'Q.850 Causes' q850-causes [IsdnReleaseCause]	Defines the ISDN Q.850 cause code. For example, you can enter "6" (without quotation marks) to represent Cause Code 6 Channel Unacceptable.

### Fixed Mapping of SIP Response to ISDN Release Reason

The following table shows the mapping of SIP response to ISDN release reason.

**Table 26-9: Mapping of SIP Response to ISDN Release Reason**

SIP Response	Description	ISDN Release Reason	Description
400*	Bad request	31	Normal, unspecified
401	Unauthorized	21	Call rejected
402	Payment required	21	Call rejected
403	Forbidden	21	Call rejected
404	Not found	1	Unallocated number

SIP Response	Description	ISDN Release Reason	Description
405	Method not allowed	63	Service/option unavailable
406	Not acceptable	79	Service/option not implemented
407	Proxy authentication required	21	Call rejected
408	Request timeout	102	Recovery on timer expiry
409	Conflict	41	Temporary failure
410	Gone	22	Number changed w/o diagnostic
411	Length required	127	Interworking
413	Request entity too long	127	Interworking
414	Request URI too long	127	Interworking
415	Unsupported media type	79	Service/option not implemented
417	Unknown Resource Priority	127	Interworking
420	Bad extension	127	Interworking
480	Temporarily unavailable	18	No user responding
481*	Call leg/transaction doesn't exist	127	Interworking
482*	Loop detected	127	Interworking
483	Too many hops	127	Interworking
484	Address incomplete	28	Invalid number format
485	Ambiguous	1	Unallocated number
486	Busy here	17	User busy

SIP Response	Description	ISDN Release Reason	Description
488	Not acceptable here	31	Normal, unspecified
489	Bad Event	31	Normal, unspecified
491	Request Pending	31	Normal, unspecified
500	Server internal error	41	Temporary failure
501	Not implemented	38	Network out of order
502	Bad gateway	38	Network out of order
503	Service unavailable	41	Temporary failure
504	Server timeout	102	Recovery on timer expiry
505*	Version not supported	127	Interworking
600	Busy everywhere	17	User busy
603	Decline	21	Call rejected
604	Does not exist anywhere	1	Unallocated number
606*	Not acceptable	38	Network out of order

\* Messages and responses were created because the 'ISUP to SIP Mapping' draft doesn't specify their cause code mapping.

### SIP-to-ISDN Disconnect Release Cause Code Mapping

For trunks configured for the Japanese NTT ISDN PRI (T1) variant, you can configure the device to send an ISDN Disconnect message if it receives from the IP network a SIP 183 response with SDP that contains a specific cause value (SIP status code) in the Reason header, in response to an INVITE message. The device translates this cause code in the Release Cause field of the outgoing Disconnect message. After the device sends the Disconnect message, it can send early media (e.g., an announcement) received from the IP side to the ISDN. If after sending the Disconnect message the device receives a SIP failure response (e.g., 4xx) or a 200 OK from the IP side, it sends a Release message to the ISDN. However, you can configure the device to send the Release after a user-defined timeout, activated from when the Disconnect is sent, if no SIP message is received. The timeout is configured using the [ISDNJapanNttTimerT305] parameter. If the device receives a SIP failure response or 200 OK before the timeout expires, it sends the Release instead of waiting for the timeout to expire.

The above described behavior is configured using SIP Message Manipulation rules.

- This feature is applicable only to digital interfaces (T1 NTT protocol variant), and applies only to Tel-to-IP calls.
- For normal Disconnect scenarios (not due to SIP 183 with specific cause), you must configure the timer to 30 seconds, using the [TimeToWaitForPstnReleaseAck] parameter.

➤ **To configure the ISDN Disconnect feature:**

1. Open the Message Manipulations table (see [Configuring SIP Message Manipulation](#) on page 856), and then configure the following SIP Message Manipulation rules:
  - Index #0:
    - ◆ 'Name': Clean var with cause
    - ◆ 'Manipulation Set ID': 0
    - ◆ 'Message Type': Invite.Request
    - ◆ 'Action Subject': Var.Call.Dst.0
    - ◆ 'Action Type': Modify
    - ◆ 'Action Value': '0'
  - Index #1 (specifies the cause value in the SIP Reason header of the 18x response):
    - ◆ 'Name': Disconnect on 183 with cause
    - ◆ 'Manipulation Set ID': 1
    - ◆ 'Message Type': invite.response.18x
    - ◆ 'Condition': header.Reason.Reason.Cause == '1' or header.Reason.Reason.Cause == '22' or header.Reason.Reason.Cause == '31'
    - ◆ 'Action Subject': Var.Call.dst.0
    - ◆ 'Action Type': Modify
    - ◆ 'Action Value': header.Reason.Reason.Cause
  - Index #2 (adds X-AC-Action header):
    - ◆ 'Name': Add X\_Action header
    - ◆ 'Manipulation Set ID': 1
    - ◆ 'Action Subject': Header.X-AC-Action
    - ◆ 'Action Type': Add
    - ◆ 'Action Value': 'SendPSTNDisconnect;Q850Cause='+var.Call.Dst.0
  - Index #3 (if SIP 410 response, translate to 102 cause in ISDN message):
    - ◆ 'Name': Add reason if not exist

- ◆ 'Manipulation Set ID': 1
- ◆ 'Message Type': invite.response.410
- ◆ 'Condition': Var.Call.Dst.0 != '0' and header.Reason !exists
- ◆ 'Action Subject': header.Reason
- ◆ 'Action Type': Add
- ◆ 'Action Value': 'Q.850 ;cause=102 ; text="recovery of timer expiry"'
- Index #4:
  - ◆ 'Name': Translate 3xx to 500
  - ◆ 'Manipulation Set ID': 1
  - ◆ 'Message Type': invite.response.3xx
  - ◆ 'Condition': Var.Call.Dst.0 != '0'
  - ◆ 'Action Subject': Header.Request-URI.MethodType
  - ◆ 'Action Type': Modify
  - ◆ 'Action Value': '500'
- Index #5:
  - ◆ 'Name': Add reason if not exist
  - ◆ 'Manipulation Set ID': 1
  - ◆ 'Condition': header.Reason !exists
  - ◆ 'Action Subject': Header.Reason
  - ◆ 'Action Type': Add
  - ◆ 'Action Value': 'Q.850 ;cause=31 ; text="normal, unspecified"'

The cause codes in the above Message Manipulation rules are used only as examples; you can define different cause codes according to your requirements.

2. Assign Manipulation Set #1 to inbound calls, by configuring the [GWInboundManipulationSet] parameter to [1].
3. Assign Manipulation Set #0 to outbound calls, by configuring the [GWOutboundManipulationSet] parameter to [0].
4. (Optional) Configure how long the device must wait before sending an ISDN Release message if no SIP message is received, using the [ISDNJapanNttTimerT305] parameter. An explanation on this feature is described at the beginning of the section.

For Step 4, make sure that the [IPAlertTimeout] parameter value is greater than the [ISDNJapanNttTimerT305] parameter. If not, the device will use the timeout configured by the [IPAlertTimeout] parameter.

## ISDN-to-SIP Release Cause Mapping

This section shows ISDN-to-SIP release cause mapping.

### Configuring ISDN-to-SIP Release Cause Mapping

The Release Cause Mapping from ISDN to SIP table lets you configure up to 12 ISDN ITU-T Q.850 release cause code (call failure) to SIP response code mapping rules. The table lets you override the default ISDN-to-SIP release cause mappings, listed in [Fixed Mapping of ISDN Release Reason to SIP Response](#) on the next page. When the device receives an ISDN cause code from the PSTN side, it searches the table for a matching ISDN cause code. If found, the device sends the corresponding SIP response to the IP. If the ISDN cause code is not configured in the table, the default, fixed ISDN-to-SIP release reason mapping is used.

You can change the originally received ISDN cause code to any other ISDN cause code, using the Release Cause ISDN to ISDN table (see [Configuring ISDN-to-ISDN Release Cause Mapping](#) on page 1021). If the originally received ISDN cause code appears in both the Release Cause ISDN to ISDN table and the Release Cause Mapping ISDN to SIP table, the mapping rule in the Release Cause Mapping ISDN to SIP table is ignored. The device only uses a mapping rule that matches the new ISDN cause code.

The following procedure describes how to configure ISDN-to-SIP release cause mapping through the Web interface. You can also configure it through ini file [CauseMapISDN2SIP] or CLI (configure voip > gateway manipulation cause-map-isdn2sip).

#### ➤ To configure a ISDN-to-SIP release cause mapping rule:

1. Open the Release Cause Mapping from ISDN to SIP table (**Setup** menu > **Signaling & Media** tab > **Gateway** folder > **Manipulation** > **Release Cause ISDN > SIP**).
2. Click **New**; the following dialog box appears:

Release Cause Mapping from ISDN to SIP

GENERAL

Index	<input type="text" value="0"/>
Q.850 Causes	<input type="text" value="-1"/>
SIP Response	<input type="text" value="-1"/>

3. Configure a mapping rule according to the parameters described in the table below.
4. Click **Apply**.

**Table 26-10:Release Cause Mapping from ISDN to SIP Table Parameter Descriptions**

Parameter	Description
'Index' [Index]	Defines an index number for the new table row. <b>Note:</b> Each row must be configured with a unique index.
'Q.850 Causes' q850-causes [IsdnReleaseCause]	Defines the ISDN Q.850 cause code. For example, you can enter "6" (without quotation marks) to represent Cause Code 6 Channel Unacceptable.
'SIP Response' sip-response [SipResponse]	Defines the SIP response code. For example, you can enter "406" (without quotation marks) to represent the SIP 406 Not Acceptable response.

### Fixed Mapping of ISDN Release Reason to SIP Response

The following table shows the mapping of ISDN release reason to SIP response.

**Table 26-11:Mapping of ISDN Release Reason to SIP Response**

ISDN Release Reason	Description	SIP Response	Description
1	Unallocated number	404	Not found
2	No route to network	404	Not found
3	No route to destination	404	Not found
4	Send Special Information Tone	400	Bad Request
5	Misdialed Trunk Prefix	400	Bad Request
6	Channel unacceptable	406*	Not acceptable
7	Call awarded and being delivered in an established channel	500	Server internal error
8	Preemption	480	Temporarily unavailable
9	Preemption - Circuit Reserved for Reuse	488	Not Acceptable

ISDN Release Reason	Description	SIP Response	Description
			Here
16	Normal call clearing	-*	BYE
17	User busy	486	Busy here
18	No user responding	408	Request timeout
19	No answer from the user	480	Temporarily unavailable
21	Call rejected	403	Forbidden
22	Number changed w/o diagnostic	410	Gone
23	Redirection	400	Bad Request
25	Exchange Routing Error	400	Bad Request
26	Non-selected user clearing	404	Not found
27	Destination out of order	502	Bad gateway
28	Address incomplete	484	Address incomplete
29	Facility rejected	501	Not implemented
30	Response to status enquiry	501*	Not implemented
31	Normal unspecified	480	Temporarily unavailable
32	Circuit Congestion	500	Server internal error
33	User Congestion	500	Server internal error
34	No circuit available	503	Service unavailable

ISDN Release Reason	Description	SIP Response	Description
38	Network out of order	503	Service unavailable
39	Permanent Frame Mode Connection Out-of-Service	503	Service unavailable
40	Permanent Frame Mode Connection Operational	503	Service unavailable
41	Temporary failure	503	Service unavailable
42	Switching equipment congestion	503	Service unavailable
43	Access information discarded	502*	Bad gateway
44	Requested channel not available	503*	Service unavailable
46	Precedence Call Blocked	488	Not Acceptable Here
47	Resource unavailable	503	Service unavailable
49	QoS unavailable	503*	Service unavailable
50	Facility not subscribed	503*	Service unavailable
53	Outgoing Calls Barred within CUG	488	Not Acceptable Here
55	Incoming calls barred within CUG	403	Forbidden
57	Bearer capability not authorized	403	Forbidden
58	Bearer capability not presently available	503	Service unavailable
62	Inconsistency In Outgoing Information Element	503	Service unavailable

ISDN Release Reason	Description	SIP Response	Description
63	Service/option not available	503*	Service unavailable
65	Bearer capability not implemented	501	Not implemented
66	Channel type not implemented	480*	Temporarily unavailable
69	Requested facility not implemented	503*	Service unavailable
70	Only restricted digital information bearer capability is available	503*	Service unavailable
79	Service or option not implemented	501	Not implemented
81	Invalid call reference value	502*	Bad gateway
82	Identified channel doesn't exist	502*	Bad gateway
83	Suspended call exists, but this call identity doesn't	503*	Service unavailable
84	Call identity in use	503*	Service unavailable
85	No call suspended	503*	Service unavailable
86	Call having the requested call identity has been cleared	408*	Request timeout
87	User not member of CUG	503	Service unavailable
88	Incompatible destination	503	Service unavailable
90	Non-Existent CUG	503	Service unavailable

ISDN Release Reason	Description	SIP Response	Description
91	Invalid transit network selection	502*	Bad gateway
95	Invalid message	503	Service unavailable
96	Mandatory information element is missing	409*	Conflict
97	Message type non-existent or not implemented	480*	Temporarily not available
98	Message not compatible with call state or message type non-existent or not implemented	409*	Conflict
99	Information element non-existent or not implemented	480*	Not found
100	Invalid information elements contents	501*	Not implemented
101	Message not compatible with call state	503*	Service unavailable
102	Recovery of timer expiry	408	Request timeout
103	Parameter Non-Existent Or Not Implemented - Passed On	400	Bad Request
110	Message With Unrecognized Parameter Discarded	400	Bad Request
111	Protocol error	500	Server internal error
112	Unknown Error	400	Bad Request
127	Interworking unspecified	500	Server internal error

\* Messages and responses were created because the 'ISUP to SIP Mapping' draft doesn't specify their cause code mapping.

## Configuring ISDN-to-ISDN Release Cause Mapping

The Release Cause ISDN to ISDN table lets you configure up to 10 ISDN ITU-T Q.850 release cause code (call failure) to ISDN ITU-T Q.850 release cause code mapping rules. In other words, it lets you change the originally received ISDN cause code to a different ISDN cause code. For example, the PSTN may indicate disconnected calls (hang up) by sending cause code 127. However, you can change the cause code to 16, which is a more typical cause code for such call scenarios. When the device receives an ISDN cause code from the PSTN side, it searches the table for a matching ISDN cause code. If found, the device changes the cause code to the corresponding ISDN cause code. If the ISDN cause code is not configured in the table, the originally received ISDN cause code is used. If the new ISDN cause code also appears in the Release Cause Mapping ISDN to SIP table (see [Configuring ISDN-to-SIP Release Cause Mapping](#) on page 1015), the device maps it to the corresponding SIP response code, which it sends to the IP side.

If the originally received ISDN cause code is configured in both the Release Cause ISDN to ISDN table and the Release Cause Mapping ISDN to SIP table, the mapping rule with the originally received code in the Release Cause Mapping ISDN to SIP table is ignored; the device uses only the mapping rule in the Release Cause Mapping ISDN to SIP table that matches the new ISDN cause code. For example, if you configure a mapping rule in the Release Cause ISDN to ISDN table to change a received 127 code to 16, the device searches for a rule in the Release Cause Mapping ISDN to SIP table for an ISDN code of 16 (ignoring any entry with code 127).

The following procedure describes how to configure ISDN-to-ISDN release cause mapping through the Web interface. You can also configure it through ini file [CauseMapIsdn2Isdn] or CLI (`configure voip > gateway manipulation cause-map-isdn2isdn`).
